Alternatively, typical discussion *forums*: are very high in number of connections made; generally exhibit low to medium diversity since they tend to coalesce topically, hence consisting of participants with similar interests; are one-to-many exchanges, thus exhibiting a more indirect than direct nature; are medium in interactivity since they allow responses to specific postings but with delayed time frames; their large-group nature makes them high in collectivity; although many forums are text-only, nonetheless the technology rates high in multiplicity since they can be set up to transmit a variety of media including text, images, and videos; are also highly historical in organization.

Finally, *wikis* typically: rate high in density, with the capacity to connect to multitudes; are low in diversity because they tend to attract very specifically-oriented users; are indirect in nature; exhibit medium interactivity since the point of wikis is for the participants to contribute, though the contributions are often evolutionary and not necessarily responsive in nature; can appeal to large groups, so they are high in collectivity; at this point tend to be primarily text-based, so they are low in code multiplicity; generally evolve over time, but earlier contributions can be altered or even expunged, so they are medium in historical capacity.

The three examples presented serve to illustrate how the group of social Internet technologies listed in Table 1 differ among themselves, sometimes slightly, sometimes more noticeably, in their capacities to facilitate social interaction. The potential value of the table is in its use to determine the propriety of a technology to support contingent social-networking requirements.

APPLYING THE FRAMEWORK: SUGGESTIONS FOR SOCIAL CAPITAL FORMATION IN AN ENTREPRENEURIAL ELECTRONIC NETWORK

In this section we present a semicase study of a localized agricultural industry and discuss applying the proposed framework to design a social-technology infrastructure to support the industry participants.

One of the authors recently conducted a series of three e-commerce workshops with a group of tropical flower growers. The workshops were designed to inform participants about the benefits of e-commerce and the essential techniques and procedures used in creating individual Web sites to access alternate distribution channels. Some participants had existing Web sites and were looking for intermediate or advanced marketing and site management lessons. A number of participants did not have Web sites and were looking for information to help get started. By the end of the third workshop, attendees had the knowledge to assess their business needs, evaluate and choose a host, set up a basic commerce site, and undertake basic marketing strategies.

Informal follow-up interviews were conducted recently with several workshop participants. For example, we asked one participant whether he had established a Web site yet and the response was, “No – I haven’t really had the time.” He felt business was satisfactory as it was and was not motivated enough at this point in time to proceed with e-commerce. When asked whether he would be interested in joining an electronic cooperative, he asked what the benefits would be. When informed about potential transaction cost reductions and increased marketing leverage, his response was that he did not think the benefits outweighed the risks. Further probing revealed some interesting concerns. The farmer described several earlier attempts to manage cooperatives in local markets, a couple in other agricultural sectors and one in the fishing industry. In all cases it seems the efforts to form a cooperative failed, sometimes quickly, other times belatedly.

These earlier situations have generated an attitude that, while cooperatives will bring in small and large customers for the participants, eventually the bigger customers will seek one-to-one relationships with a favored member of the cooperative. The belief is that under competitive pressure, the favored member will see sufficient benefits in withdrawing from the cooperative and assuming the relationship with the customer outside the cooperative structure. The essential issue, at least for this farmer, is not lack of perceived benefits in joining a cooperative. Ironically, the concern is that the cooperative will indeed be successful in garnering new business, but peers will seek unfair advantages from the system. In other words, lack of *trust* (or a deficit of relational capital) reduces the perceived value of cooperating with competitors. Thus, to be successful in this particular entrepreneurial community, an electronic cooperative will have to facilitate the development of trust among participants.

In retrospect, during the workshops we might have made a good start toward the formation of a social learning network and trust development within this community of practice by spending more time in helping workshop participants to get to know each other. Moreover, trust development may also require the development of governance safeguards that discourage opportunistic behavior, reinforce norms of cooperation, and gradually erect a structure for collective action (Flanagin, Stohl, & Bimber, 2006). While social technologies are not equivalent to governance mechanisms, they could facilitate a joint search for improved norms and processes of learning-based interactions within a community of practice.

As pointed out earlier, existing online marketplace models are primarily transaction oriented, offering to increase marketing leverage and reduce searching and monitoring transaction costs. But electronic marketplaces have encountered difficulties and have generally failed to exhibit the scale of adoption expected (Tedeschi, 2001). Transaction efficiency, while important, is only one aspect of effective competition. Management of trading and competitive relationships is an equally important, yet neglected dimension in the current generation of electronic marketplaces (Steinfield, 2004). One key to more widespread adoption of electronic marketplaces may lie in the enhancement of their functionality and value by integrating transaction-based e-commerce with social technologies, providing network participants a set of tools for managing relationships and thus developing critical business knowledge.

Entrepreneurial networks can incorporate various social technologies into a virtual cooperative, but which technologies should be emphasized in this situation? Given the lack of trust in this situation, in addition to traditional e-commerce, the cooperative's Web site should also include social technologies designed to facilitate trust-building interaction. To build trust, the network needs to support more interactivity and be collectivity-oriented, factors that directly affect trust. It would also be advisable to include support for code multiplicity and interaction history, less direct but nonetheless important factors in trust development inasmuch as they support the construction of shared meaning. Looking at the framework one can see that the need to support these dynamics suggests providing discussion forums for the farmers: forums are medium in supporting interactivity, high in collectivity, medium-to-high in code multiplicity, and high in historical capacity.

This discussion presented here should be taken only as an example of the application of the framework, not as a solution that can be generalized to all situations. The existence of other issues or objectives should be used to determine other technologies to integrate into a Web site. For example, in a different entrepreneurial community, participants may prefer to acquire technical knowledge rather than build trust, but may not have the time to attend formal classes or workshops. The technical knowledge may be possessed to some degree by the entrepreneurs themselves, and thereby made accessible by forums. But, the network may also find it useful to have field experts generate topic-specific tutorials, and provide them to the members via blogs or podcasts.

One might say, why not just include all social technologies in a network Web site? The answer is that most entrepreneurs are busy with their daily operational requirements and have limited time, skills, and resources available for learning the entire toolbox of social technologies. A member would be more likely to see value in the selection and provision of a few specific and useful tools.

FUTURE RESEARCH

This article describes a theoretical perspective suggesting that modern social technologies may be bundled in configurations designed to support greater degrees of social capital formation. Social technologies like e-mail, list-severs, discussion forums, blogs, podcasts, and so forth have the capacity to support linkages, trust development, and shared meaning among networked entrepreneurs to varying degrees. The article further acknowledges that the appropriate configuration of technologies to support a particular group of entrepreneurs depends on a combination of factors, including the social capital requirements of the group, the situational context, and the ways in which the participants decide to actually use the technologies.

Thus, a concern for future research is the contingent nature of the interaction between technology characteristics and their appropriation. For instance, a contingency perspective suggests that a technology will support greater trust development in some situations, while in other situations the same technology could allow behavior that impedes trust development. It would be helpful to practitioners if studies could be undertaken to determine how particular combinations of social technologies work together in different contexts when appropriated in specific ways.

The model and discussion presented here raise a number of other issues also worth examining in the future. For example, a logical next step for research would be to assess the extent to which trust and other dimensions of social capital exist in specific entrepreneurial networks, like the co-operative network described above. Understanding existing conditions in a network will inform participants in the design and implementation of a technical infrastructure best suited for the formation of social capital, making all network members more competitive.

A complementary line of research would be the exploration of governance processes appropriate to overcoming incentive problems that impede cooperation (Borgen, 2003) and to developing norms of interaction that build trust in networks (Calton & Lad, 1995). Burton-Jones (1999) notes that small business networks tend to be organized on democratic lines, since this arrangement favors the development of higher levels of trust, commitment, information sharing, and cooperation. Krackhardt and Brass (1994) point to the need to consider the role of leadership in developing and sustaining network relationships, particularly by studying patterns of "leader-member exchange" across strong and weak ties. Lipman-Blumen (1996) develops a model of "connective leadership" based on maximizing trust-building interactions and a collaborative search for solutions in shared problem domains. These are all promising lines of research which are beyond the scope of but suggested by the model proposed herein.

The preceding paragraphs describe the technical infrastructure in relation to contextual issues like governance and leadership in the network. Indeed, the article as a whole is concerned with a variety of interacting contextual social dimensions. Considering the model this way illustrates the need to examine a much broader sociotechnical framework, within which the social technology infrastructure discussed here plays an important but partial role.

CONCLUSION

In summary, the article presents an extension of earlier entrepreneurial network research. We develop a theoretical model describing how social capital theory can be used to configure networks of social technologies supporting entrepreneurial communities of practice. We argue that different aspects of social capital are realized to varying degrees by different social technologies. Therefore, embedding these technologies within an online marketplace can create a learning network infrastructure, requisite for knowledge creation and management in entrepreneurial communities.

A well-developed electronic network can increase interconnectedness and information sharing among participants within an entrepreneurial community. Enhancing the network this way reduces the incidence of "structural holes" which allow some participants to leverage strategic positions in the network, extracting rents at the expense of others (Burt, 1992). A social technology-based network provides the opportunity for members to increase "weak-tie" development, generating correspondingly more opportunities for information sharing and knowledge development (Granovetter, 1973). In application, this suggests that entrepreneurial network initiatives, integrated with more commonly accepted e-commerce technologies, will support members in their efforts to share knowledge and perhaps even help overcome industry problems like mistrust, thus improving participants' competitiveness.

There is significant creative potential for promoting organizational learning by mobilizing an integrated social/transaction-based technology model like the one presented in this article. As Friedman's (2005) *flat world* perspective suggests, entrepreneurs should benefit competitively from the creation of and access to a shared space among network participants. Such interaction can bring together multiple perspectives on new information, encourage development of greater congruence in shared meanings, and thereby generate knowledge-based capabilities within the entrepreneurial network to enhance each firm's ability to succeed in the connected global marketplace.

ABSTRACT

This article presents research towards the development of a virtual learning environment (VLE) inhabited by intelligent virtual agents (IVAs) and modelling a scenario of inter-cultural interactions. The ultimate aim of this VLE is to allow users to reflect upon and learn about intercultural communication and collaboration. Rather than predefining the interactions among the virtual agents and scripting the possible interactions afforded by this environment, we pursue a bottom-up approach whereby inter-cultural communication emerges from interactions with and among autonomous agents and the user(s). The intelligent virtual agents that are inhabiting this environment are expected to be able to broaden their knowledge about the world and other agents, which may be of different cultural backgrounds, through interactions. This work is part of a collaborative effort within a European research project called eCIRCUS. Specifically, this article focuses on our continuing research concerned with emotional knowledge learning in autobiographic social agents.

INTRODUCTION

In addition to the popular utilisation of social agent simulations in areas such as education and academic research, nowadays immersive online virtual worlds allow social agents to be further enhanced through highly frequent interactions with human users. For example, Second Life (Linden Research, 2005), as a well-known and quickly evolving virtual society, has attracted millions of users to experience a new kind of social interaction in a virtual space. Powerful PCs, fast broadband connections and advanced 3D graphics offer users this alternative online reality. Interestingly, users' social activity in such a virtual society involves high levels of cultural and emotional learning, as many real cases demonstrate that are reported by Ananthaswamny (2007). How well can we expect intelligent virtual agents (IVAs) to be able to cope with interactions similar to those that human users experience in a comparable social context?

To answer this question, one of the primary goals from our research project eCIRCUS (2006) "Education through Characters with emotional-Intelligence and Role-playing Capabilities that Understand Social interaction" is to promote intercultural empathy. Cross-cultural conflicts have been the source of violent acts in many countries worldwide, including conflicts involving people who come to live in a different country. This background forms a strong motivation for our goal to develop a virtual learning environment (VLE) that supports intercultural learning and fosters intercultural empathy skills for its users. Through developing an educational role-play game named ORIENT with character-based emergent narrative (Aylett et al, 2005), we aim to establish a fun way to educate boys and girls at the age of thirteen to fourteen years in the UK and Germany. The learning outcomes will be designed specifically for children native to the host countries and will be used by the entire school class.

Not surprisingly, in virtual worlds like Second Life or other popular online games, the large international user population and the freedom given to individuals to openly "live" in the environment introduce a certain level of difficulty in intercultural communication. Naturally most users can handle problems emerging from cultural differences – without much effort they can understand both verbal and non-verbal expressions from other characters, which may be either non-player characters (NPCs) or avatars controlled by other users who may be from different backgrounds[1]. To achieve the same level of social and cultural understanding, IVAs are expected to have an *interdependent* (rather than *independent*) "self" – being more attentive to themselves and sensitive to others[2] (Markus & Kitayama, 1991). Consequently, they need to have the ability to be aware of cultural differences and to learn from others. Therefore, we argue that IVAs will benefit from a type of memory which records events that are meaningful to the agent personally and also allows them to extend their knowledge about others' cultural expressions.

Like human beings, these agents should also respond to a stimulus situation with mediation by cognitive processing at several different stages. As reported by social psychologists (Wyer & Srull, 1989; Kim & Ko, 2007), effects of two factors play an important role in most phases of social and cultural information processing: (a) the affect or emotion that one experiences at the time information is processed and a judgment or decision is made, and (b) the agent's "self"[3]. If we assume that one's own emotional reaction to a stimulus is essentially an aspect of oneself, and emotions can be both cause and effect in relation to one's perceptions, then these two factors are clearly related.

In the psychological literature, two different definitions of emotion are commonly used. According to one tradition emotion is viewed as a set of internal cognitive processes of self-maintenance and self-regulation, e.g. Young defined emotion as an "acute disturbance of the individual as a whole" (Young, 1936, p. 263). Another tradition views emotion as an adaptive and organising response because it can motivate forces and direct activity (Salovey & Mayer, 1990). Both definitions seem to naturally assume that these cognitive processes or responses are universal (e.g. Plutchik, 1994), however, the emotional experience is very much culture-based (Solomon, 1984). The reason is that "emotional meaning is a social rather than an individual achievement – an emergent product of social life" (Lutz, 1988; p. 5). Furthermore, like our thoughts and the language that we use to express them, meaning and regulation of emotion are also shaped by "the interest of cultural cohesion", as pointed out by Bruner[4] (1990, p. 58).

To create the dynamic representation of different meanings of agents' emotions, it is beneficial to use schemas for agents' long-term memory that record significant events (events that are meaningful from the agent's point of view). Since the 1920s, psychologists like Bartlett (1932) have been illustrating that humans appear to deal with complex structural knowledge by using memory schemata – not by storing everything in a 'semantic bin' which works like a warehouse. In computational terms, the memory schema provides us with empty slots to be filled in by recalling meaningful episodic information from our long-term memory. This whole remembering process involves memory reconstructions of one's past experiences and thus produces coherent narratives[5] based on meaningful events which tend to be unforgettable in one's life. Psychologists in recent decades identified this type of episodic long-term memory with personally significant events for individuals as *autobiographic memory* (Conway, 1990).

In light of our interests in agents' cultural and emotional learning using computational autobiographic memory, this article reports our ongoing research into the emergence of agents' knowledge about the "self" and emotion in social simulations. We aim to develop a minimal cognitive agent architecture with essential components for IVAs to perform cultural understanding, to extend emotional knowledge and thus eventually to be able to empathise with other agents or human users. In the rest of the article, we first review psychological literature illustrating cognitive representation of emotion concepts in human long-term memory. Next we discuss research in IVAs using emotional models. Then we introduce autobiographic memory for IVAs and our previous research using autobiographic agents with emotional expressions for narrative storytelling. Following that, we briefly introduce ORIENT (Overcoming Refugee Integration using Empathic Novel Technology) – a software application that is being developed that aims at helping teenagers in emotional and social learning. The next section illustrates several important modules in our agent architecture to support the implementation of agents' personality and emotion, and the integration of autobiographic memory for extendable emotional knowledge for individual agents. Finally, future work is discussed in the concluding section.

BACKGROUND

In this section we introduce some essential ideas that support our study in cultural and emotional learning for IVAs. These ideas are very much interdisciplinary, and they cover mainly the areas including 1) *the presentation of emotion concepts in human long-term memory,* 2) *empathy,* 3) *memory and emotion*, and 4) *computational autobiographic agents*. We will illustrate the interrelations that exist between them.

Representation of Emotion Concepts

Culture not only impacts the language that we use, non-verbal behaviour that we display, our gender roles, etc, but also influences our emotional expressions. Here we specifically focus on agents' emotions because much psychological research has shown that emotion plays a critical role in our memory-encoding, decision-making, interaction with others, and overall, intelligence (Salovey & Mayer, 1990). To create socially "friendly" IVAs, emotion is certainly a critical component to be integrated into the agent architecture. From this perspective, representing concepts of emotions is fundamentally important in agents' memory.

In psychology, the way that humans encode concepts of different emotions has been commonly identified as a type of semantic representation. Emotion concepts, together with other concepts of semantic knowledge, are stored permanently in our long-term memory. Wyer & Srull (1989) suggested that, like concepts of personality, each emotion can be also conceptualised as a central node attaching different configurations as features. They further explained that these features may include verbal labels, representation of overt behaviours, etc. As an example, Figure 1 illustrates their idea about the cognitive representation of the emotion concept of "sad".

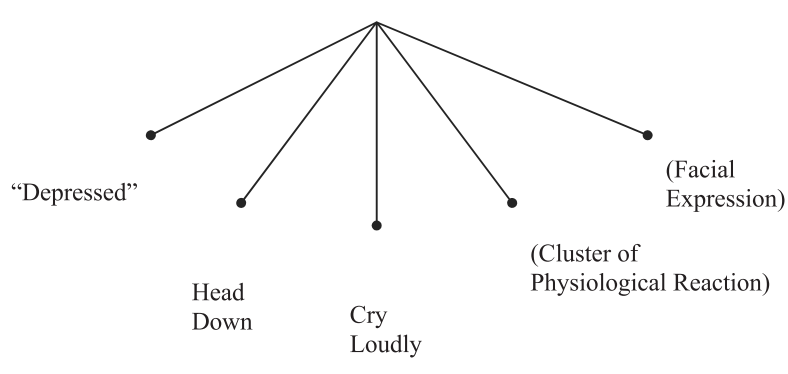
Understandably, features attached to the central node are derived from social learning. They are, however, not only used for expressing the internal emotional state of oneself; more interestingly, in social interactions they are often used directly to interpret others' emotions. Consider the following scenario: A mother who observes her young son slamming the house door or performing another behaviour that she personally labels as "angry" may ask him "Why are you angry?". Therefore, emotion concepts stored in the long-term memory are crucial to daily life because the retrieval of these concepts can often help process observable information in interaction with others and in the process of making a decision of how to react or respond to the situation.

Believable Agents and Modelling Emotion

Research on believable agents in Artificial Intelligence (AI), inspired by work on believable characters in the Arts, has been pioneered by the Oz project under the guidance of Joe Bates. A believable character is "... one that provides the illusion of life, thus permitting the audience suspension." (Bates 1994, p. 122). Work on believable agents in AI has grown significantly, a detailed overview in believable emotional agents can be found in (Loyall, 1997).

Integrating an emotion model into the design of an agent architecture is important for believable interactive virtual agents in applications such as computer games or training software. Marsella and Gratch (2003) utilised appraisal processes from the OCC model (Ortony et al, 1988) for believable characters that perform in various applications. They state that appraisal variables enable agents to characterize the significance of events from the individual's perspective as the interpretation of each event is altered by an

Figure 1. Cognitive representation of the emotion concept "sad"



agent's own beliefs, desires and intentions, and past events. To continue this research direction with computational autobiographic memory, our previous work developed a mechanism that creates *significant experience* for believable virtual characters through OCC appraisal processes (Ho et al. 2007a).

Empathy

In addition to inferring others' internal states, emotion concepts are fundamentally important for the *empathic process*. Empathy refers to "any process where the attended perception of the object's state generates a state in the subject that is more applicable to the object's state or situation than to the subject's own prior state or situation" (Preston & de Waal, 2002, p. 4). Contemporary empathy research agrees on two main aspects of the empathic process, one is cognitive, and the other is affective in nature (Davis, 1996; 2006). Both aspects are clearly relevant to our research. Cognitive empathy focuses on the "intellectual or imaginative apprehension of another's condition or state of mind without actually experiencing that person's feelings" (Hogan, 1967, p. 308), resulting in an understanding of the target's inner state. Affective empathy is described as "a vicarious affective response to another's feeling" (Hoffman, 1977). Therefore, learning emotional expressions from another culture seems to rely on the understanding of internal states of the members of the culture and creating affective evaluative reactions towards them.

Furthermore, there can be two types of development for emotional reactions during the empathic process (Davis, 2006): 1) Through a repeated simultaneous experience of an emotional expression in a target person and an emotion in the observer, 2) through associative processes, which work similarly, but rely more on memory representations of past experiences of the observer; these associations may emerge from visual perception of expressions or situational cues.

Autobiographic Memory and Emotion

Being aware of how high level empathic processes help in increasing the cultural understanding of others, we now study further a rather basic but essential concept of attributing emotion to a specific kind of episodic memory – *autobiographic memory*. In psychology, autobiographic memory has been introduced as memory that contains significant and meaningful personal experiences for a human being (Nelson, 1993). It serves important functions in providing the basis for social interaction, maintenance of a dynamic self-concept as well as the representation of the meaning of concepts (Conway, 1990). Moreover, when memories were plotted in terms of age-at-encoding highly similar life-span memory retrieval curves were observed: the periods of childhood amnesia[6] and the reminiscence bump[7] were the same across cultures – suggesting that there are culturally invariant features of autobiographical memory that yield structurally similar memories across cultures (Conway et al, 2005).

In the literature on human memory, it has been widely acknowledged that events associated with emotional experiences partly constitute highly available memory. Psychologists and cognitive scientists also propose that when experiencing an event with emotional content, a human's cognitive system is more fully engaged in processing that event, in comparison to the processing of events which are not clearly associated with any strong emotional experience. This view can be further elaborated with respect to the frequency of rehearsal (Conway, 1990) – in that highly emotionally intense events are more readily available for retrieval.

Personally significant events which are directly involved in the self memory structure, like first time experiences, can have stronger impacts on humans' lives by creating a pre-existing knowledge structure for other similar events (Conway, 1990). These life events, together with events with emotions, indicate that central knowledge structures relating to the self have been employed in representing autobiographic memory. Nevertheless, studies e.g. from Markus & Kitayama (1991) suggest that emotional processes may differ from the nature of the self-system. They further pointed out that both 1) the predominant eliciting conditions, and 2) the intensity and frequency of emotions expressed and experienced by individuals, vary dramatically according to one's construal of the self.

Computational Autobiographic Agents

Conceptually, an autobiographic agent is an embodied agent which dynamically reconstructs its individual history (autobiography) during its life-time (Dautenhahn, 1996). This individual history helps autobiographic agents to develop individualised social relationships and to communicate with others, which are characteristics of social intelligence. It has been suggested that autobiographic memory for agents may also lead to more appealing and human-like engaging interactions, making the agents more pleasant and acceptable to humans.

Different types of computational memory architectures for Artificial Life autobiographic agents have been developed and experimentally evaluated in our previous research work, e.g. in (Ho et al, 2006). These architectures include memory modules which are commonly acknowledged in psychology: short-term, long-term, and positively and negatively categorised memories. In a series of simulation experiments we showed that agents embedded with these computational autobiographic memories outperform Purely Reactive agents that do not remember past experiences in surviving in both static and dynamic environments.

In the paradigm of developing synthetic agent architectures, we previously proposed that 1) knowledge representations in the computational autobiographic memory can be based on general episodes that agents have experienced and 2) goal structure, emotion, and attention processes support and are influenced by the autobiographic knowledge (Ho & Watson, 2006). Autobiographic knowledge may also support long-term development and learning in synthetic agents as they gain new experience from acting in each new situation.

Our previous research also includes the investigation of how the engagement of users can be increased in an interaction through the inclusion of believable agents with their own emotions and autobiographic memory (Ho et al, 2007a; 2007b). Specifically, in Ho et al. (2007a), we incorporated the psychological view that emotions can arise in response to both internal and external events. More importantly, both types of events have "*a positively or negatively valenced meaning*" (Salovey & Mayer 1990, p. 186) for an individual agent.

More recently our study in Ho et al. (2008) shows that, embedded with communicative autobiographic memory, agents' behaviours can be understood as intentional, narratively structured, and temporally grounded. Furthermore, the communication of experience can be seen to rely on emergent mixed narrative reconstructions combining the experiences of several agents.

Earlier in this article we discussed the semantic representation of emotion concepts and how these concepts can be learnt. Now we define *learning* in this article as more than just acquiring knowledge. Agents use the emotional knowledge to improve their performance – in the sense of achieving believability and performing cultural interactions with other agents and human users. We therefore focus on low level symbolic learning for agents aiming to increase their cultural and emotional knowledge through gaining experiences from interactions with other agents/users and using autobiographic memory.

CULTURAL AND EMOTIONAL LEARNING FOR SOCIAL AGENTS

This section presents the challenge of creating IVAs that are able to extend their emotional knowledge based on cultural interactions with other agents or users. We start with identifying several limitations of existing research in the area. We then introduce the software application ORIENT developed within the eCIRCUS project, the agent architecture and examples of story scenarios in which agents' intercultural learning ability is required for human-agent interactions. Next, we present our agent architecture design and specify the *minimum requirements* for agents embedded with computational autobiographic memory in ORIENT to be able to learn emotional knowledge through social and empathic interactions.

Issues and Challenges

As discussed in the background section, humans represent concepts of emotion in long-term semantic memory. Importantly, these concepts are *not* innate but each individual forms them either from one's own cultural inheritance (i.e. knowledge acquired via folk tales, books or other media etc.) or from past meaningful personal experiences. For this reason, we may not be able to infer others' emotions from purely observable information during the interaction. Instead, backed up by the reviewed psychological literature, we argue that both cultural background knowledge as well as autobiographical experiences of a person or an agent play an important role in recognising and learning others' emotional expressions.

One possible approach is to create a synthetic culture for a group of agents, so that each agent can have the same set of semantic knowledge for emotional expressions that represent their culture – this is our first step in the current implementation of ORIENT, which will be introduced in the next subsection. Unfortunately, when these agents are interacting with users in different circumstances, this set of *static* semantic knowledge is too limited.

Since developing a personality model which is valid across cultures is also essential to our research, we suggest re-interpreting cultural dimensions in terms of personality traits. According to Triandis & Suh (2002), the basic personality traits in the Big Five model (Costa & McCrae, 1992) are the most suitable to incorporate cultural dimensions. They argue that 1) the Big Five model is applicable to a wide variety of cultures, 2) traits are supposedly biologically based and they show the same pattern of developmental change in adulthood, and, most importantly, 3) acculturation effects can be found in the predicted direction. To give an example of point 3: if people live as part of a culture different from their own, then their behaviour and attitudes are likely to change by acclimatising to the lived in culture.

Overall, the Big Five model represents five replicable, broad dimensions of personality: Extraversion, Agreeableness, Conscientiousness, Neuroticism and Openness to experience. These five dimensions are, however, descriptive concepts that focus on illustrating how human behaviour can be traced back to psychological variables and their interplay. Therefore, they still need to be explicated in low-level structures and processes for our implementation.

With the consideration of the developmental stages that a person may pass through, the transition includes social and psychological changes. Hence, one shall undergo a time of important changes, which can be a cause of conflict, and a positive development of personality or a clearer sense of psychological identity (Piaget, 1952). Computationally capturing these changes from all agent interactions requires a careful design specification of episodic memory that allows agents to remember those significant events. Therefore, in addition to the underlying personality model that the agent might be using, computational autobiographic memory is necessary here to establish the learning of emotional knowledge and to emphasise the cultural differences of a particular individual.

Furthermore, although we discussed above that empathy is a crucial psychological process to understand others' internal states, modelling the empathic or similar processes, such as Theory of Mind (Premack & Woodruff, 1978; Baron-Cohen, 1991; Leslie, 1994), for agents is a highly challenging task. In the research field of believable IVAs, researchers have attempted to create empathic agents by, for example, using a data-driven affective architecture with human teaching examples (McQuiggan & Lester, 2006), or analysing human users' physiological responses through skin conductance and electromyography to guide the animated interface agents in performing empathic behaviour (Prendinger et al, 2006). However, in both examples the agent's emotional knowledge is predefined by the designer and is not extendable.

Integrating emotion into agents' behaviour modulation mechanisms has recently been widely studied, e.g. as part of a large European project called HUMAINE (HUMAINE, 2004). However, not many studies of agents' emotional learning based on culture can be found. One can imagine the difficulties: learning new emotion concepts means to match the particular expression the user shows with his/her internal emotional states – however, typically virtual agents can neither perceive the user's facial expression nor detect their physiological changes easily in real-time.

We argue that the first important step towards creating IVAs with abilities of learning emotional knowledge about other cultures, and ultimately empathising with others, is to enable the agents' long-term learning from *meaningful* events. For example, through remembering its significant experiences in the past agent_A learned that event_X always has a negative impact on its internal states and thus it generates a dislike emotion. Agent_A, after sometime, creates a concept "*event_X is harmful and leading to a dislike emotion*" and an associated *avoidance* action. With this conceptual knowledge derived from its own experiences, initially agent_A assumes that all other agents whom it meets have the same concept. Therefore when agent_A sees agent_B expressing a dislike emotion, it automatically infers that event_X (or similar events that have a same effect) has happened to agent_B. Afterward, intuitively agent_A expresses its concern to agent_B and expects agent_B's "feedback". The feedback can be either a confirmation of the concept or an unexpected result, both of them will lead to an update of agent_A's existing concept for event_X and thus increase agent_A's cultural emotional knowledge. Note that the complete description of empathic processes is shown in the next subsection *Specifications for computational autobiographic memory*.

In addition to embedding computational autobiographic memory in the agent architecture, it is also essential to consider the "minimum requirements" as specifications for agents interacting with users or other agents. We aim to achieve that, eventually, both the agent's long-term "self" and emotional knowledge can emerge from such social and cultural interactions.

The Character-Based Approach

In this section we elaborate the character-based approach, with the features that computational autobiographic memory can provide, as a potential solution to address the issues we raised above. In order to allow our agents to adapt themselves to distinct cultures and to be able to establish empathic relations with others, the computational autobiographic memory model focuses on agents' knowledge representations and how information retrieved from autobiographic memory can support agents' goal processing with the PSI theory's "needs" as a foundation (see below for a detailed explanation of the PSI theory). In this model, meaningful episodic knowledge derived from an agent's past experience forms events, episodes, themes and life periods[8] in a bottom-up fashion.

Each of them has an abstraction generated for representing general meanings to the agent itself during different periods of its lifetime in a temporal sequence. The technical design for this model can be found in (Ho et al, 2007b).

The main advantage of our autobiographic memory model is that it attributes changes of internal states (e.g. emotions) in action-situation patterns to show the significance (to an agent itself) of past episodic experience. Thus this approach improves agents' learning and adaptation. Moreover, various levels of abstraction can feature the production of narrative storytelling for describing agents' past experiences as well as forming changeable personalities. Using autobiographic memory knowledge to bias planning current goals is particularly suitable in creating dramatic acting for synthetic agents.

Since the full description of the story scenario in ORIENT (eCIRCUS, 2006) goes beyond the scope of this article, we provide 1) the design of a fundamental personality model with its integration into the main architecture, 2) an example of the story scenario, and more importantly, 3) the detailed specifications of requirements for computational autobiographic memory based on the design for the ORIENT scenario and user-agent interaction.

Personality Model and Agent Architecture Implementation

In ORIENT we aim to use the descriptive trait concepts from Big Five for modelling personality. However, in order to allow agents to generate realistic and expressive behaviours in real-time from the personality model, it is not possible to simply use those five static parameters as initiated. It means that we will need to create a set of low-level internal states for agents (as main characters interacting with users in the game) to capture the dynamic changes of these states and to map the Big Five personality traits into them. As pointed out by Schaub (1999), this approach will involve three levels of modelling work:

1. Descriptive level (Big Five) that provides information regarding each main character's general tendency in five (trait) dimensions.
2. Behavioural level (e.g. being friendly, aggressive) indicates characters' expression based on their personality during the gameplay.
3. Low-level implementations of the system that generate behaviour through internal states (e.g. needs, intentions and goals)

The first step is to define the value of each character's personality trait using the Big Five dimensions[9]. Story writers for the ORIENT scenario and psychologists collaborate and revise these trait values based on the original design of each character in the story. Then these (1st level) trait values will be "translated" into low-level internal states (3rd level) for generating characters' motivations, intentions and goals. Finally, we expect that agents' behaviour (2nd level) will emerge from the dynamics of internal states, computational autobiographic memory and planning processes happening in the agent architecture.

To create the low-level system, the first step is to integrate the motivation module from PSI theory proposed by psychologist Dietrich Dörner (Dörner, 2003; Dörner & Hille, 1995). The original PSI theory is based on the idea that humans are motivated emotional-cognitive beings; therefore it integrates cognitive processes, emotions and motivation. The motivation module in our agent architecture includes existential "needs" (*Existence Preservation*, *Species Preservation* and *Affiliation*), and intellectual "needs" (*Competence* and *Certainty*). By mapping the corresponding Big Five trait values predefined by the story writers and psychologists to the set-point (threshold) of each need, an individual character's dynamic personality is created. For example, if character

A was defined as a person who is secretive, wise and rarely speaking to new people, then part of his Big Five traits are: High Conscientiousness, low Extraversion and low Agreeableness. Therefore the relevant set-points for PSI needs translated from traits are: High Competence, High Certainty and Low Affiliation. Table 1 shows a brief guideline for the translation from Big Five traits to PSI needs. Note that the mapping from traits to needs is not one-to-one in most cases.

All needs of each agent must be maintained in order to "survive" in the game environment. Therefore individual agents will try to reduce the deviation of each of their own need from the set-point as much as possible at all times. Intentions of an agent are built according to the strength (as determined by the deviation) of a need, the success probability to satisfy the need from the semantic knowledge, past significant experiences in autobiographic memory, and urgency (the timeframe to satisfy a need). Whenever a need deviates from the set point, it activates the corresponding intentions. In the case when several intentions are active in a given time, the strongest one will be selected and executed. To help depict the main ideas of the motivation-based architecture as well as the interactions between the computational autobiographic memory and other components, the overall design of the agent architecture is shown in Figure 2.

After the integration of needs for intention generation, we also utilise three types of behaviour modulators from PSI theory:

- **Activation:** Similar to the psychological concept of "arousal", activation represents the preparedness for perception and reaction on the agent – speed of information processing. It increases with the general pressure from the motivation system and the strength of the currently active intention. For example, if the environment poses threats to the agent and its activation level is high, we will expect a short reaction time from the agent – it needs relatively quick cognitive adaptations for the satisfaction of current needs. As a result, only superficial perception and planning may be observed. Thus the agent will be highly cautious and try to adapt its responses to the environmental conditions.
- **Selection threshold:** To prevent the currently active intention to be easily replaced by another equally strong intention, a selection threshold increases the strength of the current intention and prevents oscillation of behaviour by giving priority to the currently active intention. Therefore, low selection threshold means that the agent is easily distracted from its current intention, and vice versa.
- **Resolution level:** Resolution level determines the carefulness and attentiveness of an agent's behaviour – the accuracy of cognitive processes, e.g. perception, planning, action regulation. It changes inversely

Table 1.

Big Five trait	PSI needs
Neuroticism	Many needs are highly activated at the same time
Extraversion	High need for affiliation
Agreeableness	Needs are generally not very activated or need long to exceed threshold
Conscientiousness	High need for competence and certainty
Openness	Low need for certainty, high need for competence

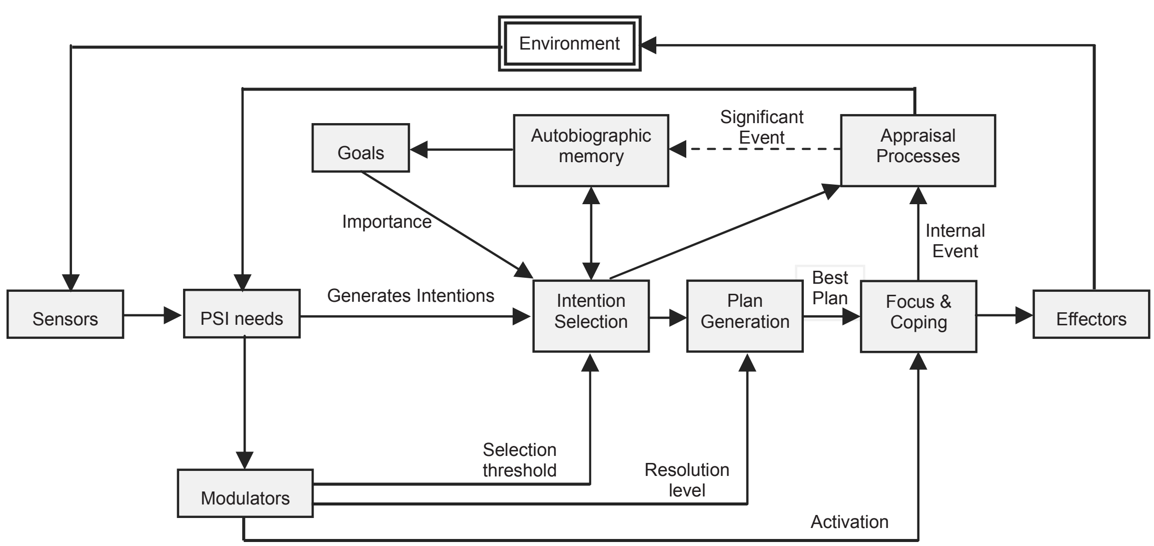
to the activation value. Generally when the resolution level of the agent is high, it performs more extensive memory retrieval and generates either more alternative plans or a very detailed plan for achieving a selected intention.

Altogether these three modulators in the agent architecture establish the dynamic model of emotion as modulation of "cognition" (here we refer to "cognition" as an agent's perception, action-selection, memory access and planning). This unique aspect was derived from PSI theory, in which emotions are not explicitly defined but emerge from modulation of information processing and adaptation to the environment, see Hille (2007) for details. In this case, an agent's complex behaviours become apparent due to the value of these modulators modified by needs.

Taking other agents and events from the environment into account, not only will they be internally represented symbolically in the agents' semantic memory (world knowledge), but the proposed agent architecture will also include their individual influence on the low-level needs. The strength of the influence is dependent upon an agent's personality specification, and is also affected by its own culture, and its existing experiences. Details of events which have brought significant impact to any of the agent's internal needs, together with other agents involved (if there were any), will be stored in the autobiographic memory for guiding the agent's future emotional and behavioural responses to the same type of events or agents. The relevant process is named *appraisal*, in line with other approaches to modelling emotions in IVA architectures, e.g. (Marsella & Gratch, 2003). Similar to our previous work (Ho, 2007a), for the interpretation of different types of emotional impact, e.g. in order to generate an agent's personal narrative, we utilise the OCC taxonomy (Ortony et al, 1988) as appraisal variables in the architecture.

Therefore, we also project the low-level needs to these appraisal variables. For example, *Like/Dislike* refers to how an event impacts the character's need for *affiliation*; *Desirability (of an event to oneself)* is determined by whether it satisfies or threatens to some extend the character's overall needs; *Desirability (for others)* – depending on

Figure 2. ORIENT agent architecture that links components such as needs, goals, emotion and autobiographic memory



how an event affects the other character's needs – is indeed important for an agent's cultural and emotional knowledge learning, and defined by a self-as-first-person evaluation process (see the next subsection *Empathising with others* for details). Furthermore, *Praiseworthiness*[10] is influenced by the agent's need for *certainty* and need for *competence*, also taking into account the social and cultural background of individuals.

At the beginning of an interaction with a user or other agents , each agent's internal needs will be initialised with random values together with a set of predefined "personality thresholds". Based on the level of deviation that each of its current needs has, it generates intention(s) and activates goal(s) that are relevant to the perceived circumstances. The goal with the highest priority to be executed can be determined by the fact that it can satisfy the current most deviated need. Moreover, the agent's competence level plus the past experiences in its autobiographic memory will provide information for the calculation of the success probability for a particular goal. Therefore, both goal importance and goal success probability will be used to manage intention and thus action selections.

We believe that, at a certain level, the composition of an agent's internal needs, goals and autobiographic memory in the architecture can attribute "meanings" to its emotional expressions. During the processes of appraisal, the agent evaluates both 1) internally, the effect of the coping action that it has carried out on its needs and 2) externally, the environmental changes based on that action. This mechanism allows agents with autobiographic memory to link their emotional expressions (for either internal or external events) to the changes of their internal needs. More importantly, their autobiographic memory records these "event-needs" relations as part of their life experiences, and thus they are able to infer the meaning of other agents' emotional expressions.

An Example from ORIENT Story Scenario

ORIENT is focused on friendship and integration strategies and is aimed at 13-14 year olds. It involves small groups of users interacting with a 3D virtual environment populated by intelligent agents from different fantasy cultures, using innovative communication and control devices and a mission that requires the teenage users to work together with the ORIENT cultures to save the planet. The users' task is to interact with each of the cultures through a number of engagement scenarios with the ultimate aim of saving the planet.

One of the scenarios will be a formal meal where agent_C has invited agent_D, which is from another culture on the planet, to join. The impact to agent_C's internal needs starts when it observes agent_D perform (what is to agent_C) a completely novel ritual when eating – the perceived situation reduces the level of both *certainty* and *competence* because agent_D's actions conflict with its own knowledge and expectation. This will then lead to an increase for these needs, and therefore, agent_C will adapt its future behaviour to take into consideration what they have just experienced. Since agent_C finds no relevant actions in the past to cope with the current situation, through the processes of *Intention Selection* and *Plan Generation* it chooses an emotional coping strategy with the display of *surprised* emotion to agent_D. The coping behaviour and changes to internal needs, together with the context as well as the reaction from agent_D are encoded in agent_C's autobiographic memory as a significant experience.

Since agent_D is from another culture, it may have a different reaction when perceiving agent_C's ritual. This is due to the inclusion of the Big Five which provides a foundational personality for each agent to show their own differences form others. The difference of reaction further leads to self-reflection and the creation of empathy – being aware of how others behave (see next subsection for details).

Generally when encountering an unexpected situation, how much agents adjust their behaviour will depend on their personality and past experiences individually. In the same way each significant event, that brings changes to their needs and triggers the elicitation of their emotion, allows them to learn from experience. Therefore, the learning of cultural emotional knowledge can emerge from intercultural agent-agent and user-agent interactions.

Specifications for Computational Autobiographic Memory

Given that the agent architecture supports both motivation-based personalities and appraisal models, the next key step is to produce the requirements that guide the integration of computational autobiographic memory. On the one hand these requirements are important to the conceptual specification of the overall architecture for ORIENT agents. On the other hand they are necessary in providing a method to validate the implementation of computational autobiographic memory.

Agents with "a life": Autobiographic Memory stores and re-constructs significant experiences that an agent derives from a *long-term interaction* with its environment and surroundings (objects, other agents, human users). By using the rich amount of information in autobiographic memory, the agent can largely extend its *temporal horizon* (Nehaniv & Dautenhahn, 1998; Nehaniv, 1999) which serves as an important foundation for an agent's planning process. The extended temporal horizon means that an agent's autobiographic memory and the remembering process provide 'extrasensory' meaningful information for the agent to modulate or guide its immediate or future behaviour – planning for future actions and storytelling about past or imagined events.

For example, it can relate the current situation to some particular moments in its memory, and then an action can be chosen based on the outcome desired by the agent. Therefore, ORIENT agents with autobiographic memory can be seen as "having a life" – a relatively long period of time – through developing such a kind of *interaction history*.

Repeated user-agent interactions: To facilitate the development of autobiographic memory, we aim to have users *interact repeatedly with the same* agent for a considerable amount of time in ORIENT. On the one hand, with an initial semantic world knowledge which is consistent with the agent's cultural background, the users' input can often violate an agent's expectations and thus create significant events in its autobiographic memory. On the other hand, while learning a specific culture in ORIENT, it is important for users to create a long-term relationship with an agent from that culture. This relationship has two important aspects: 1) the behaviour performed by the agent precisely reflects its culture – avoiding knowledge inconsistency which may be created by other agents or users that the agents is interacting with; 2) users can easily relate a currently perceived experience from a particular situation to past interactions with a specific agent. The latter aspect indicates that individualised interactions, as opposed to anonymous ones, can be more effective in learning other cultures for users in ORIENT.

Most importantly, a long-term relationship implies that users are familiar with the agent – understanding its personality through typical reactions to external events. This allows users not only to infer the agent's cultural background easily, but also to naturally engage empathically with the agent in various special occasions.

Forming relationships with agents: Other game characters in ORIENT which can provide pieces of information as cues for users to solve problems can be modelled as reactive agents (no autobiographic memory architecture) with the sole purpose of guiding users in ORIENT. In contrast, in long-term relationships developed through repeated interactions between the agent with autobiographic memory and users, both sides can gradually recognise each other's role e.g. as friend, ally, or enemy, etc. From this perspective, user-agent interactions in ORIENT emerge socially – the relationship drives the agent to behave differently when users are present, and also to behave differently in interactions with alternative users. This aspect also facilitates the link between an agents' emotion and attitude. Furthermore, agents' narratives can also be personalised for users – reconstructing events from autobiographic memory based on the history of the users' interaction.

Supporting Emotional Coping: In Ho et al (2007a) we showed that FearNot! agents (child-like characters inhabiting a virtual environment designed to teach school children how to better cope with bullying) possessing a simplified version of autobiographic memory can express their emotion by remembering past significant events (Ho et al, 2007; Dias et al, 2007). In FearNot! a user can interact with a victim character by offering potential coping strategies, after watching episodes of bullying take place in a virtual school environment. Our aim in the ORIENT agent architecture is to utilize the process of expressing emotion as one of the coping strategies when the agent is experiencing an unexpected situation.

Based on the information available to the agent from its autobiographic memory, a new set of goals will need to be formed in order to cope with the current unexpected situation and to reduce this discrepancy between expected and actual events. If no relevant information can be found to re-formulate the goals, the agent will be forced to fall back on emotion-based coping strategies. In our previous work (Dias et al, 2007), the agent architecture FAtiMA was implemented with a series of appraisal mechanisms and emotion-based coping strategies rooted in the OCC model (Ortony et al, 1998).

In addition to influencing the normal goal formulation process, agents with emotion can also generate coping strategies in the case that their autobiographic memory is lacking. Finally, these new coping strategies are themselves encoded into the autobiographic memory and can be used in the future to create and continuously update the working "self" to support the goal accomplishment.

Empathising with others: In ORIENT, we aim to create a concrete agent model with autobiographic memory and a feasible approach to enable agents to, at a certain level, "understand[11]" and thus empathise with others. The idea is to allow agents, by reconstructing past experiences, to reach the perceived physical-psychological states (e.g. emotions) of the target agents as closely as possible – perception of the target agent's feelings is a projection of the self. From the long-term autobiographic memory base, agents can remember past experiences which associate with specific physical-psychological states individually, as described in Ho et al (2007b). When a target agent's physical-psychological states are perceived by the empathiser (an agent that possesses autobiographic memory) then the empathiser will attempt to "imagine" a series of events in order to understand the target agent's situation. This first step models cognitive empathy. Afterward, through rehearsing the relevant experiences (internally re-perceiving these events from memory), the empathizing agent reaches similar physical-psychological states. This second step models affective empathy. At the end of this process the empathiser will express its physical-psychological states to the target agent; the target agent then may receive this empathy and feel experientially "understood", as suggested by Dautenhahn (1997, p. 20) "the concept of 'experiential understanding' can be described by dynamic mechanisms of resonance and synchronization". She further proposed that the metaphor of viewing artefacts as dynamic systems, studying interactions between an artefact and its environment, and correlating them with dynamics inside the agent could be a useful approach to experiential grounding of 'social understanding' in agents. The computational modelling of empathy discussed in this article is inspired by this view.

Based on the empathy cycle (Dautenhahn, 1997, Barrett-Lennard, 1993) the following necessary requirements and steps for modelling empathy in agents with autobiographic memory are suggested:

1. The "willingness" of the empathising agent after perceiving the target agent's physical-psychological states: a precondition for empathy to occur is to listen personally with truly interested attention and non-judging receptivity (Barrett-Lennard, 1997).
2. The available experience of the empathising agent: this enables the agent to "imagine" and thus "understand" the target agent's situation – remembering experiences, based on its own experiences or told by other agents, to allow an agent to reach the similar physical-psychological states that the target agent is currently in.
3. Rehearsal of the most appropriate experience: after all relevant experiences are retrieved from the autobiographic memory base and reconstructed with general event representations (Ho et al, 2007b), the empathiser selects the most similar experiences to rehearse internally[12]. The selected experience can bring the closest physical-psychological states (perceived from the target agent) to a) itself – if the experience is from its own or to b) other agents – if the experience was derived from story-telling or observation. Note that the reconstruction and selection of the most appropriate event is based on the empathiser's own perspective, therefore cultural differences may create 'difficulties' for this agent to have a good understanding of the target agent's situation. This exploration of such 'difficulties' is very relevant for ORIENT in order to support intercultural empathy.
4. Verbal or other behavioural expression toward the target agent: based on the selected experience that was rehearsed internally, the empathiser performs a certain behaviour to show its understanding of the situation to the target agent.
5. Finally, the target agent will receive empathy and thus feel "understood". Cultural differences may again create problems for the target agent to understand the expressed empathising action from the empathizer.

With this set of minimum requirements given to both agent architecture design and human-agent interaction specification, the *autobiography* of each agent can be richly developed and thus the agent can react to situations in a more believable (human-like) way. Based on the psychologically inspired approach, we can assume that 1) the agent's conceptualisation of emotional knowledge becomes more solid because meaning is now assigned to the individual agent's memory contents, e.g. as emotional impact; and 2) the inference of another's emotions based on unique subsets of internal physiological reactions can be established through the empathic processes.

As a result of having a dynamic personality model, appraisal processes and specifications of computational autobiographic memory for the implementation of the ORIENT agent architecture, we expect that agents in ORIENT can achieve social learning of the "self" and emotion knowledge from other cultures in their autobiographic memory. Eventually the selective memory encoding processes for emotion concepts from an agent will include: observing the target agents' behaviour, empathising, receiving feedback and exchanging experiences through communication with the agent.

CONCLUSION

In this article we discussed how agents can extend their emotional knowledge in social and cultural interactions with other agents or users. The computationally feasible and psychologically supported approach we proposed here for the implementation of IVAs integrates computational autobiographic memory with a cross-cultural personality model and the specification of requirements that facilitate the interactions. Essentially, computational autobiographic memory consists of temporal and episodic information encoded with sensory and emotional contents. As discussed in the previous section, it is critical to enable agents to have this kind of "autobiography" to derive the meaning of emotions and thus to learn new emotion concepts from another culture.

The main direction for this work is to complete the technical implementation of both the personality model and the computational autobiographic memory and the integration of them into the main agent architecture for game characters in ORIENT. As described in the previous section, the main agent architecture will be developed based on the PSI theory, and the emotion and appraisal models from the OCC taxonomy. Autobiographic memory will then play an important role in generating emotions and perception within the character's "mind", e.g. the character may perform individual emotional reactions while encountering other characters or users. In order to achieve this, appraisal variables must be dynamic and determined from the agent's experiences through the information stored in autobiographic memory. We also aim to carry out an evaluation in order to study whether the proposed memory model can increase the believability and interactivity of agents in the game played by different users.

Another future direction is to explore the social interaction between users and agents through gestures. Since using gestures can be a way to express one's emotion, and meanings of a gesture may vary in different cultures, this part of the research can extend the current approach of cultural and emotional knowledge learning for both users and agents. It is supposed that at any time the user can perform any gesture in front of game characters, but some gestures might have very different connotations depending on the context of the social and cultural interaction. Currently our project is examining the possibility of using the Nintendo Wii Remote[13] for recognising users' gestures as new input interface for ORIENT.

Finally, we are also interested to investigate *group* simulations in cultural learning and interactions. As reported by studies in psychology, the peer-group is increasingly important to adolescents and 90% of them identify themselves with a peer group (Palmonari et al, 1992). Also, according to the group socialization theory (Harris, 1996), teenagers' identities are shaped more by their peers than their parents because of peer pressure present in their environment. Therefore, modelling power relationships and the structure among members within a group is interesting – the expression of an agent's emotion can be influenced by both cultural background and the position of the member in the group.

ENDNOTES

1. Developmental psychologist Tomasello argues that many unique characteristics of humans are elaborations of one trait that arises in human infants at about nine months of age: the ability to understand other people as intentional agents (Tomasello, 1999).
2. Markus and Kitayama (1991) argue that the independent and interdependent views of the self in psychology can have a systematic influence on different aspects of cognition, emotion and motivation. They suggest that, in many cultures of the world, the Western notion of the self is seen as an *independent* entity "containing significant disposition attributes and as detached from context". Next they point out, however, that in many other constructs the self is viewed as *interdependent* with the surrounding context, and it is the "other" or "the "self-in-relation-to-other" that is focal in individual experience.
3. Note, we do not claim that the artificial agents possess a concept of "self" comparable to that of e.g. human beings. We are using this concept in a computational sense with reference to an autobiographic memory architecture.

4 Bruner (1990) quotes the results of Barlett's serial reproduction experiments in *Remembering* (1932), namely that the most distinctive characteristics of human memory schemata are 1) being under control of an affective cultural "attitude", and 2) any "conflicting tendencies" likely to disrupt individual poise or to menace social life are likely to destabilize memory organization.

5 In this article we define narrative as "a story being told by, perceived by, or remembered (reconstructed) by an agent", thus a narrative requires a story and an agent interpreting this story. The agent's motivations, goals and other internal states, as well as the context of when and where the story is being told, perceived or remembered, will influence how the story is being (re-)created. 'Narrative story-telling' refers to the specific process of how a story is being told by an agent.

6 Childhood amnesia suggests that children from birth to approximately 5 years of age do not seem to form extensive personal episodic memories. For details, see (Wetzler& Sweeney, 1986).

7 The reminiscence bump is the effect in the temporal distribution of autobiographical memory which suggests that people tend to recall more personal events from adolescence and early adulthood (10-25 years) than personal events from other lifetime periods (Rubin et al, 1986).

8 Life-period' or 'life-time' of an agent refers to the computational duration of its memory, in the sense of how long the agent interacts with and remembers experiences in its environment.

9 Note that we are not using the Big Five model to operationalise cultural differences in agents. We use it to create roles for a virtual role-play approach which is only an aid or auxiliary means to implement personality differences in agents through need states. Personality dimensions such as the Big Five can be compared across cultures – empirical data shows that their meaning is comparable across different cultures in each dimension (Pike, 1954; Leung & Bond, 1984).

10 Praiseworthiness is the action that an agent performed a praise- or blame-worthy behaviour, from the observer's point of view. Therefore it relates to an agent's abilities to 1) predict the consequences of actions (*need for certainty*) and 2) master problems and tasks, e.g. satisfy one's needs.

11 Note that "understanding" as used in this article in a computational sense refers to the agent's ability to relate experiences to its internal states and past experiences, it does not relate to the phenomenological nature of understanding in biological systems.

12 Rather than assigning the physical-psychological states associated with a past experience directly to an agent, rehearsing this experience is necessary to allow the agent to have another comprehension of this event based on the existing semantic knowledge and activated goals. Furthermore, when an agent rehearses a past experience internally, both the importance and endurance of this experience in the agent's memory are increased.

Chapter 2.13
Social Navigation and Local Folksonomies:
Technical and Design Considerations for a Mobile Information System

Mark Bilandzic
Technische Universität München, Germany

Marcus Foth
Queensland University of Technology, Australia

ABSTRACT

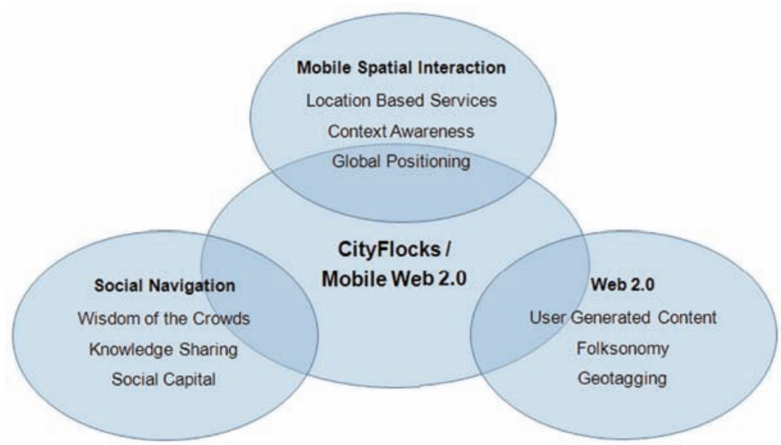
Web services such as wikis, blogs, podcasting, file sharing and social networking are frequently referred to by the term Web 2.0. The innovation of these services lies in their ability to enable an increasing number of users to actively participate on the Internet by creating and sharing their own content and help develop a collective intelligence. In this chapter the authors discuss how they use Web 2.0 techniques such as "folksonomy" and "geo-tagging" in a mobile information system to collect and harness the everyday connections and local knowledge of urban residents in order to support their social navigation practices.

DOI: 10.4018/978-1-60566-208-4.ch005

NTRODUCTION

Our physical world holds certain characteristics that enable us to interpret what other people have done, how they behaved, and where they have travelled. Sometimes, we can see traces on physical objects that provide hints about people's actions in the past. Footprints on the ground left by previous walkers can show us the right way through a forest or, in a library, for example, dog-eared books with well thumbed pages might be worthwhile reading as they indicate the popularity of the text. The phenomenon of people making decisions about their actions based on what other people have done in the past or what other people have recommended doing, forms part of our everyday social naviga-

Figure 1. CityFlocks is placed in an interdisciplinary field, embracing topics in social navigation, mobile spatial interaction and Web 2.0 technology



tion (Dourish & Chalmers, 1994). In contrast to physical objects, digital information has no such 'visible' interaction history *per se*. We do not see how many people have listened to an MP3 file or read a Webpage. In a digital environment people do not leave interaction traces, leaving us, according to Erickson and Kellogg (2000), 'socially blind'. However, the high value placed on social navigation in the physical world has motivated people to start thinking about it as a general design approach for digital information systems as well (A. Dieberger, 1995; A. Dieberger, 1997; Forsberg, Höök, & Svensson, 1998; Svensson, Höök, & Cöster, 2005; Wexelblat & Maes, 1999).

This chapter explores some of the technical and design considerations that underpin the conception and development of a mobile information system called *CityFlocks*. It enables visitors and new residents of a city to tap into the knowledge and experiences of local residents and gather information about their new environment. Its design specifically aims to lower existing barriers of access and facilitate social navigation in urban places. The technical development phase and the empirical usability research of *CityFlocks* has been reported elsewhere (Bilandzic, Foth, & De Luca, 2008). The purpose and focus of this chapter is to discuss the underlying design concepts that informed this social software. These concepts are positioned at the intersection of three broad areas of research and development that inform human-centred and participatory methods for designing interactive social networking systems on mobile platforms: social navigation, Web 2.0, and mobile spatial interaction (Figure 1).

First, the concept of social navigation and how people make use of it in the physical world are examined. Relevant previous studies and examples are discussed that apply social navigation as a design approach, e.g., for virtual information spaces on the Web. Based on the success and popularity of what has now been coined 'Web 2.0' services, the second part of this chapter analyses a number of Web development trends that foster participatory culture and the creation and exchange of user generated content. Some of these developments that introduced more and more social interaction and navigation methods to the Web, such as user participation, folksonomy and geo-tagging, were reappropriated to inform the design of *CityFlocks*. Given new generation mobile phones that allow global positioning, Web 2.0 technologies that were initially aimed to facilitate social navigation on the Web, can now be used to facilitate social navigation in physical places. The third part of the chapter discusses related projects in the field of mobile spatial interaction, a research area covering mobile applications that deal with information related to the user's surroundings. The review of the aims, strengths and weaknesses of previous research projects in this field refines the research trajectory which guides the development of the *CityFlocks* prototype and potentially similar mobile information systems. The chapter thus reveals further opportunities and issues regarding social navigation in the context of new generation mobile phone services, the 'Mobile Web 2.0' (Jaokar & Fish, 2006).

SOCIAL NAVIGATION

The phenomenon of people asking other people for advice is part of a broader concept called social navigation, at first introduced by Dourish and Chalmers (1994). They describe it as 'moving towards a cluster of other people, or selecting objects because others have been examining them' (Dourish & Chalmers, 1994). It can be seen as a form of navigation, where people make decisions about their actions based on what other people have done or what other people have recommended doing. Tourists in a new town for example, often choose to go to restaurants that are crowded with people rather than picking empty places. The fact that a fair crowd of people has decided to walk down a certain path within a space, enables us to be more comfortable to do so as well (Norman, 1988; Rheingold, 2002; Wexelblat & Maes, 1999). We might also take such interaction histories between objects and people as a warning. For example, if we observe skid marks while driving on a road, we implicitly slow down because the marks show us that an earlier driver obviously had to brake rapidly.

Mediated and Unmediated Social Navigation

Compared to physical spaces, in the digital world there are no such visible hints that naturally describe an object's interaction history. In contrast to a physical paperback book or a CD, digital documents or music files do not have dog-eared pages or scratches that give us an idea about their amount or time of usage. Similarly, footprints of earlier walkers in the wood might show us the right way, as opposed to virtual information spaces, such as the Web, that do not provide any natural traces and visible paths that could help following navigators. People have recognised that such traces on physical objects provide important information for their navigational behavior in physical spaces and have constantly been trying to transfer the same sort of navigational aid to virtual information spaces, especially to the Web (A. Dieberger, 1997, 2003; Höök, Benyon, & Munro, 2003).

In the recent years people have developed mediated techniques and technologies that provide much more sophisticated social navigation possibilities. In the physical world we are restricted to visual traces on objects (e.g. dog-eared pages on a book) that only give us a vague hint about its quality. Using the second possibility in a non-digital world to find out about a book's quality, asking people directly about their personal opinion, we are restricted to a number of friends or librarians who might have read it before. In contrast to that, the Web has some clear benefits for making use of social navigation. It connects hundreds of millions of people from all over the world in one medium. People have developed services and technologies that leverage this physical connectivity of Web users to connect them on a social level as well. To continue with the book example, Amazon (http://amazon.com) for instance has created a platform that brings together people from all over the world to comment, review and exchange personal opinions before they purchase a book. The platform keeps track of the books each user has purchased in order to identify and suggest titles that other users with the same shopping history have read as well. As all purchases, reviews and ratings are tracked and saved in a database, collaborative filtering methods can be applied to analyze the taste of many people to automatically predict the book taste of individual users. Providing such a mediated social environment, Amazon has created far more sophisticated social navigation affordances than traditional book stores ever had.

In the last couple of years the social navigation approach for designing Web services has become ubiquitous in the Web due to the appearance of a set of Web 2.0 technologies which facilitate rich user interfaces (e.g. AJAX, CSS), the use of interchangeable data formats (e.g. XML, RSS) and a user based taxonomy (e.g. folksonomy, geo-tagging). The high potential of Web 2.0 technologies combined with the fast development of mobile phone capabilities, such as global positioning technology and high-speed Internet access opens up great capabilities to develop mediated social navigation aids for mobile phone users in physical spaces. Similar to how Amazon leverages the physical connectivity of Web users to provide social aid and recommendations for book shopping, the connectivity of mobile phone users and recent mobile phone technology can be leveraged to enhance social navigational help when searching for places in the physical world.

The Evolution of Social Navigation on the World Wide Web

The problem in the early stages of the Web and its hyperlink based navigation was a lack of navigational and visual structure of space. As Dieberger claims, this very lack of visual structure was the reason that motivated people to start sharing their link references on their personal home pages (A. Dieberger, 1997). Users were ironing out the lack of structure in the Web by providing navigational help to each other. This social sharing of information or hyperlinks with others on the Web is the major enabler of what we call *surfing* or *browsing* the Internet, which turned out to be a popular search strategy for finding Websites on the Internet (Erickson, 1996). People have actually adopted the same strategy they usually apply to find information in the real world: They ask people in their social networks and if they can not help, they would know someone who knows and eventually they would get the information they were looking for. Similarly, people started to search for information on the Web by browsing through personal Websites and following their links to other personal Websites until they found the site with the specific information. Erickson describes this early phenomenon in the World Wide Web as a *"slow transformation from an abstract, chaotic, information Web into what I call a social hypertext"* (Erickson, 1996). With this social hypertext, the Web has become a medium that people can easily browse through the immense pool of social capital and knowledge available in their networks.

Social navigation has become a key principle of how we search for information and navigate the Web today. One example that illustrates its breakthrough on the Web can be seen in the history of search engines. While early search engines until 2001, such as Lycos, Yahoo or Altavista were still based on big Web directories, Google has outpaced all other players with *relevance ranking*, a search concept based on social navigation. Google implemented this concept in its *PageRank* algorithm. For any URL on the Web, it analyses the amount and content of Web pages that refer to it when calculating its position in the search results (Google, 2007). The more people set links to a particular Website, the more important Google considers it to be and the further up it appears on the result page. What Google has achieved with *PageRank* is basically an automation of searching for a Website that most other people hyperlink to from their own Webpage. Thus, for any topic or search request it provides a ranking of pages that are obviously considered to be the most popular among other people on the Web.

The CityFlocks prototype is a similar system designed for local places and services in a city. For any type of local service in a city, e.g. ‘fish restaurant’ or ‘tennis court’, the system comes up with a ranking of the most popular, relevant places in the city, based on the opinion and ratings of the local community of residents. Harnessing the intelligence of local residents and their participation on a shared knowledge platform can democratise urban information, such as opinions about a local service or place. The next section explains how participatory culture has transformed the Web from something we considered as a pure information space to what it has become today, a thoroughly social medium (O’Reilly, 2005).

WEB 2.0

The term Web 2.0 has been coined to identify – arguably – a second-generation of Web services that aim to facilitate collaboration and sharing between users, such as social networking systems, file sharing sites and wikis. These services provide means for users to engage in participatory culture that are no longer limited to the technically versed or the civically inclined. Scholars such as Jenkins (2006) and Burgess et al. (2006) have identified socio-technical trends towards a wider (‘vernacular’) ability of people to participate in digital culture through personal expressions of creativity. Many examples of how participatory culture is enabled by recent technological innovation rely on Web 2.0 applications and services such as blogs, Wikipedia, YouTube, Flickr, and social networking sites such as Facebook, which are arguably more open, collaborative, personalisable, and therefore participatory than the previous internet experience. According to Kolbitsch & Maurer (2006), the participatory qualities of Web 2.0 encourage ordinary users to make their knowledge explicit and help a collective intelligence to develop. In an urban context, Foth et al. (2007) argue that such capabilities present diverse possibilities for a profound urban epistemology to evolve. New tools and practices, inspired by user-led innovation, are springing up faster than our ability to analyse them individually. It has been claimed that such a social navigation approach can foster a new generation of user experience for mobile applications as well (Höök, 2003; Jaokar & Fish, 2006). Bypassing the terminology debate, whether the term ‘Web 2.0’ is adequate, this section focuses in particular on three characteristics of Web 2.0 developments, that is, user participation, folksonomy and geo-tagging. It prepares the discussion in the next section about the ways these characteristics can be applied to a mobile spatial interaction service that facilitates social navigation in the physical world.

User Participation: Let the Users Generate Content

Looking back at the history of the Internet, we can see that its real breakthrough as a social mass-medium first came with the introduction of the World Wide Web, the number of users skyrocketing from 600.000 to over 40 million within only five years (Friedman, 2006, p.61). One major reason for this magnificent success of the Internet was that for the first time people were given a medium which allowed them to participate in the content creation process. In contrast to other media such as television or radio which only enables professional information providers to broadcast information, the Web enabled individual users to contribute. Hypertext Markup Language (HTML) offered users means to codify, upload and share their own content with other users on the network. With hyperlinks they were able to refer and set shortcuts to other relevant or interesting pages. This is in fact how the Internet became a social medium. The combination of user participation and the hyperlink system enabled the Web to be used as a tremendous repository of social knowledge (Erickson & Kellogg, 2000).

However, the majority of Web users were

still only information consumers. The lack of technical background knowledge, such as learning a markup language, uploading a site to a Web server or take care of the site administration has prevented many people from creating their own Webpage (Kolbitsch & Maurer, 2006). This is what the introduction of Web 2.0 technologies has dramatically changed. They flattened the technical obstacles and made it easy for anybody, not only geeks and professional information providers to engage in the content creation process. With wikis, Weblogs or file sharing services for example, people do not need to learn HTML anymore in order to publish content on the Web. Such services provide frameworks, templates and tools that abstract from the technical layers and enable ordinary users to easily become authors of Web content. User generated content became a new paradigm for this revolutionary generation of Web 2.0 services (O'Reilly, 2005). Web 2.0 blurs the strict borderline between consumers and information providers which eventually leads to a trend of entirely community-driven Web services (Lindahl & Blount, 2003).

People were given a tool to discuss ideas, exchange information and give advice to each other. With Flickr (http://flickr.com) and YouTube (http://youtube.com) people can easily share their pictures and videos; Blogger (http://blogger.com) and Typepad (http://typepad.com) allow individuals to publish personal stories, and Yahoo Answers (http://answers.yahoo.com) provides a platform for people to answer each other's questions on specific topics. The content of all those services is almost entirely created by the community of its users. This trend towards flattening technical barriers and giving individuals a voice in a mass medium, what Anderson refers to as 'the Long Tail' (Anderson, 2006), is one of the key success factors of Web 2.0. While conventional Web services have mostly been providing content from a single entity (e.g. a professional content provider), they were outpaced by services leveraging the collaboration of many different entities which would all upload and share their content with others. Following this community driven approach, Wikipedia (http://wikipedia.org), an online encyclopedia, has outpaced Britannica, the most successful encyclopedia till then. The huge amount of Web users, who add or edit Wikipedia articles, renders the content creation process much more flexibly than the relatively small number of Britannica authors. Consequently, the articles in Wikipedia are more current and have a much larger range of topics, covering 3.7 million articles in 200 languages from more than 45,000 registered users who upload about 1,500 new articles every day (Giles, 2006). The benefit of such collaborative information platforms is that their content is based on the collective intelligence of a crowd of people. As Surowiecki (Surowiecki, 2004) puts it, "the many are always smarter than the few", meaning that the information content from a massive user community can not easily be outpaced by a single entity. O'Reilly argues that this paradigm is one of the main drivers of this new generation of Web applications, the Web 2.0 (O'Reilly, 2005).

The community driven design approach of those services transformed the Web in a way that they now take advantage of the dynamic intelligence and content generating power of its community to provide full-blown and highly up-to-date information (Kolbitsch & Maurer, 2006; O'Reilly, 2005). This user participation and uploading of information facilitates social navigation on a much larger scale than we have in the physical world. In fact, the very process of designing proper affordances that allow people to socialise and help each other to navigate digital systems, has been a research topic in various domains (Höök et al., 2003), e.g. online food shopping (Svensson et al., 2005) or Web browsing (Andreas Dieberger, 1995; A. Dieberger, 1997, 2003; Wexelblat & Maes, 1999), where e.g. Wexelblat and Maes have introduced Footprints, a system that tracks and visualises the navigational behavior of a Website's visitors in order to provide future visitors with navigational aids such as maps and paths (Wexelblat & Maes, 1999).

These studies have shown that social navigation affordances do enhance users' experiences in digital information spaces. They have explored a number of design principles that are significant in different use cases and domains. Additionally, there are suggestions for some key principles, e.g. privacy, trust, personalisation and appropriateness that should be considered in general when designing for social navigation in digital systems (Forsberg et al., 1998).

Folksonomy: Let the Users Organise Content

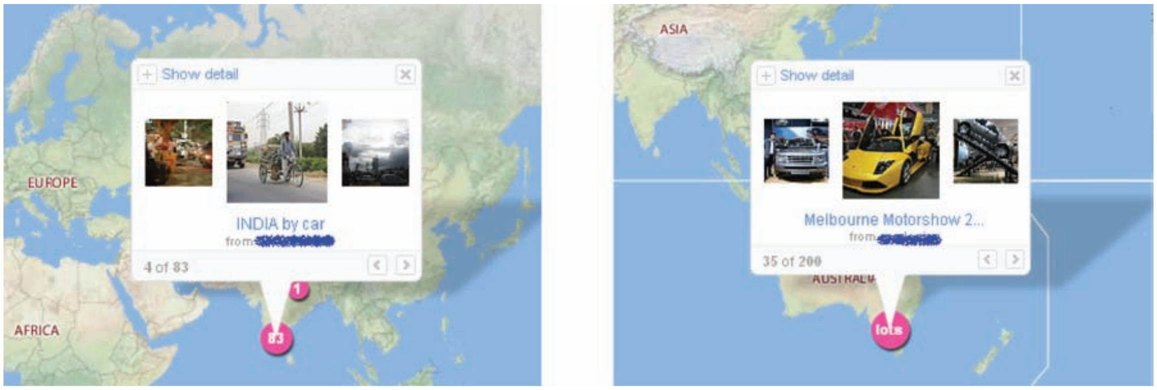
With the amount of user generated content constantly increasing in Web services, there is a need to structure and organise all the uploaded material. This would ensure that the submitted content could be identified and retrieved at a later point in time. One straightforward way is to set up an indexing system, where all the information would be put in pre-fixed categories. This process usually requires highly trained information professionals and is very inflexible, e.g. for storing information that does not fit in any of the existing categories (Macgregor & McCulloch, 2006; Vander Wal, 2007). In order to provide a more flexible storing and retrieval system, recent Web services that deal with huge amounts of user generated content like Flickr or Del.icio.us, have employed a technique that has come to be known as 'folksonomy' (Golder & Huberman, 2005; Macgregor & McCulloch, 2006; Vander Wal, 2007). Folksonomy is a user created taxonomy for people to generate short keywords about their uploaded content rather that putting them in fixed categories. By assigning these keywords or so-called tags, the semantics of various information resources can be easily described (Amitay, Har'El, Sivan, & Soffer, 2004; Casey & Savastinuk, 2007; Coleman, 1988; Macgregor & McCulloch, 2006; Torniai, Battle, & Cayzer, 2005). A user submitting a picture of her new car on Flickr could for instance use the tags 'car', 'automobile', 'porsche' and 'cabriolet'. In contrast to an index, the picture will not be saved in any pre-fixed category in the system, but can be retrieved under any of those keywords. As users can assign such decentralised keywords to their content, there are no restrictions to what information one can submit as opposed to the constraints of fixed categories. The organisation of the information resources are completely controlled by the users themselves, which makes the system cheaper and much more flexible. Most recently, the advantages of this user based contextualisation of items have been used to facilitate information retrieval in libraries as well (Casey & Savastinuk, 2007; Courtney, 2007).

This collaborative tagging method, initially developed to organise information on the Web, can be transferred to a mobile information system that people use to describe places in the physical world. Like Delicious (http://del.icio.us) uses collaborative tagging to let Web users identify, describe, recommend and organise Internet-addresses (URLs), CityFlocks was designed in a way that allows the community of local residents to do the same with physical places in a city. Comments on the ice-cream parlor next door could for example be tagged with 'ice-cream', 'dessert' and 'coffee'.

Geo-Tagging: Spatially Contextualised Content

Encouraging ordinary people as content providers for local information can be an effective way to provide a democratic, current and comprehensive pool of local information and news (We Media, 2003). In contrast to citizen journalism platforms, e.g. MyHeimat (http://myheimat.de) or EdgeX (http://edgex.org.au), which enable local citizens to upload extensive stories relevant to their wider city area, there are use scenarios which indicate that

Figure 2. Example from Flickr.com - Folksonomy and geo-tagging enable a flexible organisation and retrieval of pictures



spatial contextualisation sometimes requires finer granularity. A story or piece of information might for example only be relevant to a neighbourhood in the city or a specific place, like a shop.

In this cases geo-tagging, a method to attach latitude and longitude identifiers, enables people to put their information resources such as text, pictures or videos into a specific geographic context (Torniai et al., 2005). Such spatially and semantically contextualised information can be applied to overlay the real world with a virtual information space to be used for mobile services (Burrell & Gay, 2002; Jaokar & Fish, 2006), and more specifically, create a mediated social environment that helps people navigate physical spaces by using location aware mobile devices. Qype (http://qype.de) for example provides such a service which uses user-generated, geo-referenced comments in a mobile information service.

Similarly, recent photo cameras can automatically attach the latitude and longitude coordinates of the current geographical position when taking pictures. Later, the pictures can be displayed with special programs or Web services on a map where they were taken. Locr (http://locr.com) for example provides such an online service to organise your picture collection on a geographical map and share them with others. As all pictures are geo-tagged people can compare their own pictures with the photos that other people or friends have taken at the same place or city. Or they can use it to see pictures of a place they plan to visit soon in order to learn about it in advance. Collaborative Tagging has enabled Web users to describe the content and theme of their pictures and make them retrievable for other people. Geo-tagging allows them to additionally share the geographic location of where they have taken each of their pictures. Enriching the metadata of one's pictures with both, folksonomy tags and geographic identifiers enables a very specific and flexible organisation and retrieval of pictures in a shared database. Figure 2 shows a search request on a Flickr-map (http://flickr.com/map) for pictures that were taken in Bangalore, India and Melbourne, Australia and annotated with the tag 'car'.

Dealing with respectively large masses of stored data, Web 2.0 services have developed two very powerful information organisation methods – folksonomy and geo-tagging. With the design of the *CityFlocks* prototype we sought to transfer Web 2.0's participatory culture as well as the folksonomy and geo-tagging methods to foster a location and context sensitive mobile information system. Applying collaborative tagging and geo-tagging to a community driven, mobile information system enables people to annotate urban places in their neighbourhood with comments and recommendations and describe their entries with tags for later retrieval purposes. Such an urban information system helps collecting local knowledge and experiences in a shared knowledge platform about inner-city places and facilities. The collective intelligence and knowledge of local residents about particular places and local services in a city is much bigger than any single entity like a professional agency could provide. With the geographical identifiers in its metadata, the submitted content is used to support tourists and visitors in finding popular local services in new cities recommended by locals.

MOBILE SPATIAL INTERACTION

The previous sections have covered related projects and literature on social navigation and relevant Web 2.0 technologies. This section is dedicated to related work and research studies undertaken on the mobile platform, specifically mobile spatial interaction, i.e. location and context-aware mobile applications that refer to information relevant to the current surroundings of the user. Such applications can be classified in four different categories: Systems that facilitate navigation and wayfinding in geographic places, mobile augmented reality applications, and applications that create or provide access to information attached to physical places or objects (Fröhlich et al., 2007). In the context of *CityFlocks*, the latter two categories are of special interest.

Lancaster University's GUIDE project for example is an electronic tourist guide that provides users with context-aware information, depending on their profile, interests and location. Its focus is on providing an automated personalised guided city tour with dynamic, interactive services. However it can only read information, but does not provide any content-generating functions to its users (Cheverst, Davies, Mitchell, Friday, & Efstratiou, 2000; Lancaster University). Another example for accessing virtual context-information on mobile devices, are applications that are based on visual codes (Ballagas, Rohs, & Sheridan, 2005; Rohs, 2005; Rohs & Gfeller, 2004; Toye et al., 2004). Using mobile phones with embedded photo cameras, one can select those visual codes and request information related to the object or place where the respective code tag is attached to. A drawback of this method is that the user can request information only in-situ, but not from remote places.

The other type of applications relevant to the context of this work enables users not only to read but also create spatially contextualised content. GeoNotes (Espinoza et al., 2001) and Urban Tapestries (Proboscis, 2003) for example allow mobile users to attach virtual sticky notes to particular latitude / longitude coordinates. Equipped with Wi-Fi enabled Personal Digital Assistants (PDAs), GeoNotes users can see other users' notes that were left behind in their current immediate surroundings. Even though GeoNotes embraces users as information producers rather than just passive consumers, it is not an entirely community driven service. Its major weakness is that the user generated post-it notes are managed in hierarchical, tree-like location structures that have to be set up in advance manually. Thus people can create location based content, but are limited in specifying how it can be retrieved by other users. Urban Tapestries on the other hand allows users to self-organise their comments and relationships to different places with category-like "threads" (e.g. "my favorite pubs and clubs"). E-Graffiti, a context-aware application evaluated on a collage campus, detects each participating student's location on the campus and displays notes that were left behind by other students (Burrell & Gay, 2002). Just-for-Us (Kjeldskov & Paay, 2005) and the George Square project (Brown et al., 2005) represent context-aware real-time applications that provide an enjoyable shared social interaction of remote users that follow a common goal. While Just-for-Us helps a group of friends in a city to identify a good place to meet depending on their individual current locations, the George Square project focuses on location, photography and voice sharing functions to let on-site and off-site users collaboratively explore a city sight.

Much of the previous work in mobile spatial interaction is on enabling users to access or add content to physical places or objects. They focus on techniques that allow people to retrieve locative information or share it with others by attaching stories, thoughts, experiences and knowledge to specific places. Besides the various use scenarios, the applications primarily differ in the interaction design of specific features (Tungare, Burbey, & Perez-Quinones, 2006), e.g. access virtual post-its from remote places (Espinoza et al., 2001; Proboscis, 2003) vs. in-situ access (Burrell & Gay, 2002; Lancaster University, ; Rohs, 2005), push (Espinoza et al., 2001; Kjeldskov & Paay, 2005) vs. pull services, expiration dates of the messages or private vs. public messaging (Burrell & Gay, 2002; Espinoza et al., 2001). While most of the previous projects discuss such different features around indirect and asynchronous interaction methods (i.e. people exchange information by attaching text or multimedia content to specific places), not much work has yet been carried out on studying direct interaction methods (e.g. phone call, text message) in the context of spatial interaction.

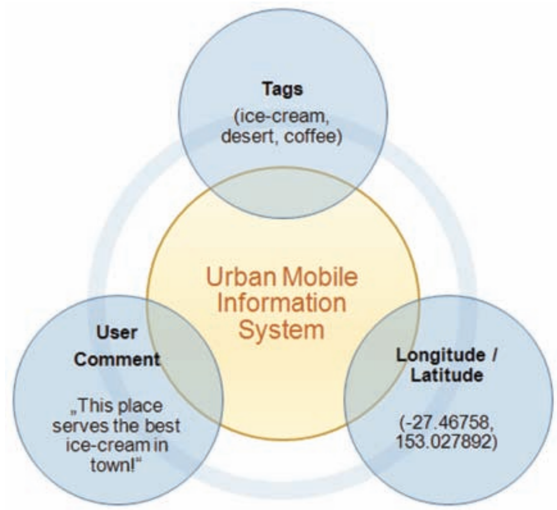
CityFlocks focuses on evaluating the performance of people using direct and indirect social navigation methods when gathering information about a specific place. In a similar context, solely the George Square study supported a voice connection and has shown to be the most valuable channel for people when collaboratively exploring a city sight. In contrast to George Square, our participants were not recruited as pairs of friends, but complete strangers. Furthermore, the context is information and knowledge sharing in urban environments rather than collaborative exploration. *CityFlocks* users can, in addition to leaving relevant text or multimedia content at specific places, also attach their contact information. Other mobile phone users who are interested in more details about the place can then contact the author of the virtual post-it directly via voice-link or a direct text message. In a field study we evaluated which method, direct or indirect communication, users prefer in which situation and context (Bilandzic et al., 2008). The outcomes inform future mobile spatial interaction systems that are targeted in providing information to its users about places and objects in their immediate surroundings.

CONCLUSION

Originally social navigation was restricted to visible interaction histories that were naturally left behind and thus clued on earlier physical interaction between people and the respective object. People interpret these hints as a message, recommendation, warning or just a note telling them something about the type of interaction the previous navigator had with the object. Above, we have seen how online social communities have improved the social navigation experience for special interest groups. With the rapid developments of mobile information and communication technology, the methods which have been developed for such communities on the Web, can also be used to enhance social navigation in physical spaces (Höök, 2003).

There is an emerging trend that sees the network connectivity of mobile phone users leveraged to create a mediated social environment where people who are interested in particular geographic locations can exchange information, personal opinions and experiences with the respective place. This would for example enable visitors of a new city to access the knowledge and experiences from local residents about inner-city facilities. Recent developments in the mobile technology sector indeed have made this scenario become realistic. Multimedia mobile phones with voice recording and photo camera capabilities as well as mobile high speed Internet networks enable users to create and upload location based content anywhere,

Figure 3. A resident-driven mobile information system: A mashup of folksonomy tags, location-based user recommendations, and geographic identifiers



anytime. Equipped with such a device, people can easily capture and digitise whatever they have experienced at the very point of inspiration, using text, video or audio recordings (Jaokar & Fish, 2006). A mobile Web application would let them upload such location based recommendations and make them available for other mobile users who plan to navigate the same space later on. For example they could create a recommendation for an ice cream parlor, saying *'This place serves the best ice-cream in town. They have a wide range, cheap prices and a very friendly service!'* and attach a rating, e.g. 8 out of 10. Applying collaborative filtering techniques, the service provides a ranking of the most popular places based on all mobile users' entries. This mind-shift in designing mobile services towards a high engagement of individuals has great potential to enhance peoples' experience when navigating physical spaces (Höök, 2003; Jaokar & Fish, 2006). Turning mobile phone users into in-situ journalist who can upload location based ratings, comments and recommendations to a shared community platform will eventually form a huge social knowledge repository decentralising control over information about local services.

This idea targets a community-driven urban information service. The service is meant to provide an infrastructure to let residents become authors of information regarding their own neighbourhoods and make them available for interested people in the city, e.g. visitors and tourists. User participation, folksonomy and geo-tagging are three design methods that have become popular in Web 2.0 community-platforms and proven to be an effective information management tool for various domains (Casey & Savastinuk, 2007; Courtney, 2007; Macgregor & McCulloch, 2006). Applying such a design approach for a mobile information system (Figure 3) creates a new experience of collaboration between mobile users, a step towards what Jaokar refers to as the 'Mobile Web 2.0' (Jaokar & Fish, 2006), that is, a chance for mediated social navigation in physical spaces on the move.

ACKNOWLEDGMENT

The author would like to thank Helen Klaebe, Greg Hearn, Ronald Schroeter, and all study participants for their support. This study was supported by the Institute for Creative Industries and Innovation at Queensland University of Technology and the Center for Digital Technology and Management at the Technische Universität München. Further support was received through the Australian Research Council's Discovery Projects funding scheme (project number DP0663854), *New Media in the Urban Village: Mapping Communicative Ecologies and Socio-Economic Innovation in Emerging Inner-City Residential Developments.* The author is grateful to be a scholarship recipient of the German National Academic Foundation (*Studienstiftung des deutschen Volkes*). Dr Foth is grateful to be the recipient of an Australian Postdoctoral Fellowship.

KEY TERMS AND DEFINITIONS

Folksonomy: In the context of the Web 2.0 discussion, a folksonomy (sometimes also known as a 'tag cloud') is a user-generated taxonomy made up of key terms that describe online content. By assigning these freestyle keywords or so-called 'tags', the semantics of various information resources can be described in a more flexible, decentralised, collaborative and participatory way than fixed categories allow for. The term has been coined by Thomas Vander Wal.

Geo-Tagging: An approach which adds latitude and longitude identifiers as metadata to online content. It enables people to embed their information resources such as text, pictures or videos in a specific spatial and semantic context to augment the physical world with virtual information. Such a mediated social environment can help people navigate physical spaces by using location aware mobile devices.

Local Knowledge: Knowledge, or even knowing, is the justified belief that something is true. Knowledge is thus different from opinion. Local knowledge refers to facts and information acquired by a person which are relevant to a specific locale or have been elicited from a place-based context. It can also include specific skills or experiences made in a particular location. In this regard, local knowledge can be tacitly held, that is, knowledge we draw upon to perform and act but we may not be able to easily and explicitly articulate it: “We can know things, and important things, that we cannot tell” (Polanyi, 1966).

Mobile Spatial Interaction: The increasing ubiquity of location and context-aware mobile devices and applications, geographic information systems (GIS) and sophisticated 3D representations of the physical world accessible by lay users is enabling more people to access information relevant to their current surroundings. The relationship between users and devices as well as the emerging oportunities and affordances are summarised by the term ‘mobile spatial interaction’.

Mobile Web 2.0: The suite of systems and mobile devices which either run existing Web 2.0 applications or re-appropriate Web 2.0 characteristics (tagging, user participation, mash-ups, personalisation, recommendations, social networking, collective intelligence, etc.) for the specific context of mobile use and mobile devices.

Social Navigation: The process of guiding activities aimed at determining our position and planning and following a specific route based on what other people have done or what other people have recommended doing. First introduced by Dourish and Chalmers (1994), they describe it as ‘moving towards a cluster of other people, or selecting objects because others have been examining them’.

ABSTRACT

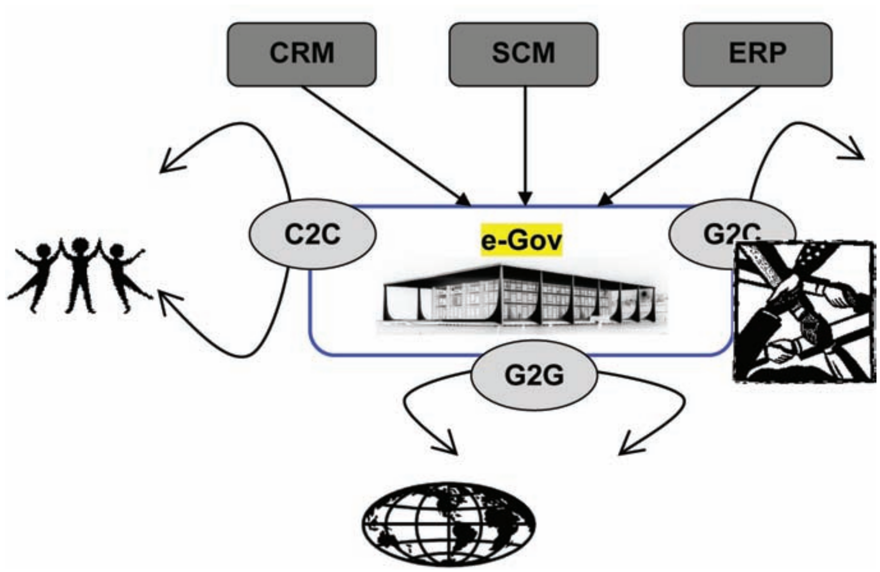
The technological advances establish new communication forms between people and have also reached the government sphere and its activities, improving access to information and allowing greater interaction between citizens through C2C (Citizen to Citizen) Services. Based on these aspects, this chapter presents a proposal for software architecture, using a social network to map the relationships and interactions between citizens, accounting and storing this knowledge in a government ontological metadata network. Using UML notation (Unified Modeling Language) for Software Engineering process and Java platform for development, a software prototype was modeled and developed in order to manage and handle e-Gov-driven social networks, using ontological metadata to computationally represent the social ties. This prototype is also capable of providing graphical display of social networks, enabling the identification of different social links between citizens, creating a tool intended for government agencies, since it allows a quantitative analysis of information in the social network.

DOI: 10.4018/978-1-60566-650-1.ch039

INTRODUCTION

The accelerated advances of Information and Communication Technologies (ICT) have facilitated information exchange among people, geographically separated or not. The availability of faster, computer-mediated interaction devices and technologies enabled the emergence of new kinds of relationships

Figure 1. e-Gov as a merge of CRM, SCM and ERP systems



among people, establishing the concept of virtual communities (Rheingold, 2000).

Similarly, governments have been following the above mentioned technological trends, as a way to improve the services they are meant to make available to their citizens, or even for training civil servants in order to improve the decision-making process. This progress enabled the emergence of a new concept for such strategies of computer-mediated governance, often called e-Government (briefly, e-Gov).

These new strategies of using computer-based solutions for improvement of governmental actions have led governments to look for digital convergence through the integration of different systems (G2G), providing faster and clearer information to citizens (G2C), creating solutions to a more participatory politics with the community (C2G) and promoting interaction and integration among citizens (C2C). The development of such structures should take into account the ability to provide high-quality services, besides facilitating an efficient integration between citizens and government agencies, thus making them each time more similar to CRM (Customer Relationship Management)-based systems (Sang et al., 2005). Such e-Gov systems must also handle massive volumes of data, a considerable number of actors, as well as the multiple variables involved in procurement and financial transactions in a similar way to SCM (Supply Chain Management) systems. Another aspect that must be implemented efficiently is the standardization and management of operations and processes, similarly to the functionalities normally found in an ERP (Enterprise Resource Planning). Figure 1 shows how the merging of such different systems could result in more efficient e-Gov systems.

E-Gov systems that are targeted directly to citizens must promote social integration and must also have tools to help people to meet their needs. A possible way to achieve this goal is through the implementation of adaptive systems that are able to modify themselves according to each information and data inserted into them. Through the use of technical analysis (Hanneman, 2005), each citizen could be represented as an actor in a network; interactions and relationships among them could be represented as relational ties, thus forming an one-mode network.

Knowledge distributed among citizens of a network could also be classified and categorized through metadata, and stored into ontological databases. Thus, ontology-driven computational agents would be able to make inferences about such data and, with this kind of semantic analysis, dynamically expand the social network, consequently extending the relationships of each actor.

Based on the information available through the network, each citizen connected to the system will be able to search and find people which have common needs and interests to discuss possible solutions for individual or common problems. In this context, a social network could be easily viewed in its graphical form, making easier the task of creating groups of citizens, which would be a useful tool for governments to examine the issues discussed in society, and to assist in the creation of more effective public policies.

In this sense, this chapter is organized as follows: first section presents the concept of electronic government, as well as the related stages, platforms and services. Second item deals with definitions, organization and usage of Social networks in the context of electronic government. In the third section it is presented a proposal of an ontology-driven representation and extraction of knowledge in social networks. Fourth item details the development and application of a methodology to implement the previously proposed architecture, showing some tests and results. Finally, last section presents some final comments and indications of future work.

STAGES AND SERVICES IN E-GOV PLATFORMS

As previously stated, ICTs provide new tools and solutions that are changing the processes of governing. Through these innovations, governments are able to create ways to reduce bureaucracy in their processes, modernizing legislation and making faster and clearer the actions of executive, legislative and judiciary branches. These strategies, investments and concepts are commonly grouped under the name of e-Government (e-Gov), as before mentioned. Analyzing the presence and development of e-Gov in several countries, it is possible to identify four main stages, commonly numbered from 1st to 4th (Layne & Lee, 2001)

The first stage, called *Presence* or *Cataloguing*, is characterized by the assembly of electronic information in an unstructured way, with no interactive elements. Each government agency publishes the information on web sites, forming a sort of online catalog. There is no integration among such information, which often leads to the problems of misinformation or, at least, information replication.

In the second stage, named *Interaction* or *Transaction*, information is presented better integrated and organized. In this stage, it is possible to download forms and other types of documents, access links to related pages, among other common functionalities. Citizens are also able to submit suggestions and questions to the responsible for the information, creating a bidirectional way of communication.

The third stage, *Exchange of Values* (*Information*) or *Vertical Integration*, is characterized by a set of processes that can be performed completely online. This is available to citizens in online systems, which enable, for instance, the payment of accounts, taxes, electronic registration in public education systems and some sort of tools for distance learning. Due to the volume of information system' processes required by this stage, these are also elements that promote the integration of different databases, as database management systems that are optimized to operate with distributed databases, components and distributed objects, among others technologies.

In the last stage of development of e-Gov, *Integrated Services* or *Horizontal Integration*, the changes are increasingly more visible and more complex. The government has usually many portals organized by functions or themes. In this stage all governmental bases are integrated and each change in a system must be propagated to other systems.

To achieve each one of these stages of development in the e-Gov-platform, it is necessary to achieve different service' levels in order to update governmental actions, leading to more effective participation of citizens and corporations.

Sang et al. (2005) divide e-Gov systems into six major areas of focus:

- **Government to Citizen (G2C):** Addresses on-line services provided by the government with the aim of providing to citizens pieces of information on procedures for legal proceedings, request and make requests for documents, among others.
- **Citizen to Government (C2G):** Refers to the provision, by the government, of services that enable citizens to introduce a flow of information from them to govern agencies.
- **Citizen to Citizen (C2C):** In this kind of service, the government acts as a provider of integration and interaction between citizens, this occurs through the provision of services and systems that facilitate the exchange of information and interaction.
- **Government to Business (G2B):** Relies on the provision of business services that usually are focused on facilitating and expedition and shipments of documents and information labor and tax, thus promoting more transparent, agile processes.
- **Government to Government (G2G):** It is intended for integration of governmental agencies, thus unifying and facilitating data transfer and internal processes between them. This sort of service could be also be used to promote cross-country integration, for instance, in common market-based economies or political block, as European Union or Unasul, in South America.
- **Government to employer (G2E):** Involves features intended to facilitate the work and enable public services to dialogue with employers, in order to expand the job offers, discuss labor taxes and so on.

In general, the organization of governments is often based on a hierarchical structure, with subdivisions, agencies, ministries and departments. All this structure is barely conducive to solve the real needs citizens have in a timely fashion. One possible solution to this problem is to provide citizens the necessary tools, based on C2C services, so they could establish relationships, though virtual, with other citizens. Through this integration, it is possible to create social networks of cooperation, thus facilitating each citizen to find other people who have, or already have had, the same needs and so being able to collaborate with them.

Next section will explain this kind of collaboration.

SOCIAL NETWORKS OF CITIZENS

By considering the relationships and interactions between people, organizations, groups, institutions, etc., besides establishing a parallel with methods, theories, models and applications normally used for networks analysis, it was coined the term Social networks (Wasserman, 1994). These networks have nodes (or "actors") and specific types of connections. Actors can represent citizens (or social groups), and the relationships between each of these elements may be represented by the connections or relational ties. These social ties between actors could symbolize different kinds of relationships or even the flow of information and resources. Thus, individuals connected to the network could gain and provide access to information or other resources, expanding the opportunities for interact, share or learn (Knoke, 1982).

In order to conduct a more detailed analysis (and at different levels), some key concepts of social networks must be observed: actors, relational ties, dyads (a pair of actors and their relational ties), subgroups, groups, relationships and the network itself (Wasserman, 1994).

Actors refer to any social entities tied together through social relationships and could represent citizens, social groups, cities, countries, government agencies, and so on. This definition allows the grouping of actors into clusters in order to facilitate the study and use of specific analyses. **Relational ties** represent the connections and relationships between the actors of a social network. With the definition of the characteristics of each link, it is possible to define the types of relationships between actors, such as the feelings one person has about another (such as affection, friendship, etc.), or the flow of resources between actors (economic transactions, information exchange, etc.). Physical connections between individuals, cities, states or countries (streets, roads, bridges, etc.) could also be represented by these ties.

Dyads are considered the fundamental social networks' units, formed by two actors and the ties between them. Its study is of utmost importance in the context of the relational aspects in social networks. Through the study of the links and dyads it is possible to identify and classify the relationships of actors in a network, describing them sometimes as central actors, who are involved in many relations with other actors. These central actors are more visible to others, and thus have a higher degree of prestige, identified through the number of links that arrive on and depart from it.

In this context, social networks can be categorized into two groups: Whole and Ego-centered networks. Whole networks can be studied in accordance to the actors involved and the nature of the relationships that they have: one-mode networks or two-mode network.

One-mode networks are formed by a number of actors of the same type, as individuals, organizations, communities, nations, countries, etc. The relational ties among these networks are commonly represented by an index of relationships between dyads of different network levels.

On the other hand, two-mode networks have the focus of study in the relationship between two different types of actors, or between one set of actors with a type of event. The first performs an analysis of links between actors of different types. The types of actors studied in these networks may be the same ones described in one-mode networks.

By analyzing actors and their relations, it can be observed that there is a flow of information and knowledge in the social network. Actors that are part of more than one community could have a continuous learning and benefits from all these communities (Hannerman, 2005), creating a continuous information flow between them.

The knowledge inherently present in social networks can be organized and stored through ontological metadata. By structuring this knowledge in an ontology-driven manner, it would be possible to provide members of a social network different ways of solving problems more effectively, using only the information already made available by other members, and semantic processing to refine that knowledge.

ONTOLOGY: PROPOSAL OF KNOWLEDGE REPRESENTATION FOR E-GOV PLATFORM

The term Ontology has been used in Computer Science from the beginning of the 1990's (Russell & Norvig, 2004) in Artificial Intelligence area, for computational knowledge representation, knowledge engineering and natural language processing. More recently, the notion of ontology has been expanded to the areas of information retrieval on the Internet (as Semantic Web, for instance), knowledge management and development of intelligent educational systems. Therefore, it is computationally possible to represent a particular area through ontological databases, so that communication between people and computers could take place automatically (Swartout, 1999). In this sense, computational agents can share knowledge increasing the relationship that they might have.

To better understand the Ontology concept, several researchers have made their contribution in order to improve this definition, describing concepts and creating new categories to facilitate the construction and use of ontologies. Gruber (1993, p. 3) says that "an ontology is a explicit specification of a conceptualization"; Swartout (1999) also refers to ontology as a shared concept and explicit phenomenon of some thing in the world, described by relevant concepts. Thus it is understood that an ontology describes a field of knowledge in an explicit way, using the relationships that exist between the concepts.

Similarly, an ontology can also be a specialized vocabulary in any field (Chandrasekaran, 1990). However, these vocabularies qualify only the concepts present in a given ontology, which means that this definition makes clear that an ontology is independent of the language in which it was modeled, so that you can translate the concepts of an ontology from English to Portuguese, for example, without changing its essence. In another sense, the ontologies refer to the knowledge base that describes a field.

Besides, according to Berners-Lee (2001), to have a proper knowledge representation, it is necessary to achieve three types of interoperability:

- *Structural interoperability*: Provides the representation for different data types, allowing specify types and possible values for each form of representation;
- *Syntactic interoperability*: Provides precise rules to promote the exchange of data on the Web;
- *Semantic interoperability*: Enables the understanding of data and their associations with other data.

In that sense, it is also possible to classify an ontology in different ways and classifying it in different levels in order to refine the analysis and enable the acquisition of knowledge in a more precise way (Araújo, 2003), as shown below:

- **Generic or top-level ontologies:** Describe general concepts such as space, time, matter, object, event, action, etc., which are independent of a particular area or problem;
- **Field ontologies:** Express conceptualizations of particular fields, describing the vocabulary related to a generic field such as medicine and law.
- **Task ontologies:** Express conceptualizations on the resolution problems regardless of the area where they occur, that is, describe the vocabulary related to an activity or generic task, as diagnose or sales;
- **Application ontologies:** Describe concepts dependent on the field and the particular task. These concepts are often the roles played by entities in the field when carrying out certain activities;
- **Representation ontologies:** Explain the underlying conceptualizations of the formal representation of knowledge.

Complementing this classification, it is also possible to identify five basic elements that define ontology (Perez, 2002): concepts, relationships, functions, axioms and instances.

The wider use of ontologies has made it possible to address different types of problems in various areas of knowledge as Semantic Web, data mining and e-Government systems (Natale, 2008). The e-Government applications that are from the second stage of development have repositories of data and data-processing capacity with volume of information and knowledge in proportion to the size of the population that uses these services.

An example of these applications is the internationally recognized and rewarded Brazilian system of income tax collection. This system has about 600 million records, powerful security features, tools for decision making, identification of fraud and access of approximately two million users. According to the Coordination of Technology-General of Revenue, it is considered the largest database of the world (Receita, 2006).

The development of ontologies for governmental area must produce shareable structures and must provide interoperability in the semantic level. For this, it is necessary to create metadata with vocabularies specific to the context, structuring the field, to allow computational agents to infer new facts and enlarge the knowledge base.

As governments' computational systems will be reaching higher levels of development, complexity and an on-growing base of knowledge, a fertile field for new technology projects appears, including those ones that rely on semantics to perform their tasks. One example is the use of an ontology field of e-Government to store and represent knowledge in a social network formed by citizens. A computational agent committed to this ontology could, through semantic analysis, help citizens to find other citizens in the social network that could, in a collaborative manner, assist to the solution of various issues.

A related work can be found on the OntoGov project, which specifies a platform composed of meta-ontologies with the objective of promoting the development of systems for e-Government services (Ontogov, 2007). In this platform, the domain ontologies consider a high-level ontology, building, in this way, meta-ontologies. From that basic meta-ontological base, it is possible to define information ontologies to represent the knowledge related to flows in services that provide pieces of information to citizens.

It is also possible to use ontologies to establish interoperability between different systems, processes and services. This is the proposal of another related work, the SmartGov platform (2007). In this platform, it is possible to achieve the integration of various areas and government departments, through a knowledge-based system available on,Internet, and directed to the public as end user (Smartgov, 2007).

This type of semantical analysis of knowledge in the social network can work to identify central citizens in a network. This identification can still identify and define characteristics such as degree of influence and importance of each citizen in a social network, creating a tool of social analysis to recognize the leaders of a city, state or country.

Based on theoretical references and on this overview on the use of computational tools in e-Gov, the next item describes a proposal for a system based on C2C social networks and ontology.

DEVELOPMENT OF ADAPTIVE SYSTEMS FOR C2C BASED IN NETWORKS AND ONTOLOGY

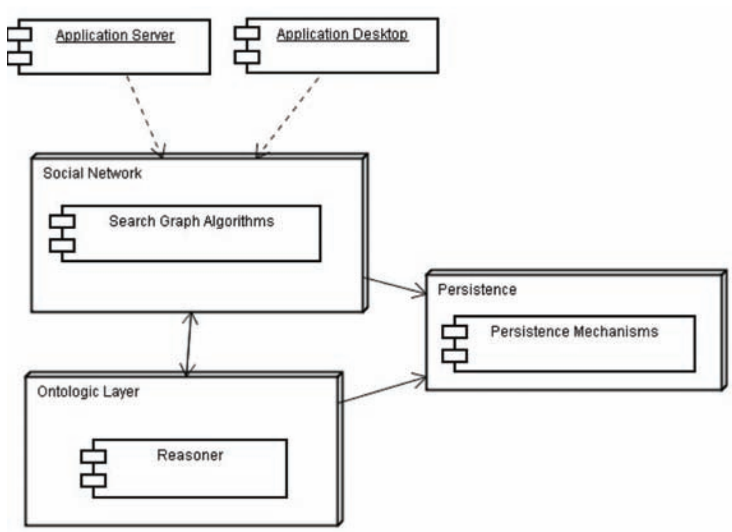
Solutions developed for C2C services must manage a large set of variables, besides every information from every citizen. With that, databases are expected to be each time more complex, making harder the task of extracting and handling, in a optimized way, the knowledge inside. Such a context encourages the use of ontologies and different ways to represent knowledge, as a manner to process such data efficiently.

Tools Used

This section shows the possibility of developing an e-Gov low-cost, design pattern-based, scalable, easily maintainable system which would be able to communicate to others systems. In this sense, a technology-independent architecture was modeled, according to UML (*Unified Modeling Language*), looking for plataform-independence, programming language-independence, easy customization to different requirements from each government, besides being easily expandable.

The diagram shown in Figure 2 presents the proposed architecture for a C2C services-based system. Such architecture is composed by three tiers, allowing the development and integration to diverse platforms, making easier the component reuse.

Figure 2. Proposed architecture



All parts of the system were developed on the Java platform. Such a platform provides a layer between application and operating system, named Java Virtual Machine (JVM). JVM is responsible by interpret the pre-compiled source code, manage memory and threads, intermediate communication and system calls, so providing platform-independence for applications.

Java platform also specifies Java programming language, which follows the object-oriented paradigm, thus allowing faster actualizations, motivating programming practices with high levels of reusability, promoting the use of design patterns and offering a large amount of APIs with diverse functionalities (SUN 2008).

Regarding to Figure 2, Ontologic Layer defines a metadata base and mechanisms used to knowledge representation, providing methods and inference logic that could be used by any computational agents. This data repository stores metadata using a set of OWL namespaces (used to facilitate the properties description), based in XML-Schema (W3C, 2004). With this structure, it is possible to represent explicitly vocabulary terms and semantic relationships among them.

In order to obtain a better expressivity of metadata, while keeping integrity and computational decidability, it was used the OWL-DL sub-language, which has all characteristics refered above. Due to the strategies of modularization used, based on design patterns, it is possible to implement the application in any other language or tools that are metadata-aware.

This layer also has a module responsible for semantic analysis, using Jena API. This API has a handler for RDF triples: (subject, predicate, object), as well as a processor for ontological information expressed in RDF-Schema and OWL. With the use of inference mechanisms, as well as tools for metadata creation, representation and handling that are provided by Jena API, knowledge present in the network is meant to be represented by syntactical, structural and semantical interoperability, allowing the reuse of resources and semantical properties, making easier the sharing of information among computational agents that are committed to the ontology.

Utility algorithms are implemented in Social network layer as tree search algorithms, as well as structures responsible to stores and handle the social network, the citizens and their relationships. This layer allows the implementation of

Figure 3.Social network, before including a new actor (NATALE, 2008)

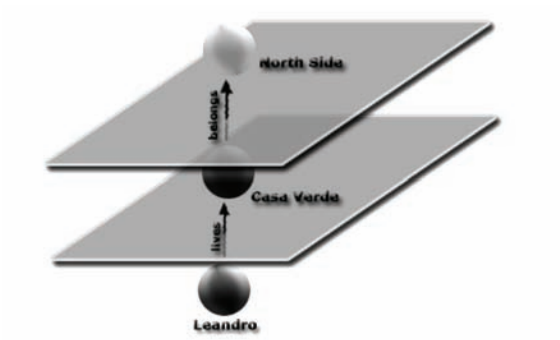


Figure 4. Social network, after including a new actor (NATALE, 2008)

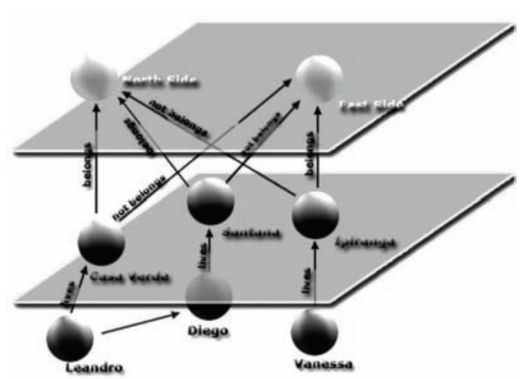


various algorithms, as graph search and minimal path generators, for instance, in a easy and quick way, depending on the specific necessities of each government.

Persistence layer uses different strategies and APIs to store data from other layers, as utilities for creating image files, specialized libraries for XML files and so on. Through a unique interface, it is provided a transparent access to the other layers, in order to store and retrieve necessary data to the system.

By keeping a consistent encapsulation, Presentation layer defines strategies and access interfaces, allowing different system and client applications to have access to specific system's modules, in a platform-independent way.

With this architecture, citizens and governments would have access to social tools provided by the system, through different applications.

Description of Application Operation

Based on typical characteristics and services of an e-Gov platform, this section shows an implementation of a C2C service, aiming to exemplify a real-world application.

The application uses information as addresses, professional activity, marital status, language, educational level, family income, and so on, which are provided by a citizen when he/she logs in the system. Such data are dealt as ontological elements, used to build an ontological database. After the building of this metadata repository, it is possible to dynamically expand a social network.

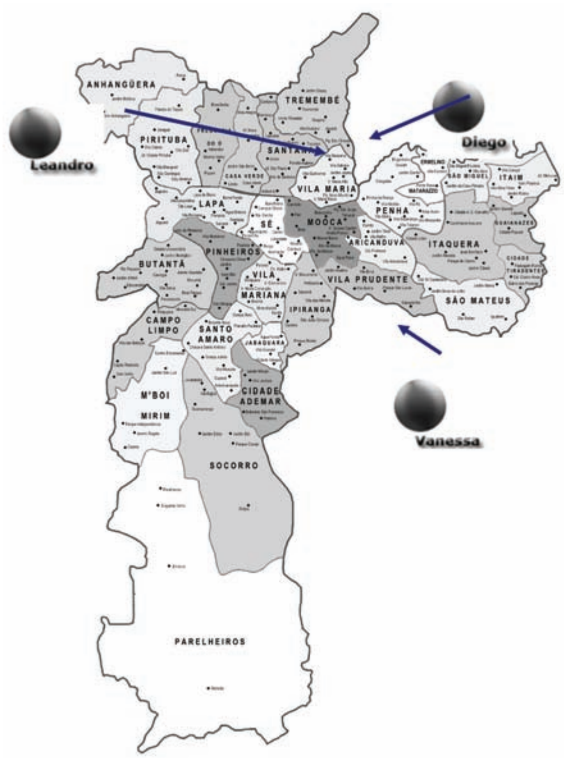
Figures 3 and 4 shows the dynamics of a social network when a new citizen logs in the system.

Figure 3 exemplifies in detail a particular example geographically located in São Paulo, Brazil, where it is possible to observe a citizen named 'Leandro' that lives in 'Casa Verde' neighborhood. This neighborhood is located in a region named 'Zona Norte' (north zone). The relationships among neighborhoods and zones of the city are stored in an e-Gov domain ontology. In this way, it is possible to assign proximity levels among different regions and neighborhoods of a city.

In Figure 4, when the citizen 'Diego' logs in, informing that he lives in 'Santana' neighborhood, the system, through the domain ontology, identifies that 'Santana' is part of 'Zona Norte' in São Paulo city. After this semantic processing, the social network is augmented, with the creation of a link of 'interacting' type among 'Leandro' and 'Diego', due to the fact of living in the same region of the city.

Still in Figure 4, citizen 'Vanessa' logs in the system informing that she lives in 'Ipiranga' neighborhood. By a semantic search on the ontological base, the system identifies that such neighborhood is part of the region known as 'Zona Sul' (south

Figure 5. Map of São Paulo city showing geographic proximity among actors



zone). Figure 5 shows a map of São Paulo city's neighborhoods, in order to clarify this example.

Since 'Vanessa' does not live in a neighborhood in the same region as to other registered actors, the social network controller, after using the information provided by ontological layer, don't create an 'interacting' relational tie among 'Vanessa' and the other citizens presents in the network. Nonetheless, this does not forbid that other information provided by citizen 'Vanessa' would allow her to establish other types of connection to other citizens.

This example also shows the multi-dimensionality of the social network graph. Looking in a dimension, there are actors of the same type (citizens), and their relationships, thus forming an one-modal social network. In a second dimension, there are actors from different types (citizens and neighborhoods) and their relationships, thus forming a bi-modal network.

Exemplification of Results Obtained

In order to exemplify the usage and flexibility of the system, it was created an Web-based interface, as seen in Figure 6, which shows the form for citizens' registering. Data obtained after the fulfilling of this form are refined by ontological layer, and afterwards the citizen in inserted in the social network and connected to other citizens according to the information provided.

Only after registering, citizens have access to search functionality (Figure 7), developed in order to allow him/her to perform a search for information in the social network. System is meant to refine the information given by a semantic search in ontological database, looking for citizens that

Figure 6. Citizen's sign-in interface (Natale, 2008)

Figure 7. Simple Interface for Information Search. (Natale, 2008)

have in their records some information that have some semantical kinship.

With target citizens identified, social network layer, by using Dijsktra's algorithm (Cormen et al., 2001), looks to find the shortest path among these target citizens and the citizen that realized the search. This algorithm was adapted to find the shortest path from only one origin and equally-weighted edges. JUNG (2007) – a Java-based API made to deal with graphs and social networks, is used to generate an applet that exhibits the path to be taken by the citizen to those citizens that could be collaborating to solve his/her questions.

The developed system has also functionalities directed to public administrators, providing different views for the same social network, which was implemented by the before mentioned applet. A JPEG image can also be generated.

Figure 8 shows an example of a complete social network, with different links established, categorized by different labels to make visualization easier.

Figures 9 and 10 shows different kinds of views a government agent could have over a social network, being able to select only the social links of interest. With these specific views, the public administration is able to perform more precise analyzes, by observing social network from the viewpoint of a specific social link. With this, it is possible to observe different social groups presents in different regions of a city, state or country, which could be used to assist in the planning of more effective public policies.

In order to simulate the execution of the system, some tests were performed with fake and real data. In the first experiment, the system was made available in a Web-based environment, running under a servlet container (Tomcat 5). All the system was packed in a single *.war* file. Fifty citizens registered themselves with their own in-

Figure 8. Complete Social network (Natale, 2008)

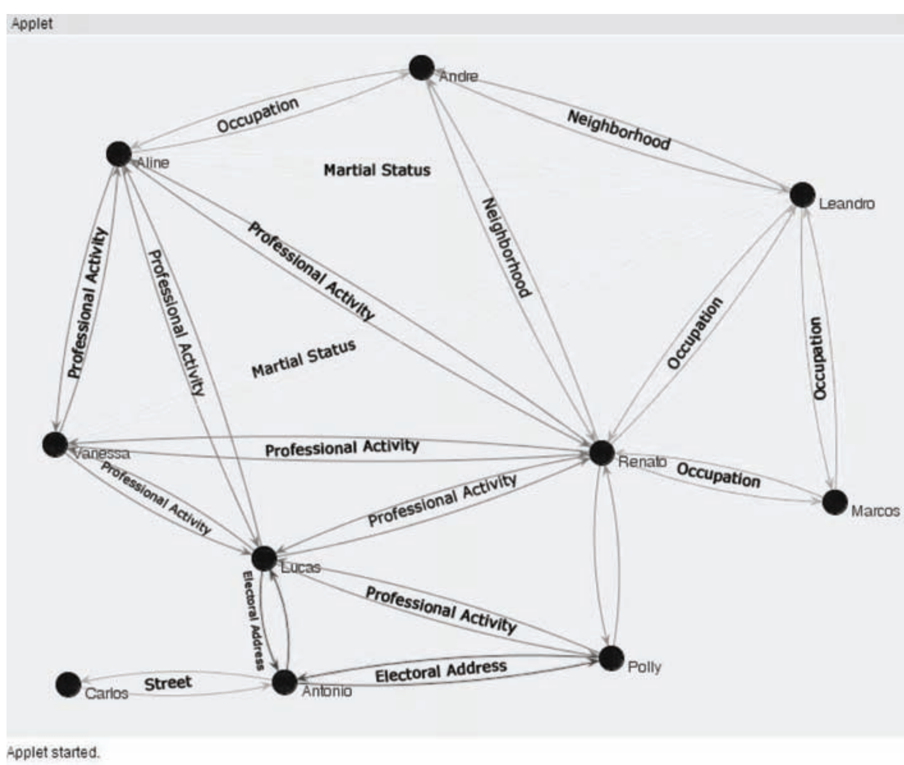


Figure 9. Social network with Professional Activity ('Atividade Profissional') ties (Natale, 2008)

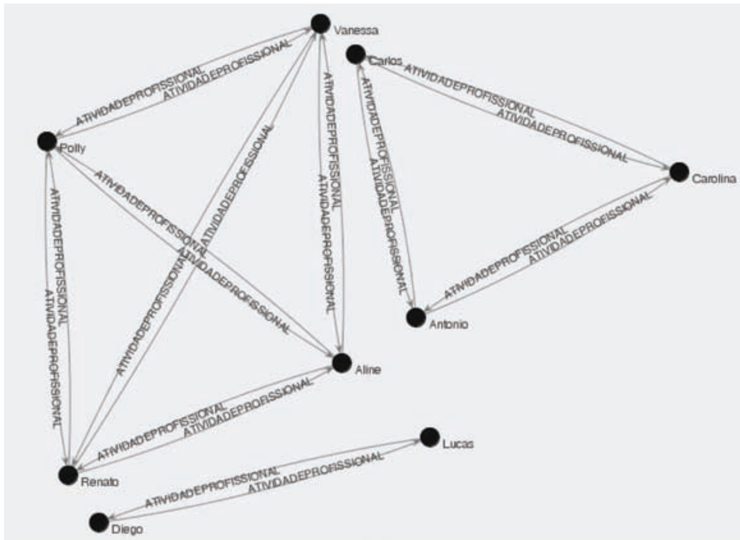
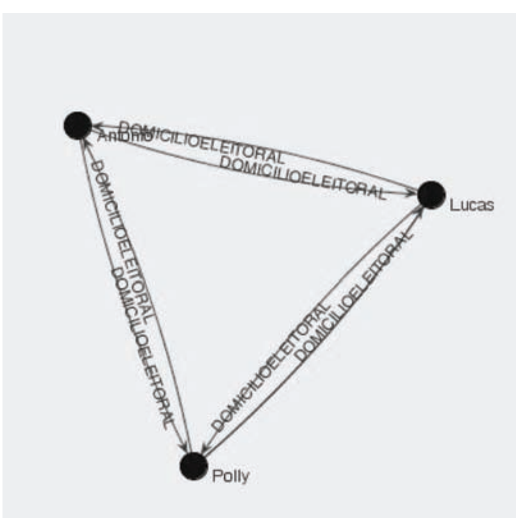


formation. None of the pieces of information was mandatory, and the time spent for each citizen to register was stored.

With semantic refining of each piece of information, a search for citizens with semantic proximity was performed each time a new citizen signed in, in order to find citizens to be connected to him/her. Figure 11 shows the time spent for each

Figure 10. Social network with Electoral Address ('Domicílio Eleitoral') ties (Natale, 2008)



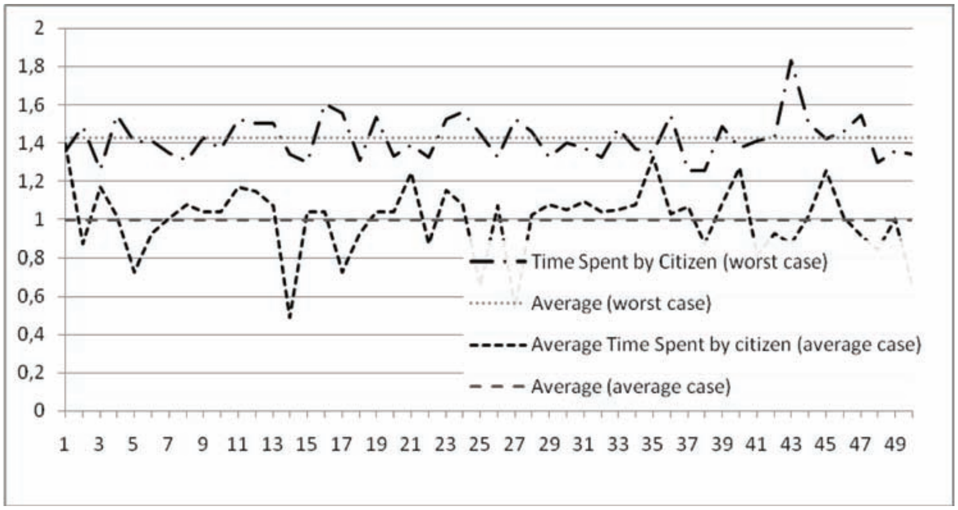
registering process (average time was 59 sec).

In a second experiment, other fifty records were fulfilled, but in this time all fields of information were required. This was done in order to simulate a more complex scenario for the social network layer, as well as for ontology layer. This experiment produced a complete graph, with every citizen connected to all others. In a similar way, the total time spent for each citizen registering was calculated, with average time of 85 sec. Figure 11 shows the results.

After these experiments, the ontological module was disconnected from the rest of the system and a new experiment was realized with the same amount of data, but with no semantical refining. Average time in this case was 10 ms for each record, showing the huge amount of time that is needed for semantic establishment of the social network.

Finally, the last experiment consisted in performing a search for information in a real-world social network, created by real citizens. In this experiment, the system validated the provided information and refined them using the methods available in the ontological layer, which allowed the performing of a breadth search in the social

Figure 11. Performance of the experiments (Natale, 2008)



network in order to find the citizens that had some desired information. After their identification, Dijkstraís algorithm, provided by social network layer, was applied, generating the path a citizen must follow in the network.

FUTURE TRENDS, FINAL CONSIDERATIONS AND FURTHER WORK

E-Gov future trends related to C2C services involve the improvement of ontological databases techniques. In the same way, with Web 2.0 development, it is relevant to point out the need for proposals that adhere to this concept. Regarding to the expansion and easiness of access by multiple platforms, as mobile and desktop, it is necessary also taking into account different ways to present information, according to the device being used. Another trend that must be noted is the dynamic refreshing of information in a way that they could be easily geo-referenced, making easier the integration with GPS systems, for instance. Finally, there is the important necessity of security policies regarding to citizensí information, avoiding information replication or leaking.

Through the studies and comparisons that were shown, it is possible to identify citizens as the main interested in governmental technological advances. Thus, it is extremely relevant to develop e-Gov solutions that follow a service-oriented model. In the case of the present chapter, it was focused the development of a C2C architecture driven to citizen dwelling in a certain area, providing low-cost, easy-maintaining tools to help quotidian information search and problem solving.

In e-Gov context, this work presents the possibility of creating a social network that was built and is able to be expanded using a domain-oriented governmental ontology.

Such structure asserted the possibility of building robust low-cost systems that are able to help citizens to reduce bureaucracy in electronic environments. The governmental strategies used to e-Gov system development must be evaluated and carefully implemented ñ since they are meant to deal with people’s lives ñ and thus reaching a meaningful social effect.

Academically, the present work contributes in the sense that it presents solutions and analysis that are based in a social-governmental context. It dealt with social network analysis, computer-based knowledge representation and retrieval, as well as software design patterns.

As a recommendation for further works, there is need of deeper analyses of the previously mentioned social networks, as well as new implementations based on these new analyses. Such implementations could present some improvements by optimizing the ontology-based mechanisms through multi-thesaurus structures or parallel or distributed engines for inference. These engines could also be internationalized, being language-sensitive. Analyzing the interfaces made to citizens, it is necessary to look for elements that make them more user-friendly, thus improving the access and straightforwardly the utilization of the system.

Another issue to be pointed out is the fact of handling and storing private information, which is meant to be kept in a secure way. Security solutions must be discussed, including basic cryptography, in order to guarantee the privacy and safety of this information in governmental platforms, improving systems' reliability. Other possibility is to apply techniques related to distributed agents to manage the information traffic on the digital e-Gov social network and analyze package exchanges.

Furthermore only authorized users can perform searches by the system. The data of users should also be stored on servers protected by the guidelines of network security organizations, with access only released to authorized analysts.

KEY TERMS AND DEFINITIONS

Adaptive Systems: Systems characterized by the possibility of adapting themselves according to the behavior of user or some other environmental changes.

Graphs: Structures formed by nodes and edges that connect pairs of vertices, allowing the study of relations between elements belonging to determinate data set.

Knowledge Representation: Abstract model of a knowledge domain that permits the construction of computer-based systems, knowledge databases or expert systems.

Metadata: Characterization/description or information about data. It is commonly used to describe, manage, and localize some data in a data store.

Ontology: Formal specification of entities' representation (as objects, concepts and so on), making possible to establish relationships among terms and attributes through the use of semantic approaches.

Social Networks Analysis: Interdisciplinary area that combines Math, Computer Science and Sociology, among other aspects (as psychological, geographical, and so on) to determinate kinds of relationship between actors – like people, groups, communities and organizations.

Virtual Communities: Groups of people determined by similar interests that establish contact and interact through use of online communications tools and/or virtual environments.

This work was previously published in Handbook of Research on Social Dimensions of Semantic Technologies and Web Services, edited by M. M. Cruz-Cunha; E. F. Oliveira; A. J. Tavares; L. G. Ferreira, pp. 802-818, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 2.15
DemonD:
A Social Search Engine Built Upon the Actor-Network Theory

Charles Delalonde
EDF R&D, France

Eddie Soulier
Université de Technologie de Troyes, France

ABSTRACT

This research leverages information retrieval activity in order to build a network of organizational expertise in a distributed R&D laboratory. The authors describe traditional knowledge management practices and review post-cognitivists theories in order to define social creation in collaborative information retrieval activity. The Actor-Network theory accurately describes association processes and includes both human and non-human entities. This chapter compares this theory with the emergence of Social Search services online and Experts' Retrieval Systems. The chapter authors suggest afterward, a social search engine named DemonD that identifies documents but more specifically users relevant to a query. DemonD relies on transparent profile construction based upon user activity, community participation, and shared documents. Individuals are invited to participate in a dedicated newsgroup and the information exchanged is capitalized. The evaluation of our service both ergonomic and through a simulation provides encouraging data.

DOI: 10.4018/978-1-60566-306-7.ch008

INTRODUCTION AND CONTEXT DESCRIPTION

During the early years of the Personal Computer research, two rather distinctive philosophical approaches competed. Artificial Intelligence believers wished to replace humans by machine whereas Human Intelligence Augmentation project, led by Douglas Engelbart, envisioned computers as a technology to augment human mind and eventually network each other's (Markoff, 2005).

This debate is still vibrant in the Information Retrieval community where the algorithmic approach is recently challenged by human approaches leveraging individual's social capital to identify pertinent knowledge sources. Our work contributes to this "Social Search movement", in a corporate environment, and identifies the challenges of a Research and Development laboratory, of 80 persons, in a French telecommunication company. The laboratory observed is distributed, in France, among three cities: Grenoble, Sophia Antipolis and Caen. Its mission is to plan, conceive and support the production of original telecommunication services for businesses. This process involves each distributed team of the laboratory. Ideas are suggested utilizing an email discussion list. Then, marketing teams identify a potential market. Business development teams confirm the financial opportunities of such project. When validated by the steering committee, the service is prototyped and developed. A partner company usually accepts to experiment the service. Business units of the telecommunication company might then decide to market this innovation. In such context, cooperation is a necessity. Teams must be well coordinated to remain creative in order to shorten the time to market of the services. Information Retrieval being a critical task for laboratory members, the company previously attempted two strategies in order to create and share organizational information in a distributed context.

First, they produced an exhaustive knowledge database, trying to externalize and share explicit knowledge. Intranet's folders were also utilized to share content among coworkers. Yet, interviewed employees revealed that the knowledge database was usually obsolete and shared folders not accessible (privileges needed to be granted on each folder) and content was not properly indexed.

Second, the organization, conscious about the shortcomings of a systemic approach of knowledge management, deployed communities of practice (Wenger, 1998). The 'not-so-informal' communities shared a virtual collaborative workplace and face to face member's meetings were scheduled monthly. Yet, this second strategy also turned out to be unsatisfactory. Employees were reluctant to ask/share information with individuals they had never met.

Unlike content, which is perishable and quickly becomes obsolete, experts' informal networks are rather permanent in R&D context. We assert that the real value of information systems is connecting people to people and encouraging them to share their expertise rather than collecting and storing de-contextualized information. (Hertzum & Pejtersen, 2000) already evidenced that individual looking for information usually explore and contact personal communications prior to using documents or knowledge bases. Following this strategy and in order to identify pertinent individuals, we need to evaluate their relevance on a specific subject along with social indicators. Thus, we leverage transparent user's profile modeling techniques to match a knowledge demand with one or many knowledge offers (Delalonde & Soulier, 2007). Relying on Bruno Latour and Michel Callon Actor Network Theory (named ANT throughout this article) our objective is then to validate a hybrid information retrieval model. This model helps specifying DemonD (Demand&responD) a search engine dedicated to collaborative information retrieval and favoring the emergence of a lightly structured information network.

The remainder of this paper is structured as follows. In section "Actor network theory in information retrieval activity" we present Actor Network Theory and its application in Information Retrieval. In section "Related works on social search" we review related work on Social Search. Section "DemonD a social search engine" describes DemonD's specifications. Section "Evaluation" is shared between a simulation of DemonD and its ergonomic evaluation. Section "Conclusion and future works" finally concludes our work with a discussion of future directions for research in this area.

ACTOR NETWORK THEORY IN INFORMATION RETRIEVAL ACTIVITY

As mentioned in the introduction of the article, we believe that information retrieval and acquisition is necessarily a social process, creating ties between individuals and expanding their social capital (Huysman & Wulf, 2003). This section aims to define our vision of "social", constructed through a review of post-cognitivists theory including the activity, the situated cognition, the distributed cognition and eventually the Actor Network theories.

Activity Theory

The Activity Theory (Vygotsky, 1978) is helpful for examining the social dimension of Information Retrieval. (Leontiev, 1979) proved user's actions only make sense in a social context of a shared work activity distinguishing between *activities*, which satisfy a need, and the *actions* that constitute the activities. Engeström's recent contributions to the Activity theory expanded Vygotsky's mediating triangle with a social component (Engeström, 1987) providing the activity theoretical community with a powerful tool for social systems analysis. Yet, the social dimension of activity, in this theory shall be better specified and not "taken for granted" as pre-existing groups (such as family, colleagues). We retain however the importance of artifacts to mediate user's thoughts.

Situated Action Theory

The situated action theory is another helpful framework to analyze information retrieval as a social process. Situated action theory was formulated in contradiction to artificial intelligence formalism. Indeed, Lucie Suchman's research demonstrated the inefficiency of action plans and suggested that activity was constantly constructed and reconstructed from dynamic interactions with the material and social worlds "situated" (Suchman, 1987). Yet, the situated action theory refuses to generalize its observations. Furthermore, the "social", in this theory, is restricted to local interactions. Distributed cognition is then appeared as a coherent theory to apprehend social information retrieval in organizations depicted in the introduction.

Distributed Cognition Theory

Relying on ethnographical methods, Edwin Hutchins analyzed sophisticated activities such as flying airplanes or sailing (Hutchins, 1995) (Hutchins, 1991). His research identified an exhaustive cognitive system formed by human and the artifacts they utilized to achieve their activity. As (Wood, 1993) indicated, "cognition is never simply 'amplified' or 'externalized', but rather cognition is 'mediated' through the external artifacts and collaborators such that the new cognitive system which is formed has a radically different character, structure and functionality than the cognition of the unsupported individual". This theory illustrates efficiently the distribution between human and non-human in the analysis of a cognitive system yet, the social dimension of the system being observed, lacks specification.

Situated Cognition Theory

Diffusion and acquisition of knowledge, in a distributed group, shall also be observed with Albert Stutz theory of social knowledge (Schütz, 1946). The author regards the knowledge as socially derived and transmitted to the individual by relations of all kinds. He describes three forms of knowledge. The store of experiences is a form of knowledge strictly individual that includes recipe and routines practical or theoretical. Second, the socially transmitted knowledge created when interacting with other agents. Third, the approved knowledge validated by members considered as cognitive authorities of a group. We are particularly interested in the second form of knowledge, since, this distribution of knowledge justifies cooperation between individuals and is built through a relation that coordinates a demand and an offer of information. When this relation is extended to multiple individuals, cooperation occurs and a community is created. Numerous researches have been conducted to utilize information technologies to support cooperation among agents distributed in the organization or geographically in virtual teams. Computer Supported Cooperative Work and Groupware developments results from this evolution.

We investigated existing typologies of communities offering a new paradigm for social information retrieval activity. The theory of socially shared cognition recognizes the importance of a network or a community in the study of human cognition (Resnick *et al.*, 1991).

Cognition as a social and cultural phenomenon requires, in a computer mediated environment, artifacts able to transmit individuals awareness and create a context for the completion of collaborative activities (Erickson & Kellogg, 2000). R&D teams which we observed share knowledge and cooperate with information technology (cf. introduction). In the related literature we found three forms of communities, observed in the organizations, and supporting the transmission of knowledge like: community of interest, epistemic or of practice. When considering the activity of information retrieval as a social practice, we are interested in a network, slightly structured, whose principal objective is the transmission of knowledge.

In communities of interest (Bergé & Périn, 2002), members share information on a specific subject whereas epistemic communities (Conein, 2003) are conducting a cognitive activity relying on globally distributed individuals. Communities of practice (Lave, 1988) (Lave & Wenger, 1991) (Soulier, 2004), initiated by employees willing to improve their professional practice, do not describe either the networks of information we observed in R&D teams. As a consequence, we suggest a new form of information network, relying on information retrieval activity as a social process in order to build an organizational network of expertise (Twidale & Nichols, 1998).

Actor Network Theory

ANT constitutes a distinctive approach to represent a society of heterogeneous entities both humans and non-humans. Bruno Latour suggests a dynamic vision of social ties constructed when entities interacts with each other (Latour, 2006). The result of this movement leaves footprints named a “social reassembled”. (Table 1)

Other post-cognitivists theories (activity theory, situated cognition, distributed cognition, situated action) previously investigated to describe Social Information Retrieval activity usually envisioned the social aspect prior to the activity. ANT appeared as the only theory crystallizing social components to achieve an activity. This theory does not assume existing social ties between entities (humans and non-humans) but constantly create

Table 1. Post-cognitivists theories to define “social” activities

	What is the “social” made of ?
Activity Theory	Takes the social for granted.
Situated Action Theory	The social is restricted to local interactions.
Distributed Cognition theory	The social is only a consequence of a distribution / repartition between elements of a system.
Situated Cognition theory	The social results from a dialectic between micro and macro structures.
Actor Network Theory	Does not pre-assume existing social ties between entities (humans and non-humans) but observes their creation through various associations.

them during each query. Furthermore, ANT's non-distinctive inclusion of both human and non-human entities seemed to be the most suitable to describe a hybrid information retrieval system relying on assembled heterogeneous resources.

ANT's author utilize a specific vocabulary including the terms "entities", "intermediaries", "mediators" and "associations" that we will describe below.

In the information retrieval activity, entities might be: a query, personal or shared documents, discussions taking place on a dedicated environment, articles extracted from a knowledge base, votes, tags, colleague's profiles… Each query catalyzes a network containing at least one entity. Entities are related between one another. The relationship between each related items is described in Figure 1. The various arrows between entities describe some type of association. For instance, tags might be set on documents, profiles, articles or discussions. Votes evaluate the quality of comments or articles.

Intermediaries are in charge of conveying information without any kind of modification.

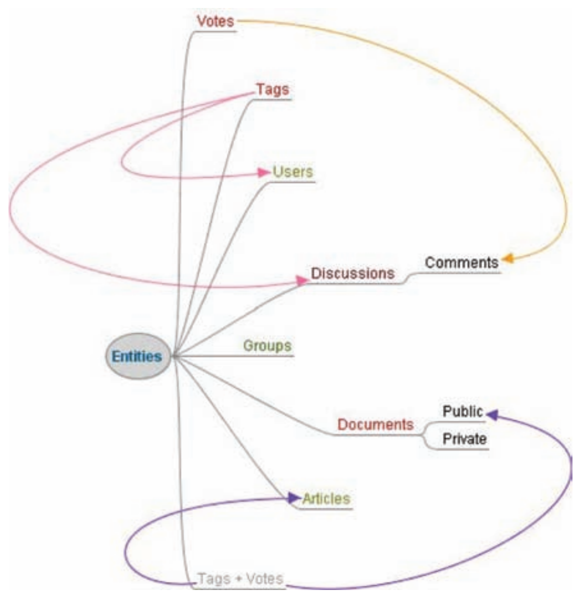
Mediators modify the information they are conveying. In fact, mediators are in charge of translating information to facilitate its propagation in a distributed system. The association of heterogeneous entities relies on such mediators.

Associations represent different stages of a network of intertwined entities. Three types of associations are relevant for the information retrieval activity we will describe: social vacuity, hybrid community and society.

The first association is a social vacuity and describes a state where entities are not linked between one another (Soulier *et al.*, 2007). The hybrid community designates a dynamic stage where entities are incessantly associating. The association eventually stabilized and give birth to a society (Whitehead, 1929/1995).

Information retrieval creates social capital in distributed teams. ANT appeared as a pertinent theoretical framework to represent such social search practices. We will now review specific implementation of this theory in Social Search services online and in organizations.

Figure 1. Relationships between various Entities



RELATED WORKS ON SOCIAL SEARCH

Considering the activity of information retrieval as a social practice, we are interested in a network, slightly structured, whose principal objective is the transmission of knowledge.

A non exhaustive definition of social search services could be: *a type of search engine that determines the relevance of search results by considering users' interactions or contributions*. Within the huge amount of available information and sources and due to frequent search engines manipulations, Social Search is recently garnering a lot of attention on the Web 2.0. In order to increase the ranking of their websites in Google search engine, unscrupulous webmasters utilize fake blogs to promote goods and services. As a matter of fact, a page will be ranked higher if the sites linking to that page use consistent anchor text.

Two significant social search services are emerging including navigating on previously recommended web sites and addressing a question to pertinent individuals. After reviewing recent social search initiatives online, we will identify Expert Retrieval Systems ERS in the corporate environment (Referral Web, Agilience and Answer Garden 2).

Social Search Initiatives Online

Social Search takes many forms online. Among them, navigating on content previously approved or recommended by other has been implemented in the Web Of People. This service has been developed by (Plu *et al.*, 2003) and helps individuals sharing relevant information with their peers. The system eventually propagates the pertinent resources to a network of individuals.

Google Co-op (Google Co-op, 2006) allows users to personalize the list of websites being suggested by the search engine. Yahoo! 360 (Yahoo! My Web 2.0, 2006) acts quite similarly by restricting search engine results to websites suggested by individual's declared social network.

More recently, Social Search methods revolve around Questions and Answers services and put in relation a demand and an offer of knowledge. Web 2.0 emerging collaborative services (wiki, weblogs) give each user the ability to be an information consumer or producer. For instance, Yahoo! Question and Answer (200520052005Yahoo! 2005!!!) let anyone ask any willing user to respond to one of his question. Yet, the questions are not automatically appointed to the respondents resulting in many unanswered questions. Yedda (Yedda, 2007) adopts another strategy leveraging light profiling techniques and to forward unanswered questions to pertinent profiles. Profile creation is unfortunately quite poor and relies only on declared keywords.

Expert Retrieval Systems

Information technologies also contribute to sharing and constructing knowledge in distributed organizations thru specific systems named: Expert Retrieval Systems (ERS). Multiple ERS have been deployed but usually failed for not taking in consideration the importance of informal social networks in the construction of knowledge or not allowing final users to manage their profiles.

Referral Web (Kauntz *et al.*, 1996) is an ERS created in AT&T labs. User's profile is constructed based on keywords extracted from web pages or shared documents where individual's name appears. Social network is also drawn based on co-occurring names on published research or public documents. Individual utilizing Referral Web selects the reach of his request and the number of hopes between him and knowledge offer.

Agilience (Agilience, 2006), another ERS, relies on sent email messages to create user's profile. During initiation phase, emails are analyzed and significant words extracted and compared to an existing taxonomy. User is able to manage his profile by adding or deleting keywords. To retrieve pertinent individuals, users send an email with a description of his request. The content of the message is analyzed by Agilience that returns back a list of documents, a list of individuals and a list of individuals able to forward the request to other potential respondents. Requests and responses are leveraged to accurately define user's profile. Agilience conceptualize knowledge construction or sharing as a dialogue between a demand and an offer. In reality, knowledge usually emerges from collaboration between multiple individuals. The creation of a dedicated collaborative workspace could definitely enhance this solution.

Answer Garden 2 (Ackerman & McDonald, 1996) follows the realization of an earlier version and relies on a multi agent system to select a recipient for a request. AG2 replicates progressively user's request based on recipient's proximity, privileging first near-by contacts. Recipients are invited to cooperate on specific discussions groups with instant messaging and emails functionalities. This powerful ERS presents a major constraint for end-users: individuals do not control the reach of their request. In fact, AG2 retransmits the request without prior approval.

In conclusion, the description of three ERS (Agilience, Referral Web and AG2) presents three challenges that need to be addressed. First of all, user's profile modeling must be extracted from heterogeneous sources (documents, user's activity, social networks…) (challenge 1). Second, a knowledge exchange should take place in a collaborative environment, with multiple participants (challenge 2). Finally, user must be able to manage the reach of his request and ensure privacy, especially in R&D teams depicted in the introduction (challenge 3). Furthermore, social search initiatives online or thru ERS usually rely on preexisting social networks of individuals. Our approach is rather different, following Actor-Network theory, a query catalyze a network of entities, human or non-human. Online social search services and Expert Retrieval Systems that we reviewed are summarized in Table 2.

DEMOND A SOCIAL SEARCH ENGINE

In opposition to the solitary information retrieval activity, we model information retrieval as a social process of association able to structure an organizational network of expertise. The information seeking process is not restricted to content retrieval / distribution but initiate a negotiation between a demand and one or many offers. The negotiation is followed by the capitalization of

Table 2. Social search services

Type of service	Name	Description	
Browsing On Trusted Websites	SoMeOne	SoMeOne arranges user's documents in shared folders along with discussion groups and suggests contacts based on a specific query.	**Online**
	Google Co-op	Google Co-op is a customized search engine allowing user to query pre-defined websites.	
	My Web 2.0 Yahoo!	My Web 2.0 from Yahoo! is also a customized search engine querying websites previously approved by members of a defined community.	
Questions And Answers	Yahoo! Answers	A knowledge-sharing community where anyone can ask and answer questions on any topic.	
	Yedda	A knowledge-sharing community where questions asked by users are transmitted to pertinent respondents based on basic profiling techniques.	
	Google Answers	A social search service for users to get help from other with expertise in a specific domain. Users post a question and specify the price they are willing to pay for an answer.	
	LinkedIn	A business social network service giving each member methods to question his network.	
Expert Retrieval Systems	Responsive	Instant messaging service in charge of broadcasting a query to user's existing contact-list.	**In Organizations**
	Agilience	Service relying on email logs to create user's profile. Agilience eventually suggests documents or pertinent individuals able to respond to any question.	
	Referral Web	Referral Web creates user's profile based on keywords extracted from web pages or shared documents where individual's name appears.	
	Answer Garden 2	AG2 creates users profile and replicates progressively user's request based on recipient's proximity. Recipients are invited to cooperate on specific discussions groups.	

exchanged information and the social structure utilized. The recurrence of the exchanges of information supports the constitution of mutual aid (caring) network and eventually the emergence of a knowledge community. ANT's specific vocabulary includes "entities", "intermediaries", "mediators" and "associations".

In the information retrieval activity, entities might be: a query, personal or shared documents, discussions taking place on a dedicated environment, articles extracted from a knowledge base, votes, tags, colleague's profiles… Each query catalyzes a network containing at least one entity. Entities are related between one another.

As mentioned previously, intermediaries are in charge of conveying information without any kind of modification. The information retrieval engine, we conceived, contains three intermediaries including a database, a collaborative environment and a knowledge base. Intermediaries are indeed indispensable in the association process.

The information retrieval engine, described in the following section, contains three mediators: the Profiler, the ContactRank and the Coop. Profiler creates, for each individual, a transparent profile based on tags declared, shared documents, and groups created. ContactRank sorts each knowledge offer (including human or non human entities) based on their proficiency on a specific subject and their propensity to respond. Coop creates a dedicated collaborative workplace and invites pertinent individuals to contribute.

DemonD is available in the corporate information systems (intranet). It is comprised of four main stages including initialization and information retrieval - diffusion - negotiation and capitalization that we will describe successively. A workflow of information retrieval activity in DemonD is available in Figure 2.

Initialization & Information Retrieval

The user's profile is modeled with the "Profiler" algorithm and consists of a list of weighted keywords also named tags. Distinct profiling techniques are utilized to provide web personalization (Brusilovsky & Kobsa, 2007) but in order to overcome the first challenge presented in 3.2, user's profile is modeled from multiple sources and updated when individual utilizes DemonD. It is important to underline that modeled profile are not utilized to personalize search engine results based on user's characteristics since profiling is leveraged to match a query with pertinent knowledge offers. (Figure 3, Figure 4, and Figure 5)

In DemonD, corporate information system directly provisions socio demographic data including (name, address, email, phone, occupation…). Individual also declares a list of competency through keywords complementing his profile (cf. Figure 6).

To enrich his profile, individual shares a set of documents (curriculum vitae, publications, patents) with the rest of the community. Recurrent keywords are extracted from these documents and enhance user's profile.

User also creates workgroups known as a list of contacts. DemonD utilized the group creation activity to extract recurrent keywords from group member's profiles. Such keywords are also utilized to complement user's profile.

Individuals are able to add or delete tags (keywords) on any resources on DemonD (his/others profile, his/others documents, and discussions) (cf. Figure 7). Various tags utilized by the individual are added to his profile. (Figure 8)

Diffusion and ContactRank

After registration and if the user is logged on, DemonD welcome page suggests recent articles or discussions. During an information retrieval activity, user enters a query in the search engine (cf. Figure 9). In Figure 10 we see that DemonD extracts the keywords from this query and suggests, to the information seeker, relevant and heterogeneous resources including:

Figure 2. Workflow DemonD

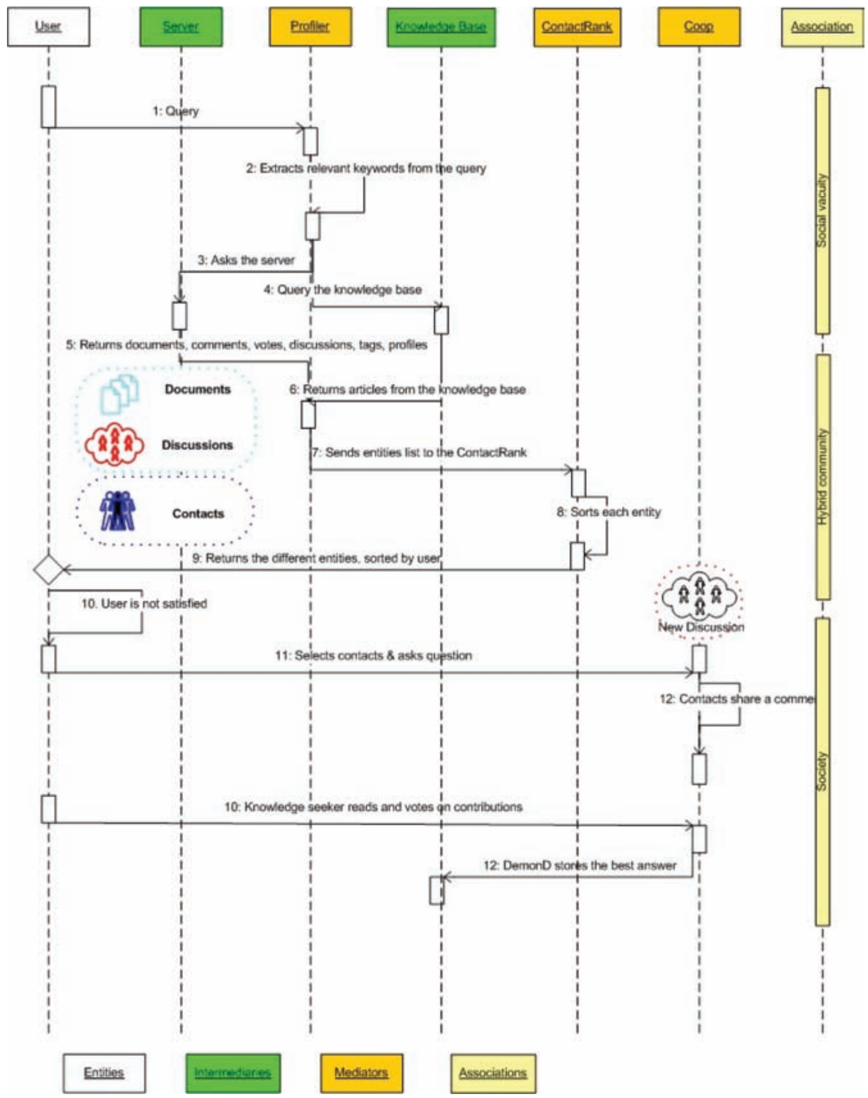


Figure 3. User's registration

Figure 4. Documents sharing

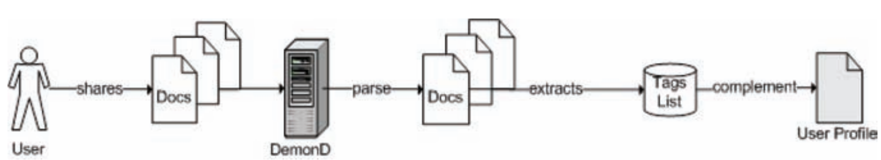

Figure 5. Extracting recurrent keywords from groups

Figure 6. User's registration

Figure 7. User's tags declared

− documents [1];
− ongoing discussions [2];
− articles [3];
− pertinent users [4].

The results are sorted according to their provenance:

− local refer to documents stored on user's computer;
− groups refer to documents, discussions or individuals declared by information seeker;
− corporate refer to documents, discussions or individuals unknown from information seeker.

Users are sorted according to the ContactRank [5], an algorithm compiled with the following criteria (knowledge, proxy, participation and reputation) (cf. Figure 10).

Knowledge Criterion

Knowledge criterion (C) suggests profiles (extracted from Profiler cf. 4.1) containing tags directly embedded in seeker's query. After being calculated, this criterion is utilized as a coefficient of the overall sum of proxy, participation and reputation criterion. This coefficient is comprised between 0,5 and 2:C(t)[o] = number of times that tag (t) is found in the profile of user o; ∑P[o] e [0.5 ; 2].

Participation Criterion

The second criterion Participation (P) is the number of times a potential recipient has responded to requests. Participation is a sum comprised between 0 and 17:∑P[o] = sum of participations of user o; ∑P[o] e [0 ; 17].

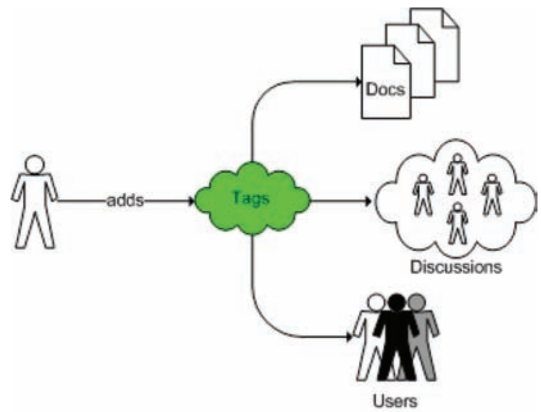
Reputation Criterion

The third criterion Reputation (R) compiles positive minus negative potential recipients' participations. Reputation is comprised between 0 and 17:∑R[o] = sum of reputation of user o; ∑R[o] e [0 ; 17].

Proxy Criterion

The fourth criterion Proxy (Pr) is the number of contacts of a potential recipient unknown from the information seeker. This criterion is also comprised between 0 and 17:∑Pr[o] = sum of contacts from user o's unknown from an information seeker and∑Pr[o] e [0 ; 17].

Figure 8. Tagging activity



Overall ContactRank

The ContactRank algorithm is in charge of sorting potential recipients of a request according to four criteria including: knowledge, participation, reputation and proxy. For a recipient "o" following a query on tag "t" ContactRank is:C(t)[o](∑P[o] + ∑R[o] + ∑Re[o]); et C(t)[o] e [0 ; 102].

If documents or existing discussions does not match seeker's query, he chooses to send a request.

Figure 9. DemonD's welcome page. ©2007 Charles Delalonde. Used with permission.

Figure 10. Potential Recipients sorted with ContactRank. ©2007 Charles Delalonde. Used with permission.

In order to follow the second challenge (cf. 3.2), knowledge seekers manage the reach of their requests by selecting one or many recipients.

Negotiation and Capitalization

The recipients selected are invited to provide a collaborative answer on a dedicated workspace (cf. Figure 11). Such workflow follows the third challenge of ERS (cf. 3.3).

When an individual initiates a request the "Coop" algorithm automatically creates a dedicated workspace. Coop also invites previously selected recipients to provide a collaborative answer. Validation takes place with peer reviewing and grading other member's participations.

Figure 11. Dedicated collaborative workspace. ©2007 Charles Delalonde. Used with permission.

During the capitalization phase, the best answer validated by the community is inserted in the organizational knowledge base. Information network constructed previously is also available on DemonD.

EVALUATION

To evaluate our Social Search engine we collected quantitative and qualitative data. First evaluation was a simulation of DemonD allowing us to test multiple scenario. Second evaluation was qualitative and is comprised of a focus group and 50 interviews with end-users.

Simulation

In the short period of time granted, it was unfeasible to collect statistically significant data in the laboratory depicted in introduction. DemonD's simulation has consequently been useful to evaluate the workflow of our system and identify efficient information retrieval strategies. The simulation has been developed utilizing a WAMP (Windows Apache MySQL and PhP) architecture and consisted of two stages: entities generation and information retrieval simulation.

Entities Generation

Before running multiple search cycles, we generated 100 users, theirs documents, their groups and built their profiles as presented in Figure 12.

In order to represent the diversity of user's involvement in social search services, Individuals' attitudes toward DemonD are distributed among: "search engine", "opportunistic" and "social network". Search engine's type of users are reluctant to diffuse their requests to other individuals and utilize DemonD only as information rather than a contact retrieval engine. Social network's type of users use DemonD as a social medium to create and maintain social ties. As a consequence, "social network's" users share documents and tag their profiles. "Opportunistic" types of users get partially involved by declaring a couple of tags and creating few groups. At the initial stage of simulation we discovered that a fourth profile was missing in our system: documents' holder. Indeed, the system could not function without the 200 documents initially shared by this last profile whom represents organizations' knowledge bases (okb). Two likelihoods are also added to each profile including the odds that this individual initiates a query at any given time (likelihood 1); the odds that this individual responds to any demand from another (likelihood 2). Each profile and information associated is described in Table 3.

Figure 12. Data generation

Table 3. Data generated (Search Engine, Opportunistic, Social Network)

Profiles	SE	O	SN	OKB
Number of this profile	50	25	25	1
Number of declared-tags	5	10	15	0
Shared documents Number of tags per doc.	0 0	2 10 tags	5 25 tags	200 5
Groups created Number of tags per group	0 0	2 10 tags	5 20 tags	0 0
Likelihood	30	40	50	0
Likelihood 2	10	20	50	0

Search Cycles

After generating the users and their documents, we ran multiple search cycles.

For each query, users might be:

− satisfied by documents ongoing, discussions / articles recommended by DemonD;
− satisfied by the responses brought by other individuals;
− not satisfied at all.

Four situations lead to an evolution of users' profiles (Likelihood 1 and 2 cf. Table 3) including:

− probability to ask a new question if a user is satisfied with previous responses received;
− probability to respond to a question if a user is satisfied with previous responses received.

During 50 cycles, 100 fictitious users queried DemonD resulting in 2133 queries and an overall satisfaction greater than 70%. 621 users were satisfied by documents / discussions and 877 were satisfied by responses given by other individuals. In addition, users (regardless of their profiles) trust DemonD's ability to retrieve the right information since 45% of the "search engine" profiles and 70% of the "social network" profiles queried the system. Furthermore profiles tend to become altruistic. Search engine's profile had an initial probability to respond to other's request of 10%. At the end of the 50 cycles their probability to respond is above 48%. The activity model of DemonD appeared coherent and able to retrieve information through pre-existing shared entities (documents, articles) or social ties.

Yet, such encouraging data hide the fact that 82% of the responses were given by users with "social network's" profile. A thorough analysis of user's selected profile indicates a malfunction in the ContactRank. Indeed, the ContactRank algorithm (cf. 4.2) selects, for each query, 10 potential respondents based on a set of criteria that auto-aliment each other. An effective methods to correct this sorting algorithm have been deployed and limit the size of certain criterion. As a reminder, ContactRank is for a user "o" and a tag "t":C(t)[o](∑P[o] + ∑R[o] + ∑Re[o]), where:

− C(t)[o] = number of times a tag (t) exists in a profile o ;
− ∑P[o] = number of times a user o has responded to user's questions ;
− ∑R[o] = difference between negative and positive evaluations from user o ;
− ∑Re[o] = number of unknown contacts between o and other potential knowledge giver.

ContactRank is frequently maximized with the criteria ∑P[o] et ∑R[o] auto alimenting each other. Indeed, if reputation and participation are high, knowledge giver (o) has a greater ContactRank. As a consequence he gets selected more often, participate more often increasing naturally the criterion ∑P[o] and ∑R[o]. To avoid this situation, we maximized the size of the following: ∑P[o], ∑R[o], ∑Re[o].

Focus Group and 50 Interviews

In order to confirm potential usages of DemonD qualitative data were also needed. An ergonomic study, with 50 respondents and potential end-users followed by a focus group, simulated a geographically distributed company willing to export "nanotechnologies" in China.

As mentioned earlier, existing ERS we evaluated usually face three challenges (cf. 3.2) that we attempted to address. DemonD's workflow appeared coherent to most surveyed users whom reacted very positively to DemonD's approach of collaborative information retrieval.

Yet, two challenges need to be taken in consideration. First, the collaborative tagging approach, critical in DemonD (users tags their/other's documents, their/other's profiles…), must be assisted. As Richard (one of the respondents) indicated:

"Tagging is costly to the User, you should consider automatic tagging functionalities. Metadata on documents should be extracted automatically" Richard B.

In fact, tagging might create inaccuracy (noise) if it does not rely on a semi-structured ontology. Furthermore, tagging is time consuming and not yet included in worker's practice. To respond to this first challenge, we are contemplating the possibility to suggest tags based on user's context following Nicolas Pissard's algorithm (Pissard, 2007).

Knowledge capitalization is also a challenge that need to be addressed. Wiki's technology are progressively entering organizations (certainly due to wikipedia's success) and constitutes a strategy to structure user generated content produced in DemonD. SweetWiki a semantic wiki is a technology that could replace DemonD unstructured knowledge base (Buffa *et al.*, 2007).

In addition, our sharing assumption embedded in DemonD must be leveraged by proper incentives. Users usually rely on their personal network of information. Sharing knowledge with unknown co-workers must be secured (in terms of intellectual property) and encouraged. To respond to this second challenge, we included a "confidential" functionality to restrain and control information diffusion. We also gave "proactive users" a specific status on DemonD.

CONCLUSION AND FUTURE WORKS

In conclusion, Social Search certainly constitutes a promising alternative to traditional information retrieval methods. Our model, relying on Actor-Network Theory, has revealed very encouraging data both quantitative and qualitative however certain flaws identified during evaluation needs to be corrected.

The Actor Network Theory utilized to specify our system might also be slightly criticized for two reasons.

First, treating humans and non-humans in an equivalent manner might also be criticized (Bloor, 1999). For instance, in social search activities, tags given by a user to define his profile and tags inherited automatically from the documents he is sharing must be treated differently. We suggest to include coefficients on tags based on their provenance when Profiler creates user's profile. Furthermore, as (Mutch, 2002) indicated in (Pentland & Feldman, In Press), ANT has been criticized as being "flat". Associations are observed at a given time but fail to encompass the history or context of the network. When social information retrieval takes place in organizations like the one described in introduction we must take into account the context.

A new version of DemonD is currently in progress and will be deployed in the laboratory depicted in the introduction. Quantitative data will then be collected based on user's improved effectiveness when utilizing the system. A beta version will also be experimented and the telecommunication company, funding this research, protected DemonD's algorithms thru a French then a European patent (Delalonde *et al.*, 2006) and plans to commercialize the system.

Chapter 2.16
RapidOWL:
A Methodology for Enabling Social Semantic Collaboration

Sören Auer
University of Pennsylvania, USA
Institut für Informatik, Universität Leipzig, Germany

ABSTRACT

In this chapter we give a brief overview on the recently emerging concepts of Social Software and Web 2.0. Both concepts stress the adaptive, agile methodological character of communication and collaboration. In order to lift the adaptive collaboration and communication patterns of Social Software and the Web 2.0 towards a truly semantic collaboration, we outline an adaptive knowledge engineering methodology–RapidOWL. It is inspired by adaptive software development methodologies from software engineering and emphasises support for small end-user contributions to knowledge bases.

INTRODUCTION

Examples from software development, communication and knowledge management show that the support for agile collaboration scenarios has an enormous potential for the reduction of resources, reducing development times and increase of quality. In software engineering, for example, the shift towards more adaptability in processes started long ago with methodologies like eXtreme Programming, Scrum and Adaptive Software Development. These individual approaches were later unified by the "Manifesto for Agile Software Development" (Beck et al. 2001). Subsequently, agile methods in software engineering led to the creation of complex software applications like the GNU/Linux operating system, the Web browser Mozilla Firefox, and the office software OpenOffice. But the success of adaptive methodologies is by far not limited to software engineering: just recently, adaptive communication methods of social software (such as blogs, the Jabber or Skype networks and platforms like LinkedIn) have enabled entirely new communication patterns. The domain of collaborative publishing and content management was revolutionized by blog and wiki technologies, which resulted in far reaching news networks without central control and made the creation of the most comprehensive encyclopedia possible, which is edited solely by volunteers - Wikipedia.

The aim of RapidOWL now is to take advantage of the potential of adaptive processes for collaborative Knowledge Engineering. The major aim of RapidOWL is to make the elicitation, structuring and processing of knowledge and thus the cooperation among domain experts and knowledge engineers more efficient. The RapidOWL methodology is based on the idea of iterative refinement, annotation and structuring of a knowledge base. Central to the paradigm for the RapidOWL methodology is the attention given to the smallest possible information chunks (i.e. RDF statements). The collaborative aspect comes into its own by allowing those information chunks to be selectively added, removed, or annotated with comments and/or ratings. Design rationales for the RapidOWL methodology are to be light-weight, easy-to-implement, and supportive spatially distributed and highly collaborative scenarios.

RapidOWL is, on the one hand, inspired by the XP.K methodology (eXtreme Programming of Knowledge-based systems, (Knublauch 2002)), which extends Extreme Programming to an agile methodology for the development of knowledge-based systems. On the other hand, RapidOWL is influenced by the Wiki idea (Leuf & Cunningham 2001}, which established agile practices for collaborative text editing. However, contrary to XP.K the RapidOWL methodology stresses the generic nature of a knowledge base and thus focuses on development of knowledge bases, whose final usage scenario is either not a priori known or a single usage scenario is not easily definable. This is usually the case for conceptualizations targeting at information integration as well as for shared classification systems and vocabularies. Different from the Wiki idea on the other side RapidOWL's artifacts are structured information and knowledge represented in statements rather than the Wiki's unstructured text documents. Wiki's are commonly seen as part of a development described by the terms Social Software or Web 2.0.

The concepts *Social Software* and *Web 2.0* were coined to characterize a variety of (sometimes minimalist) services on the Web, which rely on social interactions to determine additions, annotations, or corrections from a multitude of potentially minor user contributions. Non-profit, *collaboration-centered* projects such as the free encyclopedia Wikipedia belong to this class of services, as well as commercial applications that enable users to publish, classify, rate and review objects of a certain content type. Examples for this class of *content-centered* Web 2.0 projects are del.iciou.us (for Web links), Digg.com (for news), Flickr (for images), YouTube (for movies). *Communication-centered* services such as MySpace or XING enable individual communication and search for and within spatially distributed communities. So-called Web 2.0 *mashups* integrate and visualize the collected data and information in novel ways, unforeseen by the original content providers. The most prominent examples of mashups are based on Google Maps and overlay external content on a map. All these developments have a common approach of collecting metadata by making participation and contribution as easy and rewarding as possible.

Even before Social Software and Web 2.0 applications emerged, prior attempts had been made to enable rapid assembly of data on the Web into more informative content: the most well-known such project is the *Semantic Web*, although researchers had been working on "information integration for the Web" for many years prior (Ambite et al. 1998, Garcia-Molina 1997), with very different methodologies but a similar end goal. The Semantic Web is conceived as an extension of the existing Web to enable machine reasoning and inference: a prerequisite to this is that "information is given well-defined meaning" (Berners-Lee, 2001). This approach is based on a standardized description model (Resource Description Framework, RDF (Lassila et. al, 1999)) and semantic layers on top for semantic nets and taxonomies (RDF-Schema) as well as ontologies, logic axioms and rules (OWL and SWRL). However, the Semantic Web is not ubiquitous to this point, in part because of the

Table 1. Similarities and differences between Social Software and the Semantic Web

Social Software & Web 2.0	Semantic Web

high level of effort involved in annotating data and developing knowledge bases to support the Semantic Web.

The Web 2.0 and Semantic Web efforts, which have largely gone on simultaneously, pose an interesting study in contrasting methods to achieve a similar goal. Both approaches aim at integrating dispersed data and information to provide enhanced search, ranking, browsing, and navigation facilities for the Web. However, Web 2.0 mainly relies on aggregate *human* interpretation (the collaborative "ant" intelligence of community members) as the basis of its metadata creation, conflict resolution, ranking, and refinement; the Semantic Web relies on complex but sophisticated knowledge representation languages and machine inference (cf. Table 1). A natural question to ask is whether the different approaches can be combined in a way that leads to synergies. We discuss in this chapter how the question is being answered in the affirmative by providing an adaptive methodology – RapidOWL – for the creation of comprehensive knowledge bases. The main goal of this methodology is to support collaborative knowledge engineering in social networks, with high reward and little effort. After some preliminary concepts in Section 2, we exhibit the paradigms RapidOWL bases on in Section 3. In Sections 4 we describe the RapidOWL process in the light of its values, principles and practices. We give an overview on how these can be successfully combined in Section 5 and conclude with remarks concerning future challenges in Section 6.

PRELIMINARIES

Social Software and Web 2.0

The concepts social software (Webb, 2004) and Web 2.0 (O'Reilly 2005) were recently conceived to explain the phenomenon that computers and technology are becoming more and more important for human communication and collaboration. In particular the following aspects are important with respect to software enabling social collaboration: (1) usability, (2) community and participation, (3) economic aspects, (4) standardization, (5) reusability and convergence. In addition to that, a precise delimitation of the concept social software is due to heterogeneity of applications, applicants and application domains complex. It was proposed (Shirky 2003), to define the concept of social software not just with respect to characteristics of a certain software, but also with regard to communication patterns leading to the formation of a virtual community. Typical communication patterns of Social Software are depicted in Table 2.

On the technological side the popularity of social software is related to the development and use of the software development- and communication paradigms AJAX (Asyncrounous JAvascript and XML), REST (Representational State Transfer), and JSON (JavaScript Object Notation). These, in comparison to their counterparts Web-services, RPC or remote desktop light-weight, technologies enable completely new adaptive and interactive

Table 2. Typical communication patterns for social software

Pattern	Name	Partner	Direction	Example
	Point-to-point	1:1		Email, SMS/MMS
	Bi-directional	1:1		IM, VoIP
	Star-like	1:n		Webpages, Blogs, Podcasts
	Net-like	n:m		Wikis, content communities

application architectures and services.

Based on these technologies a number of methods for user-interaction established, which encourage and simplify spontaneous contributions, help to organize a multiplicity of contributions, as well as to syndicate and mutually integrate the gained data. These include:

- **Folksonomies:** Content annotation by means of tags (i.e. self-describing attributes attached to content objects) enables the fuzzy but intuitive organization of comprehensive content bases (Golder et. al. 2006). Tag clouds visualize tags to support navigation and filtering. Tags are co-located in a tag cloud when jointly used and emphasized differently to stress their usage frequency.
- **Architecture of participation:** Already the usage of an application creates an added value. For example, the added value can be generated by interactively evaluating usage statistics to determine popular content objects or by collecting ratings from users to classify content with respect to quality.
- **Instant-Gratification:** Active users are rewarded with enhanced functionality and their reputation in the user community is visibly increased. This promotes contributions and helps to establish a collaboration culture.
- **Mashups and feeds:** The content collected in the system is syndicated for other services (e.g. as RSS feeds, JSON exports or public APIs). This allows seamless integration of different data end transforms the Web into a Service Oriented Architecture.

From a methodological point of view these Web 2.0 and Social Software methods contribute to make communication and participation on the Web more adaptive.

Knowledge Engineering Methodology

Concerning the way humans think, the notion of knowledge is difficult to define. There has been a debate on the topic for millenniums and the field of epistemology dealing with it continues to be vibrant and dynamic. With regard to computer systems, knowledge is commonly differentiated from data and information. Since all three ultimately have to be stored as bits in the computer's memory, it is obvious that the borders between them are not clearly marked. However, within the CommonKADS methodology (de Hoog et al. 1996) a characterization system has been proposed. This is demonstrated in the following example.

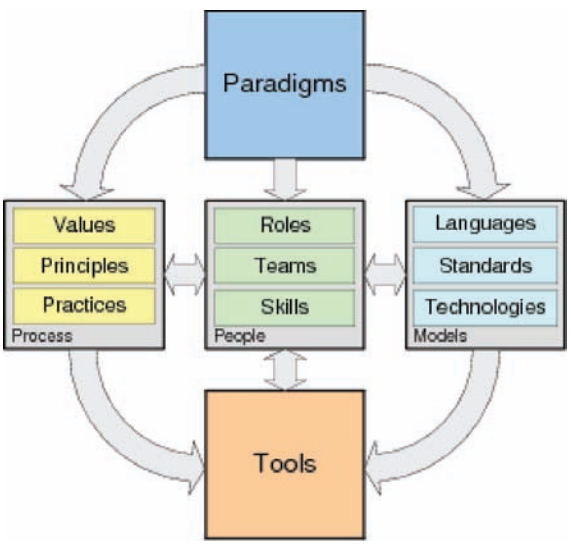
Data are supposed to be "raw signals", such as the name of a person (e.g. "Vincent van Gogh").

Information attaches meaning to data, such as the statement that a person is male (e.g. "Vincent van Gogh is male").

Knowledge in turn attaches purpose and competence to information, potential to generate action, e.g. "A human male must be a man."

Knowledge Engineering now subsumes the process of eliciting information and condensing the elicited information into knowledge by structuring, formalizing, and operationalizing. According to a widely accepted viewpoint this process is mainly carried out in order to construct a knowledge-based system that can perform a difficult task adequately (cf. (de Hoog et al. 1996)). From our point of view another aspect is important too: the structured sharing and exchange of knowledge between humans (and computer systems). The initial aim of such an approach is no longer the imitation of human intelligence by problem-solving methods of a single knowledge-based system, but the generation of human "swarm intelligence". In other words, relevant knowledge fragments from different sources can be dynamically combined, aggregated and visualized. We are convinced that such an interlinking of knowledge can have a similar impact as the interlinking of hypertext documents on the World Wide Web had.

Figure 1. The way of portraying agile methodologies according to Alistair Cockburn



In this document we will adopt the view of Alistair Cockburn (2000), who defines a methodology as "an agreement of how multiple people will work together. It spells out what roles they play, what decisions they must reach, how and what they will communicate".

A *knowledge engineering methodology* is an agreement of how multiple people will work together. It defines a process in which domain experts and knowledge engineers will build a knowledge base. This knowledge base is represented in a knowledge representation language with suitable tools. Processes, languages and tools are based on knowledge representation paradigms.

The RapidOWL methodology is presented in this document following other agile methodologies. Figure 3 summarizes the important ingredients, i.e. people, paradigms, processes, models and tools. RapidOWL is grounded on paradigms (see Section Paradigms). Paradigms influence the process (see Section Process), they lay the foundation for the models, and have to be internalized by people. Last but not least, tools implement the collaboration processes between people on the basis of the methodologies models. This docu-

Figure 2. The building blocks of RapidOWL: Values, Principles, Practices

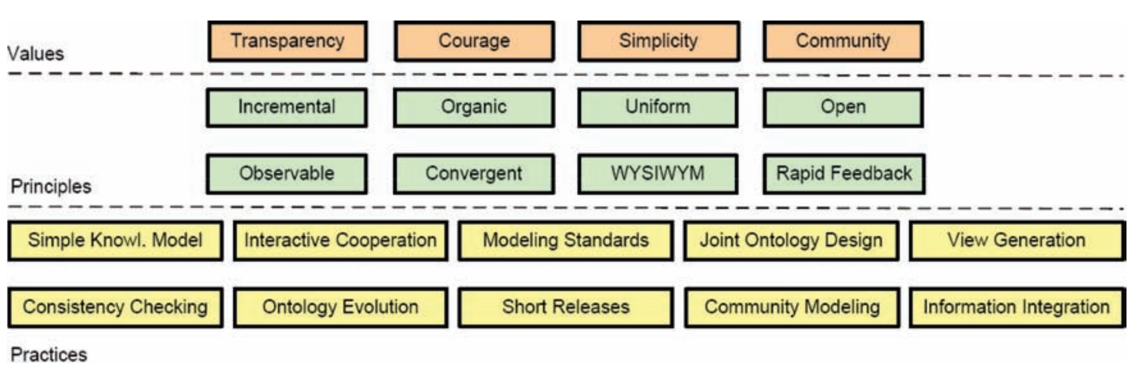


Figure 3. Collaboration between different parties on the basis of RapidOWL

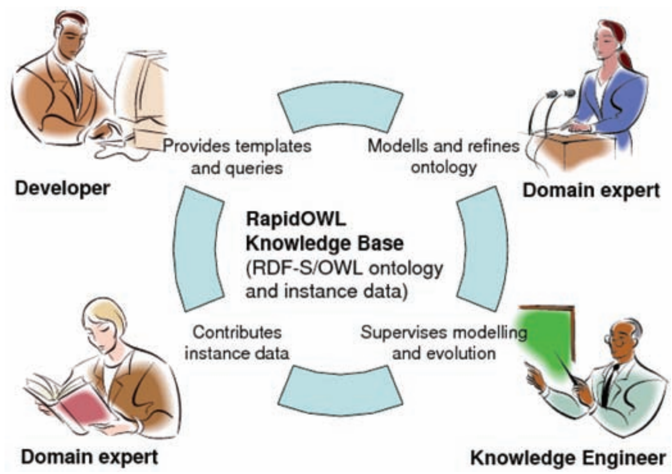


ment primarily aims at characterizing the agile Knowledge Engineering process of RapidOWL. However, prospective strategies supporting the methodology are mentioned whenever possible.

Existing Approaches

Related approaches can be roughly classified into two groups. Accompanied by the formation of knowledge engineering as an independent field of research several Knowledge Engineering methodologies were developed. Most of them are much inspired by Software Engineering methodologies. In the Software Engineering domain, in the 90's several Agile Software Engineering methodologies emerged. Triggered by the fact that flexibility, in particular fast and efficient reactions on changed prerequisites, becomes increasingly important, agile methodologies recently also appeared in other areas than Software Engineering. The most prominent representatives from each of these directions are briefly presented in the following.

Knowledge engineering. Traditional knowledge engineering methodologies, such as the ones by (Uschold 1996), (Grüninger and Fox 1995), (Methontology 1997), CommonKADS (de Hoog et al. 1996) take a task as the starting point, i.e. they suggest performing knowledge base construction with the knowledge base's usage scenarios in mind. This requires significant initial effort and makes changes to and reuse of the resulting ontologies inherently difficult. More recent approaches such as DOGMA (Spyns 2002), Diligent (Pinto et al. 2004), HCOME (Kotis et al. 2004) appeared, which conceive the building of knowledge structures and knowledge bases more in the sense of finding an agreement within a community of domain experts. This is a major step towards reusability of knowledge bases, but still requires significant initial efforts and makes processes to obtain an agreement within a community complex and inflexible.

Agile methodologies. Agile methodologies have recently gained growing success in many economic and technical spheres. This is due to the fact that flexibility, in particular fast and efficient reactions to changed prerequisites, is becoming increasingly important in the information society. This development started in Software Engineering after the realization in the mid 1990's that the traditional "heavy" methodologies do not work well in settings where requirements are uncertain and change frequently. Several adaptive or agile Software Engineering methodologies subsequently evolved (e.g. eXtreme Programming (Beck & Andres 2004), Crystal Clear (Cockburn 2004), Scrum (Schwaber & Beedle 2001) Adaptive Software Development (Orr & Highsmith 2000), Feature Driven Development). Agile methodologies are especially suited for small co-located teams and for the development of non life-threatening applications. Since the problem of uncertain, changing requirements is not limited to the Software Engineering domain, the idea of establishing adaptive methodologies, which can react to changing prerequisites, was also adopted by other domains than Software Engineering. These include "The Wiki Way" (Leuf & Cunningham 2001) for Content Management, Rapid Prototyping (Gebhardt 2003) for Industrial Engineering. Also, the Lean Management method was used to some extent in the business management domain.

SPECIFIC CHARACTERISTICS OF KNOWLEDGE ENGINEERING

The analysis of the application of the existing knowledge engineering methodologies and tools shows that they are up to now virtually not used in practice (Knublauch 2002, p 16). This stands in contrast to the often proclaimed necessity for knowledge engineering. What can be the reason for this discrepancy? Most of the existing knowledge engineering methodologies adopt techniques and apply process models from software engineering. However, in many scenarios required knowledge engineering tasks reveal specific characteristics, which a knowledge engineering methodology should be aware of. In the following, we describe some specific characteristics of Knowledge Engineering important for RapidOWL.

Knowledge engineering is not a business in itself. There is no market for Knowledge Engineering as there is for Software Development. This is not because Knowledge Engineering is less important in the economic sphere, but due to the fact that the flow of knowledge in most cases accompanies the development of products and services, rather than being an economic asset itself. Hence, Knowledge Engineering services are often required when spatially distributed users have to collaborate on a semantic level. For example, this is the case when a common terminology has to be established, dispersed information must be integrated, or when shared classification systems and taxonomies have to be developed. This type of semantic cooperation is for example often required for Virtual Organizations (Appel & Behr 1996), scientific communities or standardization boards, or intra-organizational use. Thus, the actors within Knowledge Engineering processes are often not bound together by a legal contract, or the Knowledge Engineering processes are not part of such a contract. Since this is usually the case for Software Development processes, some practices from agile software development methodologies seem to be out of place in the context of Knowledge Engineering.

Lack of a unique knowledge serialization. Agile methodologies rely heavily on sophisticated versioning and evolution strategies due to their focus on small incremental changes. However, agile methodologies, as well as their respective versioning and evolutions strategies within software development, do not seem to be reasonably applicable to knowledge engineering. For example, contrary to software development paradigms, most knowledge representation paradigms do not provide unique serializations. In other words, the ordering of statements or axioms in a knowledge base is irrelevant, while the ordering of source-code lines in software is fixed. Consequently, the use of existing software versioning strategies (e.g. delta method) and their respective implementations (e.g. CVS, Subversion) is not suitable.

Spatial separation of parties. Most agile Software Development methodologies assume a small team of programmers working closely (especially spatially) with domain experts. This is a reasonable assumption for commercial software development, where a client requests software developers to implement certain functionality. But when the involved parties are spatially separated, the use of a formal, tool-supported Knowledge Engineering becomes particularly important. Furthermore, the knowledge engineering tasks of establishing common classification systems, shared vocabularies and conceptualizations are is especially important in distributed settings. When teams are co-located implicit knowledge representation in the form of text documents in conjunction with verbal communication turns out to be more efficient and for a long time established.

Involvement of a large number of parties. The growing together of the world by Internet and Web technologies enabled completely new mechanisms of collaboration. Open source software projects as for example the Linux kernel or collaborative content authoring projects as Wikipedia demonstrate this power of scalable collaboration impressively. However, Knowledge Engineering is especially challenging when a large number of domain experts have to be integrated into the knowledge-engineering process. Agile software development methodologies claim to be best suited for small to medium sized development scenarios. This is mainly due to the accent on and need for instant communication. On the other hand, the interlinking of people and tools using internet technologies facilitates scaling of agile cooperation scenarios. Knowledge Engineering scenarios in most cases differ from software development scenarios: it is usually not optional, but crucial to integrate a large number of domain experts, knowledge engineers and finally users of the knowledge bases.

PARADIGMS

In this section we outline the paradigms RapidOWL is based on. The basic paradigms of conventional knowledge engineering methodologies are the generic architecture of knowledge-based systems, ontologies and problem-solving methods. We argue that the paradigms of an agile knowledge engineering methodology, with a focus on Semantic-Web knowledge representation standards, must both reflect the distributed interlinked nature of the Web and recognize statements as being the smallest building blocks of Semantic-Web knowledge bases.

Generic Architecture of Knowledge-Based Systems

As widely accepted, ontologies and problem-solving methods are the central components in a generic architecture for knowledge-based systems (cf. (Fensel et al. 2003; Grosso et al. 1999)). One question, however, is whether real problems can be solved on a major scale by problem-solving methods alone, or are tighter interactions with humans needed in order to perform (real) intellectual tasks? In the latter case, knowledge-based systems should initially focus more on the efficient provision of knowledge for use by humans. Thus, the RapidOWL methodology is based on a generic architecture, the core components of which are semantic enabled user interfaces in conjunction with efficient querying and aggregation strategies. The main benefit of a knowledge-based system seen from this point of view will not be achieved by the application of elaborated problem-solving methods, but by providing a scalable platform for a semantic collaboration between humans and a semantic inter-operation between machines.

Semantic-Web Data Model

The notion of ontology, from our point of view, is too vague for the RapidOWL methodology to be based on. However, in the context of the Semantic-Web activity, the use of RDF triples provides a precise frame for knowledge representation. Statements consisting of subject, predicate and object can be viewed as the smallest manageable pieces of knowledge (cf. (Kiryakov et al. 2002)). More complex facts can be expressed by using several statements with the same subject or by connecting two statements by using the object of the first statement as subject of the second one. This mechanism has proved to be reasonable to build vocabularies, classification systems and ontologies including instance data adhering to these (cf. RDF (Klyne & Carroll 2004), OWL (Bechhofer 2004)). An ontology of a distinct species is now an allowed combination of statements as, for example, has been defined in the OWL lite, OWL DL or OWL Full standards. All higher level constructs such as classes, properties or axioms can be broken down to a number of statements. For novices, moreover, this way of representing knowledge on the basis of simple subject-predicate-object statements is very easy to understand, yet expressive enough to formalize complex relationships.

Web Technologies

RapidOWL inherently requires the use of Web technologies when interlinking parties and tools in the Knowledge Engineering process. Universal Resource Identifier (URI) enable the unique global referencing of resources and concepts. Consequently, URI references can on the one hand build the basis for the referencing of arbitrary entities within RDF statements. On the other hand, they can be used within tools supporting RapidOWL to locate information about the referenced entity on the Web. The HTTP family of protocols here facilitates the exchange of digital resources, while the UTF encoding and XML technologies aim at easing the exchange and transformation of information in a serialized form. Such a procedure is simple, intuitive and eases the implementation. Beside this rather technical aspect of basing on Web technologies, RapidOWL projects should be socially Web-centered, too. Domain experts, knowledge engineers and software developers commit themselves to using the Web as a primary medium for publication and communication.

PROCESS

Conventional methodologies distinguish different phases within the life-cycle of either software or knowledge. Agile methodologies give the importance of applying a change a much higher value than being located in a certain stage of the life cycle. Consequently agile methodologies do not provide a phase model. Instead, they propose values from which (on the basis of paradigms) principles are derived for the engineering process in general, as well as practices for establishing those principles in daily life. We will describe RapidOWL along these dimensions in the following subsections, and then give an overview of how they can be combined and applied in practice.

Values

RapidOWL adopts the values of eXtreme Programming, namely Communication (to enable collaborative ontology development), Feedback (to enable evolution), Simplicity (to increase knowledge base maintainability) and Courage (to be able to escape modeling dead-ends). However, RapidOWL combines the values of Communication and Feedback in its Community value. This includes the social constructs that underlie the communication and subsumes feedback as a special form of communication. In addition to XP's values, RapidOWL includes the value of Transparency. These values are explained in the sequel.

Community. The Semantic-Web knowledge representation paradigm that RapidOWL bases on is especially suited to represent terminological knowledge, i.e. shared classification systems, vocabularies and conceptualizations. To be applied and used in a broad scope, such terminological knowledge has to be agreed on by a community. The value of community thereby induces the involvement of the community in the process of knowledge elicitation, modeling and knowledge base evolution. Since fluent communication is not easily achieved RapidOWL supports and even strengthens communication with the use of several practices such *as interactive cooperation*, *joint ontology design*, and *community modeling*.

Simplicity. In many areas it was recognized long ago that simplicity is a key factor for achieving efficiency, usability and maintainability. See for example David Ungar's and Randall B. Smith's influencing paper about simplicity in Software Development (Ungar & Smith 1991), Kristiina Karvonen's article about "The Beauty of Simplicity" for user interface design (Karvonen 2000) or Jack Trout's book on employing simplicity in the economic sphere (Trout 1998). For knowledge representation, however, the biggest opponent of simplicity is expressivity. A variety of incompatible knowledge representation languages emerged, each of them finding a different compromise between simplicity and expressivity. However, there is hope that on the basis of the RDF statement paradigm these different representation languages can be smoothly integrated into a layered architecture with increasing expressiveness. Hence, RapidOWL demands and promotes simplicity in both, the knowledge representation paradigm which it is based on and the modeling achieved by making use of this representation paradigm.

Courage. Courage enables domain experts and knowledge engineers to make relatively big changes in order to solve problems that cannot be solved with only minor changes. Courage is especially important because modeling in RapidOWL is deliberately performed with little pre-planning. Courage can be also seen as an analogue to the Wiki philosophy of "making it easy to correct mistakes, rather than making it hard to make them". In that, the value of courage also advocates to trust the expert's intuition and creativity instead of putting him on a leash of rigid processes and relying on hierarchical decision-making.

Transparency. All activities can be watched and reviewed by any other party. All changes to the knowledge model and to the instance data agreeing on it can be easily and timely observed by interested parties. This attracts attention and invites people to collaborate. Transparency results in an instant gratification of the contributing domain expert or knowledge engineer, since his contributions can be seen instantly by others. In addition to establish transparency to humans other software systems should be enabled to instantly obtain changed parts of the knowledge base, too. This enables different Semantic-Web applications (or knowledge-based systems) to interact smoothly. Transparency is (amongst others) promoted by the RapidOWL practices of *view generation*, *simple knowledge model* and *observable development*.

Principles

Based on the four values which represent long-term goals, the RapidOWL development process is guided in the mid-term by various principles. They are partly inspired by Ward Cunningham's design goals for the first Wiki system (Cunningham 2003). The principles describe the single RapidOWL process axiomatically in the sense that they define characteristics the RapidOWL process should possess. In the next section concrete practices are derived from the principles aiming at achieving these desired characteristics in daily routine without prescribing a rigid process.

Open-world. Should a concept be found to be incomplete or poorly described, any domain expert can add and change the description of the concept as they see fit. Contributions by domain experts should require little or no initial investment. Knowledge engineers are enabled to provide more detailed ontological descriptions, classifications and axiomatizations at any time.

Incremental change. Concepts can refer other concepts, including ones that have not been described yet. This promotes (small) changes by people, even if they are aware of required additional work to be done. In that it supports collaboration between people with different knowledge.

Organic evolution. The knowledge base is open to editing and evolution. Contributors need not worry about destroying something because all changes are tracked and easy roll-back mechanisms are in place. To implement reliable applications it is possible to access the state of the knowledge base at a certain point of time.

Uniform authoring. The mechanisms of modeling and organizing are the same as those of data acquisition, so that any data contributor is automatically a modeler and an organizer. Furthermore, this is very useful as the borderline between model and instance data is often not clear.

WYSIWYM. What You See Is What You Modeled - the visual representation of the knowledge bases content will suggest the input required to reproduce it. A knowledge base is usually structured on different levels: statements, classes and instances. This structuring should be made visually explicit, so that it is easy to understand which information represents a statement, which information stands for an instance etc.

Observable development. Making the authoring of the knowledge base observable is important for two reasons. Firstly, it should be possible for any interested party to watch and review activity within the knowledge base. In conjunction with effortlessness of contributing this stimulates people to actively participate. Secondly, changes and contributions should be published instantly to ensure direct editor gratification for his (hopefully) minor effort.

Rapid feedback. Observers can provide direct feedback on every single addition or change to the knowledge base. This feedback would either encourage the original contributor to intensify his efforts or to rethink his modeling decisions. Ideally, this alternation of changes and feedback leads to conceptualizations which are really shared by the parties of a community, since they are result of a clash of different (or similar) viewpoints in a social ecosystem.

Convergent. Duplication can be discouraged or removed by finding, proposing and referring to similar or related concepts. This results on the one hand in simpler and smaller knowledge bases and on the other hand allows inaugurating new insights due to the increased interlinking of the knowledge base.

Traveling light. RapidOWL suggests focusing on a single modeling artifact. This artifact is the domain model expressed in the form of statements. This model can be enriched with documentation, feedback and comments. Instead of maintaining multiple models for the different levels of abstraction, RapidOWL promotes the use of different views.

Practices

The practices of RapidOWL are inspired by the practices of eXtreme Programming (XP) and from Holger Knoblauch's modifications for software / knowledge base co-design XP.K (Knublauch 2002). Due to the specific characteristics of knowledge engineering (cf. Section 3) not all practices from XP have an equivalent in RapidOWL and inversely. However, as in XP the practices support each other, so that the weakness of one practice is overcome by the strengths of other practices. This implies that most benefit from using RapidOWL lies in applying all of the practices together. In contrast to software development, where the team of full-time programmers can be easily instructed to put the values and principles of XP into daily routine, RapidOWL aims to turn domain experts into part-time knowledge engineers by keeping practices as simple as possible and by proposing strategies to support them with tools.

Interactive cooperation. Instead of requiring an on-site customer (or as in XP.K an On-Site domain expert) we propose to establish methods of interactive on-line cooperation between domain experts and knowledge engineers. A first step, is to transparently and timely publish ontologies and traces of changes for easy access by other modeling or reviewing parties. This can be technologically supported by interactively publishing the ontology and changes on the Web. Current developments of equipping Wiki systems with support for representing semantic relationships (cf. (Aumüller 2005), (Krötzsch et al. 2005)) are good candidates to accomplish this task. By applying recent content syndication standards (such as RSS (Winer 2002) or ATOM (Nottingham & Sayre 2005)) for the announcement of changes, experts can be timely and conveniently kept up to date.

Joint ontology design. Based on the simple subject-predicate-object statement paradigm, domain experts initially only define and describe concepts in a quite spontaneous manner. For this, they make use of worldwide unique concept identifiers (URI references) as subjects, predicates and objects within statements (i.e. RDF triples). After the information is thus represented, it can be enriched by more experienced domain experts or knowledge engineers with more detailed categorizations, classifications and logical descriptions (e.g. OWL axioms or SWRL rules).

Community modeling. To enable collaborative semantic cooperation, domain experts can attach comments to the statements and vote on how usefulness of the statements. In order to technically achieve this, RDF reifications may come into effect. To observe changes on higher conceptual levels than that of additions and deletions of statements, multiple added or deleted statements can be put into change sets. This is comparable to the way that patches subsume multiple atomic changes in software source-code versioning. Hierarchically organizing changes even allow change reviews on different levels of detail.

Information integration. The awareness of the need for developing a knowledge base often arises when a multiplicity of information sources exists and their interrelations are hard to maintain. Hence, it is crucial for the success of a knowledge engineering project to integrate existing information sources. Two approaches are possible to achieve this goal: *Importing information* into the common knowledge base - all further maintenance of the information has to be done within the knowledge base. This method can be easily applied for simple structured information sources as for example Excel sheets containing tabular information (Powl as described in (Auer 2005) contains such functionality). The other possibility is to *interlink existing data sources* with the knowledge base. This method will be the preferred way if information sources are highly structured (such as e.g. relational databases or LDAP directories), existing applications rely on access to the information sources in conventional ways and the maintenance of the information should be performed in established processes. For relational databases the problem is tackled by D2RQ (Bizer & Seaborn 2004). LDAP2OWL (Dietzold 2005) is an approach to make information from LDAP directories accessible to knowledge bases.

View generation. An aim of classical knowledge engineering is to realize problem-solving capabilities comparable to a domain expert (Studer et al. 1998)). In addition knowledge engineering can be seen as a support strategy helping users and experts to transfer knowledge between individuals or to gain new insights by presenting knowledge in unforeseen ways. Generating different views on a knowledge base will support greatly the latter mentioned aspects of knowledge engineering. Views select and combine certain parts of the knowledge base for human users. On type of views are user generated views, where the user or viewer is identical to the generator to the view. Such `self service' views can be realized in a user friendly manner by provision of full-text searches in combination with filtering and sorting functionality. However, for certain investigations more sophisticated selection strategies than filtering and sorting might be needed or the presentation for humans should be tuned. In this case view generation will require either a more experienced user, able to cope with query languages and aware of the knowledge structures or knowledge engineers assisting in generating the view. Fresnel (Bizer et al. 2004) for example is a declarative way to encode presentation knowledge in RDF with the primary goal of reusability across different representation paradigms.

Modeling standards. Modeling Standards are the counterpart to the XP practice of Coding Standards. Modeling Standards are agreed-upon naming conventions (e.g., “properties should start with a verb”) and syntax rules (e.g., “classes start with an uppercase letter”). Since the ontology language RapidOWL bases on (i.e., OWL) is much simpler than programming languages, it only requires the use of a few standards. In (Knublauch 2002, p 74) standards are described as being “essential to enable model exchange, collaborative modeling, and to minimize the dependency of the team on specific members. Furthermore, they contribute to the original vision of ontology research to enable global knowledge sharing”. Whilst it is relatively easy to enforce syntax rules within tools, the compliance check for naming convention could prove more challenging. The prefixing of properties with verbs though, can be checked with the aid of electronic thesauri (e.g. WordNet (Fellbaum 1998)).

Ontology evolution. Ontology evolution is the counterpart for the XP practice Refactoring. The more spontaneous new modelings and information is integrated into the knowledge base the higher is the demand later to adopt modelings and migrate instance data accordingly. Many approaches to ontology evolution emerged recently ((Stojanovic 2004) gives an overview), most of them, however, presuppose a well-defined and fixed set of possible knowledge base changes. To be able to review changes on different levels of detail (e.g. statement, ontology, domain level) we developed a hierarchical versioning strategy (cf. (Auer & Herre 2006)) which also facilitates automatic migration of instance data by providing a framework for the detection of ontology evolution patterns.

Short releases. A long-lasting develop-release cycle as in traditional software engineering would not adequately reflect the continuous information integration and knowledge structure evolution, which is characteristic for shared classification systems, vocabularies and conceptualizations. Instead we propose to make the development process as transparent as possible, by publishing changes immediately and releasing stable versions frequently. The sooner an ontology is released to the public, the easier it is to discuss changes and the earlier it is that potential problems become visible. Short releases will be facilitated if the consequences of changes to the ontology are known, i.e. if data adhering to the ontology has to be migrated or if queries about and views on the data have to be adopted.

Simple knowledge model. According to XP.K, simplicity is a “key to making models easy to understand, communicate, and maintain” (Knublauch 2002, p 75). Hence, the best knowledge model for RapidOWL is the model that has the fewest possible classes, properties and instances, provides semantic transparency for users as well as software systems, provides the needed querying facilities and passes consistency checks without violations. RapidOWL envisions a middle-out strategy for concept identification to implicitly achieve simple modelings: Domain experts are required to initially integrate all that information into the knowledge base they assume being relevant and worth represented. Such instance and sample data is in the following only thus far condensed into classifications and enriched with logical axiomatizations as needed for querying and/or reasoning services provided to the users. Hence, a RapidOWL knowledge base is not required to anticipate (all) future requirements a priori. Increasing complexity is therefore mainly driven by domain experts (i.e. users) of the knowledge base, thus ensuring comprehensibility.

Consistency checking. RapidOWL envisions the successive enrichment of a knowledge base with additional structure and logical representations according to the Semantic-Web language stack. However, this process should be mainly driven by users insofar as the increased semantics gives them real benefits with regard to querying and reasoning capabilities. Due to the size of real-life knowledge bases a strategy to enable reasoning services is to extract distinct parts or "slices" of the knowledge base adhering to a distinct OWL species or a rule language (e.g. SWRL (Horrocks et al. 2003)) to perform constraint and/or consistency checks (e.g. by means of Description Logic reasoner as FaCT (Horrocks 1998) or Racer (Haarslev & Möller 2001).

PUTTING IT ALL TOGETHER

The values, principles, and practices described in the previous section are the major ingredients of the RapidOWL methodology. They are also the main things that domain experts, knowledge engineers and especially tool developers for RapidOWL enabled knowledge engineering and management systems, should be aware of. In contrast to systematic engineering methodologies, RapidOWL does not prescribe a sequence of modeling activities that should be precisely followed. Furthermore, RapidOWL does not waste resources on comprehensive analysis and design activities. Instead, it follows the philosophy of agile methodologies, in which agility in the face of changing requirements and knowledge models is a major goal.

The individual tasks and contributions of prospectively involved parties in building a knowledge base on the basis of the RapidOWL principles are presented in the next paragraphs.

RapidOWL encourages *domain experts* to initially express all facts they assume as true and worth being, represented by means of RDF statements. This can be simply the adding of a statement which attaches an rdfs:label or rdfs:documentation to a URI reference, to give that URI reference an informal meaning. Or, instance data can be gathered by importing existing documents (spreadsheets, listings, text documents) into the knowledge base. A spreadsheet containing structured information in tabular form, for example, can be interpreted as a class, where columns indicate properties and rows usually represent instances. This activity promotes a shallow learning curve, since domain experts can instantly participate. As soon as an expert starts working on such a knowledge representation, other experts can observe every single step. They can add comments, vote about the usefulness of certain representations, add their own knowledge fragments and/or delete other ones.

More *experienced domain experts* assist in restructuring, interlinking and consolidating the gathered data. Importing information from legacy documents often results in duplicates, because, for example, columns in different spreadsheet documents representing the same information are not labeled in a uniform manner. Such duplications have to be detected and eliminated (e.g. by merging the respective properties into one). To reduce the costs of such changes, RapidOWL will rely on implemented wizards assisting in the detection of frequent modeling errors and by providing (semi-) automatic resolution to support evolution and migration. It might also be necessary to convert literal data, as, for example, two properties to be merged can represent the same information differently (e.g. names like "Auer, Sören" or "Sören Auer"). This kind of consolidation activity also includes the establishing of relationships which are not yet represented.

Knowledge engineers can support such a community of domain experts with advice for reasonable representation methods and by providing ontology evolution and data migration strategies. Knowledge engineers can further enrich the knowledge base with logical ontology axioms. This includes property characteristics (e.g. transitivity) and restrictions (e.g. cardinality restrictions). Class descriptions are refined with set operators (owl:intersectionOf, owl:unionOf, owl:complementOf). The knowledge engineer can also extract distinct parts or "slices" of the knowledge base adhering to the OWL species, DL and lite to perform consistency checks using a Description Logic reasoner. Since RapidOWL does not restrict domain experts in their usage of RDF it is likely that the knowledge base does not fall into the OWL DL or OWL lite categories. The species validation of an OWL reasoner, however, can give hints about how the knowledge base has to be modified. Another task is the testing of existing queries and views on the knowledge base after changes have been incorporated.

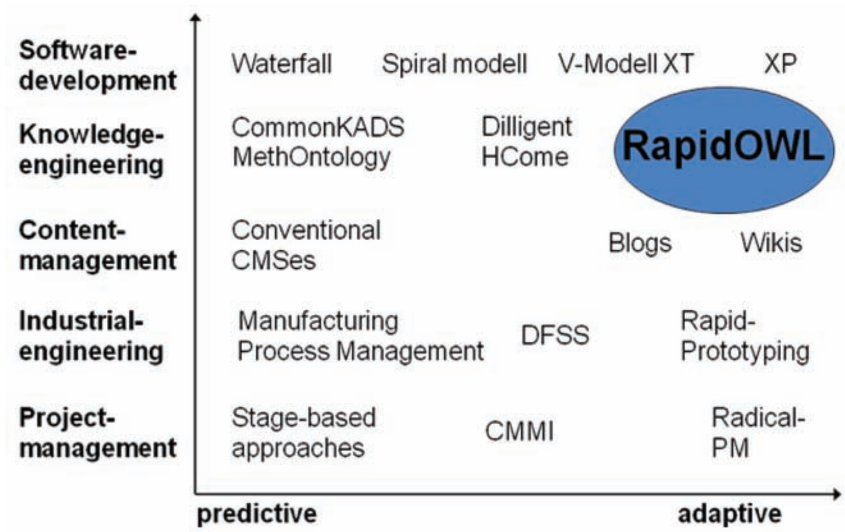
RapidOWL focuses primarily on establishing conceptualizations for information integration as well as the establishing of shared classification systems and vocabularies. Hence, tools supporting RapidOWL will have a rather generic than domain specific nature. However, *software developers* participate in the collaboration by developing domain specific applications providing specific views onto the knowledge base, or by assisting domain experts and knowledge engineers in formulation more complex queries to the knowledge base.

RapidOWL does not enforce a distinct succession; neither does it require all the just mentioned tasks and activities to be accomplished by the respective parties. The quality of the knowledge base, however, is determined by carefully performing activities related to consolidation, restructuring and modeling as well as consistency checking. Tools on the other hand, can highly automatize and integrate these activities into the Gathering activity.

In order to provide tool support for RapidOWL we developed OntoWiki (cf. Figure 5). OntoWiki facilitates the visual presentation of a knowledge base as an information map, with different views on instance data. It enables intuitive authoring of semantic content, with an inline editing mode for editing RDF content, similar to WYSIWYG for text documents. It fosters social collaboration aspects by keeping track of changes, allowing comments and discussions on every single part of a knowledge base, enabling to rate and measure the popularity of content and honoring the activity of users. OntoWiki enhances the browsing and retrieval by offering semantic enhanced search strategies. All these techniques are applied with the ultimate goal of decreasing the entrance barrier for projects and domain experts to collaborate using semantic technologies. In the spirit of the Web 2.0 OntoWiki implements an "architecture of

Figure 4. Screenshot of the RapidOWL tool OntoWiki

Figure 5. RapidOWL's placement in terms of predictive vs. adaptive methodologies



participation" that allows users to add value to the application as they use it. It is available as open-source software and a demonstration platform can be accessed at http://demo.ontowiki.net. OntoWiki is described in detail in (Auer et at. 2006).

CONCLUSION

The purpose of RapidOWL is to bring about a stable state of the knowledge base through small incremental changes from a multiplicity of contributors. To achieve that, RapidOWL applies various techniques and practices with the explicit goal of reducing the cost of change. Much of the assumption that the cost of change can be reduced is based on the value of *Transparency*. The practice *Short Releases* for example promotes that ontologies are published quickly and frequently, so that expensive misunderstandings can be uncovered and eliminated early, when the costs of changing them are still low. *View Generation* furthermore enables domain experts to timely review the representations from different perspectives. *Joint Ontology Design* and *Community Modeling* promote communication between domain experts (and knowledge engineers) and thus help by detecting errors earlier and spreading the knowledge. *Ontology Evolution* enables to undo problematic changes and to estimate prospective effects on instance data. Early *Information Integration* helps that the ontology really captures needed conceptualizations adequately. The *Simple Knowledge Model* of the statement based approach of Semantic-Web knowledge representation standards is very easy to understand. In conjunction with *Modeling Standards* domain experts are thus enabled to efficiently contribute to a knowledge base, even in absence of knowledge engineers. Finally, *Consistency Checking* helps to build robust and terminologically correct knowledge bases.

Although each of these practices has weaknesses when applied individually, their benefits greatly outweigh their weaknesses when they are used as a combined approach. In other words, the practices of RapidOWL support one and other. This analogous to other agile methodologies (cf. (Beck & Andres 2004), (Knublauch 2002)) and due to the "axiomatic" description of their single process. An example for individual weaknesses and mutual compensation of such is the interplay of the practices of *Short Releases* and *Ontology Evolution*. *Short Releases* of the ontologies may result in instabilities of the resulting knowledge-based systems. However, *Ontology Evolution* supports the early detection of prospective problems and enables the revoke of individual problematic changes in a simple way.

In (Fernández-López 1999) a number of criteria for analyzing methodologies were proposed. In the following we discuss RapidOWL in the light of these criteria.

Detail of the methodology. RapidOWL is a rather lightweight methodology. This is primarily due to the recognition that knowledge engineering is usually not a business in itself and thus significant resources for evaluating the methodology and later controlling the compliance of the processes with the methodology are not available. RapidOWL rather banks on tools supporting it than on exhaustive documentation.

Recommendations for knowledge formalization. RapidOWL bases on representation of all knowledge in the form of triples, i.e. RDF statements. A concrete degree of formalization is not prescribed. However, RapidOWL proposes to justify the degree of formalization according to the required reasoning capabilities of the resulting knowledge base.

Strategy for building ontologies. Regarding this criterion it is questioned whether the strategy to develop ontologies is (a) application-dependent, (b) application-semi-dependent, or (c) application-independent. RapidOWL focuses on the development of rather application-independent ontologies. However, RapidOWL is primarily suited for information integration tasks and tasks related to the establishing of shared classification systems, vocabularies and conceptualizations.

Strategy for identifying concepts. RapidOWL here follows a middle-out strategy, i.e. from the most relevant to the most abstract and most concrete. By stressing the collecting of example or instance data RapidOWL tries to abolish knowledge elicitation by means of face-to-face communication between domain experts and knowledge engineers.

Recommended life cycle. Due to its adaptive nature RapidOWL does not explicitly propose a rigid life cycle. However, many aspects of stages in the life cycle of conventional methodologies can be discovered in RapidOWL's single process.

Differences between the methodology and IEEE 1074-1995. This criterion is related to the conviction that knowledge engineering processes should be similar to conventional software development processes. In this regard RapidOWL is different in two ways: Firstly it stresses the need to react on changed prerequisites, i.e. being agile. Secondly it assumes knowledge engineering to be fundamentally different from software engineering in certain scenarios (cf. Section 3).

Recommended techniques. RapidOWL stresses the importance of providing concrete techniques for performing the different practices of which the methodology is composed. However, in the description of RapidOWL's practices within this document only starting points on how to put them into effect are mentioned.

Usage and application. Due to the fact that RapidOWL is rather new and significant resources had not been at our disposal for a broad evaluation the number of successfully realized RapidOWL projects is still small. However, ontologies and applications have been building on the basis of RapidOWL containing approximately 20,000 concepts and serving 3,000 parties (cf. the case study in (Auer & Pieterse, 2005)). Also, the large DBpedia multi-domain ontology extracted from Wikipedia (Auer et al. 2007), can be seen as a confirmation and working example for large-scale social semantic collaboration in the spirit of RapidOWL.

FUTURE RESEARCH DIRECTIONS

As we already mentioned earlier, a pivotal Social Software concept is the collaborative tagging of content leading to folksonomies (i.e. taxonomies created by folks). Applied to the sphere of the Semantic Web the challenge is to employ human "swarm intelligence" in the spirit of tagging to create not just *comprehensive* but also consistent knowledge bases. Consistent here is meant less from a logical point of view than from the perspective of achieving an agreement in the user community. When knowledge bases are collaboratively developed by loosely-coupled communities a way to improve the consistency is the development of RapidOWL extensions for moderation and decision processes. A field of future research is also the investigation of possible indicators for the degree of consistency.

A different approach of tackling the consistency problem represent policies and access control mechanisms for accessing, editing and annotating content. Due to the variety of the possible expressivity to be considered the formulation of policy models and access control strategies turns out to be difficult. In addition, policies should be adequate for a spectrum of knowledge bases with a varying degree of semantic richness.

Another challenge, lying less in the scientific than the software engineering field, is to increase the flexibility and robustness of storage backends, libraries and frameworks for the development of social Semantic Web applications. In addition to that standards for semantic widgets and user interface elements can support user acceptance and interoperability.

Last but not least *economic aspects* play a crucial role to make the Semantic Web a success. Due to the fact that semantic collaboration is in many cases not a direct business in itself, specific business models are needed, which are focused on services and products supporting the generation and curation of semantic content by communities.

APPENDIX: QUESTIONS FOR DISCUSSION

Name three adaptive methodologies in different domains.

Extreme Programming in software engineering, "the Wiki Way" for content management, Rapid Prototyping for industrial engineering are adaptive methodologies in different domains.

What are smallest possible information chunks in RapidOWL knowledge bases?

RapidOWL is based on statements in the shape of RDF triples consisting of subject, predicate and object.

How can the unique identification of entities be assured on the Web?

Universal Resource Identifier (URI) enable the unique global referencing of resources and concepts, both within RDF statements and for retrieving further information about the referenced entity from the Web.

What are the typical ingredients of adaptive methodologies?

Adaptive methodologies can be described on the basis of their roles, paradigms, processes, models and tools. Paradigms influence the process; they lay the foundation for models, and have to be internalized by people. Tools support the collaboration processes on the basis of the methodologies models.

How can we distinguish data, information and knowledge?

Data are supposed to be "raw signals", such as the name of a person. Information attaches meaning to data, such as the statement that a person is male. Knowledge in turn attaches purpose and competence to information, potential to generate action.

Which roles of participating actors are envisioned by RapidOWL in the creation of knowledge bases?

RapidOWL envisions domain experts, knowledge engineers and software developers to participate in semantic collaboration scenarios. However, RapidOWL is primarily focused on domain experts and should be applicable even in the absence of knowledge engineers and developers.

How is the creation of knowledge bases different from the creation of software?

Knowledge Engineering is usually not a business model in itself. It also lacks unique knowledge serializations as there are with source code for software. Knowledge engineering scenarios mostly have to deal with a large number of spatially separated parties.

Describe differences and similarities of Social Software and the Semantic Web

Both paradigms are collaboration and integration focused, based on the Web and provide enhanced means for search and navigation. They differ, however, with regard to the involvement of communities, the incorporation of business aspects as well as the complexity of content and technologies.

What are the typical communication patterns for social software?

Typical communication patterns for social software are point-to-point, bi-directional, star-like, net-like communication.

This work was previously published in Semantic Web Engineering in the Knowledge Society, edited by J. Cardoso; M. Lytras, pp. 267-289, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Section III
Tools and Technologies

This section presents extensive coverage of the tools and specific technologies that change the way we interact with and respond to our environments. These chapters contain in-depth analyses of the use and development of innumerable devices and also provide insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of specific tools, such as social television, wikis, mobile photo galleries, and personal digital libraries. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Chapter 3.1
A Modern Socio-Technical View on ERP-Systems

ABSTRACT

This chapter sketches an Organization Design perspective called "Modern Socio-technical Design", and subsequently discusses the implementation of Enterprise Resource Planning Systems from this perspective. The authors argue that the praxis of ERP-system implementation is often at odds with socio-technical insights, leading to various problems that ERP-end users are confronted with. These tensions may not be inevitable, but simply result from taken-for-granted organization assumptions underlying ERP-implementation praxis. The socio-technical insights are intended to help practitioners reflect on ERP-implementation praxis, and discuss to what extent an ERP-system is appropriate and if so, where socio-technically inspired choices may be made within configuration processes.

INTRODUCTION

Do ERP and teamwork coincide? Koch and Buhl (2001) studied 24 cases where teamworking and ERP-systems were introduced simultaneously. Their answer to the question is negative, as they argue:

[s]ince the concepts of teamwork and ERP-systems appear widely diffused, one might expect that both are closely aligned when they are implemented [...] As we demonstrate, however, this is not the case [...] Although ERP is possible to configure in such a way that autonomous teamwork on the

shop floor is supported, we found that ERP and teamwork rarely interact directly. When they do, they are potentially competing change programs, and indirect competition predominates. (Koch & Buhl, 2001, p. 165)

They argued that the problem was not the configuration of ERP-systems for autonomous teamwork, but that there were (1) no modules available for this configuration process and (2) no consultants with the necessary knowledge. To illustrate this, they discuss the case of a machine building company where an attempt was made to align ERP-systems and teamwork. The attempt was unsuccessful however, as it started from different premises: the consultants implementing the ERP-system focused on enhancing production planning and control from a central perspective and "did not push for supporting teamwork" (2001, p. 173). Furthermore, "in-built features" of the ERP-package used "were realized in a way that led to a strengthening of other parts of the planning than the teams" (2001, p. 173). Finally, the technical aspects of implementing the system were so complex and time-consuming that organizational aspects received little attention. The members of the self-managing teams in the project team could not turn this tide. Whilst the teams were authorized to take certain decisions, the key tasks of (local) production planning was centralized. In a second round of ERP implementation, the shop-floor teams' experiences were not taken into account and the new tasks were confined to data entry and providing feedback on production orders. Koch and Buhl stress that the outcome was not a necessity but "a mixture of intended and not intended actions both from the ERP-coalition" and members of the self-managing teams (2001, p. 174).

Their findings do not stand alone. At a more general level, Soh and Sia (2004) studied how ERP-systems were used in three hospitals in East Asia. They wondered whether empowerment or control would prevail in how these systems were used. The result of their study was that while both outcomes are possible, in praxis control tended to get the overhand. In terms of Orlikowski (2000), the 'control' potential of ERP-systems is apparently and in the course of time more easily enacted than the 'empowerment' potential (cf. Boudreau & Robey, 2005).

Koch and Buhl's study gives rise to the question why it is apparently so difficult to combine self-managing teams and ERP-systems. Answering this question calls for a more integrative view on organization design because teams are embedded in organization structures and information systems such as ERP-systems are to support decision-making in such organizations. This view remains implicit in Koch and Buhl's study, but is necessary if their recommendation of developing "practical templates" to support configuring ERP-systems for self-managing teams is to be realized. In a broader perspective, self-managing teams are seen as a hallmark of modern organization, for instance as part of "high performing work systems".

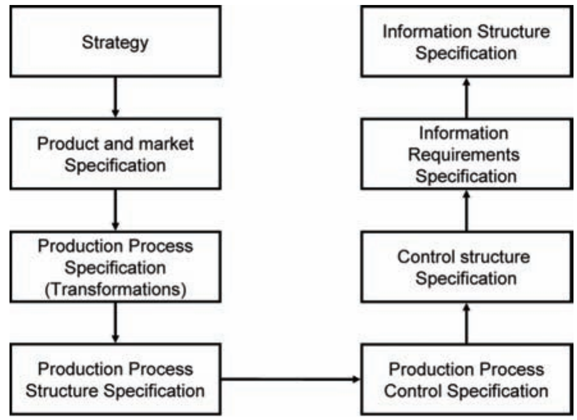
In the remainder of this chapter we first present an organizational design methodology that provides an integrated view on structuring organizations so that suitable organizational environments are created for self-managing teams and subsequently, after this structure has been designed, the informational requirements are analyzed so that information systems may be configured and implemented. This so-called "Modern Socio-technology" incorporates some organizational design principles which, as Koch and Buhl's (2001) work shows, tend to sit uncomfortably with ERP-systems in practice. These tensions are discussed after presenting Modern Socio-technology. This analysis is necessary as a first step for developing the templates for which Koch and Buhl signaled the need.

MODERN SOCIO-TECHNICAL SYSTEMS DESIGN

What was to become socio-technical systems design (STSD) started with studies in the late 1940s in a number of British coal mines. In 1951, Trist and Bamforth published a founding article on STSD while the London-based Tavistock Institute played a key role in further developing socio-technical design into practical applications. During the 1950s and 1960s these notions were picked up in many countries, with Norwegian and Swedish researchers playing key roles. In the Netherlands a strand of socio-technical scholars and practitioners developed a widely accepted research based organizational design methodology (De Sitter, Den Hertog, & Dankbaar, 1997; De Sitter, 1998). This Dutch variant, called Modern Socio-technology (MST), builds on the classic STSD. In the 1970s Ulbo de Sitter played a key role in developing this socio-technical systems theory (with some roots in German sociology). During the 1980s this design theory was enriched with a proper design methodology based on action research. MST mainly differs from STSD by its integral approach. Whereas classic STSD provides a set of static and partial design principles, MST offers detailed structural principles in terms of design content, while at the same time specifying a theory of change by means of worker participation and training (Van Eijnatten, 1993). To emphasize the integral character of this approach, Van Eijnatten and Van der Zwaan (1998) labeled it Integral Organizational Renewal (IOR).

Since MST provides an integrated body of knowledge comprising analysis methods as well as (re)design rules (Van Eijnatten & Van der Zwaan, 1998), it is this Dutch variant of STSD we use for our analysis of the effects of ERP on organizational design. Team based organizations are a central concept in this approach aimed at meeting organizational requirements, as well as improving the quality of working life. To achieve this the design order principle as depicted in Figure 1 was developed (Groep Sociotechniek, 1986; De Sitter, 1998).

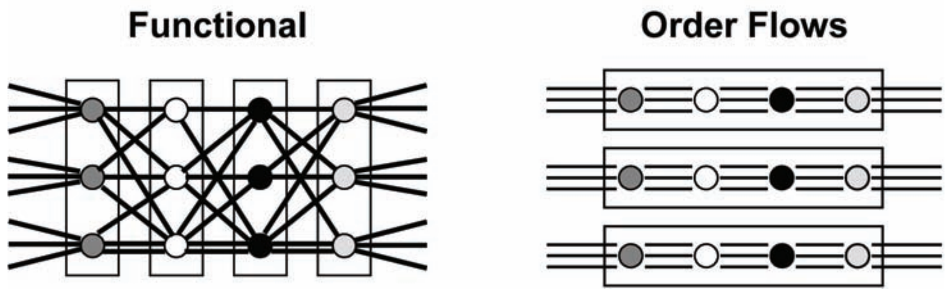
Figure 1. The Socio-technical design order principle (based on De Sitter, 1998)



The Design Order Principle: Reduction of Complexity

The production structure of an organization should reduce the variety and the number of possible interferences as much as possible. The principle is to effectively break down complex demand/transformation systems into a number of far less complex sub systems that are as independent as possible. In practice this implies parallelization and segmentation of order flows. Based on this, control structures can be governed by autonomous groups according to the principle of minimal critical specification. This actually follows Ashby's law of requisite variety (Ashby, 1969) holding that a system's control capacity should be at least equally as the variety it needs to control. By parallelization the number of interferences and dependencies between transactions can be drastically decreased. Parallelization can be contrasted with production specification into functional departments, in which every department is responsible for only one kind of transformation. Figure 2 illustrates the complexity reducing effect of parallelization in a functional organization (job shop like) compared

Figure 2. Functional Organization compared to Parallel Order Flows (based on De Sitter, 1998)



to a set of parallel order flows.

Socio-technical systems design implies a top-down development of the organizations' production structure, and a bottom-up development of the control structure needed. Starting at the left-hand side of Figure 1, the (top) management level, business strategy initially drives product and market specification. Based on this the required production processes and structures are designed. Within this top-down chain of actions, production process specifications consists of a large number of 'transformations' ranging from integrated production lines to traditional job shops. Depending on the scale and requirements of these transformations the production structure specification is defined. Each transformation has to be controlled towards a number of aspect related targets, such as quality, quantity, efficiency, costs, environmental impact and timely delivery. All these control activities can also be aggregated accordingly, ranging from task specialization in a bureaucratic hierarchical structure to self-directed work teams for specific product market combinations. At this first part of the MST design, basic decisions on production and job structure design ('what needs to be done?') are taken.

Moving to the right-hand side of Figure 1, the next steps particularly consist of the required information specification. These are derived from the control activities (information requirements specification) as specified top-down, and – bottom-up – developed into an aligned information structure (information system or set of information systems). Here, information structure specification implies the effective and efficient support of production and control activities. In this chain of the design different levels for control are to be distinguished. At the macro level strategic control of external relational are addressed. At the meso level inter-group coordination is concerned, while at the micro-level control teams and employees are responsible for controlling individual transformations. At this second part of the MST design, basic decisions on control and job design ('how should it be done?') are taken.

The Minimal Critical Specification Principle: Segmentation

Once parallel flows are created, task assignments allocated to units or groups should aim for an 'optimal' level of independency. This may be achieved by splitting the flow into a number of so-called "segments". This implies that tasks are grouped in such a way that the number and content of interfaces with other organizational units are minimized. Each interface creates the risk of interference and disturbance and hence a need for co-ordination. As shown in Figure 2, the reduction of the number of interfaces is achieved because incompatible grouping of transformations, such as welding and coating of metal parts, or nursing and operating in hospitals, are divided by flows into segments. In defining the number of transformations or people involved one should note that co-ordination and direct communication between segments or people will accumulate accordingly, leading to higher levels of required co-ordination. In this respect, the socio-technical design of teams by segmentation is also guided by the principle of minimal specification.

The Task Completeness Principle: Quality of Working Life

In an MST-design, segments are generally operated by self-managing teams. The preceding steps made sure that the tasks assigned to the teams may actually be carried out as independently as possible. The local control makes quick interventions possible in case of unexpected events.

The notion of maximum local control also applies at the level of individual employees. The organizational advantage of such local control lies in the potential for quick local interventions, but also in positive effects on employee behavior. This subscribes to Karasek's plea to balance job demands (i.e. control needs) and decision latitude (i.e. control capacity; cf. Karasek, 1979). A job is considered a 'good' job if it (1) consists of complete tasks and sufficient control capacity to deal with control needs conclusively, and (2) offers sufficient challenges to job holders. Creating such jobs removes a source of stress, namely that employees see undesirable events happen but are not allowed to intervene. By creating "good jobs", workers are to be motivated with positive effects on, behavior and absenteeism, and thus productivity.

MODERN SOCIO-TECHNICAL VS. ERP-SYSTEMS DESIGN

As stated, deploying ERP-systems may have negative consequences for employees and organizations. Below, we aim to understand these negative effects by projecting the socio-technical principles on (explicit and implicit) design of organizations through ERP. We systematically confront the key MST principles discussed above with ways in which ERP-systems are commonly implemented.

ERP-Systems at Odds with Design Order Principle

A first and key difference between a socio-technical design and ERP implementation is the starting point. ERP, both as a business concept and an Enterprise Information System (EIS) automation concept, was originally developed to fully integrate different information systems that (particularly large) organizations deal with. Instead of creating middleware applications to connect separated Information Systems (for instance production planning and billing systems), ERP radically replaces them all. With ERP, the total information architecture needs to be redesigned in order to automate all processes in a similar way. The input and creation of information by users is designed to take place according to a one single point of entry principle, to avoid data redundancy. Business rules are formally translated in work and information flows throughout all of the ERP-modules, thereby similarly modelling departmental and functional roles. And finally the information representation is designed by standard templates and forms. In ERP-systems the traditional presentation, application and database layers are strongly integrated, with one single database and meta-model as its main core. Therefore, socio-technical organization design departs from design criteria, derived from a strategic position, to design the production structure and the control structure. The information structure is derived from the production and control structure. In the case of ERP, the information system provides the starting point and must be configured to fit organization structure and processes. These often follow the ERP-system rather than the other way around. In practice the complexity of ERP software enforces that organizations tend to 'stick to the standard' offered by the ERP vendor (Benders, Batenburg, & Van der Blonk, 2006).

This design order problem becomes particularly clear when multi-site organizations are considered. The central concern is about the fit between the systems to be integrated on the one hand, and the particular practice of organizational subunits on the other. The more subunits deviate from other subunits and the more these subunits are dependent on each other, the more likely that ERP implementations will need to depart from standardization of the information structure (i.e. the IS infrastructure or architecture). Customization of the ERP-software by bolt-ons, add-ons and spreadsheet workarounds are discouraged, while from a MST perspective these might be allowed to assist local decision-making and enhance control capacity. In other words, ERP violates the parallelization principle in cases these parallel flows demand differing information support functionality. This is problematic as ERP implementations usually entail the implementation of only one business model in the software to save on implementation and software maintenance costs (Swanson, 2003).

ERP-Systems at Odds with Minimum Critical Specification Principle

In ERP-systems design there is a central database while integration by control is organized in functional software modules making use of one common IS/IT environment. The modular design of ERP-systems, however, also implies functional decomposition as there are separate modules for control domains such as finance, quality management, logistics and HRM. In addition, different functionalities, such as data input, query dialogues and management reports, are separated with ERP-systems. As modules are configured by functional specialists, the design of ERP-systems leads to a tendency to create tasks that are functionally decomposed as well. Obviously, this segregation of control aspects contradicts the fulfilling of the socio-technical requirement of integrating primary and supporting functions. In terms of Figure 2, the existing functional organization (similar operations grouped together) is maintained. The complex product flows in between different organizational units is followed by the software (as is the case with workflow management software). Figure 2 illustrates the risk of this approach, seen through a socio-technical lens. At the left, the functional structure is shown. A product that has to undergo various functional operations is taken from one functional department to the next, leading to complex routings through the organization. The socio-technical solution is, wherever possible, to place the operations in the same sequence as needed to make this particular product in multi-functional departments, as shown in the right-hand part of Figure 2.

Current ERP practices usually keep the complex functional structure intact, and follow the product through the different departments with an information system. From a socio-technical view this situation could be called 'technology-enabled complexity maintenance': instead of simplifying the situation to be controlled, the complex situation is maintained and the control possibilities are improved. In effect, this process orientation is the electronic equivalent of the 'chasseur', the French name for a person who used to be sent into a factory to track and speed up orders. The risk of using an ERP-system is that the symptoms of a complex structure are fought, but that the underlying problem of unnecessary complexity is not solved (De Sitter et al., 1997).

ERP-Systems at Odds with Task Completeness Principle

ERP-implementations directly affect job decision latitude in various ways. During the configuration process, (future) users are authorized to take particular decisions. In granting authorizations, ERP implementers directly influence job decision latitude. However, as with other organizational changes, it appears that only in exceptional cases ERP-implementers take these effects on job content explicitly into account. Instead, predefined user groups and role structures tend to be used. The control perspective often comes back in the form of the "segregation of duties", a key principle in administrative organization which is to prevent creating opportunities for fraud. Control cycles are not closed, as modern socio-technical design prescribes.

A similar aspect concerns authorizations for data access and data entry. In standard authorization schemes, these are often concentrated with a limited number of users, generally those at higher hierarchical levels. This may cause problems at the shop floor, as work can not proceed in the absence of the authorized. A frequently used option to 'work around' these authorization problems is granting employees more access rights than controllers see as proper (Pollock & Cornford, 2004; Le Loarne, 2005). A user may formally or informally arrange access to additional user IDs and passwords to be able to perform all necessary tasks. In a socio-technical design user requirements would be the starting point for getting access. Obviously, data entry jobs within ERP-systems consisting of monotonous and short cyclical tasks are, in socio-technical terms, seen as "passive jobs" (Karasek, 1979). In a socio-technical design, data entry tasks would be integrated with other tasks into complete jobs. More broadly, ERP-users often need to put data in for other functions in the organization. A comment as "SAP creates work" (Le Loarne, 2005, p. 526) signals that this may not always be efficient and is certainly not always perceived to be efficient. The empirical examples described above support this notion.

Soh and Sia (2004, p. 25-26) see the ability to track products as a form of empowerment: what they call ERP's 'process orientation' allows employees to track the progress of individual products. Compared to a situation where this is not the case and hence employees are confronted with orders, insight into these orders' process statuses may be seen as progress for employees. However, as long as they are not authorized to take action, this may have the effect of increasing stress levels, because of lack of control capacity: seeing problems happen without being able to solve them, or insight alone is not sufficient. As a result, the control capacity needs to be adjusted as well.

Implications

Implementing ERP-systems goes along with organizational changes. Their breadth and depth, however, seem generally underestimated. As Koch and Buhl (2001) showed, organizational consequences are not always, and probably generally not, taken into account when implementing ERP-systems. Consequently, unintended and negative results are likely to occur. As Koch and Buhl's machine building case showed, organizational changes as a result of ERP and teamwork ask for contradictory directions for change. Whereas ERP-implementers strive for standardization and centralization, teamwork implies empowerment and decentralization, enhancing team autonomy. Especially in terms of job decision latitude, ERP may easily be at odds with team working. If the consequences of an ERP-implementation for job design are not explicitly considered, teams' potential to deal with environmental complexity and flexibility is not used or even negated. ERP's focus on standardization, authorization schemes and central control limits the job decision latitude (control capacity) at individual and team level (Karasek, 1979). As a result, the balance between control need and control capacity at individual and team level (an objective of MST and team working for reaching organizational goals) is disturbed and increasing stress levels and organizational inefficiencies may result.

However, these contradictory directions do not necessarily have to lead to negative results. As Buhl and Richter's use of participatory design tools shows, the implementation of an IT-system "can be productive and constructive if they are explained to other employees and if they, for their part, get room to and time to develop alternative models and their own perspectives" (Buhl & Richter, 2004, p. 270). These participatory design tools fit into MST's design methodology and action research approach. Starting from organizational requirements and building autonomous teams as the building blocks of the organization, the technical systems must fit this organizational design. Participation of team members in the configuration of ERP enhances mutual understanding between different groups in the organization and, as a result, the system's productivity and the worker's enactment of the technology (cf. Orlikowski, 2000). Furthermore, it does justice to the teams' autonomy and decision latitude.

Two points of special attention are attached to this participative approach. First, it requires that ERP-systems are truly open for configuration in terms of the underlying technology (as with customization), business rules (as with parameterization), and the financial barriers of these system adaptations. Scott and Wagner (2003) state that ERP can be customized to adapt the principles of socio-technical design. By longitudinal and participatory design analysis of an Ivy League University in the US they conclude that – in contrast to the opinion that ERP is uncontrollable (or even a "technological monster") – temporal turns and negotiations during the ERP project led to "a hybrid working rhythm that is inscribed into its socio-technical infrastructure" and hence a socio-technical information system was created. It should be noted however that the adaptability of ERP-systems in practice often deviates from the "anything goes" adage that SAP and other ERP vendors use in promoting their systems as total business or industry solutions.

The second point of special attention is that staff participation may result in single-sided attention for quality of working life. Following MST's design methodology, first and foremost the organizational structure must be built in order to meet organizational (corporate) requirements. Self-managing teams are the main concept in this design, but these teams' autonomy cannot be a goal in itself. In MST balancing organizational requirements and workers' needs (quality of working life) is essential and a logical consequence of the design process. As a result, participation of teams in, for instance, decisions about authorization schemes in ERP, rather than the technical specifications, seems highly important. For instance, Buhl and Richter (2004) show that shopfloor worker participation in accessibility rights in the system resulted in modifications that supported the teams' competencies and some autonomy to plan their own time and production capacities. These are important aspects of control capacity and therefore positively influence the balance between control need and control capacity (cf. Karasek, 1979).

Example: A Board Manufacturer

A solid board manufacturer delivers special products to a number of market segments and areas. The organization faced the problem that some clients demanded rather short delivery times but were willing to pay premium prices, whereas others accepted longer delivery times and ordered longer in advance. To serve both market segments a partial parallelization of order flows was suggested, namely of sales and order acceptance functions. Nothing changed in the manufacturing process, as the heavy machinery in the mill was too expensive to re-group.

The process of order acceptation was delegated from the central planning department to the regional sales offices. To minimize mutual interdependencies between sales offices or between sales offices and production, the production capacity was administratively distributed over contingents per area. The areas only needed to co-ordinate their activities in the occasional event of over- or underbooking.

However, the standard ERP-features did not allow for this tailor-made organizational solution. Thus, to facilitate this parallelization the ERP system was extended with a bold-on, a 'sales budget and order acceptance subsystem'. This interfaced with the sales forecast, the budgeting and production scheduling modules of the ERP software used by the organization.

DISCUSSION AND CONCLUSIONS

Our analysis is a first step in identifying some of the main potential causes of tension in implementing ERP-systems while creating suitable organizational environments for self-managing teams. As Koch and Buhl (2001) described the misalignment of ERP-systems implementation and teamworking, MST provides a useful lens to describe possibilities for aligning ERP and teamworking. Both include change programs aimed at dealing with organizational problems concerning lack (or loss) of effectiveness and flexibility. The existing literature shows that awareness of the organizational consequences of ERP implementation is an important condition for aligning ERP and teamworking. Centralization and standardization that go along with many ERP implementations are at odds with the three MST design principles we discussed. These are aimed at organizational structures that best respond to environmental complexity and in which the design and development of autonomous teams is the main concept. Being aware of these possible consequences opens the route to designing effective and efficient organization structures around autonomous teams that are supported by ERP-systems that are configured to meet the organization's requirements. Moreover, following MST design principles the work in teams or individual jobs should result in meaningful and complete jobs, due to the balance between job demands and job decision latitude. As Buhl and Richter (2004) show, communication, participation and cooperation of different participants, such as shopfloor workers, line managers, production planners and IT specialists, are important means to create the necessary awareness.

A limitation is that our chapter focuses on what one may call 'traditional' ERP implementations, i.e. the deployment of product software solutions within organizations to integrate, automate and support business processes. Several developments can be recognized that go beyond the standard type of ERP implementation. A major movement is that more and more organizations use ERP software to extend and virtualize their organization, their supply chains and corporate networks. Most ERP software offers e-business functionalities to support this virtualization by tools and modules for e-sales, CRM, e-procurement, e-sourcing and so on. These cross-organizational functions put new pressures to adjust ERP-systems to these new organizational settings. Boersma and Kingma (2005) presented an in-depth case study of mutual ERP adaptation and virtualization through enforcing supply chain conditions. This type of external adaptation will obviously multiply fast if organizations increasingly extend their information exchange and system integration with other chain and network partners. As a consequences new developments within the software profession emerge like Service Oriented Architecture (SOA). SOA particularly fits the idea of transformation of a static functional organization to a dynamic network of services. Flexibility is the key competence to achieve, by rapidly creating new services from existing ones, and by adjusting the services network onto the fast changing environment. Almost all ERP-vendors have announced a reshaping of their products towards this service orientation. Applying SOA can enable software solutions to dynamically support specific organizational needs, while combining and re-using product software and existing IT.

These developments might retune the disadvantages of classic ERP we here brought up in this chapter. They do not change the core characteristics of ERP as an integrative and control-oriented system however. Research is rightly to explore about the impact of fast-moving technological developments, such as e-business and SOA on the (inter-)organizational fit of ERP. This might actually be an interesting momentum for ERP-vendors and consultants to rethink their architectures and implementation methods taking the socio-technical principles here referred to into serious consideration.

The Modern Sociotechnical design perspective seems to sit comfortably with the adage "First organize, then automate". In sharp contrast, the current ERP-implementation praxis can be characterized as "first implement, then re-organize". This has a couple of implications for practitioners. These include various IT-specialists, consultants from "implementation partners', and at the demand site, managers and (end) users. These different "stakeholders are likely to have partially diverging interests. The MST-perspective probably serves managers and end users best: this perspective may strengthen them to point to critical aspects during implementation. Given the political realities in many organizations, the ERP-implementers will probably be in a strong position and argue against "first organize, then automate" as this may lead to questioning the wisdom of ERP-systems. Less radically, however, the socio-technical perspective may influence choices within the scope of ERP-systems. These include:

- business process analyses should precede ERP-implementation;
- be critical about maximal coupling and consider de-coupling organizational units;
- use the notion of "local control" in authorizing end users;
- allow, when needed, local support tools.

Within ERP-design, templates for implementing self-managing teams may be developed. These can assist implementers to resolve the dilemma between centralistic, top-down control and specialization tendencies inherent in ERP-system design on the one hand, and on the other the socio-technical ideas of reducing system complexity, maximum local control and minimal critical specification.

KEY TERMS

Control Structure: The structure (logical set up and distribution among jobs) of control tasks that together try to safeguard the intended outcomes of an organization.

ERP-Systems: Enterprise resource planning (ERP) systems attempt to integrate several data sources and processes of an organization into a unified system. A key ingredient of most ERP systems is the use of a unified database to store data for the various system modules.

Information Structure: Information structure refers to all information that is relevant to the organization's strategic and operational processes and decision making, that can be stored, used and managed by Information Systems and Information Technology (IS/IT).

Modern Socio-Technology: Modern Socio-technology (MST) is a Dutch variant of the classical socio-technical systems design (STSD) that focuses on organizational design.

Organizational Design: The process of setting up (designing) the structure of transformations, its coordination, control and the information flows needed to manage the transformation according to the organizational strategy.

Production Structure: The structure (physical lay-out and interdependence relations) of the transformations that together result in the constitution of the goods and services that an organization intents to deliver to their customers.

Teamworking: Teamworking involves a group of workers, generally between 4 and 20 persons, responsible for a rounded-off part of the production process, and entitled to take certain decisions autonomously.

Chapter 3.2
Social Shaping of Technologies for Community Development:
Redeployment of Information Communication Technologies among the Kelabit in Bario of the Kelabit Highlands

Poline Bala
University Malaysia Sarawak, Malaysia

ABSTRACT

Using electronic-Bario (e-Bario) project in the Kelabit Highlands of Sarawak in East Malaysia, this chapter explores how the introduction of information communication technologies (ICT) as developmental tools have been mediated and reconfigured by webs of social relations and the intricate interplay of social, political and cultural conditions specific to different social and technical settings. One crucial factor conditioning the effects of the project has been the Kelabit's own desire for, and expectations of, "development" and "progress." This is a quest which ties in closely with two fundamental Kelabit concepts: doo-ness and iyuk. As a result, the social and economic effects of ICT have unfolded through countless open-ended strategic and everyday decisions made by the Kelabit themselves, who actively consume, apply and make use of objects, ideas and services in the Highlands.

'The new electronic interdependence recreates the world in the image of a global village'. -- Marshall McLuhan, The Gutenberg Galaxy in Daintith, John (ed.) Quotations, Bloomsbury (1996, p.256:1).

INTRODUCTION

Over the last 15 years information and communication technologies (ICT) have been increasingly and optimistically promoted as a means of transforming developing countries into "modern" and knowledge-based societies and to alleviate some of the social and economic problems of developing world, particularly those in rural areas. Yet very little is known about the veracity of these aspirations, much less about the long-term social and economic effects of these technologies upon development in rural areas (Keniston, 2002).

Informed by a social shaping technology (SST) framework, this chapter explores how the introduction of information communication technologies was mediated and reconfigured by webs of social relations and the intricate interplay of social, political and cultural conditions specific to the Kelabit Highlands. In this way the chapter seeks to achieve a more critical understanding of the relationship between ICT and society that provide an understanding of the implications of ICT for social and economic development and inform current discussions about the emerging "Information Society."

SOCIAL SHAPING AND CONSEQUENCES OF ICT

The social shaping of technology (SST) approach to technology-society relationships has emerged in the late 1980s as an important framework to explore whether technology can be seen as a main force that shapes society or whether society and social values shape the way in which technology affects our lives. With regards to information communication technologies, the approach builds on two main themes: the design and implementation of ICT artifacts and systems; and the implications of ICT for individuals, organizations and society. Within this broad remit the SST approach could not, and will not deny that technology has an effect on society but at the same time emphasizes organizational, cultural, economic and other factors influencing the process of technological change and innovation (Williams and Edge, 1996; Kling, 2000). In other words, deviating from a technological determinism standpoint, SST embraces the centrality of users, society and social values to shape the way in which information communication technologies (ICT), affect our lives, (Dutton, 2001; Rohracher, 2003; Fischer, 1992).

Taking the lead from the SST framework, this chapter explores the social and economic effects of electronic-Bario (e-Bario), an ICT-based community development project implemented in the Kelabit Highlands of Sarawak. This is in order to shed some light on the character and significance of ICT in different social and technical settings and at the same time to illuminate the processes of shaping the use and impacts of ICT in Bario. It takes into account the role of the Kelabit's own desire for, and expectations of, "development" and "progress." This is a quest which ties in closely with two fundamental Kelabit concepts: *doo*-ness and *iyuk*. As will be made clear later in the chapter, both notions signify movements and good-ness in terms of social status among the Kelabit. By highlighting their significance, this chapter argues that it is the local cultural logic of *doo*-ness and *iyuk* among the Kelabit which is central to the shaping of technology especially how meanings (symbolically) are "inscribed to technologies" (Rose, 2001, p.69), creating a desire for new technologies, and informing their development and appropriation by users in the Highlands. In short Kelabit notions of *iyuk* and *doo*-ness are central to functional and symbolic encoding of technologies in Bario and are crucial factors conditioning the effects of the project. This is evident by the ways in which the social and economic effects of e-Bario have unfolded through countless open-ended strategic and everyday decisions made by the Kelabit themselves, who actively consume, apply and make use of objects, ideas and services in the Highlands.

BACKGROUND: THE E-BARIO PROJECT

Considered the traditional homeland of the Kelabit, the Kelabit Highlands is situated above the rapids found at the headwaters of the Baram and Limbang in Northeast Sarawak, close to the border between Kalimantan and Malaysia in the Miri Division. Although there is no official boundary to define the area, Thong and Bahrin (1993, p.17) estimate that the Highlands comprise an area of approximately 2,500 square kilometers. With an average altitude of 1000 meters above sea level, it is surrounded by some of the highest peaks and rugged mountains in Central Borneo. This out-of-the-way situation is well noted by Harrison (1959): 'There is one [of] or two places on the map of Borneo and, more widely, on the map of the world – where you can get farther away from a known place …, from what most people call "the world." There are fewer places where you (or I) are likely to be able to feel more remote, more "cut off" from the great outside…' (p.5). Nowadays, flying into the unofficial capital of the Kelabit Highlands known as Bario, is the only practical way to get there. There is no road, and a land expedition requires a river journey plus an additional weeklong trek across forested mountains (Bala, 2002).

But, who are the Kelabit? Numbering at 5,240 in 2000, the Kelabit are one of the smallest ethnic groups in Malaysia. For the past thirty years many have left the Kelabit Highlands for education and job opportunities. As a result only a thousand still remain in the Highlands while the rest are living in cities like Miri, Kuching and Kuala Lumpur, or even overseas in the U.K., U.S.A., Canada, Holland, Australia and New Zealand. This high level of rural-urban migration has led to a geographically-dispersed community, creating almost a clear distinction between the Kelabit who remain in the Highlands (rural Kelabit) and those who have left to live in urban areas (urban Kelabit).

Ironically, it was because of these two social situations: high levels of rural-urban migration of the Kelabit and the geographical remoteness of the Kelabit Highlands that Bario became a test-bed for the e-Bario project. Initiated by an interdisciplinary team of researchers from Universiti Malaysia Sarawak (UNIMAS), e-Bario explored the use of telephones, computers, Very Small Aperture Terminals (VSATs) and the Internet to improve the lives of marginalized groups in remote areas of Sarawak. Initially funded by International Development Research Centre in Canada, it was later adopted by the Malaysian Government as one of its Demonstrator Application Grant Schemes. The project was largely initiated in response to Malaysia's approach to adopt ICT as essential developmental tools in generating a knowledge and information-based society (UN, 2000, p.9) - a form of society which Malaysia aims to attain by the year 2010 (Goh Beng Lan, 2002, p.190).

In order to facilitate this mass development program, the Malaysian government has set out specific targets. These include: to become an Information Society by the year 2005, whereby people would have access to information, and information becomes a commodity; and to be a Knowledge-based-Society by 2010, with a Malaysian society that values the culture of life-long learning and the creation of knowledge-based products and services. Known as the National Information Communication Technologies Initiatives, the following is a brief review of the mechanisms by which the government aims to attain these targets:

a) establishment of a National IT Council;
b) formulation of a National IT Agenda;
c) development of the Multimedia Super Corridor;
d) implementation of Bridging the Digital Divide Program (BDDP);
e) awarding of the DAGS (Demonstrator Application Grant Scheme).

The design of this multi-faceted strategy and the mechanisms, however, does not include a clear picture of how the rural sector of the nation will be situated within the larger framework. Therefore there exists a huge gap between what are in effect two worlds: the government's aspirations for a future knowledge-based economy, and the realities of rural living.

It was within this perceived hiatus in national development planning that e-Bario was conceived as a pilot project to explore whether provision of equal access to ICT can bring economic, social and cultural benefits to rural communities in Sarawak. This is particularly significant for the state of Sarawak, where 60 per cent of its 2.027

million people live in rural areas. Although Sarawak has been promised a full and equitable allocation within Malaysia's mass development plan, many communities have no access to good roads or to telecommunication services (Harris, 1999). Most rural areas lack both telephone lines and a continuous supply of electricity. Bario, in short, exemplified the disconnected portion of the digital divide, and presented a challenging environment in which to test the usefulness and effectiveness of ICT in rural Malaysia (Harris et al., 2001). Since access to ICT is predicted to promote new social, economic and cultural opportunities in rural areas (Enberg, 1998), e-Bario also provides a useful window to explore the roles that ICT can play in advancing community-based development in developing countries. With this in mind, the villagers in Bario were systematically connected to a range of ICT in September 2000 and have grown to include the following physical and technological components.

1) *Computer Laboratories:* Two computer laboratories were designed and equipped with 16 computers due to demand from students and teachers. The lab was also equipped with 2 printers and a scanner.
2) *Telephonic equipment:* The new technologies were installed within the existing communications network, the telephones were placed at strategic locations or important meeting places in Bario, such as the airport, the shop area, the school and also the clinic.
3) *Very Small Aperture Terminals & Network Configuration:* To provide access to telephone (voice) and Internet networks four Internet ground station technologies known as Very Small Aperture Terminals (VSATs) were installed by Telekom Malaysia Berhad. These were located at the shop area, the clinic, the school, and the airport.
4. *Telecentre:* A permanent telecentre, known as Gatuman Bario (Bario Link), was set up in 2001. It is located at Pasar Bario and has 5 rooms: a room for computing services, a visitor's room with table and chairs for meetings and resting, 2 rooms for administration purposes – one for the e-Bario coordinator and the other for technical assistance - and another for staff to monitor and run the day to day management of the telecentre. The telecentre is equipped with 10 computers, an inkjet printer, a laser printer, a laminating machine, a photocopier and Internet access.
5. *Power Supply:* Since Bario is outside the national grid, the telecentre was initially powered by diesel run generators. This power supply has evolved into a hybrid diesel (80%) – solar panel (20%) power supply, and more recently a solar panel – diesel system.
6. *Training and skills:* An Information Technology (IT) Literacy Programme was introduced by the research team from University Malaysia Sarawak in conjunction with COMServe, a local IT company based in Kuching. Training was identified as an ongoing process, and not a one-time or once only activity. The training included word processing, key-board usage, e-mailing, browsing the web, and the management of technologies including trouble shooting.
7. *Website creation:* Due to web hosting problems this information was incorporated into a web site designed by UNIMAS at www.e-bario.com. The web site contains information on the project, and also on the Kelabit Highlands. It was designed to promote Bario as a tourist destination, and is linked with other web sites developed by or used by Kelabit, such as the Online Kelabit Soceity (OKS).
8. *Storage of information – Bario Digital Library:* An experiment with recording, documenting and disseminating Kelabit songs and dances on CD ROM has been developed under the project. It is called the Bario Digital Library (BDL). The first record

contains nine lakuh songs by women in Bario with digital images of each singer singing the *lakuh*. Each song has been transcribed in Kelabit, with English translation. It is a step towards the creation of an electronic record of Kelabit oral stories.

9. *Management and Administration:* "Management and Administration" is not a physical or technological component of e-Bario, but rather a management system, which has been put in place in order to manage the project in Bario, and also the community telecentre. To achieve this, a project coordinator-cum-manager has been appointed by the Council of Elders, Authority for Village Protection and Development (Malay, *Jawatankuasa Keselamatan, Kebersihan Kampung* (JKKK)) and University Malaysia Sarawak to oversee the workings of the initiative in Bario. In addition to the project coordinator, a technical assistant was also trained and appointed to oversee the technical aspects of the project, such as trouble shooting and managing all the equipment and software.

Technologically, the initiative was a milestone in terms of providing equal access to ICT in the Malaysian context, and was identified as "one of the most notable of Malaysia's Internet development initiatives" by the International Telecommunications Union (ITU, 2003). In the international arena, the initiative has put Bario and the Kelabit on the world map - a remote community connected with up-to date technologies – leading to its selection as one of the Top Seven Intelligent Communities of 2001 by The World Teleport Association in New York.

ASSESSING "EFFECTS": WHAT REALLY HAPPENED IN BARIO?

This technological development nonetheless raises important questions. What of the Kelabit themselves? What meanings do they inscribe to the technologies? How have the new technologies come to be incorporated in existing social practices? That is, how have the technologies have been appropriated and used by the Kelabit in Bario?

To explore these questions in detail the next section will highlight two fundamental Kelabit concepts: *iyuk* and *doo*-ness. An understanding of these two concepts can help us to understand on going Kelabit engagement with e-Bario and in turn can highlight the social processes taking place that shaped meanings and usage of technologies in Bario.

Kelabit *Iyuk* and *doo*-ness

Between August 2005 and September 2006, when engaging the Kelabit with discussions on the impact and effects of ICT in the Highlands, their response was always quick and straightforward. I have been told it is about *iyuk* (movement) and the attainment of *doo*-ness (good-ness and better well being). Traditionally these two notions indicate movements and good-ness in terms of social status among the Kelabit. While *iyuk* broadly refers to the notion of movement and specifically to status mobility, *doo*-ness embodies notions of good-ness, success and better well being, or rather the qualities required to constitute a good person such as knowledge, endurance and perseverance, self discipline, hospitality, generosity, and strength (Bala, 2008).

The attainment of *doo*-ness through means and mechanisms of *iyuk* is the basis of all social status among the Kelabit: it represents an ideal that Kelabit individuals and collectively aim to attain and accumulate. It is the the images and ideals of *doo*-ness, and the interweaving processes between *doo*-ness and *iyuk* that have generated and sustained Kelabit modes of engagement with ideas, institutions and objects from the outside world. These externalities are adopted and co-opted by the Kelabit and given meanings, for example, as a means of providing a range of new options and systems for attaining and expressing social status, prestige and power in the Highlands. It is the dynamics between these that is relevant to the way in which Internet, computer, telephone and Very Small Aperture Terminals (VSATs) were received and adapted by the Kelabit in the Highlands and beyond. This is in spite of, or possibly as a response to the Kelabit insulation from much of the world; for instance, prior to World War II, little was known by outsiders of the Kelabits and their surroundings. They were self-sufficient: producing salt, planting rice and hunting and gathering jungle produce for food as main source of protein.

An ethno-historical analysis can establish how over the years the Kelabit forged connections with the rest of the world through a variety of strategies and traditions to attain *iyuk* and *doo*-ness. A clear example of this is how through the cultural activities of travelling far (*me ngerang mado*), the Kelabit came into the possession of prestige items, such as jars, beads and gongs. These were impossible to obtain locally in Central Borneo. Therefore those items that reached the highlands are considered important visible signs of prestige in the community (Saging, 1977; Talla, 1979; Janowski, 1991). Among these prestige items are the T'ang and Ming Chinese jars, locally known as *belanai ma'un* (ancient jars). These are prized as family heirlooms, particularly the150-pound ceramic jars with red dragon.

By traveling far, a person did not only accumulate prestige items but also knowledge. The experiences gained through traveling are considered knowledge, thus the Kelabit notion: *mado lawe, mula'nuk keli* (Far traveling increases one's understanding). As with other prestige objects, knowledge is a good source of high social standing in the longhouses (long structure built on stilts with common areas and separate family dwellings). This suggests that cultural practices of traveling far are important local practices and strategies for *iyuk* of status among the Kelabit; they are important means to incorporate objects and ideas from the outside world into Kelabit social system. Hence those who possessed these items are highly regarded in the community.

Kelabit *Iyuk*, *Doo*-ness and Nation-ness

At the same time as the Kelabit absorb objects, ideas and people into their social system, the Kelabit themselves have been integrated into the wider economic and political terrain. Most pertinent here is the formation of Malaysia in September 1963. Sarawak together with Sabah, Singapore and Malaya have formed a federation. Consequentially, the population on the Malaysian side of Borneo was granted Malaysian citizenship and its privileges. With the granting of this citizenship new forms of economic, political and social systems were introduced.

As noted by Anderson (1983) 'Nation-ness is the most universal legitimate value in the political life of our time' (p.12). This process inevitably did not only change how to attain *iyuk* and *doo*-ness but also the very notions of *iyuk* and *doo*-ness in the Kelabit Highlands. That is, what they constitute among the Kelabit in the contemporary world. Said differently, the Kelabit integration into Malaysia as a nation-state has transformed the meaning of *iyuk* and *doo*-ness within the community; increasingly the notions are linked with the Malaysian government's notion of "development" (Malay, *pembangunan*) which is seen as a means for individuals to attain and enjoy affluent and prestigious lifestyles whilst at the same time enabling the whole collective (in this case the Kelabit society) to command high standards of living and respect from others. This is revealed through Kelabit every-day discussions concerning their contemporary identity and standard of living as a group. These discussions often focus on how to attract and bring more development projects into the Highlands for *doo*-ness: big and small infrastructure, better roads, cars, good medical services and effective communication facilities.

In fact, there is a sense of communal pride in being considered a progressive and successful community. Although complex, there is consequently an overall general desire for "development" as promulgated by the Malaysian government as means for *iyuk* and *doo*-ness among rural and urban Kelabit. Seen in this light, e-Bario is just one of many projects being pursued by the Kelabit to promote "progress" in the Kelabit Highlands, partly as a strategy for gaining *doo*-ness and *iyuk* for the Kelabit as a whole.

It is this Kelabit contemporary desire for progress and development, which partly defined the Kelabit on-going engagement with e-Bario in the Kelabit Highlands. If in the past the Kelabit participated in travelling far in search of Chinese jars, beads and other valuable items as part of their strategies for advancement, in the contemporary world the Kelabit are eager to collaborate with the world of progress and development in order to attain better well being (*doo ulun*) in the Highlands.

In order to understand how exactly ICT as developmental tools have been used, or rather are used to increase the Kelabit's livelihood, the next section will highlight the appropriation of technologies for communication, and as means to position or reposition Kelabit interests and their identity as a group.

As described earlier, many Kelabit have left the Highlands for education and job opportunities. This has led to a highly mobile and geographically-dispersed community. As a result of their widespread diaspora the Kelabit are constantly looking for ways and strategies to ease communication between urban and rural Kelabit. It is out of this need that the Kelabit are using e-Bario as new ways and strategies to foster family relations and community connections. This is especially important for many older men and women in the Highlands who welcome the telephone especially as an improved means of communicating with their children living in the cities. The significance of this is made clear by Maren Talla who is 78 years old. He said, 'In the days before the telephone, I had to fly to and fro between Bario and Miri when I wanted to speak to my son and daughters, who currently are all living in Kuala Lumpur. It's a lot of money to fly down to Miri and Marudi just to speak with them. But now with the telephone, it is so much easier and cheaper. Although I can't see their faces, at least I can hear their voices. It is very satisfying to my soul when I hear them. I usually stop at the *Pasar* (market) to have something to eat and also to call my children on my way to my sheep ranch. It feels so good to be able to hear their voices on the phone; it makes me sleep well in the night. Listening to their voices on the phone calms me.'

The significance of e-Bario however goes beyond easing communication between rural and urban Kelabit for it also signifies that 'we [the Kelabit] are at par with the rest of the world and people.' Although many do not use the Internet in relation to daily activities such as farming and so forth, the presence of the new technologies in Bario is perceived not purely as a means of obtaining better quality information, connectedness and *iyuk*, but also as a symbol that the Kelabit are *doo* (progressive) in that they are not being left behind by others. These technologies are markers and signifiers that they are on a par with others in embracing worldwide shifts of perspective and influence. This is particularly significant in the context of Kelabit's present day marginal or even displaced position within the broader policies and discourse of the Malaysian state and ethnic framework of development.

To explore the situation in detail, the next part of this section will provide a brief overview of Malaysia's ethnic-oriented national development agenda under Malaysia's New Economic Policy (NEP or DEB for *Dasar Ekonomi Baru* in Malay) which was introduced in 1971 in response to race riots in Kuala Lumpur in 1969.

MALAYSIAN ETHNIC FRAMEWORK OF DEVELOPMENT

The Malaysian Ethnic Framework of Development under New Economic Policy (NEP) signifies a development pattern which is tilted towards distributional objectives, albeit along racial lines (Brosius, 2003; Hilley, 2001; King, 1999; Scott, 1985). Underlying the national quest for rapid economic growth is the desire to accelerate the process of restructuring Malaysian society to correct economic imbalance so as to reduce and eventually eliminate the identification of race and ethnicity with economic function (Second Malaysia Plan 1971-1975 provides a thorough outline of the aims and agendas of the policy). Embedded in the framework, however, is the requirement to identify persons based on their ethnic and religious affiliation for the purpose of resource and wealth distribution. As noted by Chandra (1986, p.33), ethnic and religious categories "carry deep meanings for people" in defining a person's existence and purpose especially in accessing political and economic resources in Malaysia.

What are the implications of the framework for the Kelabit, as one of the smallest ethnic groups in Sarawak? The Kelabit have to come to grips with their assimilation and participation within Malaysia's inter-ethnic disparities with regard access to key economic and political resources.

First of all, the Kelabit "peripheral situation" in relation to particular (Malay) political cultures is aggravated by the Highlands' physical distance from centres of power. Without numbers, constituencies, pressure groups or lobbies, and with their out-of-the-way location (Tsing 1993), there is a concern that the Kelabit are not given a hearing in the context of a national integration discourse, which places, as will be made clear later, the Malay-Muslim *bumiputera* at the top of the hierarchy.

Second, although article 153 (Kedit, 1989) guarantees the Kelabit as Bumiputera (lit. the sons of the soil) certain privileges under the New Economic Policy (NEP), the eminent position of Malay *adat istiadat* (customs and traditions) and Islamic religion has created a sense of hegemony and superiority on the part of the Malays over other groups in Malaysia. Consequentially, the prominence of Malay-ness in national discourse tends to benefit the Malays politically, socially and economically (Shamsul, 1986; Jomo, 1985). In the long run this framework has forced ethnic groups into a competitive relationship with each other, in which one group's advancement can mean the retardation of another group (Despres, 1975; Nagata, 1979).

Putting this differently, the NEP and ethnic framework of development as new and shifting political, economic and social contexts have created new form of *iyuk* competition, in which the Kelabit must engage competitively with other citizens who are not Kelabit for economic and political resources. This entails the Kelabit to compete with other ethnic groups for access to government financial support, government grants, development projects and schemes. All this has introduced a particular concern or desire among the Kelabit for new means to project their identity in relation to others in Malaysia and globally; hence constantly looking for strategies for collective political agency and to advance their social status within Malaysia's economic and political terrain.

It is partly due to this dynamic of economic competition that the Kelabit have appropriated e-Bario as a new means and strategy to strengthen and articulate their *iyuk* and *doo*-ness through what Miller and Slater describe as "dynamics of positioning," (2001:18). Dynamics of positioning is a term used to denote how people engage with the ways in which Internet media position them within networks that transcend their immediate location, placing them within wider flows of cultural, political, and economic resources.

A good example of this is how the Kelabit are currently using and transforming e-Bario as a forum and a stage to position and reposition their aspirations for cultural and political *iyuk* and recognition by others. This is reflected in the words of 80 years-old Balang Radu, who claimed that e-Bario has enabled further progress (*iyuk*) for those living in Bario by providing the means to forge connections with the rest of the world. He stated, 'With these new means of communications, our lives are made much easier, although we live isolated in the headwaters of Baram. We can now liaise with the outside world from our villages, including talking to our children in Kuala Lumpur, Kuching and throughout the world. This is progress (*iyuk*) for us. It has made our life easier and we are connected to the rest of the world in a new way. Therefore we are basically very-very pleased with its arrival. We are now on a par with the rest of the world.'

Balang Radu's remarks demonstrate that the new technologies are being incorporated into the Kelabit ongoing pursuit for mechanisms to position themselves within wider networks of interaction that transcend their isolated position in the Highlands. In this way the Kelabit can *continue* to be integrated within (and be part of) the space of global flow of technologies, skills, communication and information. As described in the beginning of this chapter, Kelabit society has long been connected to the outside world through their geographic mobility, and the dispersal of families. In tandem with their experiences, the Kelabit also see themselves as a part of the wider world of progress. Just as the cultural practices of travelling far, and the adoption of school and church have expanded their horizons, so too the Kelabits' contemporary acceptance of ICT like the telephones, the Internet, Very Small Aperture Terminals (VSATs) and computers in the Highlands is seen as an extension of their existing connections to the rest of the world.

This sense of achievement is important for the Kelabit for the specific reasons I have noted earlier. They are deeply concerned about their communal *doo*-ness or status and collective interests in relation to others, especially within Malaysia's multiracial setting. As I have suggested, one of the ways in which the Kelabit are engaging with this situation is by positioning themselves on the same level with others in their pursuit of progress and success. By their capacity to attract new ideas and technologies into their environment, and their ability to adopt, incorporate, master and recreate them, the Kelabit portray themselves as a successful and progressive people.

e-Bario in this sense can be perceived as having three-fold significance in Bario: it provides means for *iyuk* by making it easier to communicate with diasporic Kelabit; it serves as a strategy for the image management of Kelabit *doo*-ness, in terms of their prestige and social status both locally and on the larger stage of Malaysia and the expanding world environment. It is a marker of Kelabit success. At the same time, it has become a symbolic compensation and a new resource for their relative smallness in numbers, political marginalization within Malaysia's ethnic framework of development and the geographical isolation of the Highlands from centres of power.

This dynamics of positioning is revealing through the ways e-Bario has been integrated within the local political apparatus to become a versatile platform for the Kelabit to position and reposition their interests in relation to the far wider context of state and national development plans. The Internet, computers and software are becoming useful tools and means to form networks, to acquire new skills in the Kelabit Highlands and to position the Kelabit at the forefront of competition for economic and political resources in Malaysia.

A local person, whom I shall refer to as Robert, who returned to Bario on retirement, illustrates this situation. Besides making a living as a tourist guide, Robert is involved in a number of organizations at village level: as secretary to a political party, and as secretary to the development bureau of the Council for Village Protection and Development. In many ways Robert depends on the computing services provided at the telecentre both for his tourism activities and also for conducting research, gathering information and writing documents and reports, including a concise development proposal for the Kelabit Highlands to be submitted for consideration under the Ninth Malaysia Plan. It was in this context that he stated that the Internet gave him access to a mass of information and enabled him to communicate with relevant people and agencies, such as the policy makers, politicians and government officials: 'The Internet seems to reduce the amount of protocol one has to endure in order to get through to these development conveners.'

Robert's statement indicates that some Kelabit are turning to these technologies as means to strategize their actions in their encounters with ideas, intervention and people from the outside world. This is particularly important as new notions of development which include commercial logging and large-scale, futuristic development plans for the Highlands are currently being introduced and implemented in the Bario. For instance, in 2003, commercial logging as a form of development has been introduced in the Kelabit Highlands. This differing concept of development has begun to shift attention away from socio-economic development among the Kelabit to their legal rights and governance in relation to their land and cultural heritage in the Highlands. This has stimulated individuals and groups to speak up after many years of moving in tandem with state-initiated plans for development. This is because there are significant concerns about the potential impact of logging in the Highlands area. These include the effects on watersheds for wet rice cultivation in the area; the Kelabit dependence on the forest for jungle produce and wild game; and the growing ecotourism in the Kelabit Highlands. Numerous people provide guiding and lodging services for Malaysian and international tourists, many of whom are attracted by the opportunities for long-distance trekking. Seen in this light, demands for land for timber concessions are bound to come into conflict with Highlanders in competition for the same resources. This is due to the very nature of logging is in complete contradiction to the new types of tourism that the Sarawak Tourism Board and the Kelabit themselves want to attract.

Simultaneously, there is a feeling that the Kelabit are dealing with the limitations of available local institutions and practices for confronting the many problems that commercial logging and road building are generating and will continue to do so. One critical issue is the shifting notion of land ownership, which is seen as a steady alienation of the Kelabit from their heritage land, and if left unaddressed, could become a growing arena for political conflict at the village level.

All these social and political processes are beginning to shape Kelabit modes of engagement with ICT, and their outcomes in the Highlands. The use of the Internet, computers and telephone permits a form of political agency, especially as these new forms of intervention threaten to change the physical and cultural landscape of the Highlands. The new technologies inspire those in Bario to reach out to those that have left the Highlands, but still maintain a strong interest in the affairs of the village.

A good example of this is the use of community websites such as the Online Kelabit Society (OKS). As an online forum, the site features discussions on various issues which currently face the Kelabit. It is an on-line forum, and the discussions that take place within it, which allow for exchanges of ideas between members of the community both within Malaysia and beyond. Some topics or themes are the encroachment of commercial logging and the impact of development in Bario, mapping of Native Customary Land and cultural sites in the Kelabit Highlands, and the documentation of the Kelabit language, which are increasingly being managed via the Internet. A recent example of this is an Internet forum to revive the use of the Kelabit language among the younger generation. The initiative was launched by a Kelabit woman living in Miri, who is very concerned about the declining interest for and usage of the language among migrant Kelabit. As a network conducted on the Internet, the discussion list includes Kelabit who are living in Miri, Kuala Lumpur, Kuching, Bario, Bintulu and Singapore. The main concern is to find ways of documenting "extinct" Kelabit words, terms and phrases, while at the same time promoting the use of the language

All this points to the idea that the Internet has become a new means to maintain solidarity, within an increasingly stratified and occupationally mobile population, and in the face of new types of development intervention described. In fact, the significance of Online Kelabit Society, in reproducing and maintaining solidarity among the Kelabit has been likened to the traditional roles of *ruma'kadang* (the longhouse) by one of its regular users. This is because it provides space for the exchanges of ideas and advice, which are important elements of communal living in a longhouse. This suggests that ICT makes it possible for the Kelabit to form new networks and to reproduce effective organization and actions. At the same time, the presence of ICT facilitates a greater agency and capacity for political engagement to question, assess and debate these developments, and to form links with other agencies which might be useful. The various technologies available at the telecentre, for instance desk tops, associated software and the Internet, are currently being used to strategize the Kelabit position in their encounters with commercial logging activities in the Highlands. Examples of this are the documentation of oral histories and the recording of images relating to cultural and historical sites found in the Highlands, as well as the marking of their Global Positioning System (GPS) points. All these are uploaded into a Geographic Information System (GIS) database at the telecentre, to allow for the construction of a land-use history in the form of a digital map, and spatial and temporal analyses of past land use in the region. These in turn are useful historical and legal documents in negotiations with agencies involved in conservation and logging.

In so many ways, the telecentre nowadays has become more than a venue to provide equal access for new technologies in the Highlands. It has increasingly become a place and forum for the Kelabit to present and manage other "development" issues currently facing them in Bario. This trend was made evident through a recent conversation with the local manager, in which he said that, 'e-Bario is not just about ICT anymore. We are also into introducing and managing the implementation of solar power in Bario and have bought a printing and laminating machine for the Centre. So, now people in Bario can print their photographs very easily. We produce the same quality as the shops in town, but at a cheaper rate for our people.' Furthermore, he continued that 'e-Bario has now become the secretariat for all sorts of events and activities in the Kelabit Highlands. Both the church and Council of Elders use the centre to organize their religious and administrative activities.' At the time I spoke to the manager, the Centre was organizing the World Wildlife Fund "Heart of Borneo" Project's yearly symposium in Bario and also for the annual Kelabit Highlands Food and Cultural Festival. Put simply, ongoing negotiations and explorations are taking place to make e-Bario significant and relevant to the people in the Kelabit Highlands beyond the imagined practical outcomes of the initiative, and far beyond the original intentions of the project proposal.

CONCLUSION

In conclusion, what can we learn from e-Bario especially with regards to ICT for community development and its effect at the grass roots level? Experiences in e-Bario made it clear that the introduction of information communication technologies has been mediated and reconfigured by webs of social relations and the intricate interplay of social, political and cultural conditions specific to the Kelabit Highlands. As a result, the social and economic effects of e-Bario unfolded through countless open-ended strategic and everyday decisions made by the Kelabit themselves, who actively consume, apply and make use of objects, ideas and services in the Highlands. As shown in this chapter, one crucial factor conditioning the effects of the project was the Kelabit's own desire for, and expectations of, "development" and "progress."

All this suggests that real-life situations can change the purpose of technologies, and the ways in which they are used may differ greatly from what had been envisaged at the outset. Placed within local social processes and circumstances, the visions of outside policy-makers for introducing ICT as tools for social and economic development may differ markedly from the actual realities of their use and effectiveness in different political and economic settings. As drivers and developmental tools for the creation of a knowledge-based society in Malaysia, the technologies in Bario have not necessarily heralded a new form of society. Rather, they have been partly integrated with or subordinated to existing practices, internal values and socio-political arrangements in the community. Their continued use and adaptation has also provided for new forums of dialogue and communication, allowing a sense of communal identity to be rekindled. In turn, it is within these social processes that the computers, Internet and telephone have been given meaning, and their application modified and developed within the community's social context and in a wider political and economic terrain.

This social shaping of use, and the simultaneous modification of social and political processes facilitated by or inspired by engagements with ICT suggests that it is in the local circumstances that ICT is engaged with, interpreted, represented and woven into the fabric of daily life of those communities within the area. The technologies should not, therefore, be viewed as separate and independent entities, but rather as objects that gain effect, meaning and relevance through the ways in which they are adopted and become part of the Kelabit social and political life.

As we can see the Kelabit negotiate what value to attribute to the Internet, computers and telephones, and how to apply these technologies to their own political, social and economic circumstances. All this resonates closely with Norman Long's transformative process of planned development, which he describes as 'constantly reshaped by its own internal organization, cultural and political dynamics and by specific conditions it encounters and itself creates, including the responses and strategies of local groups who may struggle to define and defend their own social spaces, cultural boundaries and positions within the wider power field' (2001, p.72).

The presence and use of ICT in Bario facilitate, inspire and modify existing Kelabit social practices, strategies and actions in their on-going engagement with development. This is particularly apparent in their engagement with commercial logging as a new industry in the area. It is an example of local empowerment, whereby the use of ICT has facilitated greater agency for political engagement in the face of this shifting notion of development. The new technologies are seen to increase the Kelabit's opportunities and abilities to make choices and to translate them into desired actions and outcomes. As a direct result, e-Bario has been recreated as a new platform to manage the interface of development in the Kelabit Highlands. In short, the presence of the Internet and computers as technologies of communication and information shape, color and influence the Kelabit response to their current circumstances.

Chapter 3.3
In Search of Social Television

Gunnar Harboe
Motorola, USA

ABSTRACT

This chapter provides an introduction to and overview of social television, in an attempt to find the real meaning of the term. It explores the history and current state of social television, looks at a number of examples of Social TV systems and their features, compares different definitions of the term, and outlines dimensions of design that have been used to organize the topic. The author argues that historically the notion of social television is intimately bound up with television itself, and that the two remain difficult to separate even today. The convergence of content and communication to create social media is turning Social TV into a reality and in the process turning television into what it was originally intended to be.

DOI: 10.4018/978-1-60566-656-3.ch001

INTRODUCTION

The term "social television," or "Social TV," is not new, but over the last few years it has acquired a specific technical meaning. It is used to refer to a variety of experimental systems that claim to support social experiences for television viewers, and to the research into such experiences. This book testifies to the brisk activity going on in this area of study.

To understand what all the research is about, we should first understand more precisely what Social TV is. That is the question explored in this chapter. It is investigated from a number of perspectives. First, we look at the history of social experiences for the TV, a history that stretches back much further than usually acknowledged. We will see that it has its roots in the very earliest inspirations for television itself, and has been a persistent motif of science fiction and a recurring ambition of developers ever since. Then, examples of modern Social TV systems of different types are presented, drawing attention to the range of disparate experiences supported and the overlap with other topics. At the same time, a set of typical features is identified; features which include sharing of TV presence information, support for shared experiences, freeform communication, and the publication of TV viewing data.

With social television examples from the idea's inception to the present thus catalogued, we examine the various attempts to offer a definition of the field. These are shown to follow one of two forms, and the limitations of both are discussed. Finally, we look at theoretical models and taxonomies that lay down the important dimensions of the social television space. Using these dimensions, different Social TV experiences can be characterized.

Even after a comprehensive review of the topic from all these different angles, a precise and straightforward statement of what social television is remains difficult to articulate. However, the search shows that such uncertainties are inherent to the field, and by the end of this chapter the reasons for the vagueness should be clear. Furthermore, a consideration of these reasons suggests that the future adoption and assimilation of Social TV is likely.

HISTORY

It is difficult, if not impossible, to establish where the concept of social television first originated. In one form or another it predates television itself. In the late nineteenth century, long before video and communication technologies crystallized into their familiar modern forms, science fiction writers such as Albert Robida dreamt up extraordinary devices like the all-purpose *telephonoscope*; television, videoconference terminal and proto-Internet browser all in one screen. Truly a converged technology! Among its many functions, the telephonoscope allowed audiences to experience theatrical performances in their homes and share the experience with other viewers as if sitting in the same theater:

"So, one can applaud?" asked Barnabette.

"Of course!" Mr. Ponto replied. "Home viewers can also offer their own [applause]. Here, let me connect out to the theater. You may applaud, if you wish."

"So," a laughing Barbe inquired, "we could also send out boos if we wished to?"

"Definitely not!" answered Mr. Ponto. "That's forbidden! You understand that if expressions of disapproval were permitted, any practical joker could disturb the shows from their own armchairs."

"But then," Barbe continued, "home viewers who find the play boring are not entitled to let it be known? That's quite unpleasant; one must repress one's feelings and keep them to oneself."

"Absolutely not, you silly girl. The home viewer may boo to his heart's content whenever a play bores him, but he must make sure to shut off the connection to the theater. Thus he can express his bad mood without causing any disturbance to the theater." (Robida, 1882/2004, pp. 55–56)

Social television-like technologies, particularly variations on video telephony, went on to become a staple of science fiction. In *Nineteen Eighty-Four*, George Orwell provides an especially sinister example:

The voice came from an oblong metal plaque like a dulled mirror which formed part of the surface of the right-hand wall. The instrument (the telescreen, it was called) could be dimmed, but there was no way of shutting it off completely. […] The telescreen received and transmitted simultaneously. Any sound that Winston made, above the level of a very low whisper, would be picked up by it, moreover, so long as he remained within the field of vision which the metal plaque commanded, he could be seen as well as heard. (Orwell, 1949/1990)

Although the function of the telescreen is primarily monitoring, in the novel it is also occasionally used for communication and interactive content. At the time of the book's writing in 1948, video links were already in use, and by 1956 AT&T had created the first experimental prototype of PicturePhone, their famous videophone system (AT&T, 2008). Although years of user tests were not encouraging, PicturePhone was finally commercialized in 1970. It was a market failure, the first of many to come for video telephony (Noll, 1992).

This form of video telephony, which did not involve television content, falls outside social television as it is now generally understood. Of course, it had always been possible to socialize around the TV set, or communicate about TV content via other means (such as by telephone). After the listener/viewer call-in program format made the jump from radio to television in the 1960s (Newcomb, 1997), a small number of viewers could even join the broadcast from their own homes, in an early form of interactive programming.

Prestel, a videotex system (a type of early computer network initially accessed on TV terminals) from the UK Post Office/British Telecommunications that was launched in 1979 and remained in operation until 1994, introduced a form of email between users. However, neither this nor later videotex features such as bulletin boards and multi-player games were integrated with viewing TV content, and the services were frequently accessed from dedicated terminals rather than on the TV.

The first system to offer something akin to a remote social television experience appears instead to have been Spacephone, launched in 1980 by the US TV-maker Zenith. Spacephone was a feature offered on a number of high-end TV models which allowed users to talk on the telephone through their TV set, using the TV speakers and a built-in microphone as a speakerphone ("Zenith Electronics," 2008). Users could answer the phone and place calls with their remote control, and watch television while talking. However, the TV audio was muted during calls. Nevertheless, two Spacephone users talking to each other over the system would have experienced a simple version of social television. Unfortunately, Spacephone was not a success, and a faltering Zenith discontinued the feature in the mid-eighties (Perry, 1988).

A few years later, in 1988, a comedy show that would exert considerable influence on social television premiered on a local cable station in Minnesota (Cornell & Henry, 2002). *Mystery Science Theater 3000* (MST3K) involved a janitor marooned in space, watching old movies with his robot friends, and ridiculing them in order to preserve his sanity. MST3K's instantly recognizable visual format, showing the cast in silhouette sitting in front of the movie screen, has inspired several Social TV systems.

Social television finally started to gain traction around the turn of the century. Over a period of about two years, starting in 2000, SMS TV Chat was launched in many countries in Europe, becoming a big (and very profitable) hit. SMS TV Chat is essentially a chat room where all the text is displayed on the television as part of the broadcast. Participants write to the chat room by sending text messages from their cell phones. There are a number of different program formats. Sometimes the chat takes up the whole screen, so that there is no other TV content. Sometimes an unrelated program runs in the background or in a part of the screen. And sometimes a fully interactive live program is built around the chat (Beyer, Enli, Maasø, & Ytreberg, 2007). Especially this third case undeniably creates a social experience around the television content. However, the fact that the conversation is displayed as part of the broadcast severely constrains the type of communication and contact that is possible. All utterances are public, and the volume of messages and the possibility of delay can restrict an individual's ability to get a word in, or for groups of people to meaningfully converse (Zelenkauskaite & Herring, 2008).

Also in 2000, America On-Line (AOL) launched AOLTV, a line of retail set-top boxes to compete with Microsoft's WebTV. Like WebTV, it allowed users to surf the web on their television, but more importantly to read email, instant message (IM) and chat in chat rooms while watching TV on the same screen (Hill, 2001). AOLTV did not integrate television context with the IM presence information or provide ways for users to send links to TV content, but otherwise the box offered a near fully-fledged social television experience. AOLTV went off the market in 2002, but the chat features remain part of many Interactive TV services (Hu, 2003).

Soon afterwards, the research community started exploring social television in earnest, starting with Abreu, Almeida and Branco's (2001) description of 2BeOn. This activity continues up to the present. However, while a number of corporate research labs (including groups at Alcatel-Lucent, Microsoft, Google, PARC, Motorola, AT&T and Siemens) have published about Social TV prototypes and concepts, or even announced systems, as of late 2008 none of these have actually been launched.

At the same time, social sharing of video is becoming a reality online. YouTube[1] and other video sites have long offered the ability to share links to videos and leave comments as a form of asynchronous communication. Netflix[2] shares viewing history, ratings, comments and reviews of DVDs and online videos with a user's contacts and the wider community through Netflix Buddies. Now synchronous viewing and communication (via text, voice or video chat) are part of sites such as YouTube Streams,[3] Lycos Cinema[4] and Wi-Fi TV.[5] BuddyTV[6] offers a "TVj" feature to arrange similar sessions around TV shows, but does not provide the program itself: participants have to access it separately. Asynchronous communication is also becoming more advanced, with the ability to attach comments to particular playback positions in the video stream, so-called *deep tagging*, widely available (Click TV,[7] VeoTag,[8] ReviewTube,[9] InnerToob,[10] etc.), and several sites offering media-rich annotations and enhancements such as speech bubbles, graphics and animations (BubblePly,[11] Vidavee Graffiti[12]).

While video sites are moving into live chat, IM clients are starting to offer co-viewing of video. Zync is being integrated into Yahoo! Messenger (Shamma, Bastéa-Forte, Joubert, & Liu, 2008), and Microsoft is adding Messenger TV to their MSN Messenger[13] client. Both provide similar functionality, namely the ability for people in a chat session to watch an online video clip in near-synchronization. Finally, the internet TV application Joost[14] includes IM and "Channel Chat" plugins, where the latter is a public chat room associated with each Joost TV channel. (Given the dot-com industry's notorious turbulence, it is very likely that other sites and services will have complemented or replaced many of the ones listed above by the time this sees print.)

In some ways, history is coming full circle. Early on, as Robida's ideas became reality, parts of the telephonoscope split and diverged into different devices and services. Over the next hundred years, efforts to bring them together led to many different innovations, but a genuinely social kind of television remained science fiction. Now the technologies that have been separate for so long are converging again, and we are getting close to realizing the original thought in whole. However, currently available solutions still fall short of a comprehensive and seamless experience. They are limited in the types of content and the types of communication they support. In some systems, users have to coordinate multiple separate devices, and many do not share the video context or TV presence with other users, so that even if the communication *is* integrated with the media playback in a single device or application, the two activities remain essentially separate. For a fully integrated social television experience, we have to look to prototype systems in the research community.

EXAMPLES

Although the idea has a long history, social television has only recently come to be recognized as a distinct research topic within the field of interactive television (iTV). The best way to convey what Social TV means today may be by example—or, rather, multiple examples. There are many to choose from in the literature. Those that have been described in some detail include 2BeOn, from the University of Aveiro (Abreu et al., 2001; Abreu & Almeida, 2008), AmigoTV, from Alcatel (now Alcatel-Lucent) (Coppens, Trappeniers, & Godon, 2004; Coppens, Vanparijs, & Handekyen, 2005); Media Center Buddies, from Microsoft Labs (Regan & Todd, 2004a; 2004b); and ConnecTV, from TNO (Boertjes, 2007; Boertjes, Klok, & Schultz, 2008).

However, there is one particular example that is especially close at hand: At Motorola we have over the last few years developed a series of social television prototypes, collectively known as STV, for use in lab and field trials (Harboe, Massey, Metcalf, Wheatley, & Romano, 2008a; Harboe et al., 2008b). The design goal throughout development has been to allow a small group of friends or relatives to share a feeling of contact or togetherness while watching TV. In the current version, STV3, the key elements are:

- **Television presence** information through a buddy list and ambient display.
- Support for setting up **shared viewing experiences** through program suggestions and the ability to join what someone is watching.
- **Freeform communication** through text chat and group voice calls.
- Awareness of **viewing habits** and preferences, provided by viewing history lists and integration of viewing information into the electronic programming guide (EPG) grid.

In the selection and type of features, STV3 closely resembles a number of other social television systems. 2BeOn, AmigoTV, Media Center Buddies and ConnecTV all incorporate more or less the same capabilities. (The exception is the ambient display, which is apparently unique to STV.) However, in other systems there are some variant solutions to the same problems, as well as additional features not included in this particular prototype.

While STV3 supports creating shared viewing sessions through the presence information, the ability to join what a buddy is watching, and suggestions, some other systems take a more direct approach. ConnecTV has a "follow-friend" mode that switches channels automatically whenever a buddy does. Goldenberg (2007) and the Living@Room team (Ghittino, Iatrino, Modeo, & Ricchiuti, 2007) both propose a "shared remote control" paradigm where users who are watching together remotely all can take control of the joint content stream, pausing or rewinding everybody's TVs at the same time. The IM video player Zync uses a similar shared playback control (Shamma, Bastea-Forte, Joubert, & Liu, 2008). Coates (2005) suggests a type of voting system or game to resolve disputes over what to watch.

One feature not included in STV3 is video communication, to allow participants who are watching together to actually see each other. Video is the basis for Reflexion (Agamanolis, 2008), and is included in AmigoTV (Coppens et al., 2005) and Web Zync (Shamma et al., 2008), as well as in many social television concepts (Ghittino et al., 2007; Coates, 2005; Gross, Fetter, & Paul-Stueve, 2008).

In Telebuddies, the social interaction takes place within a multiplayer quiz game that is part of an interactive TV show (Luyten, Thys, Huypens, & Coninx, 2006). Creating content-related activities like games, wagers or fantasy sports around communication opens up many new possibilities for television-based socializing.

The increasing prominence of non–live-broadcast content, such as programs recorded on Digital Video Recorders (DVRs) or streamed on-demand from the web, has led to many proposals for ways in which users can interact around content asynchronously. A widespread idea is to record a first user's interactions as a kind of "commentary track" (whether in the form of voice, text, or non-verbal annotations such as emoticons), and play it back later for other users, synchronized to the content (Fink, Covell, & Baluja, 2006; Ducheneaut, Moore, Oehlberg, Thornton, & Nickell, 2008). This concept is implemented in CollaboraTV (Harrison & Amento, 2007; Nathan et al., 2008).

When the recorded interactions and annotations become sufficiently complex and powerful, it makes sense to consider them as a form of end-user enrichment of the TV content (Cesar et al., 2008). Such enhancements may include virtual edits, links to related content, freehand drawings or "scribbles" on top of the video, metadata tags, as well as the basic voice, text and graphical comments. It may even take the form of user-supplied closed captions and translations.

From such end-user enrichment, it is only a short step to user-generated content (Alliez, 2008) and community television (Vasconcelos, Fava, Kampf, Schilling, & Furtado, 2007; Obrist, Beck, Kepplinger, Bernhaupt, & Tscheligi, 2008). This in turn leads naturally to integration with blogs and social networks (Mantzari & Vrechopoulos, 2007; Baca & Holtzman, 2008), and to open forums where strangers meet and interact (as opposed to the fairly closed buddy lists for connecting family and friends presupposed by many other Social TV systems), described by Hess (2007). Beyond all these examples, social television bleeds over into iTV in general, as well as into telepresence, video telephony, any kind of content sharing, multiplayer games, online social networks, and collaborative filtering, among other things.

The examples listed above, although they encompass systems that support quite different experiences, seem to have something in common, when taken as a whole. Exactly what that characteristic is is more difficult to answer. The great variety of social television features and the indistinct boundaries of Social TV as a research area raise the question: How can we tell what is and what isn't Social TV?

DEFINITIONS

There have been many attempts to define social television. On reviewing the literature, it turns out that these efforts can be grouped under two definitions, one narrow and one broad, with the same researchers often using one or the other depending on the context (Table 1).

The broad definition defines "social television" as *any* technology that supports social practices associated with TV. Current social practices include things like talking about upcoming TV shows, watching TV together (at home, or in public places like a bar), and talking about TV programs after the fact.

This classification is comprehensive, but it makes the potential scope of the topic staggeringly broad. Most things in life have a social dimension, and television-related information is more or less ubiquitous in the modern world. Is a tabloid magazine, filled with gossip about television stars and a source of much potential

Table 1. The two types of definitions of social television found in the literature

Social Television Definitions	
Narrow	**Broad**
Communication technologies that create a remote, shared experience of watching TV together	***Any technology that supports social practices associated with television***
Using communication technology to connect TV viewers, in order to create remotely shared experiences around TV content. (Harboe et al., 2008b) *An audio-video system which allows distant viewers to communicate with each other using several interpersonal communication modalities, such as open audio channel, instant messaging, emoticons, etc*. (Chorianopolous, 2007) *Integration of television and computer technology to support sociable, computer-mediated group viewing experiences. […] Design for distributed, shared television viewing*. (Ducheneaut et al., 2008) *Video services that integrate other communication services like voice, chat, context awareness, and peer ratings to support a shared TV experience with one's peer groups*. (Klym & Montpetit, 2008) *Providing two or more remote TV consumers with a joint TV watching and communication experience*. (Schatz, Wagner, Egger, & Jordan, 2007)	*Interactive TV (iTV) systems that support the sociable aspects of TV viewing. This includes improvements to collocated interaction*. (Harboe et al., 2008a) *Technological support for the social practices that surround TV viewing*. (Chorianopolous, 2007) *Leveraging […] computing integration to remove the barriers to sociable interaction around video content*. (Ducheneaut et al., 2008) *Provide groups of TV spectators with technical support for collocated and geographically distributed TV watching and social interaction*. (Gross et al., 2008) *Communication and social interactions—remote or co-located—in a TV-watching context, or related to a TV experience; and technology that supports these communications and interactions.* (Geerts, Harboe, & Massey, 2007)

small talk, then a social television technology? It would seem so, especially if integrated somehow into an interactive TV system.

The other, narrow definition avoids this issue. Simply put, it states that "social television" describes systems that create an experience somehow "like" watching TV together, even though viewers are physically remote from each other. This is achieved by integrating communication technologies (such as voice communication or text chat) with the TV.

This categorization covers many aspects of the social television examples listed in the previous section, but not all of them. For example, it would not seem to include the ability to send a recommendation of a program you *just watched* to a friend, yet that kind of functionality is part of several Social TV systems. More importantly, it leaves out whole categories of related systems and features that have been envisioned but not systematically explored, like the ability for two people sitting next to each other on the couch watching a quiz show to participate and compete against each other.

Another ambiguity, shared by both definitions, is what is meant by "television." In addition to live broadcasts, many other types of content are available or accessible on television sets, including video-on-demand (VOD), internet video, and other user-generated content. Some of these media types are clearly relevant to social television. Sharing a home movie between two TVs is arguably a social television experience. Sharing a photo album may also qualify. At the same time, it is becoming possible to watch TV on other devices, such as cell phones and mp3 players. So maybe sharing a home movie between two phones is another example of social television? But sharing photos between two cell phones can hardly qualify, or the term is diluted beyond reason!

Perhaps these difficulties have less to do with shortcomings of the definitions than they are simply reflections of a world in transition, where the boundaries between traditional media types and communication services are blurring. Social TV is just one *part* of the research on content plus communication, which also encompasses social music, social photos, and more. Ultimately, the most important dimension of a user's social media experience is probably not whether or not it is classified specifically as "social television".

DIMENSIONS

By now, it should be evident that the social television space encompasses many radically different experiences. In order to bring them into some kind of organization, several researchers have put forward dimensions of design for social television.

In the analysis of Coppens et al. (2004), a social television experience consists of a mix of three basic components: personal content (including personal favorites and personally recommended content), rich communication (including all the modalities already discussed: text, voice, video and graphical messages), and community support (presence, invitations, scheduling, and support for social networking). While this is a serviceable description of the AmigoTV system, the distinction between the categories is not always clear. Program suggestions, for example, could arguably fit in any of the three.

Ducheneaut et al. (2008) divide TV-related sociability into direct and indirect forms. Direct sociability is the socializing that takes place during or just before and after the television experience, while indirect sociability refers to socializing about the content *apart* from the actual experience of it (such as when talking about an upcoming program or something that has been watched previously). This is an important distinction, but remote communication, and especially asynchronous interaction, confuse the matter, since one of the people socializing may be in the middle of the television experience while the other is not.

Chorianopoulos (2007) uses the well-established CSCW time-space matrix (Baecker, Grudin, Buxton, & Greenberg, 1995) to describe television sociability in two dimensions: synchronous—asynchronous communication and collocated—distant presence. The resulting quadrants correspond to four scenarios that could benefit from social television systems. The most valuable contribution of this model is probably to identify interesting, non-obvious potential use-cases for Social TV, such as supporting people watching at the same place at different times. However, it should be recognized that in practice, both dimensions have more than two states. Text chat, for example, has aspects of both synchronous and asynchronous communication (Voida, Newstetter, & Mynatt, 2002), and the ability to record and play back interaction sequences synchronized to the content, found in systems like CollaboraTV, mimics certain characteristics of a synchronous experience in an asynchronous communication situation (Harrison & Amento, 2007). Along the space axis, social television has an important category of nearly-collocated communication: between people watching on different TVs in the same household.

Hess (2007) identifies seven aspects of community building for Social TV systems that bring people together. Of these, group size may be the most generally relevant, making a distinction between one-to-one communication and interaction in larger groups. Because Hess's focus is on a "Find-a-Friend" scenario, he assumes an open, public forum, where participants would mostly have weak-tie relationships, and does not consider more closed and close-knit groups of friends and family who have strong ties to each other.

The most extensive taxonomy of social television is due to Schatz et al. (2007). They define six dimensions of the design space for mobile social television, incorporating a number of the axes used by others: synchronous—asynchronous, verbal—non-verbal, integrated with—separate from the content, one-to-one—one-to-many, push—pull, and high bandwidth—low bandwidth. All of these dimensions are equally applicable to non-mobile social television. The degree to which the communication is integrated with the content (allowing people to communicate *via* the content, as when sending suggestions, sharing ratings, or adding tags, annotations or other enhancements) is an especially important factor not identified in the other models.

Gross et al. (2008) divide social television functionality into three components: group TV watching, presence info and communication, and recommendations. To this, they add social, spatial and temporal dimensions that generally correspond to those outlined above, and mention the possibility of group adaptive interfaces. On this basis they put forth a model of design dimensions.

In summary, theoretical models of social television have proposed a number of different dimensions of design. For the most part the models complement each other and can be used together. Many of the dimensions are simply aspects of communication technologies and online social networks in general. However, the integration with TV content does give rise to new dimensions that define the relationship between the communication and the content.

CONCLUSION

Like the topic itself, the search for social television remains a work in progress. Our ability to delineate it, either in terms of history, by example, through definition or by analysis of its characteristic dimensions, is limited by its variety, its interconnectedness with other social experiences, and its ongoing development. Yet if a definitive description is still elusive, the idea itself appears on the verge of finally being realized on a grand scale.

Whether or not any of the prototype systems mentioned above ever make it to market (and several of them are ready to take that step), it seems a near certainty that some sort of communication, probably text chat, will soon be easily available alongside the viewing of TV content. Online, a variety of social experiences around video and television content are emerging simply from the convergence of internet and video.

Ironically, just as convergence is turning Social TV into reality, it may also be rendering the notion obsolete. Without a clear distinction between a TV screen and other screens and between television programming and other content, and with communication and content sharing available ubiquitously, social television as a separate concept might no longer make sense. When first conceived of, Social TV was not thought of as distinct from the idea that would become television. As communication and video experiences are integrated in modern-day telephonoscopes, perhaps the ability to cheer along with an audience spread out all over the world will soon be commonplace—and disconnecting before booing just good manners.

ACKNOWLEDGMENT

I would like to thank the many people who have contributed to my thinking on social television, including fellow Social TV researchers, workshop participants, and Motorola coworkers. I also particularly wish to thank Elaine Huang, Joe Tullio, Ashley Novak and Noel Massey for their help revising the manuscript for this chapter.

Chapter 3.4
Asynchronous Communication
Fostering Social Interaction with CollaboraTV

ABSTRACT

With the advent of digital video recorders and video-on-demand services, the way in which we consume media is undergoing a fundamental change. People today are less likely to watch shows at the same time, let alone the same place. As a result, television viewing which was once a social activity has been reduced to a passive, isolated experience. CollaboraTV was designed to address this new mode of television viewing by directly supporting asynchronous communication. We demonstrated its ability to support this communal viewing experience through a lab study and a month-long field study. Our studies show that users understand and appreciate the utility of asynchronous interaction, are enthusiastic about CollaboraTV's engaging social communication primitives and value implicit show recommendations from friends. Our results both provide a compelling demonstration of a social television system and raise new challenges for social television communication modalities.

DOI: 10.4018/978-1-60566-656-3.ch012

INTRODUCTION

Television is undeniably a major component of modern society. In the United States, it is not only the dominant media activity, but is also considered the most exciting and influential media type (FCC 2006; Putnam 2000; TBA 2006). Despite increasing competition from the internet, television usage has been steadily increasing, and is now at it's highest level since viewing data was first collected, a 50% increase since the 1950s, and a 12% increase from 1996. The average person watches 4.5 hours of programming a day, with the average household tuned in for more than 8 hours (FCC 2006; Putnam 2000). This consumes almost half of people's total leisure time (BLS 2006; Putnam 2000).

Given the significant place that television holds, our research focuses on understanding the social aspects of television viewing – especially in today's age of social behavior-altering technological advances – and the utility of social television systems for meeting the new challenges that such advances bring about.

Declined Social Interactions Around Television

Television was once championed as the "electronic hearth" which would bring people together (Tichi 1991). Indeed, television shows provide a common experience, often affording even total strangers a social connection on which to initiate conversation. This effect blossomed in the 1950s, when two-thirds of all Americans tuned in to watch "I Love Lucy" (Putnam 2000). However, a fundamental shift in how we consume media is degrading such social interactions significantly – an increasing number of people are no longer watching television shows as they broadcast. Instead, users are favoring non-live media sources, such as Digital Video Recorders (DVRs), Video-On-Demand services (e.g. Apple's iTunes Video Store), and even rented physical media (e.g. DVDs via Netflix). To complicate matters further, televisions are outnumbering people in the average home; less than a fifth of households have a single television (Fairbank 1995; AP 2006). This is leading to a decline in ability for people to interact and is eroding once strong social ties. People are increasingly watching TV without their families, with some studies suggesting at least half of Americans usually watch alone (Putnam 2000). However, all indications point towards a lack of ability to communicate, not a lack of desire.

The "Water-Cooler Effect": A Thing of the Past?

Television shows often act as a conversation starter, enabling the "water-cooler effect" (Putnam 2000), where groups congregate and discuss a television show, automatically assuming everyone in the group has seen it. For example, co-workers could discuss a show from the previous night at work the following day. However, this effect is heavily dependent on a property of live television: shows have a fixed broadcast time. This means that after a show has aired, everyone who wanted to see it, must have watched it (or missed it). DVRs enable people to watch shows days, weeks, and even years after they first air. This trend towards asynchronous viewing, although not omnipresent today, is becoming a dominant media consumption mode. DVRs are already found in 20% of American homes (Leichtman 2007) and worldwide adoption is predicted to reach 250 million users by 2011 (ABI 2006). On-demand commercial video downloads are also booming, jumping 255% from 2005 to 2006 (NPD 2006). Similarly, Netflix, the most popular DVD rental company, has experienced nearly 50% growth in subscribers annually since 2002 (Netflix 2006).

What does asynchronous viewing mean for water cooler talk? Many people will not have watched the most recently aired episode by the following day. In fact, some people may be multiple episodes or even seasons behind. This makes conversing about a show considerably more problematic. If a group of friends meet and talk about the latest episode, those who have not seen it are left out. It is even possible that some may avoid the conversation entirely, fearing that yet-to-be-seen episodes will be spoiled. Equally likely is that people will moderate their conversations in order to prevent revealing spoilers to friends that are one or more episodes behind. However, this hampers the exchange of important and interesting details that were revealed in recent episodes. Moreover, by the time lagging people do catch up, and want to discuss the show, it is likely others will have forgotten important details or simply have lost interest, substantially degrading the quality of interaction.

Unprecedented Level of Program Choice

Television viewers today can easily be overwhelmed by the number of channels as well as programs. Gone are the days when one could flip through a 40 page TV guide and decide on what to watch. Given the plethora of content today, the task of finding something relevant to watch has become very difficult. As a result, viewers often resort to randomly scanning multiple channels ('channel surfing') to find a show of interest. Digital TV content providers have tried to respond to this information overload problem in a few ways. Electronic program guides, which are little more than digital forms of their paper predecessors, still require viewers to sift through a multitude of static choices. Vendors also provide basic search capabilities along with TV programming service, but again the task of searching for the illusive "good" show rests on the viewer. Despite the availability of technology aids, viewers still prefer channel surfing as a method to select what to watch, often expressing considerable dislike for on-screen program guides (Taylor 2003). DVR systems, like the TiVO, even automatically record shows that it thinks the user will like. But the quality of such system-recommended shows is questionable (Zaslow 2002).

To address these concerns, a new communication paradigm for television is needed, one that captures users' comments during and immediately after watching a show. This is when the material is fresh and engaging, and peoples' commentary rich and plentiful. This content then needs to be saved – the enthusiasm and detail preserved – and shared with users who watch the content at a later time to recreate the experience of watching together. Also, the social nature of such a system involving groups of people who often watch shows together can be exploited to tackle the problem of content overload by using the viewing habits of friends as recommendations. CollaboraTV achieves all this using a unique set of communication primitives and visualization techniques.

Our efforts to address the aforementioned issues are organized around 3 research questions (RQs):

- **RQ1.** Does CollaboraTV provide users a sense of social presence? Does it enrich the viewing experience?
- **RQ2.** How well does CollaboraTV support the task of asynchronous television viewing?
- **RQ3.** Can friend networks present in social television systems be leveraged to help users choose what to watch?

The remainder of the chapter is organized as follows. We first survey related work, illustrating how we build on or advance it. We then describe the CollaboraTV system, highlighting distinctive features that appreciably affect usage. The heart of the paper describes a lab study followed by a month-long deployment of CollaboraTV to support social interactions while consuming video content; we focus on how our results answer our three research questions. Finally, we discuss the implications of our results for future design and research.

RELATED WORK

Social Television Systems

Television-based communication has been the focus of substantial research. Many of the ideas in CollaboraTV are extensions of successful elements in previously developed systems. However, CollaboraTV distinguishes itself in several significant ways.

Xerox PARC's SocialTV (Oehlberg 2006) envisioned the use of a shared audio channel, where groups of users could interact verbally. The project also introduced the idea of a movie theater-themed visualization scheme for user presence. Indeed, CollaboraTV's virtual audience is a direct descendant of this concept. However, unlike avatars in SocialTV, CollaboraTV's are dynamic and used as a conduit for communication (comments, gestures and emoticons).

AmigoTV represents one of the earliest efforts in this domain (Coppens 2004). Like SocialTV and CollaboraTV, avatars are used to visualize user presence. The system offers a series of faces as avatars, and allows users to select a demeanor (e.g. happy face, angry face). This simple mechanism allows avatars to operate on an additional dimension: emotion. Users can also generate shared video effects, for example a flaming ball whizzing across the screen. Like SocialTV, AmigoTV allows users to communicate via speech.

ConnecTV is a tightly integrated instant messaging and television application (Boertjes 2007). From a user's perspective, friends are placed into one of three groups: "watching this channel", "watching another channel", and "not watching". In addition to being able to chat with friends that are watching the same show, the system also allows messages to be sent to friends watching different shows. The latter serves as an invitation for that user to switch channels and join the friend. These invitations have the ability to operate in an asynchronous way. If a user is not available when the invitation is sent, it will be saved until that user comes online. Once logged in, the invitation is shown, and the user can start watching the associated content asynchronously from the originating friend. Media Center Buddies, system developed by Microsoft, is similar (Regan 2004).

The Telebuddies system (Luyten 2006) promotes communication amongst synchronous viewers using a series of events incorporated into the media stream. The authors offer a quiz example, where users are formed into groups and compete. A text-based chat interface is provided to allow users to deliberate.

Unfortunately, evaluation of social television applications has been fairly limited (Geerts 2006, Harboe 2007, Boertjes 2007). There has been a significant amount of work evaluating the use of ambient displays to convey TV watching status (Harboe 2008). Although there has been considerable investigation of particular social television elements (Geerts 2006; Harboe 2007; Weisz 2007), comprehensive field studies that cover the usability, impact, and potential adoption of full systems are limited. Currently, these systems do not distinctly support asynchronous communication. With a clear trend towards on-demand media consumption, systems that do not support this form of communication have significantly diminished value. In these regards, CollaboraTV is unique.

Avatars

The benefit of avatars in communication systems has been widely researched (Diederiks 2003; Persson 2003; Salem 2000; Smith 2000). The use of animated characters in television has also been investigated (Chorianopoulos 2006). Television is traditionally watched in groups, which makes avatars an obvious technique to simulate presence. Avatars humanize remote users, or in the case of CollaboraTV, potentially teletemporal (literally meaning far in time) as well. Moreover, avatars have been shown to be ideal for non-textual communication; emotions, gestures and postures offer a universal dimension of expression that people find familiar and natural.

SYSTEM DESCRIPTION

CollaboraTV was designed from the ground up to support synchronous and asynchronous viewers in a unified interface. The resulting system allows communication in and between these two viewing modes, providing an unprecedented level of interaction potential. Additionally, CollaboraTV provides a suite of novel features that leverages existing user behavior to further enhance the social experience.

Temporally-Linked Annotations

Our initial prototype version of CollaboraTV allows users to create text comments while watching a show. The text content is attached to the media stream at the corresponding time index. When other users encounter this point in the show, the comment is displayed on screen for several seconds.

This annotation method inherently supports asynchronous communication. Previously generated comments will be shown to later viewers as they watch the show. Although the mechanism is simple, the effect is great – past users appear to make comments as if they were watching in parallel with you. In a synchronous situation, when one or more users are concurrent, comments are shown immediately to all group members because the comment is attached to the show at the point everyone is presently viewing. This allows people to chat (live) like they would with an instant messaging client. Additionally, because these (chat) comments are attached temporally to the media, subsequent viewers will see the conversation unfold in "real-time" even though the conversation took place in the past.

This communication scheme has several important qualities. Foremost, synchronous user groups can communicate without hindrance while simultaneously interacting with asynchronous commentary. Secondly, lone viewers who would otherwise see no communication are exposed to a wealth of previous interaction. This may motivate them to participate in the conversation knowing that subsequent viewers will see their remarks. Lastly, as more users watch and comment, the richer the dialog becomes for later viewers.

CollaboraTV supports a second type of temporally-linked annotation: the interest point. Like comments, interest points are attached to the media stream at the time index they were created. However, instead of containing text, interest points are used to indicate a positive or negative reaction to a show's content (e.g. a particularly funny joke or exciting action scene). Users are free to associate the polar nature of this feature however they see fit (e.g. thrilling/dull, witty/cheesy, and suspenseful/predictable).

Virtual Audience

The most prominent feature of the CollaboraTV user interface is the virtual audience. A series of avatars are used to visualize both current and past viewers (i.e. synchronous and asynchronous users respectively). The effect of a movie theater, where people are seated and shown as silhouettes against the content, is used. The simple black figures are unobtrusive, immediately recognizable, and work well at a variety of scales. Each avatar is named and has a static seating position throughout the show. A "watching live" label is displayed below avatars that represent synchronous viewers. Figure 1 shows a screenshot of the initial prototype version of CollaboraTV.

In addition to embodying concurrent and tele-temporal viewers, the virtual audience is used as the primary communication conduit. Temporally-linked comments are shown in translucent, comic-book-like speech bubbles, which are rendered above the source user's avatar. In addition, avatars raise and lower their arms to make thumbs up/down gestures. These correspond to user-generated positive and negative interest points.

The virtual audience is a critical component of the CollaboraTV communication strategy. Because user actions are coupled with a personal avatar, one that is seen by friends and family, pro-

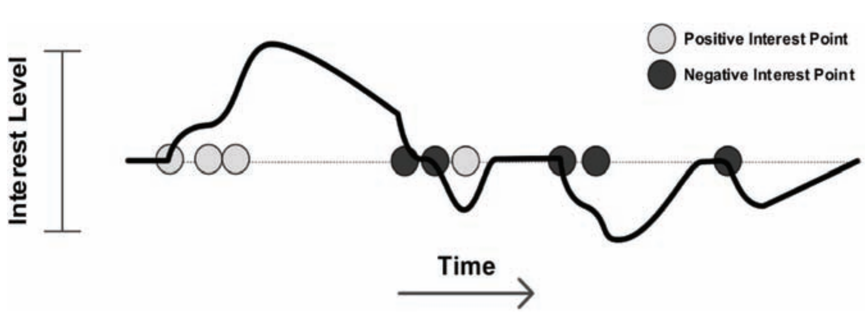
Figure 1. The CollaboraTV prototype interface with all panes active. A) Information about current show. B) Alternative, chat-room-like visualization (inset, used only in lab study). C) Interest profile visualization. D) Progress bar that displays the position in the media stream. E) Virtual Audience. Panels A, C and D fade away after a preset period of inactivity.

viding commentary and interest feedback becomes an outlet for expression and not just data entry.

Buddies, Sharing and Privacy

A user may consider their comments and interest points personal, and thus only wish to share them with friends and family. To achieve this, CollaboraTV employs a simple social network in order to determine how user-content is shared. Specifically, a unidirectional subscription model is used. If comments, emoticons and interest points are to be exchanged between two users, they must explicitly befriend each other by adding the other to their buddy list. This would be most typical among friends and families, who want bi-directional communication. However, there are some instances where unidirectional communication is valuable. For example, it would be possible to watch a television program with one of the show's actors. This would be achieved by subscribing to that user. However, because the subscription is only one-way, the user would not appear in the actor's virtual audience.

Figure 2. A set of discrete interest points is used to form a continuous interest profile.



Interest Profiles

Although temporally-linked comments, emoticons and interest points are primarily used for communication purposes, their location, frequency and content can be leveraged for other purposes. Interest profiles are a notable example. These are created by interpolating a continuous interest level from a series of interest points. Data from a single user or group of users can be used. Because positive and negative interest is assumed to be transient, the interest level slowly decays to a nominal level. (Figure 2)

These data of how a viewer's interest level swings between positive and negative over the time period of a TV show may be interesting to viewers. In response, the feature is exposed graphically in the CollaboraTV user interface. While a show is watched, two interest profiles are calculated: one for all previous viewers and one for the current user. The two interest profiles are shown together in Figure 1. This helps visualize the difference between these two profiles, displaying the magnitude of disagreement between the user and the group. It was thought that highlighting sections of agreement and disagreement may spark additional discussion, increasing social interaction.

Interface Design

The CTV GUI consists of the following 5 elements:

1. **Buddy Information (View/Join):** A list of buddies of a user along with an indication of whether or not the buddy is currently viewing CollaboraTV. A user has the ability to 'join in' on a buddy, who may already be watching a show, and start watching at the same point in the show as the buddy. Thus a user can catch-up with a buddy who may not be too far along into a show.
2. **Program Guide:** A listing of all available shows in the CollaboraTV system, along with show descriptions. Shows viewed by buddies of a user are marked in the program guide along with any collected social usage data. The program guide also has a list of shows that have been viewed by a user's buddies, as well as a list of popular shows across all users of the CollaboraTV system.
3. **Virtual Audience:** Discussed previously.
4. **Progress Bar:** Displays the current position in the media stream. The temporal locations of annotations – comments, interest points and emoticons – are denoted using icons on the progress bar (Figure 1). When the show progresses to an annotation as seen on the progress bar, the avatar corresponding to the user who made the annotation is animated to display a comment bubble, thumbs up/ thumbs down gesture or emoticon on its face.
5. **Interest Profile Visualization:** Discussed previously. Users have the option to move to particular points on the interest profile timeline and begin watching the show at the chosen point of interest.

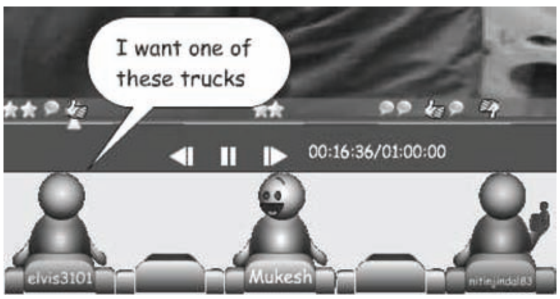
System Architecture

CollaboraTV uses a client-server architecture. The prototype client was built using Java and provides the GUI functionalities described previously to access available content, launch programming, and control playback (Harrison 2007). The prototype uses MythTV, an open source media center application with DVR capability, for recording and playing shows and accessing show information for its program guide.

EXPERIMENT: LAB STUDY

Our first study was a lab based study of the initial CollaboraTV system (Figure 3). In addition to the research questions listed above, we also wanted to see how users could communicate asynchronously

Figure 3. A partial virtual audience from a live user's perspective. Other avatars represent past viewers. Note the speech bubbles (comments), thumbs up and thumbs down avatar gestures (interest points) and the avatar emoticons (emotions). These annotations are also temporally displayed on the progress bar seen above the virtual avatars.



and what types of interactions would arise while using the CollaboraTV system. We were also interested in seeing if our virtual audience interface could provide a better sense of presence and help to elicit more interactions between users.

Experimental Setup

In this study, users were seated in a room with a large rear-projection screen. A wireless (Bluetooth) keyboard was used for entering text annotations. For all other functionally, a wireless (radio frequency) remote control was provided. A labeled color printout of the remote control was provided for reference. Twenty-three televisions shows were available for users to watch. These varied in content and genre. Advertisements were removed, and clips shortened to approximately seven minutes in length. We kept the amount of content low to help ensure overlap between users.

Before the study began, the authors watched each show and generated some preliminary comments and interest points. Thus, no less than two avatars (three including participant's avatar) were present in the virtual audience. This was deemed necessary to engage people in the asynchronous technology and help them better evaluate if comments left in the past were interesting and whether they would respond to comments knowing previous users may never see them.

In order to investigate whether the virtual audience increased user participation, an alternative commentary interface was created. This was modeled after a generic chat-room-like application. Comments were listed sequentially in a vertical orientation, prefixed with user names with no audience display.

Comments and interest points created by users, persisted between sessions. This meant that avatars in the virtual audience represented real people (in this case, colleagues). Additionally, users understood that future study participants would see their avatar's comments and interest points. This provided the necessary social context to engage users. It was thought that if users knew their comments were to be deleted once they finished, there would be no motivation to communicate. Also, this exposed participants to a variety of people, commentary, commentary styles, and audience sizes.

Participants

Thirty-two participants (24 male and 8 female, with a mean age of approximately 42) volunteered for a small food reward. Participants were recruited from a large corporate research lab using an email campaign. All but one participant watched television on a regular basis.

Procedure

Experimental conditions were balanced across participants to remove any order effects. Users were first shown a short video providing an overview of CollaboraTV. This was followed by a 10-minute, hands-on walkthrough, which familiarized participants with the system and its features.

Following the tutorial, participants were asked to select and start a show of their choosing. Based on the participant's experimental condition, either the virtual audience or the chat-room-like visualization was enabled. Users then watched the show, generating comments and interest points as they saw fit. After the first show had finished, users were asked to select a new program to watch. This time, the other comment visualization method was used. For the third (and final) clip, users watched a common show, ensuring overlap with other participants.

After the final show concluded, users answered an online survey eliciting feedback about the system and their perceptions about asynchronous communication. The survey used a Likert-style one to five scale to determine user's level of agreement to questions about CollboraTV. Each trial took approximately one hour to complete.

RESULTS: LAB STUDY

Overall reaction was positive. Users understood and appreciated the value of asynchronous communication immediately. When asked if CollaboraTV made watching television more engaging and enjoyable, over half of participants agreed or strongly agreed (m=3.58, sd=1.09). The ability to create comments was popular, with 76% of participants agreeing or strongly agreeing the ability made television viewing more fun (m=3.87, sd=1.05).

Asynchronous Communication and the Virtual Audience

The virtual audience appears to be an effective and engaging visualization. User participation was significantly greater when compared against the alternative, chat-room-like visualization ($p<.05$). On average, users generated 21% more interest points and 17% more comments when the virtual audience was enabled. This was further reinforced by survey results, which indicated that two-thirds of participants agreed or strongly agreed that they preferred the virtual audience (m=3.97, sd=0.87). A follow up question asked users to consider an alternative interface where the virtual audience was present, but comments were decoupled from (i.e. not associated with) particular avatars. Responses were overwhelmingly negative (m=2.15, sd=1.06).

The virtual audience's ability to support both synchronous and asynchronous viewers was also popular. Users had overall negative option when asked to consider a virtual audience that only displayed synchronous users (m=2.12, sd=0.89). Equally negative was the reaction to a virtual audience that only showed past viewers (m=2.09, sd=.91). Also, a pair of questions asked participants to consider two systems, one where their comments and interest points were only shown to synchronous viewers, and the other where their comments and interest points were shown to both synchronous and later (asynchronous) viewers. Users strongly favored participation in the system that supported both communication modalities (m=3.09, sd=1.07 vs. m=3.94, sd=0.83).

System Redesign

The lab study was useful in helping us evaluate the initial system. However, it is difficult, in a lab setting, to see how users might integrate this technology into their daily viewing habits and determine the true value of asynchronous communication while watching television. Since our prototype system was not very portable, because of numerous hardware constraints, we decided to re-implement CollaboraTV to run within a web browser. This would allow users access to the system from their homes and help us to reach a wider audience.

The new version of CollaboraTV uses a client built in Adobe Flex. A central JBoss server in coordination with a Flash Media Server serves out video content to the clients, and coordinates the communication between multiple clients. A central MySQL server provides a common data store for user generated data (annotations, buddy lists, show ratings) as well as show related data.

Based on user comments from the lab study, we made a few changes to the client interface. Most of these changes were required to make the interface more mouse friendly. The prototype was controlled through a remote device, but the new web version, needed to support the mouse. Besides text comments and interest points, CollaboraTV now allows users to temporally link emotion icons or emoticons to the media stream. Users can express their feelings at the time of watching a show by selecting from a set of emoticons that represent common expressions (happy, sad, angry etc.) Along with text comments and interests points, emoticons provide CollaboraTV users with a rich set of primitives that help digitally recreate the communal viewing experience. Emoticons are seen as corresponding animations of the avatars. For example, when a user selects the 'happy' icon, the user's avatar turns around and displays a smile on its face. All actions are smoothly animated. These subtle effects enhance the perceived interactivity. Figure 1 provides an example of each of these items.

EXPERIMENT: FIELD TRIAL

In order to gauge the true utility of CollaboraTV, we conducted a field study to investigate the usefulness of CollaboraTV to support the communal viewing experience. Participants accessed and used CollaboraTV from their personal computers, interacting with their television buddies freely and naturally over the duration of the study. Such an open and natural design preempted the need to simulate the experience of watching programming remotely with other users of the system, and also gave users sufficient time to form an opinion about the system.

Participants

The participants were recruited using a mailing campaign directed at students who had interned at a large corporate research. The summer interns presented an interesting group to recruit from as they had interacted with each during their internship period. They often stayed in the same summer housing, traveled to work together, had lunch together as well as socialized during many events for summer interns. Thus, new friendships were made and new cliques formed. After the summer internship, the interns returned to their home towns, within and outside the US. This group had an important property that made it ideal for our study – cliques of friends who were now geographically separated. The presence of cliques within the potential participant pool was vital, as CollaboraTV depends on the notion of buddies. We used a survey to find participants amongst this group of interns and their friends who regularly watched television. 16 qualified subjects participated (14 male and 2 female, with a mean age of approximately 25). Their backgrounds were mainly in IT.

Procedure

Participants used CollaboraTV for 4 weeks. They completed a pre-study survey about their TV viewing habits and selected a group of buddies with whom they would like to watch shows on CollaboraTV. Participants could either choose buddies from the list of interns or invite other friends. Following the initial survey, we invited each participant to view a short online video providing an overview of CollaboraTV. At the end of the study period, we conducted another online survey where participants informed us of their experiences with CollaboraTV.

Participants viewed streaming video from the CollaboraTV server using a web browser with the Adobe Flash plug-in installed. Once logged in to the system, they could select from a list of

37 shows (600 episodes total) across 17 genres. The list of shows to be recorded was based on a listing of the highest rated shows across different genres on a popular TV show rating website. During the course of the study, participants could request shows to be added to the system. They could also modify their buddy list, and make annotations while they watched a show.

We told participants to use CollaboraTV just as they wanted: they could watch any show of their choice, add or remove anybody to their buddy list and use any system feature. To ensure minimal usage levels, we asked participants to view at least 2 shows. We offered a modest incentive: a randomly selected user who participated at the minimum level received a $50 gift certificate. 70% of the subjects met the requirement.

Experimental Design

To test the effect of CollaboraTV's social features in providing users' a sense of social presence (RQ1), we asked users to create a buddy list and observed the interactions that took place between buddies. These buddies were in most cases other interns with whom participants had fostered friendships over the last year as a result of a joint summer internship experience. In other cases, participants invited a family member or a friend to be their CollaboraTV buddy. Annotations made by participants while watching a show were persisted and shown to their buddies. Users understood that their buddies would see their avatar's annotations and this provided the necessary social context to engage users. Besides observing the logs of annotations made by users, we asked about their experiences of using the social features of CollaboraTV while watching shows with their buddies.

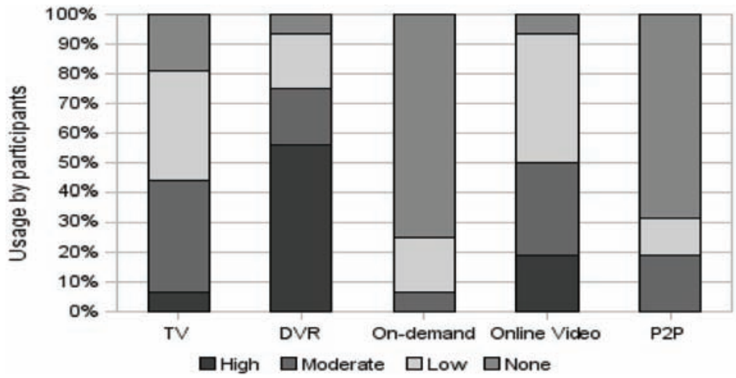
Numerous existing social television systems have explored the dynamics of synchronous communication. To better understand the potential of asynchronous communication, one of CollaboraTV's most distinctive features, our study focused on this mode of interaction (RQ2). We asked users to watch specific shows with a buddy(s) in a time-shifted manner. A new episode of a show found in the viewing history of a user or buddy was chosen. Participants were asked to view the chosen show, or alternately a show of their choice, and were given a week to complete this task.

Digital television services today pose a significant content selection problem. Rather than taking the algorithmic route such as recommender systems, CollaboraTV employs a simple yet powerful mechanism. Social Influence Theory tells us that when we do not know what to do, we often times do as others do. CollaboraTV aids such behavior via certain interface features. Users can view a list of shows that their buddies have been watching called PopularShows(Buddies). Also available is another list called PopularShows(All) that anonymously displays names of shows that have been recently viewed by any system user, not only buddies. Shows recently viewed by buddies are indicated in the program guide. To learn if friend networks present in social television systems could be leveraged to help users choose what to watch (RQ3), we observed usage logs for instances when users selected a show displayed under either PopularShows(Buddies) or PopularShows(All). We also asked survey questions to find out if participants found these lists useful.

RESULTS: FIELD TRIAL

At the start of the study, participants completed a survey that gave us sufficient background regarding their familiarity with different video viewing technologies and their attitudes towards television viewing. Given their IT background, almost all participants reported themselves as expert computer users, with high weekly computer usage. On the question of television expertise and usage, almost all of the participants had used televisions for more than 10 years, with 75% viewing between 1-3 hours per day.

Figure 4. Amount of usage of different video-related technologies



We also asked questions about familiarity and usage of DVR technology, to which 56% of participants said they use it often, while 37.5% of users had either heard of it or used it a few times. We felt that the familiarity with DVR technology would lend itself nicely to the asynchronous viewing mode in CollaboraTV. Only 3 participants had used online social television systems before. Figure 4 shows usage levels of some popular video-related technologies.

With this background about participants, we now address the core of our results, which are organized around our 3 research questions. We begin with RQ1, describing how participants felt about the social features of CollaboraTV. We follow by identifying opportunities for improving the communication primitives based on participant feedback, and then address RQ2, which focuses on asynchronous viewing. At this point, we explore the related issue of privacy in social television systems, before finally looking at a possible solution to the content selection problem described in RQ3.

RQ1. Does CollaboraTV provide users a sense of social presence and enrich the viewing experience? We asked participants questions to understand if they even valued the experience of watching with others in the first place. 81% indicated that they watched television with family or friends, and said that watching with others was more fun than watching alone. 19% also added that watching programs/films that elicit strong emotions with friends or family helped bring them closer together. These responses encouraged us to believe that participants would use and value the social annotation primitives of CollaboraTV at the onset of the study.

Annotation Activity

During the period of the study, we maintained logs of all the annotations made by the participants with the intention of using annotation activity as a measure of success of CollaboraTV in enriching the viewing experience. In all, participants created 213 annotations, an average of 14 per person (min: 0; max: 72; std: 22.5). 137 (64%) were text comments, 24 (11%) were interest points, and 52 (25%) were expressions. The difference in usage of the 3 types of annotations could be because of the ease of use and expressiveness of text chat. In many cases, viewers used chat-style emoticons embedded in their text comments.

Chat Content

After the study was complete, we assigned each of the participants' 137 messages to one of 6 categories. We adopted the classification scheme used by Weisz (2007). A reliability check was

Table 1. Examples of chat in each coding category

Category	Example chat (original form)	% chat
Television Show	"does she leave him there or something?" "that's dakota fanning indeed" "Colbert took the book apart"	34.3
Evaluations	"oh man . . . bad driver" "if this wasn't already planned, this dude's the funniest astronaut out there" "nice choice of music"	8
Personal	"I want to sit next to you" "do you like Chandler?" "I'm hungry"	18.9
System	"it works fine even with limited bandwidth" "they should cut out all commercials" "test . . . "	16.8
Laughter	":D", "hehehe", "lol" and many variations thereof "I've seen this show too many times:)"	18.9 solo 5.1 mixed
Greetings & partings	"hi", "hey", "bye" and many variations thereof "I'm out of here"	2.2

performed between two independent coders, with an inter-rater reliability of 83% after two iterations. Each line of chat was coded under one of these categories -- show content, evaluations of the show, personal topics, laughter, system-related comments and greetings/partings. Laughter, which was often embedded in text comments, was coded separately as either occurring by itself or co-occurring with text. A breakup of the chat content is shown in Table 1.

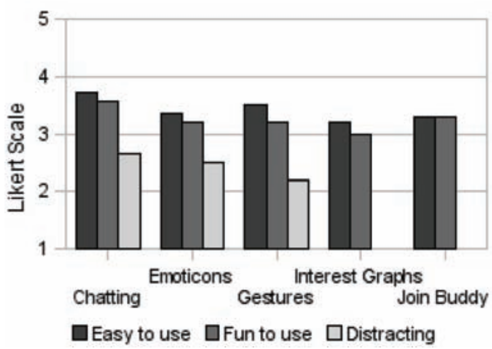
Our results were similar to those reported by Weisz (2007). A significant amount of chat was about the show content as well as personal interactions triggered by the content. For example, a participant said, "do you like Chandler? Would you date him?", to which a buddy said, "haha prob not, he's too much like my first bf" while watching an episode of a popular sitcom. Laughter in the form of "hehehe", "lol", ":)", ":D" etc. occurred very frequently, with users often mixing it in with chat, but more often occurring by itself. Close to 20% of chat consisted of solely laughter. This is roughly the same as the number of times the emoticon representing 'laugh' was used during the study. More over, the high usage of chat-style emoticons such as ":D", ":)" could explain why emoticons were not directly used as much. The chat-style emoticons are quicker to create and users are already familiar with them.

Attitude Towards Text Chat and Other Social Interaction Features

In the final survey, participants were asked if they liked the social interaction mechanisms that CollaboraTV offered such as text comments, emoticons and interest points. More than half the participants agreed or strongly agreed that CollaboraTV is fun to use (m=3.57, sd=0.65), while 71% agreed or strongly agreed that the system is easy to use (m=3.71, sd=0.73). Participants for the most part (57.1%) had no trouble learning to use the system (m=3.64, sd=0.84). When asked if the system was useful to them, 85.7% responded affirmatively (m=3, sd=0.55), saying in 78.5% of the cases that it supported what they wanted to do to a large extent (m=3.07, sd=0.73).

Participants liked the movie theater seating effect of avatars and expressed the desire for interactions between proximately seated avatars. They were not very enthusiastic about the possibility of customizing their avatars.

Figure 5. Evaluation of CollaboraTV's social features by participants, on a 1 to 5 Likert-scale



We asked participants to evaluate each of the social interaction features on the dimensions of how fun and easy they were to use. Given that viewing annotations made by others via their avatars may be considered as distracting, we also asked users if this was the case in their experiences with CollaboraTV. Figure 5 shows the responses of participants.

Note that viewing an interest graph or joining a buddy in viewing a show are activities with no direct external factors vying for the users immediate attention, unlike animated avatars. In the particular scenario of the distractions caused by chatting and viewing others comments, 64% of participants were ambivalent about creating text comments, responding with a 'neither agree or disagree' while close to half were undecided about their attitude towards viewing others comments while viewing television. Likewise, 50% of the participants were undecided about how distracting the virtual audience as a whole was. This is despite the fact that more than half the users found chatting to be a fun activity. This confirms what researchers have reported in the past about chatting while consuming video being fun as well as distracting simultaneously (Weisz 2007). To accommodate such users, it would be worthwhile to investigate alternative visualization schemes, in particular ones with smaller visual footprints. These could be offered as alternative visualization modes in a future CollaboraTV version.

Overall Activity Level

CollaboraTV had a collection of close to 600 episodes from 37 shows in 17 popular genres during the study, which were updated based on requests from participants. Despite this large and flexible selection, the positive survey responses/ general feedback to the social features, CollaboraTV experienced only low to moderate levels of activity. On average, participants viewed 4 shows and created 14 annotations. Several factors could be used to explain this paradox. One obvious reason could be the lack of critical mass. As one characteristic participant said: "very few people [online]; the more people and friends there are the better the experience". We could solve this by providing users a robust invitation mechanism.

A reason for low number of annotations could be the common habit of viewers carrying out some other task in parallel to watching television. 68% (m=3.75, sd=0.93) admitted to normally doing something else along with watching television, explaining that they seldom solely watch television. Another reason could be the current input modalities of CollaboraTV, where users are expected to use their keyboard to make annotations. We discuss alternate unobtrusive temporal annotations that could remedy this in our 'Future Work'.

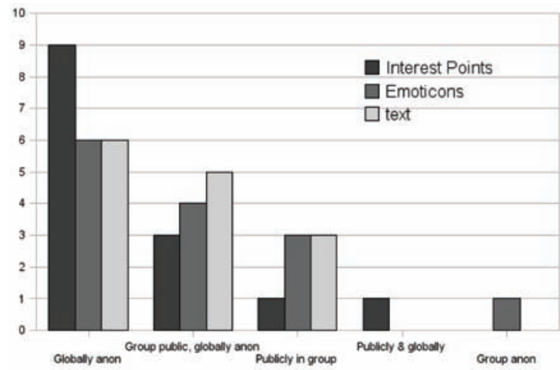
In the pre-study survey, 4 participants had indicated a preference to watch television alone, as they felt watching with others was distracting. At the end of study, we checked to see if their opinion had changed as a result of using a social television system first hand. 3 of these 4 users, who had earlier strongly agreed that watching programs with others is distracting, admitted that the virtual audience was not distracting while watching a show. All 4 were ambivalent when judging if the CollaboraTV experience with its virtual audience was more engaging and enjoyable compared to traditional TV. Finally, one of the 4 now strongly agreed that the ability to join shows and watch in parallel with other users with a virtual audience is compelling. These changes in opinion, though minor, serve as encouragement to us.

On the whole, over half of the participants agreed (m=3.21, sd=0.89) that when compared to traditional TV, the experience of viewing in the company of a virtual audience is more engaging and enjoyable. Also, participants said the ability to join shows and watch in parallel with other users was compelling (m=3.29, sd=0.83). In both cases, 35.7% agreed or strongly agreed.

RQ2. How well does CollaboraTV support the task of asynchronous television viewing? The asynchronous viewing capability of CollaboraTV is meant to help preserve interactions like the "water cooler conversations" that build social capital. But before studying the utility of this capability, we wanted to learn if participants valued "water cooler conversations". We verified this by asking users questions regarding the social role of television in their day-to-day lives. 75% (m=4, sd=0.73) strongly agreed that watching the same programs as friends or family provided them with common ground for conversations. Additionally in 19% (m=2.75, sd=0.86) of the cases they explained that watching programs that elicit strong emotions with friends or family brings them closer together.

Next we asked participants how frequently they (a) used conversations about programs/films as conversation starters (b) used examples from programs/films to illustrate points in conversations with others, (c) used conversations about programs/films as a way to clarify values and opinions to others. In response 37.5% (m=2.69, sd=1.2) admitted to (a), 37.5% (m=2.69, sd=1.2) said they often employed (b) and 18.8% (m=2.44, sd=1.03) said they clarified their values as in (c).

Figure 6. User preferences for sharing of different types of annotations



Sharing and Privacy

Any system that encourages social interaction in the form users sharing their annotations would have to address the privacy concerns of users. In CollaboraTV, the privacy of all annotation types - comments, interest points and emoticons - is handled in the same manner. At the onset, it was unclear if users placed different levels of sensitivity on these items. In the final survey, users were asked how they would prefer their different annotations to be shared. The results in Figure 6 indicate that users generally consider comments and emoticons to be more personal than interest points. When queried about the granularity of control desired in sharing comments, 57% preferred a global program setting that applies to all shows. Show or episode level granularity did not appeal to participants.

The most striking observation however, is that participants favor anonymously sharing their annotations globally, irrespective of the type of annotation, versus any other scheme of sharing. They even prefer to share annotations anonymously, over publicly sharing within their friend group. A strong bias towards anonymous sharing schemes is visible in Figure 6. However, this is not a blind bias, as participants also seem to care about sharing their comments with as many people as possible This can be seen in their preference of the ‘anonymous global’ scheme over the ‘publicly within group, anonymously globally’ scheme or even the ‘anonymously within group only’ which would seem the most conservative of the schemes. Participants seem to desire striking a balance between their privacy and benefit to others, by wanting to enrich the viewing experiences of others with their anonymous comments. The willingness of users to consider the social good and share bodes well for a system such as ours.

RQ3. Can friend networks present in social television systems be leveraged to help users choose what to watch? At the start of our study we had asked participants questions about how they plan (if at all) what they watched on television. 55% strongly disagreed when asked if they planned ahead on what to watch (m=2.63, sd=1.15). While users claimed to tune in to watch a specific show often (62%, m=3.63, sd=1.02), they also still explained that they watched programs/ films when it is convenient, rather than to see something specific for the majority of the time (56%, m=3.38, sd=0.96).

So when users do find a convenient time to watch some television in general, how do they decide on what to watch? Participants said that they mostly browse channels until they find something interesting to watch (51%, m=3.38, sd=0.96). This reiterates the popularity of the ’channel surfing’ behavior as reported in previous research such as Taylor (2003) that studied how TV users select a show to watch. Based on these responses, and using the categorization described by Logan (1995), we found 25% of participants to be “watchers” or those who know exactly what they want to watch, and 50% to be “grazers” or those who generally channel surf.

Close to 90% of our participants watch only low to moderate amounts of television weekly. This minimal television viewing, coupled with the ad hoc “grazer” habits described earlier, could mean that users would likely not want to waste their precious viewing time channel surfing. CollaboraTV employs a simple, yet powerful method to help users select a show to watch quickly. Users can view two lists -- PopularShows(Buddies) and PopularShows(All) -- which are lists of shows that have been recently viewed by buddies or all system users respectively. The idea here is that when users are having trouble deciding which show to watch, they can turn to what their like-minded friends have been watching recently, or optionally pick a show that a lot of system users seem to be watching lately. This show recommendation technique is based on the theory of social influences.

We asked participants if their viewing choices were influenced by those around them. More than half the participants said that they watched video content recommended by family, friends or colleagues (m=3.19, sd=0.75). Further, a fair number of them admitted to having watched content that others had been talking about or were the current media buzz (m=2.9, sd=0.57). These responses give credence to our recommendation technique.

At the end of the study, we asked users if they found the PopularShow() lists useful. 57% (m=3.71, sd=0.73) strongly agreed that the ability to see what others in their buddy group have been watching i.e. PopularShows(Buddies), was useful. In contrast, only 42% found the PopularShows(All) list useful. Despite responding positively towards the utility of the PopularShow() lists, observing our usage logs revealed low usage in terms of users actually clicking on shows in these two lists. This could be because the lists are not very accessible in their current location inside the program guide. To make the recommendation method using these lists more effective, future versions of CollaboraTV will have a splash screen similar to those found in popular social networking site. Recent activity traces of buddies will be displayed, which in turn would encourage users to explore and interact more with the system. 62% of participants also said that they already share video content today(e.g. by sending a friend a link to a website). Such explicit behavior will also be supported allowing users to send and receive show recommendations.

As another approach to solving the show selection problem, we can use interest profile data for collaborative filtering based recommendation. Most contemporary systems rely on an overall rating (e.g. two thumbs up, five stars). Interest profiles, on the other hand, provide essentially a scene-level granularity. For some content, even finer grained feedback may be available, for example, the individual jokes and gags in a sitcom. With this level of detail and personalization (e.g. user liked this joke, but not this one), the accuracy of recommendations could be exceptional.

DISCUSSION AND FUTURE WORK

In our studies, we have taken a first step towards creating social television systems that support both synchronous and asynchronous viewing modes. Further, we have demonstrated the importance and utility of a rich set of communication primitives in recreating the social experience of viewing television with others, while also illustrating the value of receiving recommendations implicitly from other users of the system. We now discuss the future implications of our work.

Alternate Temporal Annotations

To provide us with future direction, we asked study participants to consider 3 alternative annotation categories (1) illustrations, where users could draw something on the screen, (2) audio, where users could record short voice annotations, and (3) video, where users could attach a video clip of themselves. 52% voted for voice-based annotations, while 32% showed interest in option (1). Video annotations did not seem to resonate with respondents, which could be due to the overhead of maintaining a presentable countenance while watching television and loss of privacy in general.

Integration with Social Networking Sites

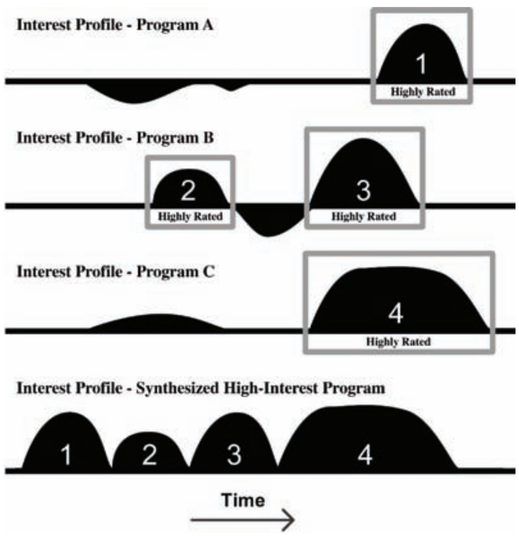
In answering RQ3, we explored the potential of exploiting buddy networks within CollaboraTV for the purpose of making implicit show recommendations. The next logical step would be to tie CollaboraTV to popular social networking websites such as Facebook or MySpace that have open APIs for developers. We are currently working on a Social EPG which integrates a social network, recommender engine, and social usage data into an EPG. It can display a visualization of shows that a user has been watching recently, allowing their buddies to discuss the show or even follow a link back to CollaboraTV to view a show that everyone is talking about.

Show Highlights

Interest profiles can be used in several powerful ways. We are currently working on features that exploit this social usage data. One application for the data is an interest-based media seek feature. Most media navigation controls provide the ability to skip forward and backward using a fixed-time step. However, by taking advantage of interest profile data, it is possible to provide a skip feature that advanced users to the next section that was highly rated by previous viewers. Consider if this feature was available for a soccer game. The portions of high interest (as rated by previous users) are likely to be intense periods of game play, shots on goal, and actual goals. Using the interest-based seek feature, one could progressively advance through the game, seeing only the most highly rated sections.

Another example is a feature that collapses programming down to a fixed time. For example, a user could ask the system to collapse a baseball game down to only the most exciting (i.e. highly

Figure 7. Highly rated sections from three programs are identified and synthesized into a new program.



rated) hits. This would be achieved by identifying the highest rated sections of the game, removing these clips, and then reassembling them into a new (and shorter) program. This feature could also be applied to a genre of programs, for example, news, where the most highly rated stories and interviews of the day would be pulled out and synthesized into a custom news program (Figure 7).

Show Recommenders

From our survey, 64% of users were willing to share their annotations with a show recommendation system (m=3.57, sd=1.28) to receive personal recommendations, while 57% were comfortable with sharing their annotations for the purpose of providing recommendations to other system users. Because this implicitly collected data provides a rich representation of a user's experience while watching video, we are exploring recommendation techniques based on user annotations. Implicit user feedback in the form of annotations can be used as a good substitute for explicit ratings. Such a method would do away with the issue of scarcity of ratings that many collaborative filtering-based recommender systems face and hopefully provide additional data to help in forming better user clusters for generating recommendations.

Limitations and Learnings

While having a set of participants who are geographically spread across the world provided an ideal setup for testing CollaboraTV, this was not without its shortcomings. Delivering instructions via email and following up with participants who we cannot meet face-to-face can be quite challenging. We believe that it would be more fruitful to have a set of users who we can meet in person at the beginning and the end of the period of study to learn first hand about their experiences with the system. Online surveys lack the ability to explore serendipitous questions and conversations that are possible with meetings.

We chose an open ended model of running our experiment to observe realistic interactions and use cases that are hard to capture in manufactured lab settings. However, we came to realize that in order to study interesting user behaviors (e.g. synchronous and asynchronous modes of communication), we would have to engage with participants with specific tasks geared towards these behaviors. It is important to balance the freedom of using the system as one wishes with specific tasks and events.

CONCLUSION

CollaboraTV allows people to interact in a synchronous, asynchronous, and mixed television-viewing situation. This unique ability offers users an unparalleled way to communicate, and ultimately reconnect with friends, family and colleagues. The lab study and comprehensive field study have yielded results that show the virtual audience was successful in engaging users and humanizing people who were remote or teletemporal. Users are enthusiastic about asynchronous communication and found value in receiving implicit show recommendations from their friends. Overall, we believe CollaboraTV achieves our goal of bringing people closer together, making the ever present "electronic hearth" social again.

Chapter 3.5
Examining the Roles of Mobility in Social TV

Konstantinos Chorianopoulos
Ionian University, Greece

ABSTRACT

Mobile TVs have been available for many years, without ever becoming very popular. Moreover, the first wave of research has been mostly concerned with technology and standards, which are necessary to ensure interoperability and market acceptance. Although, there has been a significant body of computer supported co-operative work (CSCW) and mobile human-computer interaction (HCI) research findings, there is limited investigation in the context of leisure activities, such as TV. In this chapter, the author proposes three concepts that drive the main paths for research and practice in mobile and social TV: (1) Mobile TV as a content format, (2) Mobile TV as user behavior and (3) Mobile TV as interaction terminal. Further research should elaborate on these three concepts and highlight the cultural impact of mobile TV.

DOI: 10.4018/978-1-60566-656-3.ch014

INTRODUCTION

One explanation for the slow diffusion of interactive TV (ITV) in the information society is that the difference between the broadcast and the telecommunications mentality has imposed an artificial distinction between content distribution and interpersonal communication. As a result, content has to be distributed and consumed through broadband, unidirectional and inflexible TV channels and interpersonal communication takes place over low-bandwidth bidirectional channels. However, the convergence of the telecommunication and content distribution platforms could be beneficial for viewers, as well as the commercial TV stakeholders. In addition, new devices and new types of content facilitate the emergence of novel consumer behaviors. In this article, we explore the interplay of these three concepts (device, content, behavior) in the context of mobile and social TV

TV content gradually finds its way through Internet and mobile platforms. Besides triple-play services, which offer integrated access to voice, content and data services, there are opportunities for new services enabled by the mobile infrastructure. Indeed, the convergence of broadcast, mobile and data platforms has offered many opportunities for integrated content and communication services, which we refer to as 'Social TV'. We define social TV as a socio-technical system that involves more than one user and networked audiovisual devices.

Previous definitions were focused only on the technological aspects and ignored the fact that even traditional TV is inherently social. For example, viewers compete mentally with quiz show participants, or between co-located groups. Moreover, viewers react emotionally to TV content, they record and share TV content with friends and discuss about shows either in real-time, or afterwards. In this context, it is necessary to not only pay attention to usability issues, but also to sociability. Indeed, ethnographic and survey studies have documented the social uses of TV (Duchenaut et al 2008, Lee and Lee 1995), but they have not described the user requirements of applications that facilitate the social uses of TV. For this purpose, we explore the related academic literature, we identify the user interface requirements of those computer mediated communication applications that enhance the social dimension of TV.

The rest of the article is structured as follows. We begin with an analysis of the social uses of mobile TV. In Section 3, we outline the multiple roles of mobility in Social TV. Finally, we describe the implication of such systems for practice and future research.

SOCIAL AND TECHNOLOGICAL ASPECTS OF MOBILE TV

This section explores the social and technological dimensions of TV and other related audiovisual media. In addition, we present a brief overview of technological support for TV sociability.

Social Value of TV

Although TV has been blamed for the reduction of social interaction within the family and the local community, there is a significant body of previous research that considers TV as a social medium, because it provides opportunities for shared experiences and group viewing. In particular, mobile phone applications that support sociability within families or distant groups might enhance the attractiveness of ITV as a leisure activity. This section draws on interdisciplinary literature and empirical research in order to raise the main research issues of the multiple roles of mobility within Social TV.

Despite the many criticisms on the quality of TV content and on the passive nature of the watching activity, the social uses of TV have been documented in acclaimed research (Gauntlett and Hill 1999, Kubey and Csikszentmihalyi 1990). It has also been established that viewers have adapted TV in many ways to meet their everyday life needs (Lee and Lee 1995, Rubin 1983). The findings of these works frame a set of opportunities for the design of social communication services in mobile TV.

The majority of previous research on ITV has over-emphasized the benefit of increased choice of content and of the interactivity with content. Instead, a worthwhile effort would be the fulfillment of seamless communication over, or about televised content. Such services could support human connectedness (Agamanolis 2006) over a distance (e.g. synchronous communication over a TV program between diasporic households), or enhancement of the shared experience that comes with TV co-viewing. For this reason, we explore an integrated view of the interpersonal communication together with the shared experience of mass communication.

There is a growing academic interest on Social TV systems, which consist of technological solutions for integrated interpersonal communication and content distribution. Although, there has been a significant body of computer supported co-operative work (CSCW) research on supporting interaction among geographically distributed co-workers, there is limited investigation in the context of leisure activities, such as TV. Similarly, research on interpersonal communication in the human-computer interaction (HCI) field has regarded video-mediated communication at work (Veinott et al. 1999). As a matter of fact, there is not much knowledge on designing applications for leisure or informal content enriched communication.

Cross Media Infrastructure

In the past, TV content in the living room has been provided either by broadcast, or optical discs. A basic ITV system includes a set-top box (STB) that decodes the signal and provides processing and storage capabilities that enable interactive applications. Nevertheless, the disagreement on a common open middleware platform has been an obstacle for the development of sophisticated interactive applications that are independent from the STB hardware. On the other hand, there is agreement over the specifications for the digital video broadcasting (DVB-S/C/T/H specifications satellite, cable, terrestrial, mobile). Furthermore, TV content can be efficiently distributed over peer-to-peer (P2P) networks. In this way, the variety of video content has been increasing with the support of new internet technologies, which allow new ways of distributing video (e.g. broadband connected TV set-top-boxes). Thus, ITV applications are neither limited to the traditional TV device and broadcast delivery, nor to the typical channels of satellite, cable, and digital terrestrial networks. Alternative and complementary devices and distribution methods should be considered, such as mobile phones (mobile DTV).

Social TV builds upon the convergence between different technological infrastructure, such as broadcasting, telecommunication, and internet. The convergence has been realized in different forms. On the one hand, Internet content may be accessed through television web browsers, or linked to ITV programs (e.g. interactive advertisements). Communication applications such as messaging, chatting, or voting during certain programs (quizzes, contests etc.) strengthen viewer's loyalty to the specific program. However, Internet access via television may disrupt current viewing patterns. Besides user interaction, at the network-level, internet connection facilitates video transfer over P2P networks. Moreover, the distribution of TV content over IP-based platforms, known as IPTV (Internet protocol TV), provides additional opportunities for the delivery of a wide variety of TV programming. In addition, 3G mobile networks could be used to distribute and control TV content.

Related Research in the HCI and CSCW Fields

One of the first approaches for a closer integration between TV content and social communication was the "Inhabited TV" research effort (Craven et al. 2000), which developed a collaborative virtual environment, where viewers could interact with other viewers or virtual objects. In this case, viewers were watching TV within the virtual environment and not within physical space. Thus, the TV experience was extended by enabling social interaction among participants and increased interaction with content. In an Inhabited TV application, the television becomes an actor and a part of a group interaction within a virtual online world.

There are various approaches to integrate social communication features into TV, such as chat, IM and email. There has been particular commercial interest on integrating the SMS into TV. Indeed, SMS TV is very popular, which is based on the familiarity with SMS and the availability of the technical infrastructure. Besides SMS services, there is a growing body of research and development, which is presented next.

Coppens et al. (2005) have reported the development of a 'Social TV' system, but their description focuses on the technical details, the features and the potential of the system for end-users. The 'Amigo TV' system provides a technological platform for integrating content delivery, communities, and interpersonal communication (Coppens et al. 2005). In addition, the content of the broadcasts can be personalized by sharing personal photos and home videos. Amigo TV supports online user meetings and buddy lists. Interpersonal communication is based on voice, text, and video formats, as well as animated avatars.

Regan & Todd (2004) describe a system for messaging over TV content. The Media Centre Buddies system integrated TV technology into an instant messaging application. The main aim was to allow multiple users to log into an instant messaging client that was running next to a TV channel.

User Generated and Distributed Content

TV content production has been regarded as a one-way activity that begins with the professional TV producers and editors and ends with post-production at the broadcast station.

As a matter of fact, television viewers have long been considered passive receivers of content, but a new generation of computer literate TV viewers has been accustomed to make and share edits of video content online. Furthermore, the wide-availability of video capture (e.g. in mobile phones, photo cameras) and easy-to-use video editing software (standard in many desktop computer operating systems), opens up additional opportunities for wider distribution of home made content (e.g. through peer-to-peer, portable video players, etc). User generated content and social communication about media content has been also proposed by Resnick (2001), who suggested that interactions could create productive resources, which he refers to as socio-technical capital. This capital may consist of artifacts created from the interactions or relationships and practices developed through repeated social interactions. Such capital can enable future social interactions.

Mobile media players transform the traditionally solitary media consumption into a social experience. Mobile and wireless technology open up opportunities for new interesting social practices, where media consumption and sharing can take place in a variety of social, physical and temporal contexts. Advanced mobile phones are equipped with digital cameras, multimedia processing and multiple mobile communication technologies (such as short or long-range, low or high-bandwidth). Since a mobile phone remains constantly with the user, it could potential store a large amount of details about social interactions. Then, search and sharing of media content could benefit from this social dimension of smart phones: the user could share audiovisual content with those related (in terms of place or terms of social proximity) without investing effort on selecting these people. TunA (Agamanolis 2006) is one example of a mobile application where users can tune in to eavesdrop on the playlists of nearby users and listen to the same music in a synchronized way.

Content Enriched Interpersonal Communication

Social TV systems offer one or more computer mediated communication features, which are closely integrated with the TV watching experience. Computer mediated interpersonal communication over distance, or over time could employ various communication modalities such as: (1) audio, (2) text, (3) video, (4), photos and (5) non-verbal cues (e.g. emoticons, avatars). We refer to integrated content and communication services as 'content enriched communication.' Content enriched communication over a distance refers to two types of sociability: (1) synchronous, when viewers get together and watch the same show at the same time and (2) asynchronous, when viewers interact after the show has already been seen by each one, independently and at different times. Communication between spectators is realized at two levels: (1) direct communication, such as chat or instant messaging and (2) indirect communication, such as cooperating in a team to win a quiz. In brief, there are four basic scenarios of Social TV (Chorianopoulos and Lekakos 2008):

- **Synchronous viewing over a distance:** This is probably the most interesting scenario, because the requirement it poses is to recreate the experience of co-located group viewing, when the viewers are located in two or more distant places. For example, distant viewers should be able to watch together popular social TV content, such as sports, quiz shows, series, reality shows. A good starting point is to consider ways to disclose presence and status of viewers, to continue with support for multiple interpersonal communication modalities (non-verbal most notably), and to summarize the social experience with automated highlight production, which could motivate further discussion and social bonding between the distant viewers.
- **Asynchronous viewing over a distance:** This a feasible scenario if we consider that distance viewers might have very different time-schedules, patterns of daily life activities, or even live in distant time zones. Then, the probability of synchronous co-viewing is rather limited. In this case, a Social TV system could record and share shows and viewing habits with the members of the social circle. In addition, a Social TV system should allow annotation of content and recording of interactions, such as pausing, skipping, replaying and content browsing. In this way, each time a particular TV program is accessed keeps a trace, which is exploited at the next access, in order to personalize the content and most notably to provide a motivation for asynchronous communication. This could be rather subtle, such as visual annotation of the content highlights, or could be more explicit such as audio and text comments.
- **Asynchronous viewing at the same place:** The main motivation for the development of Social TV systems is based on the need to bridge the distance between social circles of people, but there is also the case that co-located groups of people do not manage to meet as often as they wish for a social TV night. A subset of the functionality that was described in the previous case might be the most appropriate here.
- In addition to the above, Social TV designers should consider the traditional TV watching scenario, where a group of viewers gathers in the same place to enjoy a favorite TV program. Although this is a case that content enriched communication is least needed, there might worthwhile benefits in employing a Social TV system. In all cases, designers should consider extended functionality for user generated content. For example, the ability to upload personal music, photos and videos might be used to achieve communication through content. In particular, the automated production of personal TV channels that keep track of individual life streams captured with a mobile device (e.g. music, photos, personal videos) could be multiplexed with broadcast TV watching behavior. Indeed,

> Kubey and Csikszentmihalyi (1990) have found that everyday life experience is correlated with TV watching behavior. Thus, interpersonal communication could start with a screen displaying media use of each party during the past few days or hours. In practice, this scenario is rather feasible to implement, because the respective services have been very popular (e.g. YouTube, MySpace, Flickr)

Although mobile and social TV is thought to be suitable for the distant and synchronous communication scenario, there are several other opportunities. For example, multiple mobile terminals could be employed at the same place to control content on a shared big-screen. Moreover, user generated mobile TV content could be posted online and latter-on be annotated by other mobile TV users, when triggered by a particular location or other condition.

MULTIPLE ROLES OF MOBILITY

In this section, we propose three main directions of mobile TV research, and we offer suggestions for future research and market developments. Besides TV watching on-the-move, mobile TV has significant potential, both as a personal TV set and as a tool to establish a closer interaction with the television programs (e.g., TV voting).

Mobile TV as a Content Format

Digital mobile TV systems have been designed to complement mobile networks with broadcast and multicast capabilities for spectrum-efficient delivery of multimedia services on mobile devices in both outdoor and indoor environments. In particular, the DVB-H standard is based on the widely deployed series of DVB standards (DVB-S/C/T) and includes enhancements for mobile terminals, such as reduced power consumption and reception while on the move. Although the technical standards are suitable for mobile TV reception, it is clear that mobile TV prospects should be examined not as an alternative but as a complementary service to traditional living-room TV. This is because the perceived quality of TV on a mobile phone and the solitary experience are not the favored mode of watching TV, at least with regard to popular living-room content formats (e.g. TV series, sports).

For some time television has been the only major media format that has been missing from mobile phones. Technological advancements in wireless broadband (e.g. WiFi, 3G, 4G, DVB-H) and multimedia mobile terminals (e.g. multimedia mobile phones) have made a reality the reception of digital TV on the move. The distribution of TV content to mobile devices over broadband wireless raises the issue of video quality. Video quality depends on many aspects of the video encoding systems, such as bit rate and algorithms that model human perception of video on small screens. Most of the research on the effect of screen sizes in the field of consumer electronics has examined the impact of increasing the image size in the viewer's visual field by means of large physical displays or projection areas. The results show that larger image sizes are more arousing, better remembered, and generally preferred to smaller ones (Reeves et al. 1999).

There are many services that aim to provide users with audiovisual content while on the move. Although many of these services sound appealing, the end-users' subjectively perceived quality is an important factor for their success. The properties of video quality have many similarities between the different application domains (e.g. internet, broadcast), but the characteristics of mobile devices define a special set of constrains. The biggest differences to other application domains are the limited bandwidth, which leads to high-level requirements of compression and the limitations of the mobile devices such as display size, power resources, processing capabilities and memory. In addition, the wireless transmission of the content is error prone. Accordingly, the production of video under these special requirements should regard the possible distortions in the subjectively perceived quality (Knoche et al 2008). For this reason, subjective quality evaluation tests during product development are necessary, in order to ensure acceptable quality of service. In particular, the subjective quality of service for mobile TV depends on the perceived audio-visual quality of the consumed content and the interaction through which the user has to go to access it (e.g. the delay between selecting content and start of play).

Further research in mobile TV should investigate authoring tools that enable automatic post-production of video that is targeted for viewing on the move. Currently, mobile service providers encode and deliver existing broadcast material and interactive applications without additional editing, because it is more cost-effective than re-editing. Future research should improve on intelligent cropping mechanisms that present only a part of the original shot. On the application side, cross-media multimedia authoring tools should consider the diversity of screen formats and sizes in mobile devices. Besides content adaptation, further research should investigate the uses of user generated content and provide templates that facilitate creation and distribution (sharing) of end-user content.

Mobile TV as User Behavior

Early studies on user behavior and mobile TV systems have indicated short watching sessions (Södergård 2003), which are suitable for particular TV genres, such as news and sports highlights, and music videos. More recent research by the same group (VTT, Finland), has tracked the evolution of mobile TV usage (Oksman et al. 2007). They have identified that in mobile TV there is no prime time, only 'prime place', such as while commuting.

In contrast to living-room TV sets, which are shared displays for audiovisual content, mobile phones are natively social devices. Since their introduction, users have learned to use them as social connectivity tools, with voice-calls and text messages as basic functions. Therefore, the mobile TV user behavior might be shaped by established practices of interpersonal communications over a distance. Indeed, researchers have identified that for some users mobile TV might be a rather personal activity (Cui et al. 2007). In particular, they have identified that mobile TV is employed to privately watch content, at places and situations that are not socially appropriate for TV watching (e.g., business meeting, school lectures). They have also reported that mobile TV is also employed at home, when other TV sets are employed for different programs than the ones preferred by the mobile TV users.

Mobility means that content consumption takes place in various dynamic mobile contexts e.g. on the go, in the bus or at work, a direct contrast to the static embeddedness of living-room TV. Mobility thus means limited attention spans, but with increased user readiness for interruptions and interaction. Furthermore, mobile displays are considerably smaller than living-room screens. The consequence of these contextual factors is that static TV is superior in creating immersive, passive media experiences. Mobile TV might never be able to lull people in the same way as high definition television, but on the other hand it allows for more interactive and intimate experiences. Although there is a significant body of research on sharing content such as photos and music through desktop and mobile media, there is not much research on video sharing and content enriched communication through mobile devices (Schatz et al. 2007). Therefore, further research should consider the practices of sharing user generated video content.

Mobile TV as Interaction Terminal

Mobile phones include some kind of standard and familiar input and output facility. The most common input device on a mobile phone is a simple numeric keypad, a few function keys and navigation keys. In short, in terms of input capabilities, a mobile phone is very similar to a common TV remote control. Some contemporary phones have removed the numeric keypad in favor of a larger touch screen, which might dynamically render a numeric keypad or many any other input arrangements depending on the application. Moreover, mobile phones feature media rich output capabilities, such as full-color high-resolution (in comparison to size) screens and audio support. As a matter of fact, the output capabilities of contemporary mobile phones are equal or better to early TV sets. In addition to user input and output devices, mobile phones have several data networking capacities. Text messages are a common standard in mobile phones and they have been successfully exploited by TV channel operators as voting and chatting input devices.

The use of the input and output facilities of mobile phones as alternative communication channels for TV programs (e.g. voting, chatting, TV on the move) has been a straightforward and expected development. Cesar et al. (2007) has explored the use of mobile multimedia touch screens to augment the living room TV experience. They have demonstrated that besides remote control, personal mobile terminals could provide additional content, as well as annotation of content. Mobile TV broadcasts transmit content to all mobile terminals within the footprint of a base-station, which is relatively narrow when compared with terrestrial broadcasts. The presence of multiple base-stations is the main advantage of mobile broadcasting, because the content could be personalized to fit both the terminal and the context of use (e.g., time of the day, geographic location).

CONCLUSION

Mobile and Social TV applications could be feasibly offered through triple play infrastructures, which combine content delivery, voice, and data services. In this way, the network operator can provide interaction between the TV viewers on TV channels using an interactive broadband link. Triple-play services have been introduced on the assumption that telecommunication, content and data services could be delivered over the same technological infrastructure thanks to the convergence of the respective technological platforms. Although the convergence of previously distinct technological platforms is a significant benefit both for consumers and service providers, there are also additional benefits from a closer integration of platforms at the user-level. Content providers could be benefited by metered communication services, while telecom providers could be benefited by content distribution. In both cases, the users could gain access to intuitive content enriched communication.

In addition, mobile DTV infrastructure offers many opportunities for converged personal communication and content services. In particular, the availability of broadband wireless technology is rather suitable for the delivery of content enriched communication services (e.g. active content sharing, synchronous co-viewing or asynchronous notifications over a distance, discussion and annotations about shared content). Wireless network operators have invested in broadband licenses and infrastructures, but most of the services offered are only video communication, or only video on demand. The introduction of content enriched communication services is a worthwhile direction, because it offers an excellent balance between the basic need of users to communicate with a mobile device and the need of network providers for increased revenue by added value broadband services, such as mass media content distribution.

In summary, multimedia phones are essential elements of the next generation of Social TV services. They are established social connectivity providers, personal media interfaces, content capture and sharing tools, and thus complement stationary interactive TV setups very well. The proposition of mobile TV has a major difference with the analog predecessor. Most notably, it has the potential to offer localized and interactive programs and not just the same broadcasts as seen in living-room TV. In conclusion, while counter-intuitive to many, the activities that happen during television watching can be a very sociable. Therefore, the ultimate objective is to develop technological support and content for the social practices that surround mobile TV viewing, while retaining the centrality of TV as a leisure pursuit.

Chapter 3.6

From 2BeOn Results to New Media Challenges for Social (i)TV

Jorge Ferraz Abreu
University of Aveiro, Portugal

Pedro Almeida
University of Aveiro, Portugal

ABSTRACT

This chapter focuses on traditional and emergent challenges for the Social (i)TV area focusing on explaining the development and evaluation of one of the first Social iTV prototypes and looking at the challenges new media is introducing to this research field. The authors begin by explaining the conceptualization, development and evaluation process of the 2BeOn system and continue with the most important results from it's evaluation with a particular focus on the results that can be important when developing any Social iTV platform. In the last part of the chapter recent developments in the broadcast of TV and Audiovisual content, namely considering the Internet as a medium, are addressed. In this scope authors propose a categorization of emergent online distribution platforms along with a set of social activities users perform on those platforms. Taking in consideration some of the challenges surrounding the presented scenario the chapter ends with the conceptualization of UMCA, a system that could increase social interaction activities performed during the consumption of online AV/TV content.

SOCIAL (I)TV: PROGRESSES AND CHALLENGES

Interactive television platforms that promote services aimed to support socialization practices around TV viewing, acting as a kind of "social glue" (Light, 2004), are at the core of Social (i)TV research (Harboe, 2007). Despite the introduction of the first iTV systems with real time communication services being considerably recent, it is interesting to notice that a considerable amount of research as been done in this area. Since the year 2000, with AOLTV being the first commercial iTV system integrating an Instant Messaging service (Kawamoto, 2000), there have been a number of iTV conceptual models, prototypes and systems that enriched this concept adding user awareness in relation to what others are watching. This type of presence/information, besides enabling a feeling of togetherness, opens up several interaction possibilities among users of an established social network: a user can alert his buddies to something interesting that is on air or simply peep at what others are watching and start a conversation based on a common TV content, no matter their geographical location. In this context, numerous developments have emerged, such as: 2BeOn—University of Aveiro (Abreu, 2002); Reality IM—Accenture Labs (Chuah, 2002); Amigo TV—Alcatel (Coppens, 2004); Social TV—PARC (Kharif, 2005), Social Software - described by Coates (2005); ConnecTV—TNO (Boertjes, 2007); CollaboraTV—AT&T (Harrison, 2007); Find-A-Friend - University of Siegen (Heß, 2007); Living@room—CSP (Andrea, 2007).

However, even with this considerable number of prototypes, applications and related research, there are still a lot of open questions, being Social (i)TV far from a fully explored area. In the following sections, and based on the experience gained with the 2BeOn prototype, some answers to the following topics are addressed:

1. Considering the different sociability practices promoted by television viewing, what are the communication, presence and content sharing services for a suitable mediation of those activities in an iTV system?
2. As the interface design of a Social iTV application is a central piece to achieve its' proposes, what are the fundamental issues in this domain?
3. How to evaluate a Social iTV application in order to find out if there is a correlation between users' digital literacy and: (a) learning curve; (b) the suitability of the application to support and promote interaction between viewers allowing an increase of the communication frequency; (c) the users' wish to make use of such an application.

Taking into account the ever-increasing sociability practices that arise from the current use of AV (audiovisual) distribution platforms (for both PC and mobile based devices), this chapter also focuses on the techno-social context in which users are currently sharing AV content and interacting through it.

THE 2BEON SYSTEM

The 2BeOn system was conceptualized, prototyped and evaluated with one main goal: to support and promote interaction between viewers, enabling an increase of communication and sociability practices (Abreu, 2007). Users involved in the evaluation of the prototype were not restricted to members of an existent social network (e.g. friends or family members), since viewers that did not know each other but that were in tune with the same TV content were also considered.

As stated by Gray (1992) *"A very important part of the pleasure of television serials is to gossip about them the following day."* (Gauntlett, 1999, p.128). In this context and in parallel with its main goal, 2BeOn aims to capitalize the TV ability to induce conversations, strengthen sociability practices and enable a new form of TV enjoyment in a virtual, nevertheless collective, viewing environment.

Conceptualization Process

The conceptualization process of this application was based on a theoretical framework[1] (mainly centred on sciences and technologies of communication) in order to define a set of functional requirements needed to support viewers' social practices. These include commenting, criticizing or gossiping about TV content, in real time or after the broadcast (Dahlgren, 1995); warning someone of a TV program being broadcasted; or sharing AV content. At this stage of the development process, a central issue was the identification of these typical communication practices around TV content and the evidence of emergent transmedia and multitasking behaviours, like using PC mediated communication services while watching TV (Lafrance, 2005; Oumard, 2008).

Design Guide Principles

The aforementioned theoretical contextualization also reflected about behavioural aspects of viewers (the main users of the application); visualization patterns; and television's technical constraints, in order to supply relevant inputs to establish a suitable set of Design Guide Principles (DGP) for iTV interfaces. These DGPs (21 in total), which were applied in the development of the prototype, can be arranged in the following 3 categories based on their impact at:

- Functional level (based on behavioural factors, such as attention levels to the TV set, predisposition for interaction and social contexts of visualization).
- Graphic design.
- Interaction design.

Main Features

Awareness about user status and channel viewed is of great importance to enable a feeling of togetherness and to promote interaction between known viewers. The role of such presence mechanism is even more important in the current scenario of TV audience fragmentation and ever-increasing individual TV consumption. As sustained by Chuah (2002), this kind of information can have the ability to change the motivation for the selection of TV programs, it being based not only on their content but also on the social context surrounding it.

One necessary feature of these awareness systems is the possibility of guaranteeing users' privacy. When the user does not want others to be informed about the current TV channel he is watching, he can simply "block" that particular channel. In this situation the users' status changes automatically to "busy"—the same status when he is performing other tasks, like instant messaging, reading messages or managing his social network. The portability of personal information was also guaranteed allowing users to login in the application wherever they were.

The support of informal interaction between known users was based on 3 services:

1. ClipEmail used for sending short alerts
2. IM designed to support longer real time conversations[2]
3. TVPR (TV Program Recommendation).

Communication between unknown viewers and identification of matching telly profiles was also considered, since occasional conversations about TV also occur between unfamiliar people and affinities might emerge among unknown viewers sharing the same type of TV consumption. For these purposes a TVChat service (whereas chat rooms are in sync with TV zapping) was implemented and a search tool for matched television profiles was conceptualized.

These features have been grouped into 4 sections of the system:

- FriendsOn - buddy list and access to IM, ClipEmail, TVPR and Email services;
- MsgOn - management of incoming messages while offline or busy;
- ChannelsOn - management of channels and access to the TVChat service;
    - + FriendsOn - management of the social network.

The Development Process

Since the beginning of this research it became clear that it would be necessary to outline a strategy for demonstrating the sociability concept of the application to a group of pilot users, in order to try and test its functionality and interface approach and to determine its acceptability level. This is the global goal of a high-fidelity prototype (Chorianopoulos, 2004).

The prototype development was carried out based both on a functional and a technical dimension (Strauss, 1997), targeted at fulfilling the identified functional requirements.

The functional dimension comprised the design of the graphical and interaction user interface, which was assisted by the achieved set of DGPs (based on behavioural, technical and usability factors) and interaction storyboards. The main communication strategies, choice of colours, fonts, iconography, spatial distribution and other graphical elements of the interface were also defined at this stage.

Some of the solutions that were applied, based on a sample of DGPs, are shortly described here, since they can be of value for the development

Figure 2. automatic dimensioning of the IM interface: normal size (left) / expanded field text (right).

of other iTV applications (for details please see Figure 1 and Figure 2).

Considering DGPs with impact at the functional level, it is necessary that the application is set to:

- *Different levels of users' attention to TV program*—it is important to consider the situations in which the user, consciously or not, reduces its level of attention to television programs. Adopted solutions:
    a. sound alerts were incorporated to catch the user's attention to special events.
    b. based on the user's typing frequency, when using the IM service, the interface (with an embedded layout) is dynamically dimensioned. This way, as the typing frequency increases, the text field expands and the TV area shrinks and vice-versa.
- *Predisposition for interaction*—the application must be designed so that users don't feel forced to interact and perform tasks (Peng, C., 2002) allowing the interaction to occur only when wanted. Adopted solutions:
    a. any communication by instant messaging is preceded by an invitation. Thus, the user can easily refuse the beginning of an interaction.
    b. if the user does not login he can watch regular TV, that is, without any interactivity. If logged on he can define himself as being offline, simply by pressing a dedicated key on the remote.
- *Different social contexts of visualization (individual or in group)*—in a situation where the user is not alone in the room there are several factors to consider. It is required to ensure privacy (for example, preventing that messages addressed to him are viewed by all) and it is also required that his interactions do not mix with other elements being watched. Regan (2004) also addressed this problem from another perspective. Adopted solutions:
    a. a family/group account was implemented so that the user can login with a contact list based on people known to all elements of the group.
    b. conceptualized, yet not fully implemented, was a feature that allowed the user to choose to have his messages directly displayed on the TV set or, for example, to be redirected to his mobile phone. This solution fits in the secondary screen approach, which has been used in a number of different iTV prototypes, more than a decade ago, as described by Cesar (2008).

Regarding some of the DGPs that influence graphic design, the interface must be designed in order to:

- *Avoid irrelevant information*—given the limitation on the amount of information that can be displayed on a standard definition TV set, it is advisable to limit the maximum number of selectable icons that are available at the same time on the screen. Adopted solutions:
    a. limitation of the number of icons in each screen to a maximum of 4, which also allowed to trigger them through the chromatic shortcuts of the remote.
    b. use of colour codes to differentiate users status (online and offline) and privacy of channels (active and blocked channels).
- *Give primacy to television programs*—it is essential to preserve, as much as possible, the integrity of television content in order to guarantee traditional television experience. Thus, the interface must be designed and positioned to obstruct as less television images as possible. Adopted solutions:

a. positioning of the logo and interaction menus in the right upper corner of the screen.
b. vertical placement of menus.
c. use of overlaid and embedded interface layouts.
d. automatic scalability of the IM interface.

Finally, there are DGPs with impact at the interaction design level, pointing out that the application needs to fit to:

- *User interaction adapted to television*—it is not accurate to assume that users of iTV platforms have high digital literacy, so interaction with TV should avoid typical PC navigation/interaction patterns, like drop-down menus and vertical scroll of pages (Gawlinski, 2003). Adopted solutions: The initial purpose of using a remote control acting like a mouse was quickly abandoned and replaced with:
  a. chromatic keys—shortcut buttons to activate screen icons matching the same colour.
  b. standard orthogonal cursor—the selection area activates, for a brief period of 2 seconds, on screen labels linked to each icon.
  c. reserved keys for some special features.
- *Optimization of the navigation experience*—by reducing the number of steps needed to perform a particular action and keeping the response time below one second. Adopted solutions:
  a. prediction and anticipation of the next interaction.
  b. automatic sorting of contacts and channels lists, based on the frequency of communication with each of the contacts and viewed channels.

As far as the technical dimension is concerned (which addresses the design of the hardware and software architecture that supports the required features), its development was assisted by block diagrams of the architectural modules and flowcharts correlated with the interaction storyboards. The prototype was not based on a commercial middleware; instead, Macromedia Director was used with PC clients (running as Set Top Boxes) connected to regular TV sets via VGA to PAL adaptors. Two components or plug-ins were essential: BuddyAPI (which allowed the control of the TV tuner application) and WinShapper (used for the definition of transparent areas supporting both overlaid and embedded interfaces). For more details on other technical solutions please refer to Abreu (2002).

The Evaluation Process

At the time the 2BeOn prototype was developed, published iTV evaluation methodologies were very scarce and mainly based on traditional usability engineering concepts and methods (Chorianopoulos, 2004). With the growing number of available Social iTV solutions, there is an increasing need to understand how these systems should be evaluated, both from a technical point of view and HCI and Social Sciences perspectives. In this scope and despite current publications like Chorianopoulos (2006) it is believed that the methodology used for the evaluation of 2BeOn can still be a relevant contribution to this area.

The goal of the 2BeOn evaluation phase went beyond simple usability tests. Actually, it was aimed to enable regular users with an adequate level of hands on experience with the system, so that it would be possible to extract a wide set of results. This purpose meant, therefore, a set of 3 goals that the evaluation was intended to attain, namely:

1. Validate the usability of the prototype, to check if the various functional solutions were

suitable and if they ensured a straightforward use of the system. This goal was mainly centred on the verification of the proper operation of the DGPs in order to analyse potential correlations between demonstrations of dissatisfaction from evaluators and technical implementation errors.
2. Evaluate the conceptual model of the system and the suitability of its functional solutions. This second goal implied the validation of the various hypotheses that sustained the main functional requirements. It also aimed to identify the user's level of interest regarding future use of such an application.
3. Synthesise a number of opinions and suggestions, raised by the use of the prototype, to enable future improvements.

Considering these goals, the evaluation process was structured in three distinctive, but complementary, phases (each with its purpose, method and tools)—see Table 1 and Figure 3.

Evaluation Results

1st Goal: Usability of the Prototype

The validation of proper use of the DGPs was made from the analysis of results gathered by different combinations of the aforementioned instruments (tools) for data collection. Exemplifying, the solutions adopted to face *different levels of users' attention to TV programs* were verified by two questions on the final questionnaire, one in the interview and through the observation tables.

Only two minor problems related with two DGPs were detected. These are here described to show their importance on the usability of the prototype. They regard the solutions adopted to:

- Face different levels of users' attention to TV program—the volume of the sound alert linked with the incoming messages was to low, so some of the received messages were not immediately detected.
- Guarantee the consistency of the interface—a mismatch in the colour of the exit icon in two services resulted in an inconsistency and consequently in some interaction errors.

Correlation Between Users' Digital Literacy and the Usability/Learning Curve

Considering the mean time spent by each group at each of the 3 evaluation sessions and the mean number of uses of the "back" key, it was possible to observe: (Figure 4)

- An evidence of a correlation between digital literacy and ease of use in a first contact with the prototype (users of the EXP group took less time).
- A stabilization of the learning curve as sessions progress - evaluators with different levels of digital literacy tend to have, after some practice, identical levels of ease of use of the prototype.

2nd Goal: (a) Validation of the System's Conceptual Model

Based mainly on the analysis of the final questionnaire and the interview it was possible to conclude that all the research hypotheses that sustained the main functional requirements proved to be valid.

2nd Goal: (b) Achievement of the Main Objective

This refers to the evaluation of the suitability of the application's features in supporting and promoting interaction between viewers, enabling an increase of communication and sociability practices. It was

Table 1. Evaluation process

Phase 1	
Purpose:	to characterize a broad range of potential users (TV viewing habits and dynamics of communication around television) enabling the selection of three groups of non-expert evaluators with different levels of digital literacy. This allowed the application of a causal-comparative methodology with a non-probabilistic sample.
Method:	quantitative and qualitative analysis of the gathered data.
Tools:	questionnaire, enabling the selection of 3 groups of 5 evaluators with the following levels of digital literacy: low (first year students attending the course of Pre-School Teachers) - EdI; average (2nd year students attending the course of New Communication Technologies) - NTC; high (professionals in the area of information and communication technologies) - EXP.
Phase 2 (this phase occurred in two stages)	
Stage1 (3 non-consecutive sessions for each group of evaluators)	
Purpose:	to supply a substantial and uniform knowledge of the prototype (through the interaction with a remote moderator performing a series of tasks presented by a local assistant) and to test usability analysing the evolution of evaluators' performance (learning curve), throughout hands on sessions (Preece, 2002).
Method:	Journaled Sessions (Hom, 1998).
Tools:	internal mechanism for the registration of the evaluators' interactions; synchronized recording (video - what was happening on the screen; audio - evaluator's verbalizations during the evaluation of the prototype); opinion screen (that appears at the end of the session, inviting the evaluator to write down his opinions); and direct observation (using observation tables filled in by a local assistant).
Stage2 (at the end of the 3rd session)	
Purpose:	to allow free use of the prototype, in a close simulation of a real environment; verify the sort of actions and reactions that evaluators (who already knew the prototype) assumed in these conditions.
Method:	this stage started with a small set of interactions to integrate all evaluators in a similar situation. From then on the moderator remotely promoted the use of the application and evaluators did not have to follow a script of tasks. The assistant examined the type of problems evaluators faced.
Tools:	the tools for data collection were the same used in the first stage of this evaluation phase.
Phase 3	
Purpose:	to check the opinion of evaluators on qualitative factors of usability, suggestions and their level of interest regarding a future use of the application.
Tools:	final questionnaire and interview.

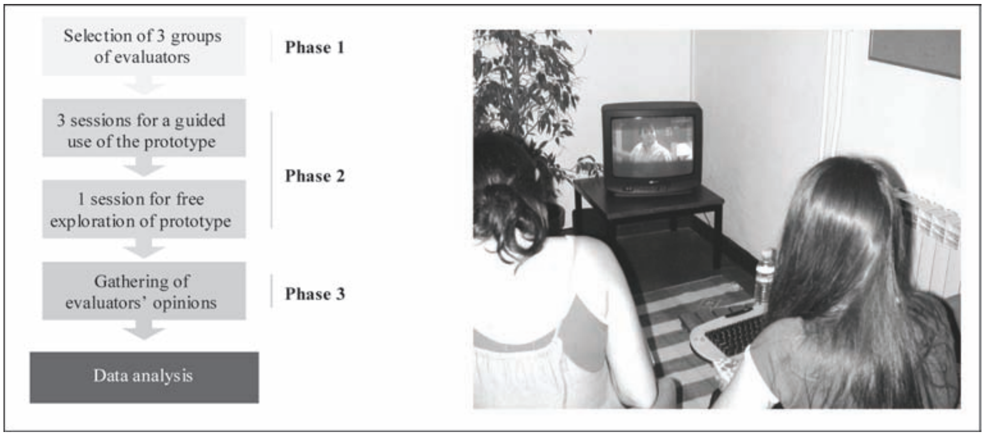
possible to conclude that:

- Information of presence (status and TV channel) acts as a catalyst of communication - most users agreed that, having this type of information from their contacts (in the FriendsOn section), they would have a higher propensity to start a conversation. This can be either encouraged by the fact that users detect they are watching the same channel of the person to be contacted, or by the need to alert about something they find interesting. (Figure 5)

Some evaluators said this type of awareness also gave them a feeling of comfort and togetherness, stating, for example, that:

"it creates proximity..."—Evaluator NTC-C;

Figure 3. 2BeOn evaluation phases (left) / hands-on sessions during phase 2 (right)



"Maybe comfort in knowing that a person is not alone (…) know that there is someone there who is in the same situation"—Evaluator EdI-E.

- IM and TVChat were the services users found to be more suitable to support interpersonal communication (classified as "high" support). ClipEmails and the feature for sending TVPRs were classified as "middle" support. (Figure 6)
- IM and TVChat use was also considered to be very compatible with television reception with minor intrusion on the attention to the TV program.

"I can monitor both (communication and television) perfectly"—Evaluator EdI-E.

- Users were also asked to predict the level of distraction to TV reception if voice communication was used instead of text messages. It is important to notice that on average they all said that text communication was less distractive than voice would be and only one of the evaluators agreed with a future integration of voice communication in the system. (Figure 7)
- Most evaluators, when asked if they would speak more about TV content with a Social iTV application like 2BeOn, answered that

Figure 4. The progress of the average time spent per session

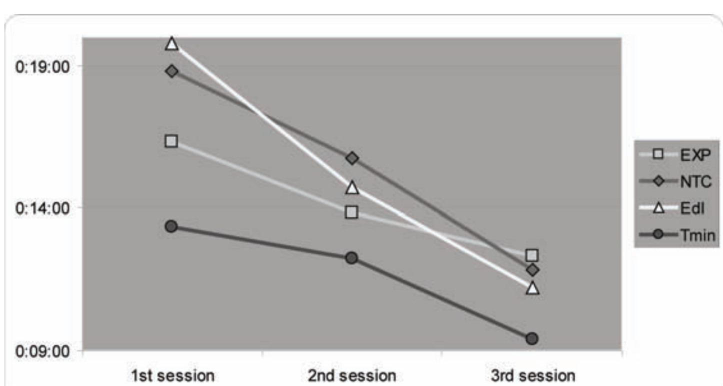


Figure 5. Influence of the information in section FriendsOn as a catalyst of conversations

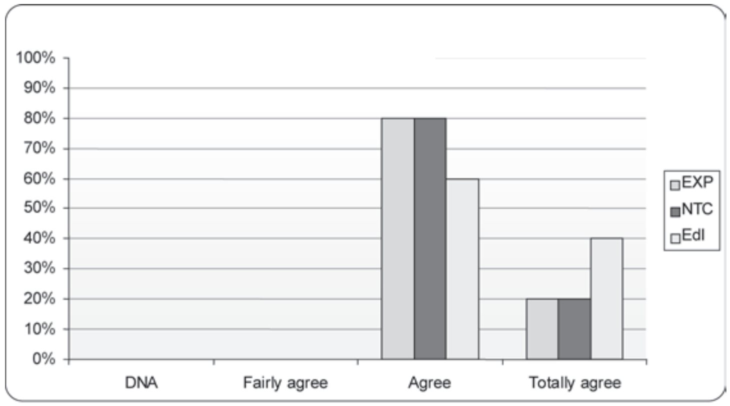

they would do it up to four times more than without such an application. (Figure 8)

- Regarding the user's level of interest concerning a future use of such an application, very positive answers were given. 80% of the evaluators of NTC and 60% of the evaluators of the groups EXP and EdI expressed having "great interest". Comparing the answers given before and after the use of the prototype, a relevant change in opinion was observed, with an increase of 40% in the option "high interest". (Figure 9)

Correlation between Users' Digital Literacy and the Suitability of the Application to Support and Promote Interactions and to Increase Communication Frequency

Regarding the suitability of the various communication services there were no significant differences between different groups of evaluators. However, considering the predicted increase of conversations expected by having an application like 2BeOn, the evaluators with the lowest digital literacy where the ones that predicted higher increases.

Figure 6. Classification of interpersonal communication support by various services

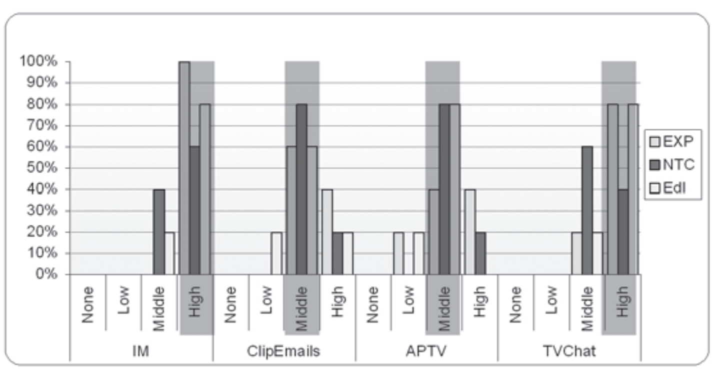

Figure 7. Prediction of distraction on the attention to the TV program if voice was used instead of text communication

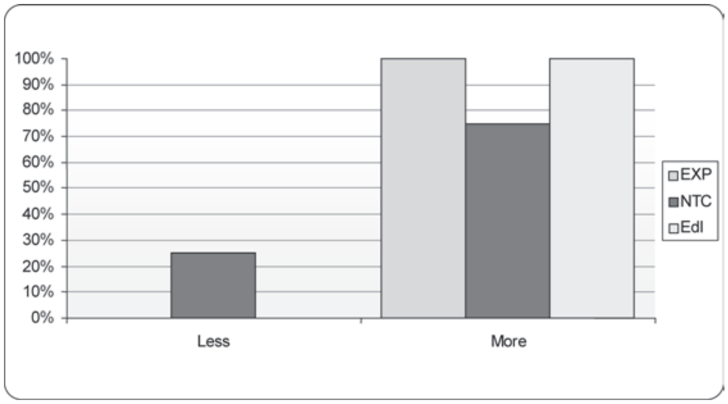

Figure 8. Prediction of the increase in conversations about TV content using 2BeOn

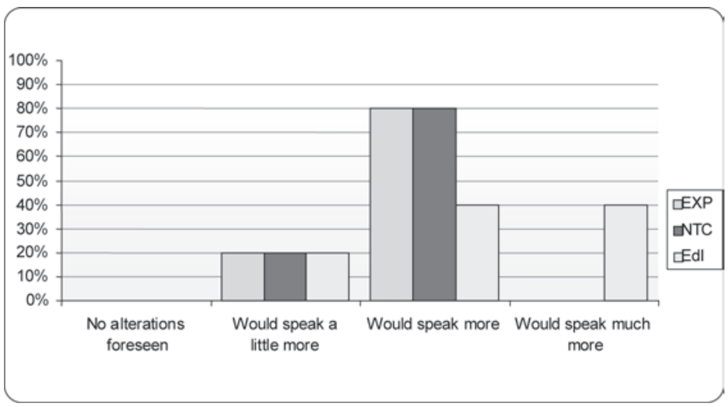

Figure 9. Level of interest, shown after the use of the prototype, in an application like 2BeOn

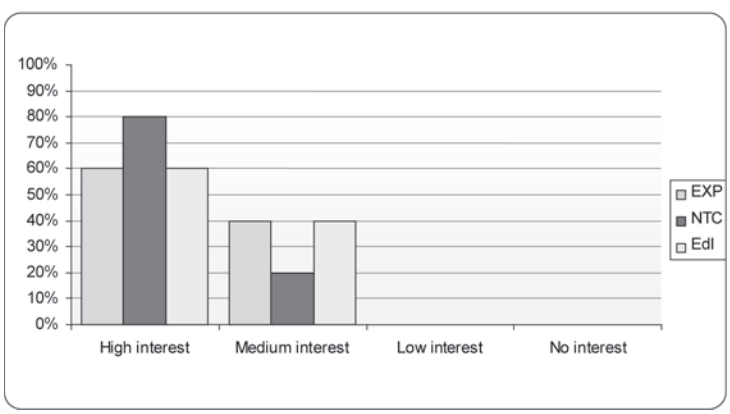


Correlation between Users' Digital Literacy and the Users' Wish to Use Such an Application

The results gathered allow predicting that, regarding the evaluators involved in the evaluation process (that are, within certain limits, a reflection of a generation between 19 to 31 years), there is a considerable interest in using this kind of Social iTV applications. However, no differences were detected between evaluators of different groups (with different levels of digital literacy).

NEW BEHAVIOURS AND PLATFORMS FOR SOCIAL (I)TV

The results from the 2BeOn evaluation along with results from other similar research projects show that users are willing to talk about the TV content they consume, and are ready to do it while they watch it. But before (a possible) widespread penetration of these kind of social features in iTV platforms occurs, users are already socializing, in large scale, using PC based AV distribution platforms or using other communication tools in parallel (like IM in PCs) while watching Webcasts or regular TV. Leurdijk (2007) and Lafrance (2005) refer not only to the ability of young people to multitask but also to consume different types of media simultaneously. Oumard et al (2008), in their ethnographic study, also concluded that "*Internet video consumption is already strongly integrated in social communication*".

In this part of the chapter a description of these emergent scenarios, its tools and levels of sociability are described and a proposal for increasing social interaction around multiplatform distributed AV content is presented.

Where Users are Watching TV Content?

The online developments in Audiovisual (AV) distribution have been fast and diverse, mainly after the YouTube boom in 2006 and 2007.

Today, we can find multiple formats of platforms that broadcast AV content and promote different levels of participation for users. Some of the available platforms can be classified under the following categories:

- **You Tube like and User Generated Content (UGC) distribution platforms:** The YouTube like platforms are very popular and have been widely used for individual upload (UGC). But these platforms are also used for creating institutional, well planned and full budget broadcast channels, as it can be verified by the U.S. presidential campaign and the candidates' channels created in YouTube[3]. The media consumption in these platforms is very significant, as 75% of Internet users in the U.S. watched, in May 2007, more than 2,5h a month of online video (Lipsman, 2007). A report from Pew Internet shows that 27% watch videos from You Tube, 11% from Yahoo Videos and 6% from MySpace (Madden, 2007);
- **Stream+peer-to-peer platforms:** Joost is probably the most well known service of this category of TV distribution platforms. Using a combination of streaming video server and a peer-to-peer architecture, these platforms allow good video quality providing some popular (traditional) TV channels to be viewed in the computer along with some social and communication features. Babelgum and Zatoo are other important examples;
- **Online TV with UGC platforms:** Broadcasting powered by Internet platforms is no longer an exclusive of traditional media channels. Current Tv, Mogulus and Veoh TV, just to name a few, propose different online TV channels with some own production but mainly allowing users to contribute with their shows. These platforms are distinct from the You Tube like platforms by selecting the content to

go online and presenting it in a pre-ordered playlist;

- **Online AV content archives and stores:** One example of a popular online music and video store is iTunes, being BBC iPlayer another important platform;
- **Other:** Other platforms with specific characteristics allow users to have easy access to AV content. Examples are SopCast and TV Ants (peer-to-peer TV channels streaming applications) or Messenger TV (like other IM applications with A/V support it allows users to share and watch a video while commenting on it. Examples of these tools are later described in this chapter).

What About Social AV/TV Features?

Some of the platforms described in the previous topic were not originally designed with support for collaborative social media consumption. However, with the emergence of Web 2.0, many of these platforms have been upgraded with awareness, collaborative and communication features that support a set of social activities. These activities include:

- **Rating:** Classifying the video content quality and helping other users decide to watch it or not. The classification can be completed with comments associated with a video or channel. 13% of video consumers do this (Madden, 2007);
- **Forwarding:** Recommending a video content or TV channel to friends by sending the URL via email. This activity is very popular as 57% of video consumers on the Web share recommendations with others (Madden, 2007). As stated by Oumard (2008) some users even bookmark videos for future recommendation, engaging in chat/IM sessions around the video content;
- **Embedding:** An indirect recommendation feature by promoting the re-broadcasting of a video content in a blog or other platform;
- **IM or Chatting:** Some platforms allow users to chat with others watching the same channel or video content. Joost also allows users to talk to friends even if they are not tuned in the same channel;
- **Collaborative production:** The users' participation related to a TV channel or video content is not limited to the discussion or recommendation about content produced by others. The user can now be an active part in the production process. Current TV, Mogulus and other platforms allow users to create their own collaborative channel or send their programmes to be broadcast (if accepted) in the official channels.

These examples from Mogulus show that users can easily create their own channels using regular webcams and feeding them with the collaboration of others around the world. Al Gore, co-founder of Current TV, stated that they are trying to open the television business in order for viewers to be able to do television (Ribeiro, 2007).

Figure 10. The set of Joost widgets available for interacting with content and other users

Figure 11. The home-page of Mogulus showing some of the collaborative channels available (left) and the online editing tool (right).

As a Pew Internet (Lenhart, 2007) report states, "*The posting of content does not happen in a vacuum. Content is posted so that it might be seen by an audience (...). And often that audience responds to the content posted online, making the content as much about interaction with others as it is about sharing with them*" (p. 15). The same report confirms that Internet users that share their own content online (39% of online teens) are more active communicators. (Figure 10 and Figure 11)

Challenges

These data concerning the use of new AV distribution platforms and the social activities of a "new" Internet generation of users bring out a new set of challenges when referring to Social (i)TV or, in a broader analysis, to social practices surrounding AV content:

- It is harder to have a specific content at a specific time as a common referential to viewers;
- Each platform offers its own social features, usually not compatible with each other;
- Users can have similar AV content consumption but watch it in different platforms and terminals (PC, TV, mobile, …);
- Users are now content (co)producers, searching for new ways to interact or influence content. As Leurdijk (2007) refers "*broadcasters' endeavours could also lead to highly valued new services for a general audience, (…) to new and fruitful exchanges between professional and amateur programme makers (content producers)*" (p. 94).

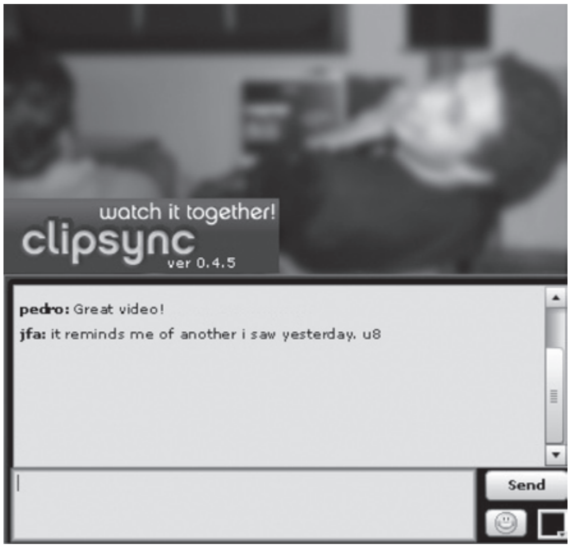
These challenges have restricted the Social AV/TV support in web based platforms to asynchronous tools. Users comment, forward, rate or discuss a video content in an asynchronous way precisely because they can watch the same content in any platform at any time. But what about synchronous Social AV/TV features? Platforms like Joost and a new set of applications are now offering some interesting features.

Tools for Supporting Synchronous Social AV/TV Activities

Recent developments have revealed some tools that promote Social AV/TV features for PC based users, such as the ability of different users to watch the same video collaboratively.

Some of the most relevant applications include:

Figure 12. The ClipSync interface[4].



- YouTube Streams (http://www.youtube.com/streams_main)—this feature from You Tube allows users to create rooms with their selection of videos (from YouTube of course), share these rooms with others and chat about them. It does not allow synchronization between users but allows different levels of participation such as the ability to add videos to the room;
- You Tube—Active Sharing—this feature allows users to know who is also seeing the same You Tube video. It does not provide features to manage a list of buddies or synchronous communication features to interact with other users.
- ClipSync (http://www.clipsync.com/)—this Flash based tool also allows creating and hosting rooms/sessions with video playlists (from different sources) and chat about them, but it adds some important features. It allows the synchronization of playback with the participants in the session and allows the integration of Skype friends lists; (Figure 12)
- Messenger Zinc—a plug-in for the Yahoo IM service, introduced in 2007. This plug-in provides the ability to integrate a video player in the IM application allowing to share a video from popular video sites (like YouTube) for collaborative and synchronized viewing with others (Shamma, 2008);
- Microsoft Messenger TV—this new feature from Microsoft, introduced in May 2008, is part of the company's efforts to promote social video, using, in this case, the Windows Live messenger. It allows

Figure 13. Microsoft Messenger TV—a social video tool[5]

users to watch videos together from the MSN video service and chat about them. (Figure 13)

THE USER MEDIA CONSUMPTION AWARENESS SYSTEM (UMCA)

If all AV viewers had Joost, a Social iTV platform like 2BeOn, host the same room/session in a social video tool or all had a compatible iTV system, it would be easy to conceive that one could check what one's friends were watching and interact with them based on that referential.

But in online video platforms, considering their huge numbers and diversity[6], it is hard to track what your friends are watching and promote instant interaction based on this. Messenger TV or Zinc allow users to share an AV consumption session but this feature depends on the initiative of the user to share each new video he decides to watch collaboratively.

Taking into account this constraint, in this final section of the chapter, a proposal for a general conceptualization for a new system, the User Media Consumption Awareness system, is presented. The proposed system could allow users to know (at any time and independently of the platforms used) what their friends are watching, allowing them to chat or to make recommendations based on that information.

Figure 14. An example of the Peeko Chat in action

Technical and Functional Model

Peeko Chat[7] for Firefox browsers is an example of a plug-in that tracks users in the same page and allows them to chat instantly. There is no content evaluation or correlation in this system, just URL tracking. Two or more users visiting the same domain can interact by chat. (Figure 14)

The proposed *User Media Consumption Awareness* (UMCA) system extends the features of this type of browser chat, like Peeko, and of tools like ClipSync or Messenger Zync by allowing to:

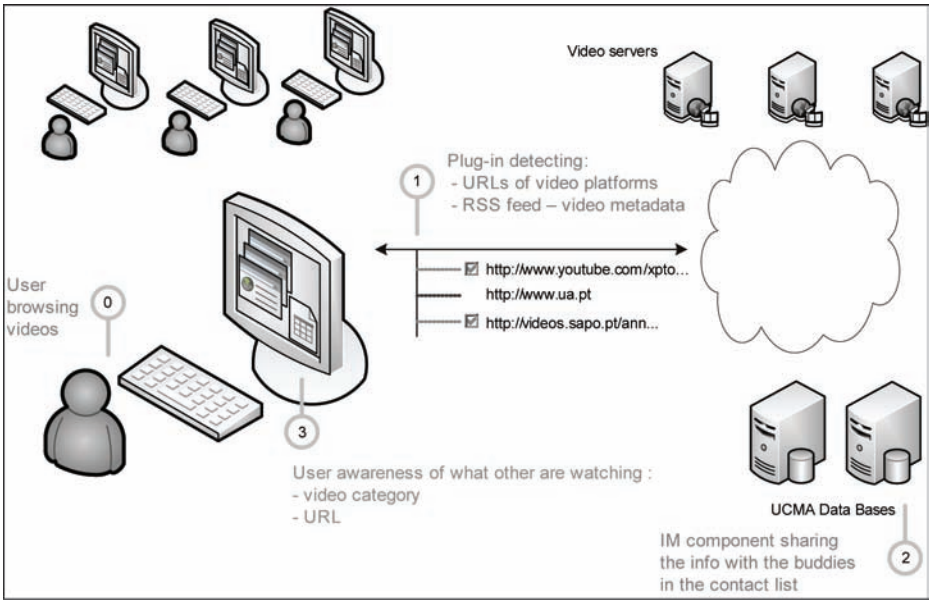
- Track which video content or channel each user is watching and categorize it according to associated metadata (for example by examining an RSS feed and the tags associated with the video/channel)
- Keep a buddy list, like in a common IM service, allowing users to build their own network of friends and to get information about their instant AV content consumption[8]
- Give users a set of collaborative features that include an IM platform and a recommendation system.

System Configuration Proposal

For it to be successful, this kind of system should be simple and fully integrated in the operating system, like a regular IM tool is. It should act like an add-on to any browser. ClipSync, for example, allows some collaborative features but demands the use of a proprietary application to watch the videos.

The proposal for the UMCA system, as shown in Figure 15, should include the following components:

Figure 15. Conceptual model of UMCA system



1. One component, acting as a plug-in for the browsers, detects in real time the URLs visited by the user and compares it with a list of popular video server sites. This list is permanently updated in the UMCA server. The structure of each new site is analysed to maximize compatibility of the sniffer component. If the user is visiting a site, classified as a video site, the component can read the RSS feed related to the page to read the meta information associated with the video. The information provided by the feed allows the component to define the video being watched, the URL and related meta information.
2. Another component, close to an IM service, shares the information from the video with the buddies in the contact list. The user can define the level of privacy wanted for each video site or for each category of videos.
3. Users can know, in real time, which videos others are watching, their categories and URLs. Tools for video recommendation and synchronous text chat are also provided.

Another component of the system aggregates all the information to allow ranking buddies according to their video consumption, identifying the categories of preferred content (ex. Sports, news …) and creating individual profiles for each user[9]. Finally, another component, derived from the previous one, defines a set of automatic recommendations based on buddies' video consumption. After watching any new video this tool can present the user with a contextual recommendation (received from UMCA) of other related videos, as in the following example:

- *User A just finished watching a video of a Cristiano Ronaldo goal in MSN videos;*
- *UMCA alerts the user with a list of related videos his buddies have watched (similar to Amazon's recommendation system). Ex. "User B watched "Manchester United—Euro champion" in You Tube; User C watched "Top ten goals" in Meta Café".*

The widespread use of a tool like UMCA could contribute to support social activities around online AV/TV consumption. Apart from having participatory viewers contributing with their own content, they could be more active in sharing videos, influencing others' choices and specially talking about what they are watching. This tool could have, potentially, the ability to recover to AV/TV online consumption some of the habits and behaviours we could experience with television decades ago.

CONCLUSION AND FUTURE WORK

Social (i)TV is a very relevant and wide-ranging field. Some of the platforms mentioned in this chapter try to promote social activities around TV consumption, but the transversal adoption of these activities is still in its early phases. The results from the evaluation of Social iTV systems, like 2BeOn, have shown the willingness of viewers to interact with their friends/colleagues while watching TV. Users want to talk about TV content and iTV providers are now alert to this reality and are trying to promote new ways of doing it.

In parallel, the proliferation of AV/TV online distribution platforms (PC, TV or mobile based) with consequent changes in the video consumption habits has added important new challenges to the Social AV/TV field. In the existing scenario, content distribution ranges from regular broadcasters to a set of websites and applications making it harder for synchronous interaction activities. The users no longer share a unique platform and a unique terminal, the TV set.

Although in its early stages of specification, the proposal for the User Media Consumption Awareness system presents a range of technical, design and interaction research concerns and challenges. It is expected that the UMCA system may trigger this research field further in searching for a new Social AV/TV add-on for online video distribution. Yet further software development is needed in order to have a prototype available for the validation of this proposal with real users.

Therefore the authors believe that in parallel with the development of social features for traditional iTV platforms that are currently taking advantage of the new IPTV infrastructures, important steps must also be done in online AV/TV platforms, since it is expected that these will enhance the potential for social interaction practices around AV online content.

ENDNOTES

1 The impact of television in the social interaction among televiewers has been researched for many years. J. Klapper (1960) quoted by McQuail (1993); Katz, Gurevitch and Hassem (1973) quoted by Fiske (1990); and Wolton (1997) are only a few of the authors that reflected upon this subject.

2 In recent years, authors like Geerts (2006) and Weisz (2007) have studied the pros and cons of using textual versus voice communication. At the time the 2BeOn prototype was developed, IM sounded more compatible and less disturbing for TV reception than voice communication, despite the existence of a buddy list that helped an initiator of a communication to judge when the recipient was apparently available, enabling a minor number of interruptions (Nardi, 2000). As discussed in the "evaluation process" section this hint was corroborated by the participants during the evaluation phase.

Chapter 3.7
Evaluating the Effectiveness of Social Visualization Within Virtual Communities

ABSTRACT

Participation and system usage is crucial for virtual communities to develop and sustain. However, many communities report very low participation rates of members. Finding and studying strategies for fostering participation in virtual communities is therefore a growing field of research and different approaches for strengthening participation in virtual communities exist – among them social visualization. While many tools for visualizing social interactions have been developed, not much empirical evidence about their actual effectiveness exists. To find out more about the effectiveness of social visualization on the participation rate (number of logins, forum posts, personal messages, and chat posts) the authors conducted an empirical study within CyberMentor – a virtual community for high school girls interested in science and technology. In their sample of N=231 girls the authors did not find a significant difference between the number of logins in the phases before and after the introduction of the visualization tool. The number of forum post, chat posts and personal messages however increased significantly after the incorporation of the visualization tool. Long-term effects were found for one-to-many communication technologies (forum, chat), but not for personal messages (one-to-one)

INTRODUCTION

In this chapter we present results of an empirical study about visualizing usage behaviour of community members within CyberMentor – a virtual community for girls who are interested in science, technology, engineering, and mathematics (STEM). We conducted a timeline study and divided the ten months duration of our study (September 2006 till June 2007) in four phases: starting phase (month 1 and 2), consolidation phase (month 3), short-term effect phase (month 4 and 5), and long-term effect phase (month 6 through 10). The visualization tool (CyberCircle) we developed was incorporated into the platform after the consolidation phase. To find out if social visualization has an effect on the users' participation behaviour we compared community members participation rates (number of logins, forum posts, personal messages, and chat posts) of the consolidation phase with average participation rates of the short- and the long-term phase.

We will start with some background information about virtual communities in general, the technology acceptance model which serves as our theoretical background, and social visualization. The chapter focuses on virtual communities or online communities in general rather than on virtual communities of practice. The virtual community described in this chapter offers great opportunities for formal and informal learning though, which will be discussed later. Since virtual communities and virtual communities of practice are extensively covered in other chapters, we will not go into detail concerning this topic. As background of our own work we chose the technology acceptance model which will be described before defining and showing examples of social visualization. An overview of evaluation approaches of visualization techniques within communities shows that only little evidence of the effects of social visualization within virtual communities exists (e.g. concerning the participation rate). Next, we describe the aim of our research and the hypotheses concerning the effects of social visualization on participation. In the method section we will present the virtual community (CyberMentor) that we used as a research tool for our study. We also describe the community platform, and the social visualization tool (CyberCircle) we developed. After a description of the subjects, research design, and measurement variables, we present the results of our study and discuss them. We conclude our chapter by naming some limitations of our study and making suggestions for future research and practice.

BACKGROUND

Virtual Communities

In the research literature a wide variety of definitions on virtual communities exists, which range from technical to people-centred. Lazar and Preece (2002) define virtual communities as "a set of users who communicate using computer-mediated communication and have common interests, shared goals, and shared resources" (p. 128). Preece (2000) identifies key elements of virtual communities: (1) people, who interact as they strive to satisfy their own needs, (2) shared purpose, such as a common interest or need that provides a reason for the community, (3) policies, that guide peoples interaction, and (4) computer systems, to support social interaction and facilitate a sense of togetherness. Virtual communities encourage research of different disciplines (e.g. computer science, psychology, sociology, anthropology, etc.) and one finds various methods for studying and answering research questions about virtual communities. One important research field deals with investigating usage behaviour of community members. Reasons for joining an online community are examined (e.g. Ridings & Gefen, 2004) as well as reasons for lurking (reading but not posting) (Katz, 1998; Nonnecke & Preece, 2001; Preece, Nonnecke, & Andrews, 2004). A growing body of research examines strategies and mechanisms to foster participation and contribution in virtual communities based on theories from social psychology (e.g. Cheshire, 2007; Cheshire

& Antin, 2008; Harper et al., 2007; Ling et al., 2005; Rafaeli, Raban, & Ravid, 2007; Rashid et al., 2006). Harper et al. (2007) for example conducted field experiments involving members of an online movie recommendation community (MovieLens) and studied effects of personalized invitation messages designed to encourage users to visit or contribute to the forum. They found that personalized invitations led to an increase in participation (reading and posting). Cheshire & Antin (2008) examined the effects of various feedback mechanisms on repeated contributions. The types of feedback they examined were "Gratitude" for providing a contribution, a "Historical Reminder" on one's entire contribution record, and the "Relative Ranking" on one's contributions compared to others (p. 712). The authors report significant impacts of all three feedback mechanisms on repeated contributions of users. Techniques of visualizing social interaction within the community platform offer another approach for strengthening participation in virtual communities. Our research focuses on that approach. Before we give a short overview over some main ideas and findings in the field of social visualization, we describe the technology acceptance model (TAM) (Davis, 1989, 1993; Davis, Bagozzi, & Warshaw, 1989) and its successor TAM2 (Venkatesh & Davis, 2000) on which our assumptions concerning social visualizations are based on.

Technology Acceptance Model

Besides other models of technology acceptance (for an overview see Venkatesh, Morris, Davis, & Davis, 2003), the technology acceptance model TAM (Davis, 1989, 1993; Davis et al., 1989) and its successor TAM2 (Venkatesh & Davis, 2000) are influential models to explain and predict system usage behaviour. The technology acceptance model (TAM) is theoretically based on the Theory of Reasoned Action (TRA) by Fishbein and Ajzen (1975). According to the TRA behaviour is directly influenced by the intention to perform a behaviour. The intention in turn is influenced by the attitude towards the behaviour and the subjective norm concerning the behaviour. Attitude stands for "an individual's positive or negative feelings (evaluative affect) about performing the target behaviour" (Fishbein & Ajzen, 1975, p. 216). Subjective norm is defined as a "person's perception that most people who are important to him think he should or should not perform the behaviour in question" (Fishbein & Ajzen, 1975, p. 302). The theory states that people perform the anticipated behaviour if they a) judge the behaviour as positive and b) believe that important others do so too. The TAM, proposed by Davis (1989) adapts the TRA to the field of Information Systems. Two new constructs, perceived usefulness and perceived ease of use are introduced in the TAM. Perceived usefulness is "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis, 1989, p. 320); perceived ease of use is "the degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320). In the TAM those two constructs are seen as determinants of an individual's attitude towards using an application.

The subjective norm component is not included in the first version of TAM. However, research conducted on the influence of subjective norms on intention led to mixed results. While some researchers found significant effects of subjective norm on behavioural intentions (Cheung, Lee, & Chen, 2002; Igbaria, Zinatelli, Cragg, & Cavaye, 1997; Riemenschneider, Harrison, & Mykytyn, 2003; Taylor & Todd, 1995), others found no significant effects (Lau, Yen, & Chau, 2001; Mathieson, 1991; Roberts & Henderson, 2000). Although Davis, Bagozzi, & Warshaw (1989) also found no significant effect of subjective norm on intentions they highlighted the need for more research to find out more about "the conditions and mechanism governing the impact of social influences on usage behaviour" (1989, p. 999). In a further study Venkatesh & Davis (2000) hypothesized that subjective norm would influence perceived usefulness and usage intention if system use is mandatory. They found that subjective norm indeed exerts a significant direct effect on usage intentions for mandatory systems. Further on, subjective norm influenced usage behaviour via perceived usefulness (Venkatesh & Davis, 2000). Venkathesh & Davis (2000) summarized their new findings in a follow-up model called TAM2 including subjective norm into the model.

With the aim of examining the convergence or divergence of published research results Schepers & Wetzels (2007) conducted a quantitative meta-analysis with 63 studies in which TAM/TAM2 had been assessed empirically. Besides confirming the original TAM relationships (significance of perceived usefulness and perceived ease of use towards attitude and behavioural intention to use) via correlation analysis and structural equation modelling, the authors examined the influence of subjective norm. Correlations between subjective norm and behavioural intention were tested in 22 studies. They found that in most studies (19), subjective norm is directly and significantly related to users' intention to use a system. According to the research reviewed, one possibility to strengthen the subjective norm component and thereby the system usage is to make the social group salient to the users. Important here seem to be perceptions of group distinction (e.g. Henri Tajfel & Turner, 1986) which lead to higher commitment towards the own group, as well as an increased ambition to strengthen in-group identity through participation. Although Michinov, Michinov & Toczek-Capelle mention that in computer based environments "nonverbal and paralinguistic cues may prevent the development of a sense of belonging among group members who are geographically distant from one another" (2004, p. 28), they concede that the social identity theory (H. Tajfel, 1978) contradicts this assumption by providing an alternative perspective. In their view identification with an online group becomes possible when the salience of the group is enhanced. This enhancement of salience of a group could be achieved by social visualization techniques. Visualizing additional information – for example usage behaviour of community members – makes the platform a less anonymous place. Utz (1999) conducted a study about MUDs (Multi-User Dungeons) and found out that users with a higher identifiability showed a higher orientation towards collectivist norms than users who were less identifiable. Therefore we assume that visualizing social interactions (and thereby making community members more identifiable) has a positive influence on the subjective norm and thus on the usage behaviour. Before presenting our aim of research we define social visualisation, show some examples and discuss first findings concerning social visualization and its influence on participation rates.

Social Visualization

Erickson (2003) defines social visualization as 'a visual (or sonic or other perceptual) representation of information from which the presence, activities, and other characteristics of members of a social collectivity may be inferred, and, by extension, can provide the basis for making inferences about the activities and characteristics of the group as a whole' (p. 846). In the literature one can find different operationalizations of social visualization within virtual communities (e.g. Bouras, Igglesis, Kapoulas, & Tsiatsos, 2005; Bradner, Kellogg, & Erickson, 1998, 1999; Erickson, Halverson, Kellogg, Laff, & Wolf, 2002; Erickson & Kellogg, 2000; Erickson & Laff, 2001; Erickson et al., 1999; Lee, Girgensohn, & Zhang, 2004; Perry & Donath, 2004; Sun, 2004; Sun & Vassileva, 2006; Vassileva & Sun, 2007; Xiong & Donath, 1999). They all visualize "hidden" information about users and usage behaviour. Erickson et al. (2002) believe 'that such systems – by supporting mutual awareness and accountability – will make it easier for people to carry on coherent discussions; to observe and imitate others' actions; to engage in peer pressure; to create, notice, and conform to social conventions; and to engage in other forms of collective interaction' (p. 40). They developed a communication tool called Babble (Bradner et al., 1998, 1999; Erickson, 2003; Erickson et al., 2002; Erickson & Kellogg, 2000; Erickson & Laff, 2001; Erickson et al., 1999) which allows synchronous and asynchronous multi-channel text chat. The Babble system provides a social proxy, "a minimalist visualization of people and their activities" (Erickson et al., 2002, p. 40) called Cookie, which visualizes cues about the presence, number and ways of participation in the online environment. Participants are represented as coloured dots within the Cookie. The distance of the person's dot to the circle's centre indicates how recently that person had either "spoken" (typed a command) or "listened" (scrolled or clicked on the interface). A second social proxy within the Babble system, the Timeline, represents each user as a row. When logged on to Babble, users leave a line, and when "speaking" in the chat, they leave a vertical mark to the line. That way other users can see when people were online and when they were involved in conversations. For this social visualization no detailed evaluation but rather user experiences are reported and summarized as "in general, users report that the social proxy is engaging and informative" (Erickson et al., 2002, p. 41).

Another early visualization approach, the PeopleGarden, was developed by Xiong and Donath (1999). The PeopleGarden is a message board community that visualizes users' posting histories. Each user is represented as a flower. The height of the flower shows the length of membership. The number and colour of the flowers' petals indicate the number of messages sent and how recent they are. Also for this approach no empirical evaluation was conducted; instead the authors summarized the users' informal feedback and conclude that users prefer realistic encodings.

Lee et al. (2004) developed two social browsers (People and eTree) for two different community Web sites - CHIplace and Portkey. CHIplace (see also Girgensohn & Lee, 2002) was developed for the ACM CHI 2002 conference to extend interactions among people. The Portkey Web community was developed for summer interns at IBM TJ Watson Research Center to enable them to exchange with others and develop social networks. The CHIplace People browser provides a community map of the site members' different roles. Each user is represented as a dot and grouped with others who are having similar roles. Related clusters of member dots are closer together than unrelated ones. The own user dot appears in red and one can easily see the own position within the community. By clicking on a dot one can open the person's profile page. For the eTree visualization within the Portkey community Lee et al. (2004) used an ecosystem metaphor consisting of the different parts of a tree.

Forums are represented as branches; threads are mapped in form of leaves. The colour of the leaves indicates the age of the posts. The community members are represented as coloured circles placed around the tree. The circle's colouring tells the user's role (intern or IBM authors) and its distance from the tree shows how active the user participates. The Portkey eTree was introduced shortly before the end of the interns' stay and the authors could only collect informal feedback about the metaphor. They reported that many people found the visualization attractive and that they liked the ability to view the growth and evolution of the discussions.

A main concern that came up was privacy. For the CHIplace People browser, usage data was collected and reported. The announcement of the People browser caused an overall usage spike. However, the percentage of sessions in which the People browser was used decreased from 35 percent in the announcement week to about six percent after eleven weeks. Lee et al. (2004) concluded that user feedback and comments provided strong support of the value of the two browsers and suggested "further studies to examine how such techniques can alter people's participation and behaviour in Web communities" (p. 75).

A more recent version of a visualization tool was developed by Sun and Vassileva (2006). They developed a paper sharing online community called Comtella. Within this community each user is represented as a star. The size of it indicates the users' participation level (number of shared links to papers). Based on the activity level each user is assigned to one of four levels, restricting the "best" 10% to the top level, 36% to the second level and 27% to the two lowest levels. The authors evaluated their visualization tool within an online class of students (N = 35) over a period of three months and reported increases in participation after their social visualization tool was incorporated into the platform after 6 weeks usage. However the methodology is not described exactly and no statistical test is mentioned. In a further study of Vassileva and Sun (2007), students (N = 32) were divided in two groups showing the visualization to each group half of the time (about 5 weeks to each group). However, as one group was more active independent of working or not working with the tool, the authors' initial hypothesis that the visualization would motivate the subjects to participate more actively could not be confirmed.

AIM OF RESEARCH

Social visualization tools that display hidden information about members' interactions have been developed and deployed within several virtual communities. While many researchers hope to increase participation and interaction of community members with the help of social visualization, not much empirical evidence exists. Only few evaluation results are reported in the literature and too many shortcomings exist to suppose that social visualization leads to an increase in participation. In our research we want to evaluate the effectiveness of social visualization on the participation rate of virtual community members. As most studies concerning participation in virtual communities study short-time effects, we will differentiate between short-term effects and long-term effects. We also distinguish between various participation criterions like (1) the number of logins into the platform, (2) the number of posts to the discussion forum, (3) the number of personal messages sent to other community members, and (4) the number of chat messages.

Based on findings by (1) Hartwick and Barki (1994) that system usage drops significantly after about three months due to subsiding subjective norm as well as by (2) Agarwal and Prasad (1997) who reported that mandating system use can increase initial system utilization, we assume that participation declines after the starting phase (see H1). We further assume that visualizing social interactions has an impact on community member's subjective norm and thus leads to increased system usage, like predicted by the technology acceptance model TAM2 (Venkatesh & Davis, 2000). We therefore expect that after the introduction of the social visualization tool CyberCircle the participation rate of community members increases within a short-term phase (see H2a) as well as for a long-term phase (see H2b). To test our assumptions we propose the following hypotheses:

H1: *Participation in virtual communities decreases significantly after the starting phase.*

H2a: *The incorporation of the CyberCircle increases the short-term participation rate of community members.*

H2b: *The incorporation of the CyberCircle increases the long-term participation rate of community members.*

The three hypotheses will be tested for four different participation criterions: (1) the number of logins into the platform (visits), (2) the number of posts to the discussion forum, (3) the number of personal messages sent to other community members, and (4) the number of chat messages.

Conducting a study aiming to test those hypotheses requires an appropriate virtual community plus platform. Using an existing virtual community does not usually allow such kind of research since log files are not available. Further on, many communities are based on one communication technology (e.g. discussion forum, mailing list, etc.) instead of the different kinds of technologies we are interested in, such as discussion forum, personal messages, and chat room. In order to conduct this study we first needed to create an appropriate virtual community and to build a platform. The community, its platform, and the social visualization tool we tested within this community will be described in the method section below.

METHOD

In the following the community itself, its platform and the visualization tool called CyberCircle will be described, followed by a description of subjects and the study design.

CyberMentor: Virtual Community for Girls Interested in STEM

Building a sustainable virtual community from scratch is a challenging task. You need a good purpose and the idea of the community has to be attractive to potential members. Doing research in the field of gender and science (Stoeger, 2007; Stoeger, Ziegler, & David, 2004; Ziegler & Stoeger, 2004, 2008) and knowing about the female shortage of skilled labour in science, technology, engineering, and mathematics (STEM) in Germany (Statistisches-Bundesamt, 2006) we decided to build a virtual community to foster girls' interest and participation rate in STEM. Mawasha, Lam, Vesalo, Leitch, and Rice (2001) identified strategies to foster interest in science and technology among girls. These strategies involve (1) increasing girls' knowledge about STEM, (2) providing information about career opportunities in STEM, and (3) allocating role models, contact persons, and mentors. Based on these requirements and further empirical evidence about gender, girls and STEM (for more information refer to Deaux & Lafrance, 1998; Eccles-Parsons, 1984; Eccles, 1994; Packard, 2003; Packard & Hudging, 2002) we developed the virtual community CyberMentor. One important aspect of our community is "mentoring" between girls (mentees) who are interested in science and female mentors who are vocationally engaged in STEM. Over the course of ten months mentors and mentees communicate via e-mail in one-to-one relationships. This approach provides the girls with female role models and increases their knowledge about the field of STEM and possible careers in various STEM domains. By offering this virtual community, formal and informal learning about science topics takes place. On the one hand, participants learn from their mentors, on the other hand, they also learn from and together with other female students. As same-age role models are as important as older role models (Breakwell & Beardsell, 1992) the participating girls are encouraged to engage in team work projects (Schimke & Stoeger, 2007) and to communicate with each other via our community platform.

The Community Platform

"Just as traditional communities require a vehicle for participation, virtual communities require a system that supports the exchange of electronic information among members" (Moore & Serva, 2007, p. 154). The community platform we developed serves as a virtual meeting place for the community members. It is accessible for community members only. Each applicant's identity is verified (mentees need signatures from legal guardians; mentors need to name two contact persons for enabling the program administrator to recheck identities) before login information is provided. Within this platform, each participant can introduce herself by filling out a personal profile and uploading a picture. Each personal page includes a wall for posting comments. For group communication we incorporated an open source discussion forum (http://www.phpbb.com/) as well as an open source chat room (http://www.phpfreechat.net/). The personal message system – like the whole community platform - is based on common Web technologies (PHP, HTML, CSS, JavaScript, and Ajax) and was developed by us. One important function of the platform is its tracking capacity, which allows us to store information about logins, number of posts to the discussion forum, number of chat messages and the number of personal messages in a MySQL database.

The platform was developed, tested and adjusted in a first CyberMentor season from September 2005 till June 2006.

CyberCircle: Visualizing Social Interaction

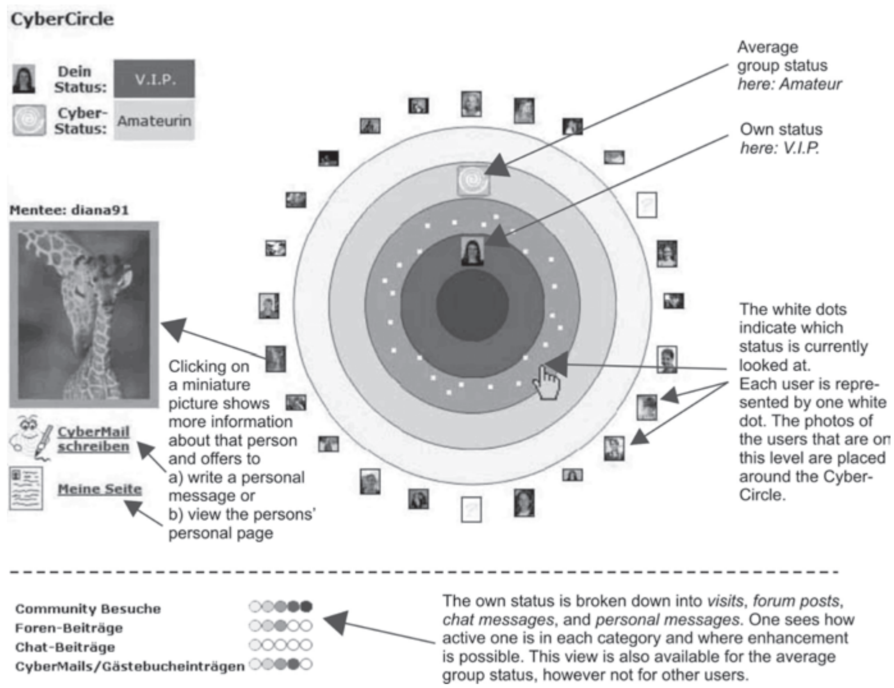
The CyberCircle is a social visualization tool that provides information about the users' participation rates. It assigns each community member to one of the following categories: Beginner, Amateur, Professional, V.I.P., Top-CyberMentee. The assignment to either category or "status" is based on different criterions: (1) number of community logins, (2) number of posts to the discussion forum, (3) number of personal messages, and (4) number of chat posts. For each category each person gets points according to her activity level; the sum of all points assigns a person to one of the five categories. However, the assignment is not fixed. It involves the factor "time" and calculates the current status based on an algorithm which values more recent activities stronger than older ones. Unlike Sun and Vassileva (2006) we did not apportion the levels; instead every member could be in the top or any other level. The users' status is displayed on the first page within the community platform as well as on the CyberCircle site. Within the CyberCircle view users can click on the different levels (Beginner, Amateur, etc.) to see all members assigned to these levels. To get an idea of the average usage level of all users, the mean group level is also displayed. Figure 1 shows and explains the visualisation tool.

SUBJECTS AND STUDY DESIGN

The study was carried out within the CyberMentor platform which is accessible to registered members only. During the time the study was conducted (September 2006 – June 2007) the CyberMentor community had 231 female student members and as many female mentor members. The mentors however were not included in this study and will not be mentioned in the following anymore. The 231 student members – the subjects of this study – were all middle and high school students visiting grades six through thirteen. The mean age was M = 15.19 (SD = 1.97). Since CyberMentor is about science, technology, engineering, and mathematics (STEM), the participating girls were all interested in those topics. For being accepted into the CyberMentor program interested girls had to apply and state reasons for participation. After applying online, they had to print out the e-mail with their application data, sign it (under aged girls also needed a signature from legal guardians) and send it or fax it back to the program administrators. By signing the application they agreed to take part in our research study.

To answer our research questions we conducted a timeline study and divided the ten months duration of the study (September 2006 till June 2007) in four phases: the starting phase (month 1 and 2), the consolidation phase (month 3), the short-term effect phase (month 4 and 5), and the long-term effect phase (month 6 through 10). The CyberCircle was incorporated into the community platform

Figure 1. Visualization tool CyberCircle

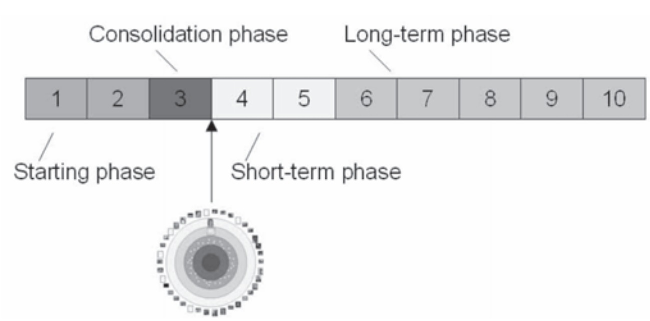


after the consolidation phase (between months three and four). Figure 2 shows the phases and lengths of phases as well as the time of inclusion of the social visualization tool CyberCircle.

Data Selection and Measurement Variables

For this study we did not use questionnaires as measurement instruments, instead we used data stored in a database and gathered through log file analysis. Based on the technology acceptance model TAM2 (Venkatesh & Davis, 2000) we assumed that the incorporation of a visualization tool would lead to greater system usage. To be able to measure and compare system usage rates in different phases, we stored the timestamps and number of (1) logins into the community platform, (2) posts to the discussion forum, (3) personal messages, and (4) chat messages for each subject

Figure 2. Phases of our ten months study and point of time of inclusion of the CyberCircle



in a MySQL database.

Due to different lengths of the phases (starting phase: 2 months, consolidation phase: 1 month, short-term phase: 2 months, and long-term phase: 5 months), we calculated mean values of the mentioned variables for each phase for each subject. Doing this we had the following sixteen variables for each subject:

- **visits phase1, visits phase2, visits phase3, visits phase4:** Mean number of logins into the community platform in each phase.
- **forum phase1, forum phase2, forum phase3, forum phase4:** Mean number of posts to the discussion forum in each phase.
- **messages phase1, messages phase2, messages phase3, messages phase4:** Mean number of personal messages sent to other community members in each phase.
- **chat phase1, chat phase2, chat phase3, chat phase4:** Mean number chat messages in each phase.

RESULTS

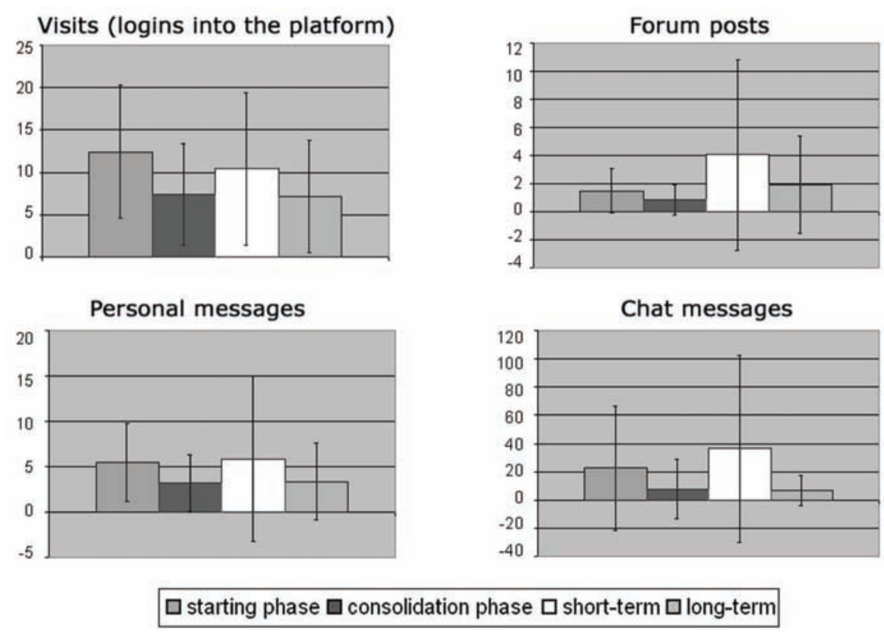
Since our data showed no normal distribution, we could not use the t-test. For this reason we used the nonparametric Wilcoxon test for paired samples to test our hypotheses. Figure 3 shows the average participation rates and standard deviations for each criterion (visits, discussion forum posts, personal messages, chat messages) for the four phases (starting phase, consolidation phase, short-term phase, and long-term phase).

Hypothesis 1: For hypothesis 1 we wanted to test if participation in virtual communities decreases after the starting phase (two months duration). We compared the mean participation rates for the four participation criterions (number of visits, forum posts, personal messages, and chat messages) of the starting phase (first bar in each diagram in figure 3) to the consolidation phase (second bar). We found a decline for the number of visits ($Z = -10.52$, $p < .001$), the number of discussion forum posts ($Z = -4.76$, $p < .001$), the number of personal messages ($Z = -7.34$, $p < .001$), and the number of chat posts ($Z = -5.26$, $p < .001$). Hypothesis 1 *"Participation in virtual communities decreases significantly after the starting phase"* can be confirmed for all four participation criterions.

Hypothesis 2a: We assumed that the incorporation of the CyberCircle tool would enable an increase in the participation rate of community members. To test this hypothesis we compared the participation rates of the consolidation phase (no *CyberCircle* yet; second bar in the diagrams in figure 3) to the short-term phase (this is the phase right after the *CyberCircle* was incorporated into the platform; third bar in each diagram) using the *Wilcoxon* test for paired samples. Concerning the number of visits to the platform, no significant increase could be found ($Z = 1.15$, $p > .10$) between the consolidation and the short-term phase. For the discussion forum ($Z = 6.19$, $p < .001$), the number of personal messages ($Z = 2.24$, $p < .05$), and chat messages ($Z = 5.29$, $p < .001$) we found significant increases in the short term phase. Hypothesis 2a "*The incorporation of the CyberCircle increases the short-term participation rate of community members*" can therefore be confirmed for the number of discussion forum posts, the number of personal messages and the number of chat posts. It can not be confirmed for the logins into the platform (visits) however.

Hypothesis 2b: For hypothesis 2b we wanted to test if the incorporation of the CyberCircle increases the participation rate of community members in the long run. We compared the mean participation rates before the *CyberCircle* was incorporated into the platform (consolidation phase; second bar in each diagram in figure 3) with the participation rates of the long-term phase (forth bar in each diagram), which covers months six through ten. We did not find a significant increase in the number of visits, instead we found a significant

Figure 3. Means and standard deviations of activity levels of interest in the four phases



decrease (Z = -3.24, p < .01). The participation rate within the discussion forum however was significantly higher in the long-term phase compared to the consolidation phase (Z = 2.44, p < .01) as well as the participation rate in the chat room (Z = 1.96, p < .05). No significant increase was found for the number of personal messages. Instead we found a significant decrease (Z = -3.24, p < .01). Hypothesis 2b "*The incorporation of the CyberCircle increases the long-term participation rate of community members*" can be confirmed for the number of discussion forum posts and chat messages. It can not be confirmed for the number of visits and the number of personal messages sent to other community members.

Table 1 gives an overview of all hypotheses and participation criterions tested in this study.

DISCUSSION

The purpose of this study was to find out if the incorporation of a tool that visualizes social interactions within a community platform affects the amount of system usage of virtual community members. To answer this question we tested three hypotheses (***H1***: *Participation in virtual communities decreases significantly after the starting phase,* ***H2a***: *The incorporation of the CyberCircle increases the short-term participation rate of community members,* ***H2b***: *The incorporation of the CyberCircle increases the long-term participation rate of community members*) and analyzed the four participation criterions (1) number of visits to the platform, (2) number of discussion forum posts, (3) number of personal messages, and (4) number of chat posts.

For hypothesis 1 we tested the assumption that the participation rate of community members decreases after a starting phase (2 months). The hypothesis could be confirmed for all participation criterions (visits to the platform, number of discussion forum posts, number of personal messages, and number of chat posts). These results are in line with findings of Hartwick and Barki (1994) and Agarwal and Prasad (1997) who report higher system usage in beginning phases versus later phases. Within the CyberMentor community

Table 1. Overview hypotheses and results

Hypotheses	Tested for participation criterion	Hypothesis confirmed?
H1: Participation in virtual communities decreases significantly after the starting phase.	Visits	yes
	Discussion forum posts	yes
	Personal messages	yes
	Chat posts	yes
H2a: The incorporation of the *CyberCircle* increases the short-term participation rate of community members.	Visits	no
	Discussion forum posts	yes
	Personal messages	yes
	Chat posts	yes
H2b: The incorporation of the *CyberCircle* increases the long-term participation rate of community members.	Visits	no
	Discussion forum posts	yes
	Personal messages	no
	Chat posts	yes

the decrease in activity makes also sense because mentor's names and contact information were announced in the beginning and members were curious to find out more about other community members. The decline in participation after two months was therefore not surprising. As participation is crucial for virtual communities to survive we needed to find strategies for fostering members' participation. On the basis of the TAM we assumed that this could be done by the incorporation of a social visualization tool. For this reason we built a visualization tool and introduced it to the community after a three months period. To test its effectiveness we compared mean participation rates of the phases before and after the incorporation. We found no increase in the number of visits to the platform – neither for the short-term, nor for the long-term phase.

However, we found significant increases of the actual amount of interaction within the virtual community platform, concerning posts written in the discussion forum and messages posted within the chat room for both, the short and long term, phases. A possible explanation for the increases in these two participation criterions might be that people who were reading others posts without contributing before (such community member are usually defined as lurkers; for more information about lurkers and lurking refer to Nonnecke & Preece, 2000) got motivated and actively engaged in discussions after the incorporation of the *CyberCircle*. Preece, Nonnekce, and Andrews (2004) studied reasons for lurking and conveyed strategies to get lurkers (more) involved. These strategies involve clearly stating that interaction is wanted and honouring activity with a high(er) status within the virtual community. Both those strategies are fulfilled by the *CyberCircle*: its incorporation clearly states that interaction is wanted and if getting involved more users reach a higher status.

Interestingly, an increase in participation for personal messages could only be confirmed for the short-term phase (H2a), not for the long-term phase (H2b). A reason for this result might be that users feel more pressure to interact within public spaces where their presence is witnessed by more than one other person – which applies to the discussion forum and chat room. This would fit the idea that the subjective norm does have an influence on usage intention – especially when there is a higher visibility in the community that might lead to pressure, like in mandatory systems. Another explanation could be through social facilitation, which states that the presence of others serves as a source of arousal (Zajonc, 1965) which might influence participation. Contributions to a discussion forum or a chat room have a greater audience than one-to-one communication via personal messages. Therefore social facilitation might have a greater effect. This might explain why we found long-term effects among one-to-many communication technologies but not among one-to-one communication technologies. However, more research is needed to confirm this assumption.

LIMITATIONS AND DIRECTIONS FOR FUTURE RESEARCH

Some important factors need to be considered regarding our study. First, we did not have a control group, which means that we cannot completely disqualify the assumption that the results are based on effects other than the incorporation of the visualization tool. Since only few research results about the effectiveness of visualization tools exist so far, it was important for us to conduct a study evaluating the *CyberCircle* systematically. Based on experiences of our pilot study (September 2005 till June 2006) and from literature review (e.g. Preece, 2000; Whittaker, 1996) we knew, that a critical mass of users is needed in order to initiate a sustainable interactive discourse. Splitting all members in two halves and creating two separate communities with the same conditions would probably not have worked in our case due to too few members. Having enough members and the opportunity to set up two comparable communities of which one uses social visualization while the other one does not would be an interesting investigation for the future.

Another shortcoming of our study is that we used the technology acceptance model only as an explanation. We did not actually measure the components of the model such as subjective norm or perceived usefulness. For future research it would be important to test the components of the model and see if and how strongly subjective norm is influenced by social visualization. With our approach we tried to build a community that fits accepted definitions of a virtual community and that allows us to conduct our research and collect the data we needed. However, more research in different virtual communities and with different target groups needs to be done to find out if our results can be generalized.

There is also a shortcoming concerning the design of our social visualization tool as it is only applicable for relatively small virtual communities with three hundred community members or less. For virtual communities with more members it might get too crowded and unclear. For this reason different design options should be tested in future research. We see, there is a wide range of factors that needs to be considered and many more questions have to be answered before a clear statement about the impact of social visualization tools within virtual communities can be made. Concerning our future research we plan to answer some of the questions mentioned above.

CONCLUSION

First studies on virtual communities were reported in the early nineties. Back then, the research mainly focused on the question if virtual communities are "real" communities and what consequences arise through participation in virtual communities. Some critics worried that the involvement in virtual communities would cause the disengagement from "real" communities (e.g. Kraut et al., 1998). In the mean time, research has provided evidence that virtual communities can indeed be "real" communities (e.g. Baym, 1995; Utz, 1999) and many people today use virtual communities as a new way of "meeting" and staying in contact with each other, while still being engaged in face-to-face interactive groups. Utz (2008) supposes that fundamental principles underlying virtual communities are similar to those underlying face-to-face groups. However, she names some aspects in which virtual communities differ, such as (1) an easier connection of people from all over the world, (2) the facilitation of large-scale collaboration, and (3) access to information that would not be available otherwise.

Based on these findings research nowadays focuses mainly on topics like the emergence and persistence of virtual communities, the content exchanged within virtual communities, or the potential of virtual communities for learning. Researchers agree that virtual communities depend on its members and their interaction, thus one important field of study deals with participation in virtual communities. This is also the domain we are interested in. For our study presented in this chapter we conducted an empirical study based on theories from social psychology and computer science and found interesting hints how to increase participation in a virtual community. After the incorporation of a visualization tool displaying community members' usage behaviour, the number of forum posts, chat posts and personal messages increased significantly. While the results of our study give answers to some first questions concerning the effectiveness of visualization in virtual communities, many questions remain open and need to be answered. For example: "Does visualization encourage participation in all virtual communities?", "Does it affect all users in the same way?" or, "What happens if people want to stay anonymous in the virtual community – do they get discouraged by a visualization tool?". There is more research needed in this young field of study. Cooperation of researchers with different backgrounds and from different disciplines is surely needed to further advance this field of research.

KEY TERMS AND DEFINITIONS

E-Mentoring: Mentoring that is mainly based on computer-mediated communication like e-mail, chat, or bulletin boards.

Mentee: A less experienced person who is mentored by a more experienced and usually older person. A common synonym for mentee is protégé.

Mentor: The term was derived from Homer's epic tale The Odysseus. In the tale, Mentor, a friend of Odysseus, served as a friend and council to Odysseus's son Telemachus, while Odysseus was in the Trojan War. Today a mentor is usually an older and more experienced person who guides, instructs, and encourages a less experienced person.

Mentoring: Mentoring aims at promoting less experienced persons. One can differ between informal and formal mentoring. Informal mentoring usually develops randomly – for example between a faculty member and a student. In formal mentoring programs the mentor-mentee-tandems are usually arranged and temporal.

Social Visualization: Erickson (2003) defines social visualization as "a visual (or sonic or other perceptual) representation of information from which the presence, activities, and other characteristics of members of a social collectivity may be inferred, and, by extension, can provide the basis for making inferences about the activities and characteristics of the group as a whole" (p. 846).

STEM: Abbreviation for Science, Technology, Engineering, and Mathematics.

Technology Acceptance Model (TAM): A theoretical model by Davis (1989, 1993), based on the Theory of Reasoned Action (TRA) (Fishbein and Ajzen, 1975), that explains and predicts usage behaviour of information systems.

virtual community: A simple but appropriate definition of a virtual community (synonym: online commuity) is from Lazar and Preece (2002) who define virtual communities as "a set of users who communicate using computer-mediated communication and have common interests, shared goals, and shared resources" (p. 128).

Visualization Tool: A tool that visualizes usage behaviour of community members or relationships between members of a virtual community.

National Research Council, Canada

ABSTRACT

Broadband visual communication (BVC) technologies—such as videoconferencing and video sharing—allow for the exchange of rich simultaneous or pre-recorded visual and audio data over broadband networks. This chapter introduces an analytical framework that can be utilized by multidisciplinary teams working with BVC technologies to analyze the variables that hinder people's adoption and use of BVC. The framework identifies four main categories, each with a number of sub-categories, covering variables that are social and technical in nature: namely, the production and reception of audio-visual content, technical infrastructure, interaction of users and groups with the technical infrastructure, and social and organizational relations. The authors apply the proposed framework to a study of BVC technology usability and effectiveness as well as technology needs assessment in remote and rural First Nation (indigenous) communities of Canada.

INTRODUCTION

People, groups, organizations and communities are increasingly using broadband visual communication (BVC) technologies for social interaction in a wide range of settings - from institutional uses such as business, government, health and education to more informal uses, such as entertainment for family and friends, social networking and digital storytelling.

Researchers use the terms *broadband visual communication* and *broadband video communication* interchangeably. The term *broadband* refers to both broadband networks and broadband Internet - telecommunication in which a wide band of frequencies is available to transmit information. BVC technologies allow both simultaneous and pre-recorded exchange of rich visual and audio data over Internet. The visual and audio data may also be accompanied by text data. The National Research Council Canada (NRC) has used the term "BVC" for many years to refer to videoconferencing which allows synchronous audio-visual communication. More recently, we use "BVC" to refer also to asynchronous communication using pre-recorded videos, such as video sharing on the Internet by people with the capacity to both create and view videos. Increasingly, synchronous and asynchronous BVC are used together for social interaction.

Videoconferencing was introduced commercially in the 1970s. For the next decades, it was used almost exclusively in health care, military, and educational institutions, failing to gain more widespread adoption. In the past few years the decreasing costs and increasing penetration of broadband Internet has stimulated a huge uptake in videoconferencing. Set-top videoconferencing units are now found not only in the previously mentioned settings but also in voluntary organizations, community centers, community health clinics, and schools. Videoconferencing has several immediate and tangible benefits: it encourages interaction between people who cannot meet in person and allows the exchange of visual information, such as facial expressions that encourage trust and intimacy; it encourages "green" meetings that reduce participants' travel and carbon footprint. Videoconferencing can also be an important tool for knowledge sharing, provide essential social services, support for people in rural or remote communities, and aid in community building and development (Molyneaux et al., 2007a; Molyneaux et al., 2008a).

Sharing videos online has exploded in popularity in a very short time as home computers with webcams and digital video cameras have become ubiquitous. The most popular video sharing website, YouTube.com, claimed to receive more than 100 million views per day by more than 20 million users internationally with more than 65,000 new user-generated videos uploaded daily - a mere 22 months after its launch. YouTube users also posted millions of comments about the videos and engaged in exchanges with other users. In 2006, *Time Magazine* named its "Person of the Year" as "You," claiming that the users of YouTube and other user-generated content-sharing Internet sites were "seizing the reins of the global media… founding and framing the new digital democracy …and beating the pros at their own game" (Grossman, 2006).

The objective of this chapter is to discuss the requirements for analyzing social interaction using BVC technologies and to provide an overview of our solution – creating an analytical framework. The analytical framework is a common reference point for multi-disciplinary teams working with BVC technologies seeking to understand the variables that help and hinder people's use of social interaction technologies. We use our research framework to understand the social implications of BVC technologies and the social aspects of technology design and implementation. We also apply the framework to the study of technology usability and effectiveness as well as technology needs assessments. We illustrate how this framework can by used by presenting a case study of BVC in remote and rural First Nations (Indigenous) communities in Canada.

BACKGROUND

BVC involves both simple and complex social and technical interactions. The complexities arise as the interaction grows from communication between two individuals in the same location to communication between multiple individuals in multiple locations, working for multiple organisations rooted in different communities. The main technologies are a camera, a microphone, and some recording and viewing software and hardware. There are multiple hardware and software versions and platforms with compatibility problems, using broadband networks that have access, bandwidth, and management challenges.

In 1997, a study was published that outlined different ways to approach research on video-mediated communication (Finn, Sellen, & Wilbur, 1997). Referring to this publication, in 2002, colleagues working on BVC at the National Research Council developed a cluster of evaluation factors for analyzing BVC among multiple stakeholders in different geographical locations. Five evaluation factors were identified: social infrastructure, technical infrastructure, physical space, interaction style, and content (Barfurth et al., 2002).

Since 2002, broadband Internet capable of supporting high-quality visual communications has become mainstream in most developed countries. This has led to a virtual explosion of visual communications. Applications such as online video sharing, which until 2006 were unknown by the general public, are now used regularly by hundreds of millions of Internet users globally. The use of desktop videoconferencing has also seen a huge upsurge, particularly in young people: a recent study of 1,060 adolescents found that 57% occasionally use webcams while instant messaging and 32% sometimes use microphones (Peter et al, 2007).

Given these new developments, we decided it was time to propose a more comprehensive framework for analyzing social interaction using BVC technologies. Our framework started with our colleagues' earlier work (Barfurth et al., 2002). We then reconfigured it to focus on social interaction and include videoconferencing and online video sharing. This moves it from the realm of small groups to both small very large groups of people, communicating synchronously, asynchronously, or both.

ANALYTICAL FRAMEWORK

Basic Requirements

We aimed for the analytical framework to meet four basic requirements.

Provide a Common Point of Reference for Multidisciplinary Teams

There is a shift in technology research and development toward multi-disciplinary teams. (Members of our research team have advanced degrees in 10 different disciplines.) The framework needed to be flexible enough to embrace a wide variety of theoretical and methodological approaches and research interests. We envisioned the framework as a focal point that would let us share a common language.

If we review literature from disciplines as diverse as those found in our research team - communications and media studies, computer science, clinical psychology, cognitive psychology, educational psychology, philosophy, electrical engineering, sociology, history, and educational technology - we find that there are literally hundreds of variables involved in social interaction using BVC. The concept that many different variables will help or hinder communication using technology is understood and theorised in many different fields. The framework needed to encompass many variables – enablers and constraints – of many kinds. To give a practical example, excellent audio quality during a videoconference enables communication in one location, while poor audio quality constrains it in another location. Other constraints would be if certain participants in one location cannot access the technology to make videos or view them online because they cannot afford it or if their rural community does not have adequate bandwidth. These enablers and constraints shape social interaction. The framework needed to accommodate variables that address different types of concerns from different disciplines.

Include Both Social and Technical Elements

Along with the trend toward multidisciplinary research teams, there is a growing recognition in the technology development field of the need to address both the social and technical elements of technology use and deployment. Actor network theory and the social actor concept posit that the technical and the social are inseparable: people together with their technologies comprise social networks while social actors are simultaneously enabled and constrained by socio-technical affiliations and environments (Blechar, Knutsen, & Damsgaard, 2005; Lamb & Kling, 2003; Rowlands, 2006). In particular, our framework is guided by the social informatics approach of Kling: that is, the relationship between the social and technical is complex and mediated by context, structure and agency, history, culture and meaning systems, political and social processes and symbolic and material interests and resources (Kling, 1999; Lamb & Sawyer, 2005; Robbin & Day, 2006).

Emphasize Both the Production and Reception of Visual Content

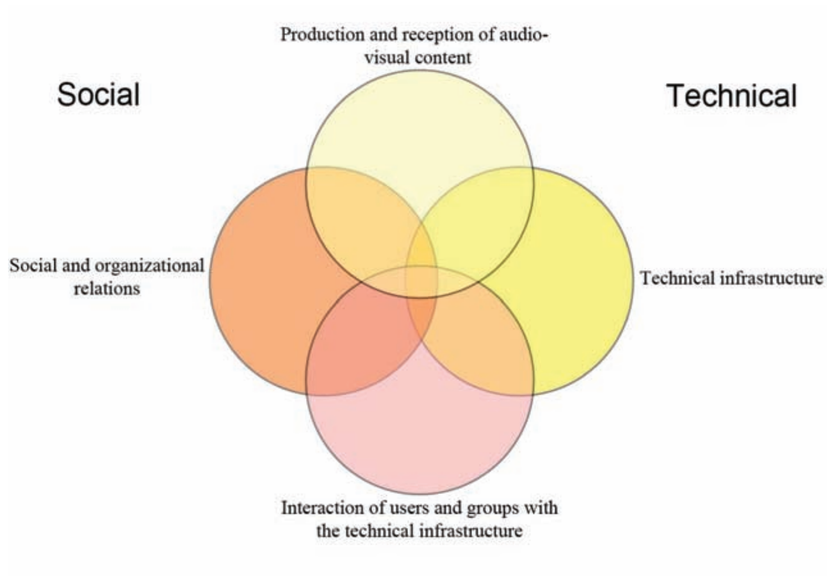
A novel feature of new media is the ability for people to be both producers and viewers of digital content (Lievrouw & Livingston, 2006). Traditionally, videoconferencing research has included both the production and reception aspects of communication, but research on traditional forms of video and visual content generally has focused on either the production or the reception, but not both. Analysing online videos presents a new challenge for researchers because it is important to understand the users of the technology as both producers and viewers or audiences (Molyneaux et al., 2008b).

The most influential theorist of how people respond to visual images is Hall (1999). His central argument is that although creators of a visual image may have a message in mind when they create or "encode" it for its viewers, it does not necessarily follow that the viewers will "decode" the message the way it was intended. Viewers actively construct meanings rather than passively receive them. Both encoding and decoding are socially constructed activities, and Hall's theory stresses that visual messages will be constructed and interpreted differently depending on socio-cultural contexts. Some messages are connected to specific beliefs, practices and interests and are thus dominant in social groups that share these perspectives. Therefore analyzing visual images can reveal the dominant beliefs held by the encoders, and analyzing the viewing audience can reveal the different interpretations decoded by different social groups.

Focus on Multiple Levels of Social Interactions

As noted earlier, using BVC for social interaction is a complex process. Visual communication among multiple people in multiple locations rooted in different contexts implies many analytical variables. There are numerous theories and approaches that build understanding of social interaction using communication technologies at the levels of individuals, groups, organizations and communities. For example, at the group level, the concept that different groups of people have different levels of acceptance and use of a new technology is implicit in influential theories: such as, Rogers' (2003) diffusion of innovations in the field of communication and media research and Davis' technology acceptance model (TAM) in management information systems research (Davis, 1989). In the TAM model, people who

Figure 1. Analytical framework



perceive technology as useful and easy to use will accept it more readily than those who do not, with usefulness more important than ease of use. Extensions of the TAM model identified gender differences (Gefen & Straub, 1997) and cultural differences in e-mail perception and use (Straub, Keil, & Brenner, 1997). The framework needed to include variables for social interaction using BVC at the individual, group, organization and community level.

Core Categories and Variables

Based on the essential requirements outlined above, our analytical framework includes social and technical variables in four core categories: the production and reception of audio-visual content, technical infrastructure, interaction of users and groups with the technical infrastructure, and social and organizational relations (see Figure 1). The categories are not entirely discrete: there is some overlap among the variables in each category.

To identify variables within these four categories, we first conducted a wide-ranging review of almost a hundred published articles and reports on the use of videoconferencing and multi-site videoconferencing and participatory communication in many different contexts, including health and medicine, education, government, corporate, non-profit, research and community uses (Liu, Molyneaux, & Matthews, 2008; Molyneaux et al., 2007a; Molyneaux et al., 2008a). The studies included: literature on virtual teams (Becker &Goodwin, 2005; Jarman, 2005; Jarvenpaa & Leidner, 1998; Mankin, Cohen, & Fitzgerald, 2004; Mansour-Cole, 2001; Nemiro, 2000), literature on multi-party videoconferencing (Anderson, 2006; Blignault, 2000: Sonnenwald et al., 2002), and literature on videoconferencing in health, education, and other areas (Blignault, 2000; Ho & Jarvis-Selinger, 2005; Rees & Haythornthwaite, 2004). The review focused on identifying issues and variables of concern under the four core categories.

We then refined our framework through a series of studies that allowed us to validate the existing variables and add new variables under each of the core categories. These studies produced publications on the use of: YouTube (Milliken et al., 2008; Molyneaux et al., 2008a, 2008b; O'Donnell, 2008), the use of videoconferencing and online video technologies in a live discussion on topical issues by students in six high schools across Canada (O'Donnell et al., 2007; Simms et al., 2008); the use of videoconferencing and online video by First Nation (Indigenous) communities in remote and rural areas of Canada (O'Donnell, Perley, & Simms, 2008); challenges to conducting participatory research on videoconferencing in a health organization (Gibson & O'Donnell, 2008a); and the use of multi-site videoconferencing by a regional health board in Canada for non-clinical health administration and education (Gibson & O'Donnell, 2008b). Whenever possible we also solicited and included feedback from our research partners and participants to inform our procedures, findings, and thinking. Some of our studies also used participatory research approaches.

The four core categories and their associated sub-categories are described below.

Technical Infrastructure

This category covers the variables that are primarily technical. To date we have identified four main sub-categories:

Quality and Availability of Networks and Bandwidth

Broadband visual communication requires considerably more bandwidth than text exchange, and two-way communication requires similar upload and download speeds. The term *broadband* is used to describe many different types of networks and Internet connections, not all of which support adequate two-way exchange of audio and visual data. For example, some people have "broadband" Internet connections that allow them to download and play videos easily, but they run into difficulties when uploading their own videos to share with others. Another infrastructure variable affecting social interaction is the need for managed networks and quality of service (QoS) for synchronous visual communication in remote communities - especially areas serviced by satellite connections. For example, a videoconference from a community with limited bandwidth may have poor visual and audio quality if QoS is not managed, thus limiting the quality of social interaction. Another variable in this sub-category is firewalls in corporate networks.

Type of Software and Hardware for Video Capture, Storage, and Playback

For videoconferencing, there are several brands of set-top units and a wide variety of desktop options. Videoconferencing by mobile phone is now possible as well. Each of these options presents different possibilities and challenges. Some of the variables include: the capacity of the devices and software; the flexibility of the technology to support different group setups, locations, and time constraints; the maximum number of users and groups who can communicate synchronously and asynchronously using the technology; the availability of a critical mass of the technology; the technical compatibility of systems, hardware, software; and the flexibility and capacity of a system for incorporating new features and elements.

Availability of a Videoconference Bridge and Video Sharing Server

For some kinds of multi-site videoconferencing, a videoconferencing bridge (also known as an *MCU*) is required, and technical challenges for bridging different kinds of software and hardware can be considerable. A server is required for sharing videos, and again there can be many technical challenges associated with this.

Quality and Placement of Cameras, Microphones, Screens, and Speakers

In other publications we have discussed the many issues involved with cameras and microphones for BVC (Molyneaux et al., 2007a; Molyneaux et al., 2008a). Not having a good quality audio or visual connection when communicating with this technology can be a significant inhibitor to communication in many settings.

Interaction of Users and Groups with the Technical Infrastructure

This category includes variables that have both technical and social elements. To date we have identified four main sub-categories:

Access by Users and Groups to the Hardware, Software, and Network
As noted earlier, BVC, and its software and equipment requirements, is more complex than text-based communication. Most households in the US and Canada have computers and an Internet connection; however, not all of these households also have a digital video recorder or a webcam and microphone as a part of their computer setup. Accessing higher-end videoconferencing equipment can be a challenge and may have prohibitive associated costs.

Levels of Awareness, Comfort, and Technical Skills of Participants
Different people have varying levels of awareness, comfort and technical skills with BVC, and these will have an impact on the communications and social interaction. One variable is that some people are camera-shy. Our study of online video production and viewing by 150 high-school students in three Canadian provinces found that more than 25% said that in general they do not like to appear on camera (Simms et al., 2008). Our work with the health board found anecdotal evidence that sometimes participants will point the videoconference camera at the site location sign rather than themselves if they do not want people looking at them that day.

Levels of Technical Support
For videoconferencing in particular, the technical support required is generally beyond what an ordinary computer user can manage. Participants who have ready access to technical support will find it much easier to participate in many different forms of BVC.

Ease of Use, Ease of Viewing
Many variables are involved in making BVC easy to use and easy to view. These include the computer interface, position of the screen or monitor, and a wide range of human-computer interaction variables.

Production and Reception of Audio-Visual Content

This category also includes both social and technical variables. To date we have identified four main sub-categories.

Task Relevance and Usefulness of Broadband Visual Communication
Broadband visual communication can be very useful for supporting certain kinds of interactions and tasks. At other times BVC might not be worth the effort. For it to be successful for social interaction, BVC must be a good fit with the group or organization process and be a real solution to a real communication need. Participants will not be motivated to use the technology effectively if they do not believe it will be useful for them (Davis, 1989).

Use of Protocol and Etiquette
Successful meetings by videoconference will use established etiquette (Molyneaux et al., 2007a). Sharing online videos successfully also requires that certain protocols be followed: for example, considering privacy concerns and not sharing material without permission from everyone on camera.

Use of Communication Modes and Methods
For video sharing in particular to have a communication impact, the video producers should

be thinking about the communication value of their production. It does not necessarily follow that the message intended would be the one received by the viewer; however, a video made without any consideration of the communication intent and impact on the viewers will likely not have a good communication outcome. There are many variables involved in making an effective audio-visual message, from body language and clarity of the speaker to the production values of the video. For videoconferencing as well, if the speakers are not actively trying to communicate with people at the remote sites, their communication is not likely to be effective. Other variables in this sub-category include: how the visual is framed, the use of color and movement, and other visual elements.

Use of Participants' Physical Space

For videoconferencing and also for making and viewing videos, there will be an optimum use of the physical space. Variables include furnishings (position, quality), room (size, obstructions), lighting, room configuration, and even the color of the wall or background. To give an example, in our multi-site videoconferencing study in a health authority organization (Gibson & O'Donnell, 2008b), it was clear that room size could have a significant impact on the success of a videoconference. In one instance, the room could comfortably fit up to 16 people; but it was not uncommon for 45 individuals to be put into this room for the videoconference event, leaving many people without a view of the videoconference screen, without a seat, and without the opportunity to ever appear on the video.

Social and Organizational Relations

This category includes purely social variables. To date we have identified five main sub-categories.

Impact of Group Dynamics: Trust, Norms, Group Size, Leadership

Many variables in the sub-category of group dynamics can make the difference between a successful and unsuccessful social interaction using BVC. Trust is a primary consideration. Participants who prefer to build up trust by meeting in person rather than by video and who have that option readily available will not be very interested in meeting by videoconference or by sharing videos. Other variables in this sub-category are: group size, structure, and stage of development; group norms; and group leadership. For multi-site videoconferencing, we have identified a tendency for people who come together for a committee meeting to rate their feelings of connection (e.g., perceive that a warmer environment is created, feel more like part of a group) with the other videoconference participants as higher than people who do not consider themselves to be a part of a group and who meet for educational videoconference events (Gibson & O'Donnell, 2008b).

Influence of Gender, Class, and Race

A sociological perspective on communication will always consider the core sociological issues of gender, class and race; and they do need to be considered when analyzing BVC for social interaction. There are many ways that these variables will have an impact on social interaction using BVC technologies. Our study of gender on YouTube, for example, found differences between how females and males used video sharing to connect with the YouTube community (Molyneaux et al, 2008b).

Participants' Culture and Community Membership

Broadly speaking, BVC is used among people separated by geographical distance; often this will mean participants are living in different cultural and community contexts. Some communities and cultures will have different levels of comfort with and attitudes toward communicating visually using technology. For example, in our research with First Nations (Indigenous) communities in Canada, we found concerns about cultural exploitation by sharing videos online. One participant interviewed said it was important to get the permission of community leaders before making a video about their culture (O'Donnell, Perley, & Simms, 2008).

Location of Participants

One's social location and position will shape the social interaction experience – in our multi-site videoconferencing study within a health organization, we found that often the remote and rural sites were at a disadvantage. For example the majority of individuals in a videoconference session, including the event's chair or facilitator, were situated at an urban site. The rural and remote sites were sometimes forgotten, as noted by several participants in our study who added that if they are lucky they may be solicited for feedback a few times during a session (Gibson & O'Donnell, 2008b).

Economic and Political Factors

Finally, structural social relations can shape social interaction using BVC technologies in numerous ways. If there is a stakeholder organization involved, it will make a difference if it has a governance model that is top-down vs. community-based and bottom-up. Other variables are the availability of funding and business models to support development of audio-visual content and the demand for and marketing of services and information.

Case Study

Our analytical framework is a tool that can be used by multidisciplinary research teams to explore how BVC is used and can be used for social interaction. The expectation is that every investigation we conduct will consider not every single variable in the framework – that would be unrealistic. Rather, we will consider variables from each of the four core categories: social and technical issues, production and reception issues, and social relations. In this section we present a case study based on our recent research using the framework (O'Donnell, Perley, & Simms, 2008).

Challenges for Broadband Visual Communications in Remote and Rural First Nations in Canada

For Canada's remote and rural communities, BVC provides a vital lifeline. We used our analytic framework to explore the challenges for BVC in remote and rural First Nation (Indigenous) communities. We collected data from actual users of visual communications technologies in First Nation organizations and communities. The study, part of an ongoing participatory research project with First Nation partners, draws on data from 18 in-depth interviews, 43 completed survey questionnaires, and the transcripts of two public meetings held by multi-site videoconference with participants from many remote and rural First Nations across Canada. This research, and all our other research involving people, was approved by our institution's research ethics board.

We used our analytical framework at four stages of the research. First we used it to develop the questions for the in-depth interviews and survey questionnaires. This involved selecting variables from each of the four categories and formulating questions for the interview participants and survey respondents about their experiences with these variables. Second, we used the framework to identify major coding categories for qualitative data analysis of the interview transcripts. This involved creating codes for variables in the four core categories and their sub-categories. With these codes, we coded the transcript text using a qualitative data analysis software tool, *NVivo*. Third, we drafted the research report using the four core categories from the framework as headings and the relevant variables as sub-headings. Finally, we verified the draft findings by consulting with our First Nation research partners. This checking process allowed us to validate the framework in the specific community context, add more variables to our framework, and strengthen our confidence in this framework as a research tool.

Using the framework in this specific study enabled us to identify the many and varied challenges to using BVC for social interaction in remote and rural communities. All the examples and quotes below are from our publication about the study (O'Donnell, Perley, & Simms, 2008).

The main technical infrastructure challenges identified in the study were network and bandwidth constraints, the need for network management and quality of service in remote communities serviced by satellite, the need for a critical mass of quality videoconferencing units in communities, and specific technical challenges for sharing videos online in communities with limited bandwidth. For example, one participant interviewed stated: "In our regions, in our communities and in our organizations, we have to carefully manage a limited resource. There is no such thing as unlimited bandwidth, so it has to be carefully managed, just like the highway has to be carefully managed and taken care of."

The main challenges identified for community members interacting with the technology were the lack of awareness of and comfort with using BVC technologies in communities, low levels of skills training and few community champions, the low level of technical support in many of the remote communities, and difficulties accessing equipment in the communities. To give an example, we found that although a community center may have videoconferencing equipment, it may only be available at certain hours that are not convenient for everyone in the community, and it may be difficult to find the key to the room with the equipment.

The main challenges for the production and reception of audio-visual content included: the varying levels of time, interest and motivation to produce audio-visual content, the low levels of knowledge about topics of interest to other community members, low levels of knowledge of videoconference etiquette, the lack of visibility of existing audio-visual content in the communities, and concerns about cultural exploitation by sharing video content online.

Finally, the two main challenges for social and organizational relations were the need for program developers and sponsors of broadband infrastructure to have a community development focus and the low level of BVC activity by urban organizations. One participant interviewed described the need for a community development focus for funding BVC: "Because too often in the communities, there's such a small pool of people that are comfortable enough and trained to use the equipment, and if we can support those persons and if we make sure they're compensated, then they're going to take a lot better interest in keeping the equipment and therefore be more willing to use it. So it's not only supporting the community network, but supporting the community people as well."

FUTURE TRENDS

We are confident that social interaction using BVC technologies will continue to increase in both institutional and informal settings. Market research reports predict that videoconferencing will see solid and steady growth over the next five years – 19% growth in North America and 24% for Europe, the Middle East and Africa (Frost & Sullivan Reports, 2008a, 2008b). The use of online video is exploding – predictions of 40% growth per year are common. There is little doubt that the rapidly growing use of these technologies will involve increasing levels of social interaction.

The analytical framework described in this chapter identifies the core categories and subcategories with variables that enable and constrain social interaction using BVC technologies. Using the framework and exploring these variables in specific situations is the focus of future work. We consider this framework a work in progress and will continue to refine it as our research on BVC technologies continues. Further research needs to be conducted to find ways to encourage the enablers and mitigate or overcome the constraints using practical and innovative social processes and technological solutions.

One of the next steps for us as researchers is to explore and expand our use of participatory research methods for doing this kind of research. We are mindful of the feminist approach of standpoint theory (Harding, 2004). Standpoint theory suggests that although there are commonalities and differences between various members in a group, there can also be solidarity among diverse group members. Drawing on the assumptions of standpoint theory we value the experiential knowledge and perspectives of the users of the technology. Consequently, much of our research is participatory-action research and involves working closely with authentic user groups and using their knowledge and experience to inform our needs assessments, interventions, and evaluations.

CONCLUSION

The use of broadband visual communication (BVC) technologies for social interaction is increasing rapidly as digital video cameras, webcams, videoconferencing equipment and broadband approach ubiquity. Analysing social interaction using BVC technologies is challenging. We created an analytical framework as a reference point for our multidisciplinary research and development team working in this area. We developed our framework initially by reviewing almost a hundred studies of BVC technologies and participatory communication. We further developed and validated our framework by conducting a series of studies of social interaction using BVC technologies in different social and cultural contexts. Our framework is a key research tool that guides our work from the development phase through to data analysis and interpretation and presentation of findings. We will continue to strengthen and develop our framework in the coming years through ongoing and new research projects. Our hope is that our analytical framework will be useful for other researchers in this exciting research area.

ACKNOWLEDGMENT

The authors would like to thank their colleagues working on the National Research Council Canada's Broadband Visual Communication Strategic Initiative (BVC-SI) who contributed to many discussions of the analytical framework and variables introduced in this chapter.

KEY TERMS AND DEFINITIONS

Actor Network Theory: Related to the social actor concept, actor network theory states that people, together with their technologies, comprise social networks. Technical and social elements cannot be separated in this theory.

Asynchronous Visual Communication: Communication using pre-recorded videos, such as video sharing on the Internet.

Broadband: In this chapter, *broadband* refers to both broadband networks and broadband Internet. In general, the term refers to telecommunication in which a wide band of frequencies is available to transmit information.

Broadband Visual Communication (BVC): BVC technologies allow the simultaneous or pre-recorded exchange of rich visual and audio data over broadband networks.

First Nations (Indigenous) communities: First Nations are recognized by the Canadian Constitution as one of the founding nations of Canada.

Online Video Sharing: Posting and viewing asynchronous (pre-recorded) videos over broadband networks.

Social Informatics: A theory that argues that the relationship between the social and technical is complex and mediated by context, structure and agency, history, culture and meaning systems, political and social processes and symbolic and material interests and resources.

Synchronous Visual Communication: Simultaneous video communication, accomplished by videoconferencing.

Technology Acceptance Model (TAM): In the TAM model, people who perceive technology as useful and easy to use will accept it more readily than those who do not, with usefulness more important than ease of use.

Videoconferencing: Synchronous audio-visual communication using broadband networks.

Videoconferencing Bridge: The multipoint control unit (MCU), commonly known as the *videoconferencing bridge*, is a device that allows multiple sites to videoconference simultaneously.

Chapter 3.9
The Hybrid Course: Facilitating Learning through Social Interaction Technologies

Lorraine D. Jackson
California Polytechnic State University, USA

Joe Grimes
California Polytechnic State University, USA

ABSTRACT

This chapter surveys the benefits and challenges of hybrid courses, which blend face-to-face instruction with online learning, and opportunities provided by the introduction of Web-based social interaction technologies. It discusses the pedagogical implications of various Web 2.0 tools: that is, asynchronous discussion boards, blogs, wikis, podcasts, RSS, e-portfolios, folksonomies, educational gaming, data mashups, and simulations. The authors argue that as hybrid courses continue to evolve to meet the needs of students, instructors, and institutions of higher learning, the integration of Web 2.0 applications in a hybrid model requires thoughtful course design, clear educational objectives, and carefully planned activities.

DOI: 10.4018/978-1-60566-368-5.ch020

INTRODUCTION

The traditional face-to-face classroom, in which an instructor lectures, demonstrates, and leads discussion, has been the primary method for acquiring an education in colleges and universities. However, advances in social interaction technologies have resulted in greater variation in educational experiences for online learning. A study by the National Center for Education Statistics surveying over 4,000 two and four year degree granting institutions found that 88% plan to increase or start offering courses using asynchronous computer based instruction as the primary mode of delivery (National Center for Education Statistics, 2003). Asynchronous instruction means that students and faculty are not required to be present at the same time (either electronically or in person) to participate in the class. Technology is clearly transforming the educational landscape.

On the continuum from fully face-to-face to fully online courses, *hybrid* or *blended* courses are centered somewhere in the middle merging the most desirable aspects of both approaches (So & Brush, 2008). In a hybrid course, students spend more time learning online through planned activities, tutorials, assignments, and discussion. To make time for online activities, the face-to-face class meeting time is reduced significantly. Unlike the traditional lecture-based classroom (also known as face-to-face teaching), students have more flexibility regarding the time and place where learning occurs (Aycock, Garnham, & Kaleta, 2002). Some contend that this promotes students' active engagement in their learning, typically called *student-centered* or *constructivist learning*. Bransford, Brown, and Cocking (1999) argue that active, as opposed to passive, learners are better able to understand complex information, are more likely to transfer concepts learned in one setting to another, and are more likely to retain information.

BACKGROUND

As recently as the mid 1990's, most students did not own a personal computer, used single function technologies (e.g., phone, camera, video player), and had irregular access to the Internet. Today's students typically own computers, have multi-function mobile technologies, and use the Internet on a daily basis (McGee & Diaz, 2007).

The technological environment continues to change for faculty as well. During the 1990's the "technology" in the classroom originally consisted of chalkboards, overhead transparency projectors and VCRs. Classroom Internet access was not common. Additionally, faculty may or may not have had access to email from home, and if they did, dial-up service made home use of the Internet slow and sometimes unreliable. Today, more classrooms are equipped with various types of technology including Internet access, integrated projectors for computers and DVDs, audio and video devices for distance learning, and document cameras, to name a few. Typically, faculty members have home access to campus computing resources using improved broadband connections. Learning management systems, sometimes called *course management systems*, are becoming more commonplace and are enabling communications, learning materials, assignments, and grading to occur online.

Although face-to-face lecturing is still a mainstay of many professors' teaching repertoire, emerging technology is shifting the methods used by faculty (Maloney, 2007). Educators are no longer solely lecturers, but are increasingly becoming designers and facilitators of learning environments. Along with changes in technology, advancements in learning theory also play a role in this paradigm shift. Educators are now advised to incorporate more constructivist pedagogy in which active learning is accomplished (Rovai, 2007). Instead of focusing exclusively on the transfer of knowledge from teacher to student, educators are encouraged to find ways to motivate and involve students in the discovery and even the creation of knowledge. The expected outcomes of effective teaching are also changing. As educators move from a teaching-centered to a learning-centered model, student recall of information is not necessarily the preferred outcome. Student understanding, integration, and application become salient desirable outcomes. Indeed, changes in technology and learning theory are having an impact on how contemporary educators approach instruction. Many educators are beginning to teach in ways that differ from how they were taught when they were students (Hartman, Dziuban, & Brophy-Ellison, 2007).

According to Burbules (2007), education needs to be understood in the current context of technological ubiquity. Although definitions of Web

2.0 vary, the term acknowledges development of web applications beyond read-only websites that now allow Internet users to increasingly become content providers as well as receivers. The earlier developments on the World Wide Web served to disperse information in a top-down manner. Today, the web has evolved to be more participatory with collective users building information from the bottom up or interacting with each other in real time or asynchronously. The web is also increasingly accessible and user-friendly. Web feeds or web syndications update relevant information automatically, harnessing the combined intelligence of users. Social networking and resource sharing sites have emerged rapidly and "students have turned these sites into the nexus of their social and even academic universe" (Hartman, Dziuban, & Brophy-Ellison, 2007, p. 66). The current uses of technology are blurring traditional spheres previously viewed as separate. Work and play, learning and entertainment, accessing and creating, and public and private areas are no longer demarcated with clear distinction (Burbules, 2007).

This chapter reviews newer and emerging applications of technology, many of which are being used in education, particularly in hybrid courses blending traditional face-to-face teaching with enhanced technology. Learning management systems, user-created content, social networking, collaborative learning, podcasting, virtual worlds, and educational gaming are beginning to broadly affect higher education, and will continue to do so in the near future. The benefits and challenges of these emerging applications for hybrid learning are discussed.

HYBRID COURSES AND SOCIAL SOFTWARE

Courses taught in hybrid mode do not simply "add technology" to the existing curriculum, but should involve thoughtful course redesign in order to apply principles of good pedagogy fully augmented with outside-of-class activities enabled with technology. Bloom's taxonomy describes several categories of learning. In the cognitive learning domain, instructional activities range from lower levels to higher levels of learning. For example, as one moves up the hierarchy (knowledge, comprehension, application, analysis, synthesis, and evaluation) the development of intellectual attitudes and skills become increasingly sophisticated (Bloom, 1956). Higher thinking rests on a foundation of lower order thinking. For most courses, hybrid mode is best implemented by having the students do preparatory work outside of class so the in-class activities can provide an opportunity for learning at higher levels of Bloom's taxonomy with very little traditional lecturing occurring.

A Learning Management System (LMS) is an important component of most hybrid courses. It is a software application or web-based instructional technology used to develop, implement, and evaluate student-learning activities. Examples of learning management systems include Blackboard®, Webboard®, or WebCT®. Some faculty members create their own websites providing resources analogous to an LMS. An instructor may use the LMS to provide learning materials (e.g., readings, assignments, brief video, links to external websites, etc.) and social software applications (e.g., interactive chat, blogs, etc.).

A typical tool embedded in an LMS is an *asynchronous discussion board*. According to Martyn (2003), the asynchronous discussion board lets the students post technical and content-oriented questions, clarify assignments, post and answer each other's questions under the supervision of the faculty member, and build community. Gannon (2004) explains how she incorporated active learning into her course by giving students weekly online assignments, which included using the discussion board. Students were informed that their postings would be graded for quality and quantity, and Gannon observed that most students were motivated to participate and successfully completed the work. Likewise, a sample of 413 students in a hybrid setting reportedly found the discussion board tool more useful than in-class discussions because: (a) they could take their time to compose a response, (b) they were required to participate online as opposed to face-to-face where participation was not required, and (c) students who normally do not participate in class were less reluctant to participate online (Amrein-Beardsley, Foulger, & Toth, 2007). There is also evidence that participation in online discussion can enhance engagement during face-to-face in-class discussions (Vess, 2005).

Rovai (2007) provides a thoughtful synthesis of current techniques for facilitating online discussion effectively. Among his recommendations, instructors should provide forums for socio-emotional discussions as well as content and task oriented discussions. This serves to build a sense of community within the course. Similarly, instructors should balance developing a social presence in the virtual environment while avoiding monopolizing discussions. Additionally, instructors need to attend to social equity issues, and have an awareness of the communication patterns of culturally diverse students.

The LMS can also be used to observe student participation online, evaluate student work, exchange material with students, hold virtual office hours or classes, manage groups or teams, anonymously deliver student evaluations and grades, and provide for wikis or blogs. One study found that students identified the online grade book and announcements as most useful (Amrein-Beardsley et al, 2007). In this study, students appreciated timely posting of assignment grades, found it helpful to monitor their progress, and felt more college instructors should use the tool.

A web-based LMS should have the capability to link transparently to other web resources such as educational games, simulations, or other resources. Often a teacher will collect a number of resources in an organized fashion within the LMS, known as a learning module. The learning module enables students to accomplish one or more learning outcomes by performing a series of activities in an organized fashion. An LMS may be open-source, purchased for a license fee, or developed by a teacher to meet specific course requirements. LMS developers are encouraged to adhere to standards by following the Shared Content Object Reference Model (SCORM) to enable compatibility between LMS (for more information about SCORM, see http://www.adlnet.gov/scorm). LMS can have various Web 2.0 capabilities including: blogs, wikis, virtual classrooms, podcasting, Really Simple Syndication (RSS®), and e-portfolios, which are described below.

Blogs

A *blog*, short for *weblog*, provides the capability for the user(s) to post information about a particular topic or to maintain a diary with entries typically posted in reverse chronological order. Currently the fastest growing area of the web, blogs account for around 27% of all Internet use (Ramos & Piper, 2006). In March 2005 there were approximately two million blogs worldwide. Technorati®, a blog search engine, is now tracking over 70 million blogs, and notes about 120,000 new blogs are created worldwide each day. In academic settings, student blogs may be used to share information, to report on events, to practice writing, to develop argumentative and editing skills, and to engage in collaborative design. Students reading blogs may benefit from exposure to a variety of perspectives, values, and life experiences. Ramos and Piper (2006) argue that as the Internet becomes more accessible around the world, so do "the voices in the blogosphere, representing viewpoints from a diversity of cultures, and allowing glimpses into people's lives that have never before been possible" (p. 571). Blogs can be authored by groups or individuals, and may be authored by instructors or students.

Research on blogs has looked at their personal journal or storytelling function. Herring, Scheidt, Bonus, and Wright (2005) examined a random sample of blogs and found that more than 70% could be classified as personal journals. However, blogs differ from diaries in the sense that they are public and others can comment on blog entries. Stefanone and Jang (2007) studied the personality characteristics of bloggers and observed that individuals high in extraversion and self-disclosure tend to have larger online social networks with stronger ties. Furthermore, they found that rather than promoting isolation, blogs tend to enhance existing relationships. Research on educational uses of blogs is presently limited. Stefanone and Jang (2007) remark that the potential exists for studying the effects of public accessibility of personal information. Other potential research areas include: the strategic use of blogs by students, student decision-making on blog content, demographic and psychological factors affecting blog behavior, perceived student benefits of blogging, and faculty experiences with the use of blogs as an educational tool.

Wikis

A *wiki* is a writing space that is created and edited by a community of users (Saxton, 2008). Wikis provide the opportunity for educational collaboration where users may create text, link web pages, and edit their work. Wikis enable bottom-up editing where expertise is not limited to a few, but rather emerges from the combined efforts of the many (Ramos & Piper, 2006). Wikis and blogs can incorporate text, images, audio and video. They may be included in an LMS, or available as an open source product or licensed product. Wikis may be private to the class, often by authentication through the LMS, or open beyond the class. It is important to choose a wiki that meets the instructor's educational objectives. Phillipson (2008) identifies several different types of educational wikis, three of which are presented here. For example, he describes the *resource wiki* as an assemblage of a collaborative knowledge base, much like the popular Wikipedia®. The *presentation wiki*, on the other hand, may aim to represent class content to the outside world, and may also highlight the process the class followed to assemble the information. A *simulation wiki* is an interactive environment where exploration, decisions, and branching pathways dominate. Phillipson (2008) describes how students involved in the Holocaust Wiki Project, used background information to invent a family. Then, using multiple actors, narratives and story lines, they were able to explore and study this historical event through participation in the wiki. Although these and other potential uses of wikis as an educational tool are just beginning to be explored, clearly, wikis have wide ranging potential in student learning.

Podcasts

Podcasting, a term derived from the combination of Apple's *iPod*® and *broadcasting*, involves transferring digital media files, such as audio and video, over the Internet for replay using portable media players and/or personal computers. The function of a podcast is communicative; it is useful for sharing ideas and information, and enables learning to occur in a convenient and portable format. Podcasts appear to have significant potential as a mobile learning tool. Evans (2008) explored the use of podcasts as a method for students to review material after taking a traditional lecture class, but prior to their final examination. In this study, podcasts were not used as an alternative to attendance, but rather as a supplemental method of review. The findings demonstrated that students were receptive to using podcasts and felt that podcasts were more effective than their own textbooks and notes in helping them to learn. Podcasting can also make material more accessible to diverse learners (Cebeci & Tekdal, 2006). Some have even converted entire lecture courses into podcasts, allowing class time to be dedicated to problem solving and group project sessions. However, McGee, and Diaz (2007) advise against transmitting entire lectures through podcasting; instead, they recommend selecting shorter, more pointed segments for transmission which they contend will result in more student use. Villano (2008) provides practical advice for designing better podcasts in areas, such as communication skills, sound quality, length, and editing, to name a few. Additional research is needed on the effectiveness of podcasting as a learning tool (Evans, 2008). Podcasts have the ability to be syndicated, or subscribed to using an aggregator, such as an RSS® reader.

Really Simple Syndication (RSS®)

An *RSS® reader* receives feeds from content that is frequently updated, such as blog entries, podcasts, and/or news headlines. The reader or *aggregator* will frequently check the content of subscribed sites for updates and will display the new material. It will *aggregate* material from multiple sites into one location so that the user does not have to check multiple sites for updates. The RSS® reader may be incorporated in other educational tools, such as an LMS, wikis, or blog.

E-Portfolios

E-portfolios are an integrated collection of web-based multimedia documents that may include curriculum standards, course assignments and corresponding student artifacts, and reviewer feedback to the student's work (Gathercoal, Love, Bryde, & McKean, 2002). The evolution of web-based technology has made it easier to construct, store, and present evidence of academic work online. This, coupled with a shift toward competency-based education where students demonstrate what they have learned makes electronic portfolio development a growing trend (Johnson & Rayman, 2007). One example is the Digital Notebook project at Georgetown University. Students have an online space for learning, creating, collaborating, and storing the evidence of their work. Maloney (2007) explains: "Our hope is that the *Digital Notebook* will help students track how their thinking developed from their freshman to their senior year, in part by giving them the tools to map connections between the pieces of information they have learned and to share those connections and knowledge with others" (B27). As a practical matter, it is important to choose an e-portfolio format that meets the instructor's education requirements.

Virtual Classroom

Another possible component of some hybrid courses is the *virtual classroom*. "Virtual office hours" are possible through synchronous interactive chat (the equivalent of Instant Messenger®). The virtual classroom also provides other resources, such as an online "whiteboard" which has the capability to project material onto a "shared" screen which can be viewed by students when they are online. These sessions may be recorded and made available so that students can view them at a later time.

Folksonomies

With this capability, it is possible to add *tags* (keywords) to information providing the user with the ability to manage the information. This is also known as *collaborativetagging* and *socialclassification*. These tools make it possible to categorize and annotate content using tags and to provide the capabilities to associate tags with individuals. A *folksonomy* is user-driven and directly reflects the vocabulary of users. Folksonomies often arise in communities of web users, such as the Flickr® photo sharing site. It is anticipated that they will become popular because they place the responsibility of organization on the user. Folksonomies will likely become an important tool in student learning.

Educational Games

The video game market is currently the third fastest growing segment of the entertainment media market, and is expected to be a 48.9 billion dollar industry in 2011 (Scanlon, 2007). Two areas slated for growth are the so-called "serious games" which are used for non-entertainment or educational purposes, and the innovative attempts to begin combining gaming with the social networking features of Web 2.0 (Scanlon, 2007). These games (sometimes called Massively Multiplayer Online Educational Gaming) bring multiple players together in a goal-oriented activity that can be collaborative or competitive in nature. Educational games (*edugames*) typically involve role-playing exercises where player-learners work towards achieving educational objectives. For example, games designed to make business deals and build wealth help learners practice strategy and apply knowledge competitively (New Media Consortium, 2007). Another educational game might include virtual immersion (Multi-User Virtual Environments) in a foreign language or culture, where players read directions, travel, and interact with others to complete a quest.

One advantage of these games is that learning may be accelerated when there is an emotional response involved, such as excitement or interest (Waters, 2007). Another advantage is that the virtual world may provide a safe environment for trying new skills and making mistakes. In the virtual world, player-learners often use *avatars* (a computer user's one, two or three dimensional representation of himself or herself). These representations can enable player-learners to save face as they try to improve their skill (Waters, 2007). Research demonstrates that well designed *edugames* have the potential advantage of increasing intrinsic motivation and deepening learning (Moore, Fowler, & Watson, 2007). Although educational gaming is not heavily used today, the proliferation of open-source gaming engines will make it more realistic for developers to produce these tools for educational purposes.

Data Mashups

According to Maloney (2007), *mashups* are websites that "take dynamically changing pieces of information from completely different sources and compile the data into an integrated user experience, one that continues to change and grow as the underlying information changes" (B26-27). For example, the U.S. Environmental Protection Agency has created a Google® Earth mashup that generates maps of the earth displaying air quality based on pollutants from businesses (New Media Consortium, 2008). It is anticipated that mashups will help educators show their students relationships between large data sets in ways that are meaningful. They can also be used for artistic and creative expression.

Simulations

Because it is impractical or too costly to execute some educational experiments or events, often *simulator* tools are used to represent key elements of a physical or conceptual system. Because of the complexity of many of these systems, it is necessary to limit the number of elements represented. The *simulation* may be used to represent such things as a scientific experiment, a business process, or an engineering system. There are tools available for creating simulations such as those developed by Carnegie Mellon University as a part of their Open Learning Initiative. As these and other tools are developed further, it is anticipated that hybrid courses will play an important role in the evolution of the educational landscape.

BENEFITS OF HYBRID COURSES

Well designed hybrid courses have the potential to benefit students in a variety of ways. Students have access to multiple course resources, and are not limited to learning in a particular physical space. In many ways, hybrid courses shift the focus away from the instructor, and promote a more *learner-centered* model. The extended access to the materials allows students to learn at their own pace. Additionally, students typically participate in online discussion and networked shared learning. So and Brush (2008) found that students who perceived high levels of collaborative learning in their course tended to be more satisfied with their hybrid experience. Building community, having exposure to other points of views, expressing ideas, and giving and receiving peer feedback are important aspects of hybrid courses. Students also benefit from practicing technical and online skills they will need upon entering the workforce.

Marcketti and Yurchisin (2005) emphasized that undergraduates preferred the hybrid format to traditional offline format, and to a course that had exclusively online elements. Some argue that a good hybrid design can result in better student learning of past course objectives and achievement of new objectives. DeNeui and Dodge (2006) observed a significant positive correlation between students' usage of online components and their success in the course. In their study, those who used Blackboard® more frequently scored better on exams than those who used it less frequently. Furthermore, research using a blind review process demonstrated that students in well-designed hybrid courses completed projects that scored between 10-12% higher grades than those written by students in lecture format classes (Martyn, 2003). Also, well-designed hybrid courses add new learning outcomes, such as life-long learning and team-based learning skills. Institutions with increasing enrollments and limited physical space may find that reducing in-class time can lead to more effective utilization of classrooms and meet the greater demands for education (Olapiriyakul & Scher, 2006).

CHALLENGES OF HYBRID COURSES

Developing new methods of teaching takes motivation and an investment of time. When considering hybrid courses and the use of social software tools, it would be worthwhile for educators to conduct a *Strengths, Weaknesses, Opportunities and Threats* (SWOT) analysis of the objectives of the project. This will provide an opportunity to consider the various factors that are either favorable or unfavorable. The results of the analysis will be unique to the faculty member and the course involved. There are several good models for moving to a hybrid mode on various university websites. Also, some learning modules have been developed by universities and are freely available for use by other universities. The efforts of Carnegie Mellon University and the Massachusetts Institute of Technology (MIT) are noteworthy. Other modules are generally available on the Merlot.org website, and there are commercially developed products.

In addition to the specific technical aspects of the LMS software and other technology, faculty may need training in pedagogical principles that apply to hybrid courses. Training may include understanding the impact of various learning styles and principles, creating learning outcomes, and designing appropriate online content, assignments and assessment methods. Faculty members need institutional support in the form of incentives or release time from teaching to take on the additional work that comes with converting a face-to-face course into one with an online component (Grosjean & Sork, 2007). They also need access to faculty development professionals who have technical and pedagogical knowledge, as well as awareness about how to facilitate compliance with the Americans with Disabilities Act (ADA). Some of the other challenges that faculty and administrators should consider follow:

1. Faculty who are using hybrid mode will find it beneficial to explain to students how the use of this approach will help to achieve specified learning outcomes. In other words, explaining *why* they are participating in new educational activities is helpful. "Today making the transition from passive to active learners means engaging them [students] in the conversation from the beginning" (Moore, Fowler, & Watson, 2007, p. 52). Because this may be a new experience for the students, they will also need training and rules for professional behavior ("netiquette") in this environment.
2. The skills of research, critical thinking, and evaluation will be increasingly important to students who have unprecedented and instant access to user-created content of varying quality (New Media Consortium, 2007).
3. Most student evaluations of teaching effectiveness instruments were designed to assess face-to-face instruction, focusing primarily on an individual instructor. In hybrid courses, a broad spectrum of elements shapes the learner's experience (Grosjean & Sork, 2007). Some of these include the technology itself, the design of content, the organization and integration of materials, and even the faculty member's ability to moderate an online community. Methods of evaluating instructors may need to be modified to assess the instructor as a designer and facilitator of an interactive learning environment. In this learning environment, teaching excellence is becoming more multifaceted (Hartman et al, 2007).
4. Because faculty may be using the web and commercial products, they need to be aware of the Family Educational Rights and Privacy Act (FERPA) requirements as well as copyright and intellectual property requirements when using the products of others, including the copyright and intellectual property rights of their students.
5. Hybrid courses emphasize more self-regulated learning on the part of students. Although this develops students' active involvement, the research by Aycock and colleagues (2002) suggests that students' poor time management skills can be an obstacle. Understanding student motivation, appropriately pacing workload, providing sequential tasks, and having discussions about students' self-directed learning roles may be helpful.
6. It is also useful when implementing new instructional methods to provide students with opportunities for regular feedback. Grosjean and Sork (2007) recommend that instructors should be prepared to change aspects of their hybrid course if something is not working as intended. Evaluation, feedback, and reflection are necessary to make adjustments to hybrid courses over time.

FUTURE TRENDS

Although there is extensive research on students' satisfaction and perceptions of learning, only a few empirical studies have examined the influence of hybrid course technology on objective measures of student learning (DeNeui & Dodge, 2006), and more outcome-based research is needed. As a result, professional conferences and workshops related to hybrid learning are increasing in number and quality, with the non-profit Sloan Consortium (Sloan-C) as one of the leaders (http://www.sloan-c.org).

Shih, Feng, and Tsai (2008) examined research and trends in the field of e-learning between 2001-2005 and concluded that studies related to instructional approaches, information processing, and motivation will likely be influential topics for subsequent research. They predict that an essential issue in future research will be "how to maintain and enhance students' learning motivation and teachers' teaching motivation in a constantly changing educational environment" (p. 965). Additionally, they contend there may be enhanced "personalization" of education, whereby increased variety in the ways in which teaching occurs can accommodate various learning styles.

Many of the Web 2.0 tools now available have been developed with little thought about using them for educational purposes. It is anticipated that the future will bring seamless ties between these tools allowing them to be geared more towards educational applications. For example, although not used significantly in education currently, it is anticipated that social resources, such as Second Life®, will be incorporated as a learning tool along with social software networks that were developed primarily for industrial use.

According to the most recent *Horizon Report* (New Media Consortium, 2008), as globalization increases, online collaboration webs and the tools that support them are also expected to increase. Collaborative webs are networking sites that interested individuals or groups can access to foster educational sharing capabilities. Some examples include San Francisco State University's Digital Information Virtual Archive (diva.sfsu.edu) and Skoolaborate® (www.skoolaborate.com).

As ubiquitous as the broadband mobile phone has become, the varied features of it have also become more common: e.g., music playing, recording, camera and video capability, and photo storage. It is anticipated that these portable multimedia features will also be increasingly used for educational applications (New Media Consortium, 2008).

CONCLUSION

This chapter has discussed the benefits and challenges of hybrid courses that blend face-to-face instruction with online learning and opportunities provided by the introduction of web-based social interaction technologies. The best hybrid courses are based on thoughtful design and utilize active learning, both in online education and interactive face-to-face meetings. The success of a hybrid course will be enhanced by: (a) effective planning and integration of the face-to-face and online activities to achieve the desired learning outcomes for the course; (b) choosing the appropriate tools to achieve the desired outcomes; (c) faculty preparation to enable the effective use of the new learning environment; and (d) developing a plan positioning students to understand their new role and how they can be successful in it. If a hybrid course is designed properly, the strengths are likely to be: (a) increased learning by students; (b) more engagement by students because the course can be designed to allow them to bear responsibility for its success; (c) more enthusiastic participation by the students; (d) an opportunity for faculty to participate in a completely new way of teaching by having student-centered activities; and (e) ultimately a course that is more organized. The use of technology and development of hybrid courses will continue to evolve to meet the needs of contemporary students, faculty, and institutions of higher learning.

KEY TERMS AND DEFINITIONS

Asynchronous Discussion Board: An online bulletin board where users may post and respond to messages in *forums* which are specific topic areas for discussion. Subordinate discussions within a forum are often called *threads*. Since users do not have to be online at the same time, they can enter the discussion board according to their own schedules.

Avatar: A computer user's one, two or three-dimensional representation of himself or herself in a virtual space (See Multi-User Virtual Environment).

Blog: Short for *weblog*, a *blog* provides the capability for the user(s) to post information about a particular topic or to maintain a diary with entries typically posted in reverse chronological order.

Electronic Portfolios or E-Portfolios: An integrated collection of web-based multimedia documents that may include curriculum standards, course assignments and corresponding student artifacts, and reviewer feedback to the student's work.

Folksonomy: Also known as *collaborative tagging* and *social classification*, *folksonomies* make it possible to categorize and annotate content using *tags* (keywords) and to provide the capabilities to associate tags with individuals.

Learning Management System (LMS): A software application or web-based technology used to develop, implement, and evaluate student-learning activities. Examples of Learning Management Systems include Blackboard®, Webboard®, or WebCT®.

Multi-User Virtual Environment (MUVE): A virtual environment that enables simultaneous participants to represent themselves with avatars, interact with other participants and digital artifacts, and practice building skills or solving problems that have applications in real world contexts.

Podcast: A method of publishing digital media files for transfer to and playback on a computer or a portable media player.

Web 2.0: An improvement in the application of the web infrastructure to support communities on the web and deliver services such as *wikis*, *blogs*, *folksonomies*, and other social interaction technologies.

Wiki: Software that provides the infrastructure for faculty and/or students to collaboratively develop and link Internet web pages. Each *wiki* has its unique characteristics, but most have tracking of individual effort and recovery of past versions.

Chapter 3.10
The Use of Social Interaction Technologies in E-Portfolios

Swinburne University of Technology, Australia

Julie Mulvany
Swinburne University of Technology, Australia

ABSTRACT

The chapter focuses on the potential of electronic portfolios (e-portfolios) to engage and motivate the learners and presents a framework for the informed inclusion and adoption of social interaction technologies as a means to increase the effective use of e-portfolios. Electronic portfolios are a Web-based format for providing genuine evidence of student performance, self-reflection, competence, career planning and leadership. The e-portfolios meet the needs of the digital learner in the knowledge society. The collaboratively constructed artifacts enable the articulation of shared knowledge building and self-reflective practice, further confirming the status of e-portfolios as living documents. By their electronic nature, e-portfolios open promising opportunities for the assimilation of social interaction technologies such as blogs, wikis, podcasts, video, and photo sharing. The authors trace the development and use of e-portfolios within the context of higher education. Various e-portfolio tools are discussed along with their educational potential and the associated challenges.

DOI: 10.4018/978-1-60566-368-5.ch021

INTRODUCTION

A significant body of research exists that identifies electronic portfolios (*e-portfolios*) as a first-rate tool for providing genuine evidence of performance, self-reflection, competence and leadership in students. The collaboratively constructed artifacts enable the articulation of shared knowledge building and self-reflective practice, further confirming the status of e-portfolios as living documents. e-portfolios, by their electronic nature, open promising opportunities for the integration of various social interaction technologies, such as blogs, wikis, podcasts, video, photo sharing, and others.

The chapter focuses on the potential of social interaction technologies to engage and motivate learners to extend their participation in the e-portfolio process and so enable them to document lifelong learning capabilities as well as promote deeper learning (Tosh & Werdmuller, 2004). The authors trace the history, development and use of e-portfolios within the higher education context. Theoretical frameworks and educational potential are addressed along with the associated developmental challenges including individual commitment and engagement, deep learning and reflection, and assessment. The theories of "constructivism" and "connectivism" (Siemens, 2004) that underpin the adoption of social interaction technologies are reexamined. Finally the chapter concludes with arguments for the informed inclusion of social interaction technologies as a means to address factors currently impeding the effective use of e-portfolios.

BACKGROUND

The use of e-portfolios in higher education is preceded by the traditional use of paper-based portfolios. Portfolios have had a long history as the showcase tools of artists, whereby they contained completed pieces of work to demonstrate skills and talent. Since this time portfolios have been widely used in a variety of disciplines, particularly in the field of education. The extensive use of paper-based portfolios in education (Tomkinson, 1997) has informed the transition to electronic portfolios, also known as e-portfolios.

In the U.S. and Western European education and training, extensive resources have been allocated to assist in a system-wide adoption of e-portfolios. Portfolios are being increasingly used as a career advancement tool (Redish, Webb, & Jiang, 2006). In Europe, The Centre for Recording Achievement in the United Kingdom (Beetham, 2006) and the European Institute for eLearning (The Higher Education Academy, 2005) are promoting the use of Personal Development Plans whereby each individual has a personal electronic portfolio that contains "evidence of an individual's achievements over a lifetime of learning and employment." In the teacher education sector, for example, some graduates in the United States are required to demonstrate mandated National Standards prior to being granted teacher registration (Ma & Rada, 2005). With the introduction of Teacher Registration Boards and other accreditation bodies in all Australian States, it appears that Australia is moving in the same direction.

In its simplest form, an e-portfolio is a collection of evidence that reflects a learner's progress, development and achievement over time. Depending on the discipline, the e-portfolio usually contains education history, certificates, work-samples, awards, personal values, interests, photos, videos, observation, feedback from supervisors/peers, evaluations, and—importantly— reflections on each piece of evidence. The reflective comments highlight the reason for selection and the learning that occurred. These reflective processes and comments are the key to an e-portfolio. It is through this reflective process that the learner is provided with "learning spaces where he or she "can gain insights and a better understanding of him/herself as a learner" (Greenberg, 2003, p.12).

The expansion of the World Wide Web has considerably transformed the potential of e-portfolio. The graphical nature of the web and ability to link digital artifacts has revolutionized how information is located and reviewed. Web technologies now allow authors to seamlessly integrate text with graphics, audio and video. This visual capacity provides additional options for showcasing the authors' accomplishments. Importantly, the linking mechanism of the web allows for tight integration between the elements of a portfolio and adds opportunity to connect the portfolio to the whole world.

According to Siemens (2004), the growth of e-portfolios has been "fuelled by three broad factors: the dynamics of functioning in a knowledge economy, the changing nature of learning, and the changing needs of the learner." In a knowledge economy, he argues, it is important for individuals to demonstrate their knowledge effectively, and the e-portfolio can display competencies and attributes undetected in an academic transcript. Siemens (2004) asserts that learning is also changing and that it is important to recognize that learning occurs in communities. Formal education becomes simply one aspect of one's learning journey. The final factor influencing the adoption of e-portfolios, as Siemens (2004) claims, is that the social impact of technology has changed learners' needs. Learners currently entering higher education are comfortable with the electronic environment, and actively seeking to engage with it.

Although, e-portfolios, conceptually are similar to paper based portfolios, they have some distinct advantages over their paper counterparts. It is easier to organize, view and search an electronic portfolio. Depending on the software being used, a larger number of records can be securely stored, retrieved, and managed, and records and artifacts can be refined with little effort. e-portfolios enable the inclusion of more varied and extensive material, such as audio and visual artifacts, thus allowing for a multidimensional representation of the learner. The electronic nature of the e-portfolio enables a more creative and non-linear organizational structure. Their reduced size enables easy portability and access. This ease of access allows the learner to receive rapid and regular feedback from others.

Unlike traditional portfolios e-portfolios may be reviewed by anyone, anywhere and anytime, and the author can control the nature of the interaction through organizing access (Greenberg, 2003). Exchanges can be private or public – teachers can provide feedback and discuss the student's progress, students might discuss their work with each other, feedback can be sought from a wider audience, and individuals can reflect on their learning experiences (Greenberg, 2003). E-portfolios are relatively simple and inexpensive to reproduce and distribute. In addition, e-portfolios can showcase the technical and communication skills of the creator. A growing body of research documents the advantages of electronic over paper based portfolios to enhance student reflection and learning and to provide improved evidence of student achievement to external groups (see, for example, Barrett, 2000; Butler, 2006; Greenberg, 2003; Jafari & Kaufman, 2006; Wetzel & Strudler, 2005). The use of e-portfolios in an educational environment facilitates student centered, reflective learning practices to complement flexible curriculum design. In addition, it provides students with a vehicle to demonstrate the acquisition of attributes and competencies valued by potential employers.

Integrating Electronic Portfolios with Web 2.0 Technologies

Institutions of higher learning around the world are embracing student centered learning as a dynamic and effective approach for higher education: an approach which places the student at the center of their own learning experience and allows them to become active participants in their learning endeavors, constructing knowledge on their own terms (Biggs, 2003; Entwistle, 1997; Entwistle & Ramsden, 1983; Laurillard, 2002). In response to this trend, curriculum design in colleges and universities is increasingly focusing on capabilities rather than content. Students are progressively being asked more to demonstrate not only their general knowledge and skills within their discipline areas but also to articulate explicitly how they analyze, reconstruct and apply knowledge contextually in a variety of real life learning situations (Bowden, 2004; Bowden & Marton, 1998).

Student e-portfolios are extremely responsive to current curriculum reform because they can be used to satisfy a variety of assessment and evaluation requirements in courses and programs. e-portfolios offer a suitable environment for a range of summative assessment tasks, as well as provide for continuous growth and reflection in the formative development of students and professionals alike. They are particularly well suited to holistic and iterative assessment and offer a forum where group work, self-assessment, and other employability skills can be articulated and evidenced.

By their very nature e-portfolios are flexible tools which can be tailored to specific educational contexts (Meeus, Questier, & Derks, 2006) and are used in a wide range of ways in student learning contexts. Meeus, Questier and Derks (2006) suggest that e-portfolios are grounded pedagogically or educationally because they are student centered, competence oriented, and multimedia oriented; they are also cyclical with regard to action and reflection. It is these characteristics and the flexible nature of the technology which optimizes their educational use.

From a learning theory perspective, e-portfolios support student centered learning approaches as they give students the opportunity to display a broad range of learning skills and attributes across an extensive range of learning domains (Knott, Lohani, Griffin, Loganathan, Adel, & Wildman, 2004). However, as Norman (1993) points out, modern day curricula often provide students with learning activities that are more concerned with experiencing various phenomena than encouraging reflective cognition. Electronic portfolio practitioners (Barrett, 2006; DiBase, 2002; Knott et al, 2004; Lambert & Corrin, 2006; Richards, 2005) claim that e-portfolios facilitate the reflective process in students by recording and articulating students' learning experiences on multiple levels, thus enhancing the learning experience and engaging the student in a more profound analysis of the subject content.

David DiBase (2002) in his long term e-portfolio work at Pennsylvania State University notes that the key benefits of e-portfolios relate more to the process of developing and constructing the portfolio than to the final portfolio product. The constructive stages of collection, selection, reflection, projection, and presentation of the e-portfolio help to facilitate and encourage students to adopt a more reflective approach to learning. It is through this constructive process that students become more actively involved in planning their learning and more personally responsible for setting and achieving their educational goals (DiBase, 2002; Meeus et al., 2006). e-portfolios empower learners by allowing them to take control over their personal learning journey (Siemens, 2004; Tosh & Werdmuller, 2004). The reflective nature of e-portfolios encourages transformative practice. This notion is consistent with constructivist theory which argues that learners construct their own knowledge rather than simply receive it from others. Institutes who have a university wide commitment to curriculum that is student centered, or based on authentic learning models, are more likely to be able to encompass the broad range of educational opportunities that e-portfolios can provide.

The adoption of a more student centered, authentic approach to learning ultimately promotes the notion of life-long learning. e-portfolios can be shared with other staff members and a systematic record of student progress can be established. When staff members collaboratively participate in the assessment process of e-portfolios, either formative or summative, they not only provide students with feedback concerning their progress toward achieving their learning goals, but also provide feedback about the effectiveness and impact of the learning experiences the course provides. When this process is adopted, students have evidence they can plan the advancement of their personal learning and staff can see how their teaching, and ultimately the course, can be improved (Raison & Pelliccione, 2006). This three-way approach benefits the learner, staff and the institution.

Traditionally universities have been successful at developing knowledge and skills within defined discipline areas; however, both global challenges and pressure from industry to produce work ready graduates (see, e.g., European Ministers of Education, 1999; UNESCO, 1998) has forced academic staff to rethink how they can explicitly develop and assess less tangible capabilities. These include: the ability to deal with new, changing situations and problems, self-reflection and critique, the application of prior learning to new contexts, the ability to understand and deal with others' perspectives, and how individual students can work within a team to resolve and deal with multiple issues and problems. These skills and abilities are frequently referred to as graduate attributes, key competencies or generic attributes. Many colleges and universities are now looking to e-portfolios as tools to demonstrate and articulate students' acquisition of these attributes.

Social interaction technologies, often referred to as "Web 2.0 technologies," are providing academics with flexible online learning environments to stimulate and record complex social interactions that can evidence student acquisition of "work-ready" attributes and skills. These new technologies along with other "digital traces" or "digital knowledge artifacts" (such as writings, images and digital media files) are already allowing for sophisticated representation of relational concepts or processes (Vuorikari, 2005). A range of Web 2.0 technology tools is being utilized for e-portfolio development which afford learners different degrees of control, flexibility, and skill requirement: including specifically designed digital portfolio systems (such as PebblePad, Learning Assistant, and QuickStep); and, content-management systems offering e-portfolio functions (for example, Blackboard, WebCT, and LearnWise).

Weblogs and wikis are being increasingly and successfully used within electronic portfolios to establish collaborative learning environments that both engage and motivate students, and promote greater retention of knowledge (BECTA, 2007, Shelley, Cashman, Gunter & Gunter, 2007). Hiler (2003) refers to the *blog* as "the latest disruptive technology" and the "killer application." He claims that blogs provide a space for a variety of interests and promote collaborative activity, knowledge sharing, reflection and debate. Oravec (2002) also found that blogging encourages personal reflection and collaboration. The exposure to blogging tools empowers students and encourages them to become more sophisticated critical and analytical thinkers (Ferdig & Trammel, 2004; Oravec, 2002). In addition, Ferdig and Trammel (2004) suggest that the relaxed and conversational tone makes the experience more conducive to improved student and lecturer relationships.

The potential of Web 2.0 technologies to enhance educational learning environments, in particular e-portfolios, has not escaped the notice of commercial vendors. Waters (2008a, 2008b) documents the influence of these new tools on a number of commercial electronic portfolio systems -- Digication, Desire2Learn, Angel Learning and Epsilen. Waters (2008a) refers to the *Epsilen* as a "new species of electronic portfolios." The Epsilen software was developed by the CyberLab at the Indiana University-Purdue University of Indianapolis which is directed by Ali Jafari, computer technology professor, who has a long history working with electronic portfolios. A basic Epsilen e-portfolio account is available free to registered students and staff at all United States colleges and universities. They currently have members from 950 institutions (Epsilen, 2008). A similar environment to Epsilen, named *PebblePad,* was developed in the UK and claims to bridge the gap between social and institutional learning: "PebblePad supports personal learning whilst providing a powerful suite of tools to improve learning in institutional contexts" (PebblePad, 2008).

In addition, a number of open source e-portfolio systems have embedded various Web 2.0 features, such as blogging, wikis, messaging and group collaboration capabilities. An example of this system is the OSPortfolio (OSP) which is part of Sakai (an open source web-based collaboration and courseware management platform); it has been adopted by at least 60 institutions across 8 countries (Cambridge, 2008). One of the most recent open source e-portfolio systems was designed and funded in New Zealand by New Zealand's Tertiary Education Commission's e-learning Collaborative Development Fund (2006). *Mahara,* which is colloquial Maori for "think" or "thought," is an open source e-portfolio, weblog, resume building and social networking system. It differs from other e-portfolio applications by its particular emphasis on social networking and system architecture inspired by *Moodle* for better interoperability (Wyles, 2008).

Integration of the Web 2.0 technologies and electronic portfolios continues. In a recent paper "The Value of eJournals to Support e-portfolio Development for Assessment in Teacher Education" presented at the 2008 Annual Meeting of the American Educational Research Association, Crichon and Kopp (2008) introduced an application called Electronic Documentation of Learning (eDOL) which allows students to document their field experiences in the form of an eJournal using text, photo, and video entries. Other software developers also continue to refine the assessment mechanisms of e-portfolio systems and are now attempting to extend the learning capabilities of the e-portfolio by taking advantage of the interactive facilities of the Web 2.0 technology. Subsequently, e-portfolios are beginning to take the form of a collage with various applications: namely, file sharing, databases, search facilities, wikis, podcasting, and other social media. Perhaps, the future of these new and other emerging tools will see the merging of e-portfolio systems with the personal learning environments (PLE) of new digital age students.

FUTURE TRENDS

Gary Brown, the director for the Center for Teaching, Learning, and Technology at Washington State University, has argued that the advent of Web 2.0 technologies will invariably change the boundaries between e-portfolios and personal learning environments (cited in Waters, 2008b). He views electronic portfolios as being part of a continuum with assessment management systems at one extreme and personal learning environments at the other. Personal learning environments can be viewed as systems that are designed to help learners take control and manage their own learning space. It is argued that a personal learning environment can enable students to set their own learning goals, monitor their progress, manage the process and content of their learning, and set up communication networks that support both their formal and informal learning.

In an earlier article from Handley and colleagues (Handley, Wilson, Petersen, Brown, & Ptaszynski, 2007) the concept of creating personal learning spaces in higher education is further explored. The authors suggest that university educators move beyond the traditional "walled gardens" approach to the point of designing learning spaces for each learner. In this way the learner is able to "aggregate, synthesize and reflect upon their learning." The key concept is to place the learners at the center of their educational universe by providing them with the tools to control who has access to their own personal "walled garden." The Microsoft SharePoint System (2007) is seen as a functional platform that can provide such an environment. Washington State University has recently adopted this collaboration and document-sharing platform to introduce e-portfolios across the university. Specifically they suggest: "In the model facilitated by SharePoint as an e-portfolio, the student is the central node in the learning network. A course, learning object, learning activity is available and students are invited to engage, but they are the owners of their own space and the work they will do, share, and showcase in that space" (Handley et al., 2007, p 3).

Siemens (2006) stresses that educators need to continuously reflect on how learning has changed and how this change impacts the way the learning spaces and structures are designed. He argues that the utilization of new technology tools alters the way people work and function and posits a new theory of learning called "connectivism." This theory acknowledges trends in learning, the use of technology and social and learning networks, and the "diminishing half-life" of knowledge (2005, 2006). Connectivism integrates elements of a number of learning theories, social structures, and technology to present a theory more conducive to the needs of the knowledge society. Siemens (2006) notes:

Our desire to connect – to externalize – is a vital component of the learning process. Instead of merely developing learners for careers, we have an obligation to create a learning ecology where learners are able to shape their own meaning.

Siemens (2006) challenges educators to design learning spaces that reflect a new understanding of learning and meet the needs of the digital learner in the knowledge society. The challenge has implications for the future landscape and use of e-portfolios. He claims that freedom and flexibility to design such learning spaces will be lost if the trend to centralize and standardize e-portfolio tools and services continues (2004).

The web is shifting from being a utility where information is transmitted and consumed into a platform where content is created, shared, and remixed with a community of learners (Downes, 2006). Brown (2002) considers this as a fundamental shift from using technology to support the individual to using technology to support relationships between individuals. The new social media applications and social networking sites support learning communities by providing tools that enable and promote dialogue, collaborative content building, and the sharing of information, giving learners access to a range of knowledge and ideas (Lee & McLoughlin, 2005). The merge of e-portfolio tools and processes with social software has the potential to deliver the dynamic and flexible learning spaces required for digital age learners. This union will not only build knowledge but will build relationships and encompass the powerful elements of reflective practice, higher order thinking, learner control, "connectivism," community of learners, social integration, and lifelong learning.

There are many benefits associated with the use of e-portfolios; there are also many hidden costs, obstacles, and challenges involved in their implementation (DiBase, 2002). Most practitioners and institutions that adopt e-portfolios report that they are labor intensive and require considerable time in planning, monitoring and provision of feedback to students (Linn & Gronlund, 2000; Strudler & Wetzel, 2005). Students need time, support, technical training and guidance (Heath, 2005; Pecheone et al, 2005; Smith & Tillema, 2003; Tosh et al, 2005; Wade & Yarbrough, 1996). Technical skills required may disadvantage the student if the student is being assessed on their technology skills over their learning (Abrami & Barrett, 2005). If used predominantly for assessment purposes, e-portfolios can be difficult to assess, requiring extensive preplanning in the establishment of reflective evaluation and performance (Abrami & Barrett, 2005).

Students also need to be given clear guidelines as to the validation of claims and authenticity of evidence as artifacts are easily plagiarized from the Internet (Abrami & Barrett, 2005). Students need briefing about issues surrounding digital rights, intellectual property, copyright, privacy and free speech (Challis, 2005; DiBase, 2002). Many of the Web 2.0 technologies require extensive moderation and skill development. Institutions need to be aware of the ramification on their curriculum accreditation processes, professional development of staff, and the hidden costs associated with the technological "up-skilling" of students.

Institutions will need to address ways of storing the large volume of data produced by students as well as developing policies on how long they support and maintain the data. Issues of access, security and privacy will also need to be addressed.

Future consideration will need to be given to the development of new learning spaces to enable the crossing of the social, educational, cultural, professional, and political boundaries of students to give voice to a learner's efficacy in a variety of overlapping contexts.

E-portfolios will need to become living documents that are "portable" through the life of the learner to meet a variety of usages encompassing assessment, promotion, cultural identity and professional reflection (Vuorikari, 2005). An integrated approach to e-portfolios can certainly support community building among learners but is unlikely to be driven by educational agendas alone. The technology associated with these new environments will also need to deal efficiently with the rapid re-contextualization of content for a variety of different purposes in the learner's life.

CONCLUSION

Electronic portfolios offer students the prospect of reflecting on their personal and profession skills and the opportunity to demonstrate a range of lifelong capabilities. e-portfolios can be used to reflect the knowledge and skills obtained in an academic context; they can also incorporate social abilities and skills acquired in community, work and familial settings. e-portfolios can be constructed in such a way that they become living transportable documents used in a variety of career and professional contexts. The e-portfolio has the potential to become a living document managed and maintained dynamically over time; it can be constructed and reconstructed to meet a variety of social, professional and personal needs. Social interaction technologies have the power to add dynamic dimension to the e-portfolio process by creating spaces that encourage the development of a reflective community of learners that will motivate and inspire individuals to revisit, revise and reshape their experiences to reflect their learning journey.

KEY TERMS AND DEFINITIONS

E-Portfolio: A collection of evidence that reflects a learner's progress, development, and achievement over time in a digital format.

E-Portfolio Artifacts: Tangible evidence (i.e., work samples, reflections, photos, videos, feedback from supervisors/peers, awards, etc.) that demonstrates knowledge and skills and their application to various tasks and situations.

Epsilen: A comprehensive e-learning environment designed in the U.S. that includes an e-portfolio feature.

PebblePad: A flexible commercial e-portfolio system designed in collaboration with the University of Wolverhampton, UK.

Personal Learning Environments (PLE): Learning systems that are purposely designed to help learners take control and manage their own learning space.

Sakai: An open-source course management system that includes a full-featured online portfolio.

Student Centered Learning: An instructional approach that places the student at the center of the learning experience and allows students to become active participants in their learning endeavors and construct knowledge on their own terms.

This work was previously published in the Handbook of Research on Social Interaction Technologies and Collaboration Software: Concepts and Trends, edited by T. Dumova and R. Fiordo, pp. 233-244, copyright 2010 by Information Science Reference (an imprint of IGI Global).

Chapter 3.11

The EduOntoWiki Project for Supporting Social, Educational, and Knowledge Construction Processes with Semantic Web Paradigm

Corrado Petrucco
University of Padua, Italy

ABSTRACT

The Web is going to produce a revolution in learning and teaching: the debate on the role of ICT in educational processes leads to a reconsideration of how we deal with information and knowledge. The widespread use in educational contexts is also due to the ease with which learning resources can be retrieved and shared: for example, the recent introduction of learning objects means that the contents which reside in different e-learning platforms is easy to find and access. But knowledge is also deeply embedded in millions of Web pages. Nonetheless, searching for information on the Web is not a simple task and the great number of documents found using search engines, such as Google, is beyond the human cognitive capacity to deal with this information overflow. Teaching information literacy skills or stimulating collaborative information filtering that supports the discovery of resources in a way that is responsive to the context of users may help, but there is a need for more efficient cognitive tools to search, organize, and discuss information in order to codify it in shared knowledge structures.

INTRODUCTION

The Web is going to produce a revolution in learning and teaching: the debate on the role of ICT in educational processes leads to a reconsideration of how we deal with information and knowledge. The widespread use in educational contexts is also due to the ease with which learning resources can be retrieved and shared: for example, the recent introduction of learning objects means that the contents which reside in different e-learning platforms is easy to find and access. But knowledge is also deeply embedded in millions of Web pages. Nonetheless, searching for information on the Web

DOI: 10.4018/978-1-59904-845-1.ch026

is not a simple task and the great number of documents found using search engines, such as Google, is beyond the human cognitive capacity to deal with this information overflow. Teaching information literacy skills or stimulating collaborative information filtering that supports the discovery of resources in a way that is responsive to the context of users may help, but there is a need for more efficient cognitive tools to search, organize, and discuss information in order to codify it in shared knowledge structures.

In a more and more complex world we need support to think at a high level so the technologies let us develop strong knowledge structures that do not have the representational problems of the old schemas. An attempt in this direction is the Semantic Web: if we succeed in making the Semantic Web available and useful for education, it could revolutionize the way we think about teaching and learning with ICT. Our current research is aimed at the development, experimentation and evolution of an integrated learning environment called EduOntoWiki that is backed up by a semantic structure based on the active consent of communities of practice.

BACKGROUND

Current research suggest that it is not correct to assume that the introduction of ICT necessarily changes the way students learn. We have to acknowledge that the teacher plays a critical pedagogical role in creating the conditions for technology-supported learning through selecting and evaluating appropriate technological resources and designing learning activities (Galliani, Costa, Amplatz, & Varisco, 1999). We can distinguish between two approaches to ICT: a technology-centered approach and a learner-centered approach (Mayer, 2005). The former generally fails to lead to lasting improvements in education: looking back at the many predicted educational revolutions, in which the current "new" technology (radio, television, computer, multimedia, the Web) would have been the "killer" application for teaching and learning processes, we see that they failed to materialize (Cuban, 1986) and so was the case with the claims and worries, during the 1960s, that computers-as-tutors would replace teachers (Cognition and Technology Group at Vanderbilt, 1996). A learner-centered approach can, on the other hand, help students and teacher to learn and teach through the aid of technology with a focus on how ICT can be used as an aid to human cognition and consistent with the way the mind works solving complex tasks and dealing with today's information overflow. The quantity and kind of information students today need to assess has expanded exponentially in the last few years, due mainly to the World Wide Web and improvements in the capabilities of search engines. In this context, it is important to consider both student and teacher roles using a constructivist approach that can stimulate collaborative formalization and knowledge building.

SEMANTIC WEB AND ONTOLOGIES

The Web has arrived at an important epistemological crossroad and there is a need to integrate the current dialogic-informative model, which allows us to interact with people and search for documents on the Web, with a model based on the contextual knowledge domains within which we operate: the Semantic Web approach (Berners-Lee et al., 2001). Both models are strongly based on a learner-centered approach so the applied research, in particular in the field of ICT and educational technologies, is moving in two directions:

1. The development of solutions for information exchange, and in general, for intelligent knowledge management;
2. The development of a collaborative/cooperative approach to knowledge building.

The Semantic Web was coined by Tim Berners-Lee to refer to a vision of the next evolution of networks that can add meaning to the navigational context of the current World Wide Web. It is the new-generation Web that makes it possible to express information in a machine-interpretable form, ready for software agents to process, as well as to understand what the terms describing the data mean both on the syntactic and semantic levels (Hendler, 2001). An important role in the development of the Semantic Web is played by ontologies (Gruber, 1993). The term is borrowed from philosophy but it is used in a different and more pragmatic sense: they are an explicit specification of a conceptualization, that is, a formal description of concepts and relationships that can exist in a knowledge domain, that is intended as a knowledge base to be shared and re-used in the real world. These ontological structures will, for instance, allow us to no longer surf the universe of documents on the Web through hypertext links from text to text, but from concept to concept; or even to retrieve information in a relevant way without the "noise" that characterizes search engines. In order to achieve this aim, formalized languages have been created (XML, RDF) to mark texts semantically. These languages, which are able to codify knowledge through domain ontologies, can be easily understood both by humans and by ad hoc programs such as semantic browsers (Dzbor, Domingue, & Motta, 2003) or by specific software agents.

The importance of ontologies has been recognized in different research fields, and even from an operational point of view the current application areas are different: from medicine to knowledge content standardization, from legal information systems to biological and geographical information systems, from e-commerce to natural language processing, and finally education (Devedzic, 2004). Our current research project is aimed at extending and integrating the construction and evolution of a semantic learning space that is backed up by ontological structures relative to educational sciences (Petrucco, 2003) based on an active consent of communities of practice.

THE EDUONTOWIKI PROJECT

The different training and background of those who contribute to educational theory, the different cultures they belong to, and the rapid development of scientific work today require the development of a series of shared conceptual schemas. It is important then to generate these schemas not as general principles but as justified, motivated, documented and finally usable schemas as control "criteria" of pedagogic discourse. As an ontology is basically a conceptual organizer of scientific discourse, it is a formidable support to hermeneutic work.

Within this context we developed the idea to build an ontology of education. The project takes into account the state of the art of educational research in Italy, France, Spain, Germany, England and Spain. The three thematic areas studied, at least in this first step of the project, are: *didactic planning*, *educational communication*, and *assessment* and *evaluation*. The ontology is "negotiated" in working exchanges and dialogical moments in order to develop a circularity of information flow within the virtual community of the experts involved in the project and other actors participating.

The project has been developed with the immediate aim of building an integrated semantic learning environment called "EduOntoWiki" (http://multifad.formazione.unipd.it/eduonto), a wiki-based environment where it is possible to construct, discuss, and contextualize ontologies suitable for describing the actors, processes and technologies of educational sciences. A wiki was chosen because it enables easy and immediate insertion, modification and sharing of texts and materials by a community of users (Wikipedia is a good example) and because it gives freedom over the knowledge creation process to users. The recent promising research in the application of the semantic Web to wiki software (Campanini, Castagna, & Tazzoli, 2004; Hepp, Bachlechner, & Siorpaes, 2005; Scaffert, Gruber, & Westenthaler, 2005) confirm this decision.

Indeed, our initial vision conceived the instrument as a tool to help in the creation of an ontology and the description of a specific knowledge domain mediated by a discussion within a community of practice. To be really useful an ontology requires the active consensus of a committed community of practice in a knowledge domain (Domingue, 1998; Trentin, 2004) as experts of do not always completely share the same categorizations, interpretations and distinctions. Often this is not only because of the reciprocal irreducibility of fundamental theoretical orders, which is both physiological and necessary, but rather because of the confusion created by the different meanings given to "key" terms in the discipline in question.

If it were possible to have an "ontological" reference model with shared lexis and semantics, as regards both terms and their relations, this would probably help to reduce conflicts which arise from misunderstandings and incomprehension. Ontologies created in this way would also have a significant side-effect for all the actors involved: first of all the definition of a common lexis (Wenger, 1998), then a strong push towards the conceptualization of tacit knowledge, and finally the sharing of a metamodel in which processes, knowledge and relations are shared. Defining ontologies which support educational applications based on the Web is therefore no simple task, above all because of the difficulty in formally conceptualising a domain which has always played on the idiosyncratic interpretation of each philosophical/pedagogical approach.

Ontologies would be useful not only to the academic community, but as far as their didactic use is concerned, we can think of an ontology or a series of "educational" ontologies, that could be used and discussed by students, teachers, and people interested in the real world of applications and training contexts. This "open" ontology paradigm can offer considerable advantages. For example, it could provide a medium which would foster the sharing of the basic knowledge in a discipline and a place where students could easily find educational resources (learning objects) with a strong context relation to the subject. Today the learning objects paradigm means that the contents which reside in the different systems used in e-learning platforms, need to become reusable, accessible and interoperable. Each object therefore needs to be described beforehand by others through unambiguous formalisms (so-called LOM, learning objects metadata) so that people can retrieve them more easily. But this retrieval paradigm is often wrong: the meaning of the metadata must be shared by most communities of users possible and this is not the common case. The practice of describing resources may at first appear to be simple and straightforward, however, when a system of description is analyzed deeply it becomes evident that it is actually ambiguous. The use of metadata presupposes not only a set of logical relations but also a specific vocabulary generally agreed upon by a linguistic community (Downes, 2004). Ontologies, integrated with social tagging processes (i.e., folksonomies) (Mathes, 2004), could indeed offer a strong support for solving this problem because every learning object would be *embedded* in the structure of the ontology itself; in this sense there is a side-effect that consists of the collaborative setting up of a learning object repository that uses the ontological base for "intelligent" consultation. Learning objects have always existed in teaching: in their practice, educators operate within a deconstruction and reconstruction process of materials and resources, but what is missing is often a conceptual and disciplinary framework to go back to, which, in today's world, could be easily accessible and consultable through the Web. It is precisely this that the various domain ontologies could provide.

The wiki interface of the ontologies is well suitable for developing a constructivist environment, where people of a learning community can add and modify the concepts dialogically (Souzis, 2005). If we then assume that the learning process is never confined to the materials used in an online course, but that it is also fruit of the interaction among the members of the group, with the wiki-based ontologies we provide a *scaffolding* (Devedzic, 2004) which will facilitate communication and the construction of meaning among all the actors involved (academics, teachers, tutors, students) and at the same time represent the structure and contents of the discipline.

FUTURE TRENDS AND DEVELOPMENTS

As ontologies in EduOntoWiki will be the result of the active involvement of both a community of practice of academics and actors from different educational fields (teachers, students and trainers), the social/relational aspect which turned out to be increasingly significant in the course of this research, led us to systematically further the study of the relationships within a community, as well as between different communities, in relation to the knowledge construction process supported by the wiki-based software. We want to verify how this environment can ease knowledge construction and formalization as "instance" from different communities of practice interacting together. In fact, the direction that the most promising, current research is taking involves the study of so-called "complex constellations of communities of practice" (Wenger, 2004). This definition has been used to describe the special relationships which unite various communities and render them permeable in such a way that they can reciprocally share knowledge, contextualizing, and enriching it with new meanings, thus favoring creative solutions to complex problems.

On the basis of these premises, we will seek to verify whether a social theory of learning can effectively lead to the overcoming of rigid borders between training/educational systems, work environments and social activities. In this sense, we can try to "free" learning so it is no longer seen to be linked to a specific area or moment of one's life, but actively constructed in the inter-community interactions of a lifelong learning continuum.

What will be investigated in particular are the negotiational interrelations between people who, in various forms, are members of different communities, people who share an active interest in all training environments and who bring valuable examples of "good practice" even if they belong to different work contexts. This aspect, led us to expand a new learning dimension, aimed at stimulating reciprocity, transferring and recontextualization processes, insofar as learning is recognized as a social/relational process, and the multiple contexts where learning takes place that becomes a precious alternative representation (Lave, 1988), effectively expressed by the learning subjects by means of a narrative description (Bruner, 1996) that a rigid codified ontology formalization would, on the contrary, risk penalizing. Narrative is used in education and training contexts to motivate and to illustrate, the reason for this is that the cognitive structures we use to understand the world around us are similar to the cognitive structures we use to understand narratives. It is assumed that the interaction, comparison and reciprocal recognition of the different communities involved will succeed in triggering off a virtuous process of crossfertilization able to transfer skills, processes, and models.

An important challenge highlighted by a close examination of international research on this theme, is that inter-community relations are not easy to manage or formalise since the members can only count on relatively limited shared meaning and practices (Friesen, 2002). Interoperability among communities, which our EduOntoWiki environment wishes to foster, is thus closely linked to a negotiation of meanings, identities and roles. Identity and roles for example, can be formalized using the semantic standard FOAF, (friend of a friend) while other important personal relations are more difficult to express. Maybe the only way is to include the innovative approach of the folksonomies (Petrucco, 2006) and/or the creation of specific "instances" in the ontologies intended mainly as a narration of personal and contextual experiences lodged in a precise space, time and place. It is not by chance that social networking tools, such as LinkedIn, Friendster and Orkut, are now considered a necessary extension of the recent blog phenomenon. In fact, we intend to evaluate whether, and in what way, it is possible that this process of *narrative conceptualization* can lead from the formulation of "descriptive instances" to spontaneous formalization, on behalf of community members, of "normative instances", that is, knowledge models which can be reused in multiple experiential contexts for solving problems.

CONCLUSION

Our research group believe that the potential effects of the Semantic Web for the world of education and training, and in particular for e-learning, will certainly be positive, but only if governed by a strong pedagogical-methodological reference structure which facilitates integration of the new technological-semantic paradigm into the more recent social theories of learning. Given these assumptions, combining the Semantic Web with social software appears to be a natural choice: it can support the creation of semantically enriched content using simple interfaces and by allowing domain experts and novices, teachers and students to collaborate within rich inter-cultural communities, sharing their true life experiences. To conclude, while it is true that the EduOntoWiki project presents considerable challenges both on a technical-scientific and on a theoretic-methodological level as it attempts to integrate the most innovative instances of international research on the Semantic Web and on pedagogic research, we also believe that fast and complex contemporaneous social evolution necessarily requires adequate instruments able to interpret and manage it.

KEY TERMS AND DEFINITIONS

Communities of Practice: Communities of practice are groups that form to share what they know and to learn from one another regarding some aspects of their work. People in organizations often realize they could benefit from sharing their knowledge, in-sight, and experiences with others who have similar interests or goals. For the most part, this process of informal gathering and sharing of expertise is a voluntary.

Folksonomies: Folksonomies are bottom-up taxonomies that people create on their own, as opposed to being created and imposed by a group or institution such as by professional librarians using complex and lengthy rule sets (e.g., Dewey decimal system or Library of Congress index). Synonyms include folk categorization, social tagging, and ethnoclassification. They are grassroots classification systems for data. The value in folksonomies is derived from many people adding their own tags. The more people tagging one object, the better, because it gives alternative ways of searching for and finding information.

LOM (Learning Objects Metadata): We can define metadata as "information about information", and a LOM is a metadata about a learning object that can refer to multimedia or digital educational resources. Sets of metadata are used to identify and meaningfully describe characteristics relevant to these resources, for example, the learning resource type, the intended end user, difficulty level, educational goal, and so forth. The Learning Technology Standards Committee (LTSC) give rise to the IEEE LOM (Learning Object Metadata) 1484.12.1-2002 standard of educational metadata.

Ontologies: An ontology is a formal representation of knowledge about an area of interest. The part of the world conceptualized or described is called the "knowledge domain." Ontologies provide a vocabulary for representing and communicating knowledge domains and a set of relationships that hold among the terms in that vocabulary.

Semantic Web: The Semantic Web is an extension of the current Web in which information is given a well-defined meaning, better enabling computers and people to work in cooperation. The mix of content on the Web has been shifting from exclusively human-oriented content to more and more data content. The Semantic Web brings to the Web the idea of having data defined and linked in a way that it can be used for more effective discovery, automation, integration, and reuse across various applications. For the Web to reach its full potential, it must evolve into a Semantic Web, providing a universally accessible platform that allows data to be shared and processed by automated tools as well as by people. [W3C]

Social Network: A social network is a set of people or organizations or other social entities connected by a set of social relationships, such as friendships, coworking or information exchange. The connections between them may show specific patterns and can be represented by graphs. Recently many online social networking sites have begun to flourish with millions of users describing themselves in terms of who they are, what music they listen to, what books they read, and so forth, and trying to discover other people with similar interests.

Wiki: A Wiki is a collaboratively-edited Website that uses a software publishing tool. The distinguishing feature of wikis is that they typically allow all users to edit any page, with full freedom to edit, change and delete the work of previous authors. Collaborative knowledge creation is thus a central aspect of a wiki system. Wiki pages are accessible and usable at any time, and the content constantly evolves. The first wiki was created by Ward Cunningham, and the word "wiki" came from a phrase in Hawaiian—"wiki wiki"—which means "quick". It's quick because the process of editing is entwined with the process of reading. Both are done using a standard Web browser. Unlike most Websites, there's no need to edit a file, upload it to a Web server, then reload the original to check it.

Chapter 3.12
Course Management Meets Social Networking in Moodle

Matt Crosslin
University of Texas at Arlington's Center for Distance Education, USA

ABSTRACT

Moodle is currently one of the more popular opensource course management systems in online education. Some evaluations have also indicated that Moodle is one of the top-rated programs when compared to other open-source course management systems (Graf & List, 2005). The creators of Moodle describe their program as a course management system built on social constructivist pedagogy. Social constructivist pedagogy is a collaborative approach to learning based upon the works of Jerome Bruner, Lev Vygotsky, and Jean Piaget. Moodle's unique focus on pedagogy allows online learning to cross over from the traditional educational realm of factual recall and rote memorization into the realm of social networking. Social networking has recently become one of the more popular uses of the Internet, with sites like MySpace and FaceBook attracting millions of users every month. Social networking Web sites began to appear on the Internet around 2002 (Downes, 2005). Social networks are now seen as an important component of modern society – even in educational contexts (Finin, Ding, Zhou, & Joshi, 2005). Current online social networking sites thrive on social constructivism pedagogy – whether the users or designers know this or not.

INTRODUCTION

Moodle is currently one of the more popular open-source course management systems in online education. Some evaluations have also indicated that Moodle is one of the top-rated programs when compared to other open-source course management systems (Graf & List, 2005). The creators of Moodle describe their program as a course management system built on social constructivist pedagogy. Social constructivist pedagogy is a collaborative approach to learning based upon the works of Jerome Bruner, Lev Vygotsky, and Jean Piaget. Moodle's unique focus on pedagogy allows online learning to cross over from the traditional educational realm of factual recall and rote memorization into the realm of social networking.

Social networking has recently become one of the more popular uses of the Internet, with sites like MySpace and FaceBook attracting millions of users every month. Social networking Web sites began to appear on the Internet around 2002 (Downes, 2005). Social networks are now seen as an important component of modern society – even in educational contexts (Finin, Ding, Zhou, & Joshi, 2005). Current online social networking sites thrive on social constructivism pedagogy – whether the users or designers know this or not.

The following discusses research conducted on the relationship between social connection and success in online courses and examines how some tools in Moodle – such as blogs, Wikis, and chat rooms – can be used to support learning. Additionally, instructional design issues that can be addressed with these tools are also explored.

BACKGROUND

Generally speaking, most online courses are delivered through a program called a learning management system (LMS), sometimes also referred to as a course management system or virtual learning environment. Learning management systems are used in many fields, including education and business. From a business perspective, Szabo and Flesher (2002) define the LMS as "computer based database and presentation systems which manage the entire instructional program and learning progress of employees with respect to the competencies specified by the goals and objectives of an organization" (p. 2). From an educational perspective, students would be the employees and the school would be the organization. Therefore, learning management systems can be seen as the administrative storage area for online courses as well as the portal for content delivery.

Since some might consider learning as something that can't be managed by a computer program, some LMS designers refer to their programs as course management systems or virtual learning environments. The designers of Moodle have chosen to use the term course management system (CMS). The stated goal of the Moodle CMS is to create online communities – not just deliver course content and store course records. This distinction is important when examining social constructivist pedagogy.

Social constructivism is a theory of knowledge used in many disciplines. Moodle's official online philosophy looks at social constructivism as a "social group constructing things for one another, collaboratively creating a small culture of shared artifacts with shared meanings" (http://docs.moodle.org/en/Philosophy). The creators of Moodle see social constructivism as an extension of constructivism and constructionism – constructivism being the point of view that learners construct new knowledge as they interact with their environment, and constructionism being the belief that learning happens best when you construct knowledge for other people.

Another key concept that Moodle developers find helpful in guiding their philosophy is that of constructed behavior. Learners that exhibit constructed behavior know when to work as a team (or connected behavior), and when to work as an individual (or separate behavior). Moodle gives instructors tools that allow for learners to learn on their own as well in groups.

THE SOCIAL ASPECTS OF MOODLE

One of the more popular activities online today is social networking. Social networking sites such as MySpace, FaceBook, and Friendster have all had their fair share of exposure as well as controversy. The main idea of these sites is that users sign up, connect with people, and share information. Therefore, these sites thrive on social constructivism pedagogy – whether the users or designers know this or not. Social constructivism basically says that learners will learn best when they are constructing shared knowledge as a group.

The question then becomes "how can we harness the social nature of the Internet to increase learning and academic performance?" This is a question that the designers of Moodle have been wrestling with since day one. Moodle's design is based on social constructivist pedagogy. This focus means that instructors using Moodle have access to a wide range of tools that help them increase social activity in their online classes.

In general, online learners need to have a higher level of self-motivation, persistence, and commitment than learners in face-to-face courses (Martinez, 2003). This would seem to indicate that online learners need to be the independent, "work on their own" type. However, as discussed below, some research has indicated that increasing immediacy and social presence in online classes will lead to greater learner satisfaction and academic achievement – even though more research is still needed in this area.

Social Presence is generally seen as a student being aware of the other students in a course and those students' involvement in the course communications (Xu, 2005). Some researchers feel that there is still not an agreed upon method for measuring social presence (Lin, 2004). In spite of this, many studies have explored the impact of social presence in face-to-face classes (Tu & McIssac, 2002). However, these studies examine factors that can not be replicated in online learning, such as posture, dress, and facial expressions. Some research has shown that social presence can affect student satisfaction and learning outcomes in an online course (Richardson & Swan 2003). Other recent literature, such as that by Reio & Crim, has called for more research into the importance of social presence in online learning (2006).

Immediacy generally refers to the perception of distance between two people in a class. Swan (2002) noted that several researchers have found that instructors can increase learning in face-to-face classes by decreasing the perceived distance. Some of the methods for decreasing perceived distance include methods that might not work in online classes – such as verbal clues. Recent studies into the impact of instructional immediacy have called for more research into the impact of immediacy in online courses (Melrose & Bergeron, 2006).

Some researchers feel that imitating face-to-face communication in an online environment is not necessary. Rogers & Lea (2005) believe that a sense of belongingness to a group can be achieved online through other methods. For example, one such method to create belongingness is to create a shared social identity.

Social Tools in Moodle

Some evidence suggests that a course management system can increase interactions between the instructor and the student (Morgan, 2003). Other studies have found that learning management systems are heavily used for social activities such as peer support and collaborative working – sometimes even more so than for other uses such as assignment submission (Jenkins, Browne & Walker, 2005). Moodle is designed to take advantage of these increased interactions by providing several tools that can increase social presence and immediacy, while at the same time creating a shared group identity. Tools that will be examined here are blogs, wikis, discussion boards, groups, profiles, and chat rooms.

Blogs. Recent versions of Moodle have been slowly introducing a site-wide blog feature. Moodle blogs allow users to add personal thoughts on a site wide basis. Bloggers can use a set of site-defined or personally-defined tags to connect their blog entry to all the other entries that have been contributed. This connectivity allows students to construct shared knowledge on a social level. Moodle blogs do not currently allow comments on entries, but designers claim that this feature is coming. Discussion boards can be used for comments.

Wikis. In Moodle, wikis are used as a collaborative class project. Students can works as a class or in smaller groups to create content that is shared with everyone in the course.

Discussion Boards. Discussion boards in Moodle are used in much the same manner as they are used in other LMS applications. Students discuss and comment on a question, sometimes proposed by the teacher and sometimes proposed by other students. In Moodle, teachers have the option of allowing students to rate other students' posts.

Groups. Most activities in Moodle, including some of the activities above, allow teachers to place students in groups. This works in much the same way that it does in other learning management systems. Instead of getting lost in a larger class, placing students in groups allows more students to participate in activities.

Profiles. Moodle allows students a large degree of control over their personal profile. Moodle users have the option of creating a customizable "About Me" section. This section has full html support. In addition to this, Moodle allows users to upload pictures (if the site admin allows) that will post next to all class contributions, including discussion posts, blog entries, and chat messages. This feature helps personalize all contributions to the course.

Chat Rooms. Moodle chat rooms have fewer features than other chat room programs, but they still handle the basic chat. The reason that they lack some features is due to the fact that Moodle designers try to avoid using Java applets for functionality. The Moodle chat rooms will work with any browser without installing extra software. This system has the advantage of being lightweight in regards to system resources, but also lacks some features (such as a whiteboard) that some instructors may be accustomed to using in chat sessions.

Instructional Design Issues

Due to the large number of tools available for instructional use, course designers can become tempted to use a particular tool just because they find the tool new and exciting. All tools in Moodle, including the ones listed above, need to be examined in order to insure that they meet the specific instructional need of students in a course. However, the built-in flexibility of the Moodle program allows instructors to try an activity out, see how it works, and remove or change the activity as needed.

Another issue that Moodle is built to address is course work flow. Instructors need to ensure that course lessons flow in a logical manner from one activity to the next. However – smooth work flow is sometimes difficult to predict. Moodle allows instructors to quickly rearrange course activities in a matter of seconds, or to completely customize the work flow from unit to unit.

FUTURE TRENDS

Online learning will continue to become more social in nature. Recent research has shown that teen computer users are increasing their use of online social networking services (National School Boards Association, 2007). As these learners advance in their education and enroll in more online courses, they will help encourage this shift towards more socialization in online courses. More research into the effects of social presence and immediacy needs to be conducted, as well as specific research into the effectiveness of various online tools. Also, research into the interface preferences of online learners is needed to see if the design of Moodle is preferred over the interface design of other learning management systems or not.

Another future trend that may affect Moodle and other online educational programs is the growth of online virtual communities such as Second Life. Virtual interactions in online worlds like these appear to be gaining momentum and attention in the online education community. Some projects, such as Sloodle, have started to find ways to integrate Moodle with the social aspects of virtual worlds. This is still a very new area, but the possibility does exist that one day online learning could move into these virtual worlds.

CONCLUSION

This article has examined the nature of social learning tools in the Moodle course management system, as well as why social tools are important to online learning. Many other tools exist in Moodle that also enhance the learning experience. The social aspect is only one factor in designing an online course.

Social constructivist pedagogy has proven effective in face-to-face courses. Some of these concepts and techniques can be transferred in to online class environments. Like any teaching method or activity, caution must be exercised in order to ensure that the instructional needs of students are met first and foremost. Despite popularity or predictions of future growth trends, solid pedagogical principles must underline every tool and activity added to the online learning community.

KEY TERMS AND DEFINITIONS

Constructed Behavior: Refers to a learner's ability to know when to work as a team, and when to work as an individual.

Constructionism: Learning theory that states that learning happens best when learners construct knowledge for other learners.

Constructivism: Learning theory that states that learners construct new knowledge as they interact with their environment.

Immediacy: The perception of distance between two people in a class.

Learning Management System: Computer based presentation program that manages an instructional program and student progress.

Social Constructivism: Learning theory that states that learners learn best when functioning as a social group that collaboratively constructs a shared culture of artifacts with shared meanings.

Social Networking Service: Web-based program that focuses on building online communities of people with common interests.

Social Presence: Refers to a learner's awareness of the presence and involvement of other learners in a course.

ABSTRACT

This chapter presents the services and functionality that a personal digital library (PDL) system should provide. The chapter includes a reference architecture for supporting the characteristics and functionality of the personal digital library. In particular, a currently available project called PDLib is used as an example of this type of system. The authors address some of the particular problems that personal libraries impose with respect to the overall administration of personal collections of digital documents and how personal libraries may become a commodity and a way of social interaction. The chapter objective is to increase the research interests on personalized digital libraries and their usability in our daily live.

DOI: 10.4018/978-1-59904-879-6.ch005

INTRODUCTION

As digital and information technology advances, the effects of the adoption of such advances to our daily life are more evident. Today we, as users of information technology goods, produce a large amount of digital documents such as e-mail messages, office paperwork, personal documents, school homework, and even still-images, audio, and video. These myriad of digital documents usually reside in our personal computers or workstations, and some of them are placed on public places (i.e., our personal Web page and/or a Web sharing repository) where others can access our digital content. We are not only producers, but also consumers of digital documents; more and more frequently we get our daily news from the Web or via an e-mail service subscription. Also, while doing research in our area of interest, we consult the digital content available through the digital library services that our local library provides.

The personal computer is the place where we collect our personal digital archives and we have been using hierarchical folders to classify this information; with the increase in volume data the search utilities provided by operating systems are inadequate to ease the finding of documents, e-mail messages, or multimedia files because they do not analyze content. In the last couple of years, the search engine industry has introduced desktop search engines, tools that try to index the data in the file and gather as much metadata available (Cole, 2005) to provide a better search experience.

We organize all of those documents into collections, which will form in a way our personal library. Each user decides the contents of each collection following the user's own classification schema. Creating, organizing, sharing, searching, and retrieving documents from our personal collections are the intentions of personal digital libraries. A personal digital library (PDL) includes traditional digital library services for individual users.

In this chapter, we present and discuss the services, functionality, and characteristics of personal digital libraries in the context of our own development project called PDLib (Alvarez, Garza-Salazar, Lavariega, & Gómez-Martínez, 2005). PDLib is a universally available personal digital library. It is "universally available" in the sense that it allows the user to access personal digital library from most computing devices connected to the Internet, including mobile phones and PDAs, therefore granting access "from anyplace at anytime." We also discuss how social interactions happen at different levels in the context of PDLib.

BACKGROUND

Digital library research has produced specialized, cohesive repositories, typically delivered via a Web interface and targeted to support both academic and industry organizations. A requirement to bridge organizational boundaries has been issued as the interoperability challenge (OAI, 2006), which calls digital library systems to take measures to share data with other digital repositories. Traditional digital library systems are seen as large data repositories that provide services to multiple users. Many of these systems are supported by distributed architectures for scalability purposes (Janssen, 2004; Smith, Barton, Bass, Branschofsky, McClellan, Tansley, et al., 2003; Witten, Boddie, Bainbridge, & McNab, 2000; Witten, Moffat, & Bell, 1999).

We propose a different perspective of the digital library, that is, a PDL universally available. The objective of personal digital libraries is to take the concepts of traditional (or collective) digital libraries to the user level and provide tools to promote the social interaction. Our PDL's concept proposes the notion of providing one repository for each user, enabling users to interact with each other with regards to both personal and shared data objects. We also emphasize on universal access, that is, users should be able to access their own personal libraries wherever they are.

Personal digital libraries provide traditional digital library services such as document submission, full-text and metadata indexing, and document search and retrieval, augmented with innovative services for the moment-to-moment information management needs of the individual user. These innovations include provisions to customize the classification of documents, interact with other digital libraries (whether personal or collective), and support user-to-user exchange of generic digital content.

The creation of the personal digital library implies the submission of digital documents and their placement on the personal digital library under user-defined classification schemas. The documents of a personal digital library must be accessible via a mechanism capable of providing meaningful answers to users' queries. In a personal digital library system, search and retrieval mechanisms must adapt to the personalized classification schema defined by the users of the system. The effectiveness of the document retrieval process from personal digital libraries must be assured with the provision of an intuitive classification schema and the indexing of documents. A personal digital library must provide each user with mechanisms to restrict unauthorized access to their personal digital library and with administrative tools to manage digital library content.

Since PDLs extend the traditional library services for the mobile environment in order to realize the abstraction of personal libraries, we must cope with the technological challenges imposed by the implementation of digital library services (Adam, Holowczak, Halem, & Yesha, 1996; Bhargava & Annamalai 1995; Garza-Salazar & Lavariega, 2003), the mobile environment (Barbara 1999; Madria, Mohania, Bhowmick, & Bhargava, 2002; Pitoura & Samaras, 1998), and the specific requirements of personal digital libraries. In the next sections we present the services, characteristics, architecture, and relevant problems presented in personal digital libraries.

PERSONAL LIBRARY SERVICES

Traditional digital library systems grant to a group of users access to a digital library. Personal digital library systems provide a digital library to each user with supporting functionality found in traditional digital libraries plus services that allow users to form their own collections, share documents with other users, and have universal access to the library contents.

Traditional digital libraries provide services such as digital document creation, efficient storage, classification and indexing, capabilities to search, filter, and summarize big volumes of data, images, and information, use of interfaces suitable for the presentation of results, distribution of the library content to the end user, and administration and access control. Also in traditional DL systems there are at least three types of users:

- **Administrators:** This group of users is the technical people who create users accounts and access rights to the collections in the DL. Administrators are responsible of the normal operation of the DL system.
- **Contributors:** This group represents people authorized to submit documents in the digital collections. They are authors, curators, or information science experts.
- **Common users:** This group represents the information consumers. People that browse in the DL collection or search for specific works based on some metadata such as author, topic, publication date, and so forth. Searches may be also set as a combination of metadata elements and document content.

In traditional DL a user may play more than one role simultaneously, but it is not a requirement. In contrast, in a personal digital library, a user necessarily plays the three roles simultaneously. The user needs to define who is granted access in the user's personal collection (or collections); also, users are responsible for placing content in the user's personal collections and set a classification criterion for the submitted documents. And of course the user can search for information inside the user's own collection or in the collections of other users who have authorized others to browse and search in their collections.

Another notable difference between traditional and personal digital libraries is the notion in normal DL that users "go" to someplace to search and browse in well-formed collections (i.e., collection which content has been validate and approved by a collegiate body). On the contrary, in personal DL, personal collections "travel" or move with the user, and collections' content is defined by the user. In personal digital libraries there exists the notion of universal available collections due to the "traveling" of user's collections. This notion is mainly realized by providing access to collections through any personal device (i.e., laptops, PDAs, and cellular phones). Dealing with mobile devices of limited capabilities presents interesting challenges for a personal digital library (Barbara, 1999) such as limited display space, and connection availability.

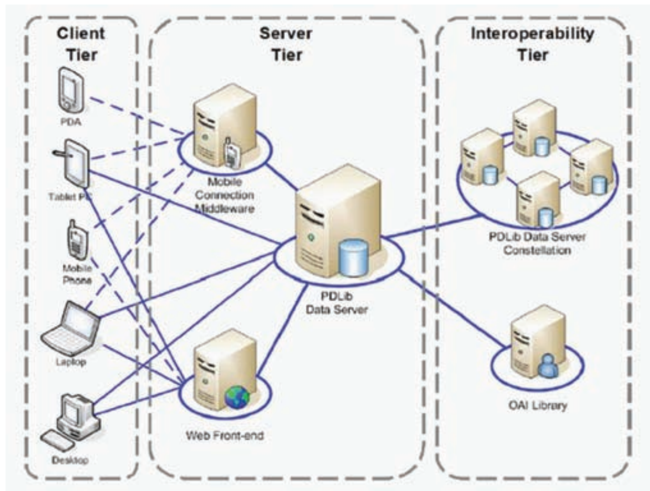
In order to support our vision and illustrate the functionality and capabilities of the PDL concept, we developed PDLib. PDLib is a personal library system that allows the user to shape and access the user's digital library from anyplace at anytime using nearly any computing device (i.e., universal access). To realize universally available digital libraries, the following requirements were defined for the PDLib system. The following functional requirements define the personal digital library services available in PDLib:

- **Flexible collection and metadata management:** Collections must be provided as a mechanism for document classification. Users should be provided with the ability to define the metadata set that will be used to describe the contents of each collection. These interactions will allow the user to customize a personal library as desired.
- **Digital document submission:** The user should be able to add any digital document to a personal digital library. Submission from several device types should be supported. The personal digital library must be able to accommodate several document formats for the same document. Additionally, the user must be able to (a) select or create the collection that will contain the document and (b) provide metadata information for the document according to the collection's metadata set.
- **Search and retrieval:** Search and retrieval mechanisms must adapt to the personalized classification schema defined by the users of the system.
- **Universal access:** In order to provide universal access to the documents and services of the personal digital library, several client application types suitable for mobile and fixed hosts of mobile environments must be considered. Clients with diverse capabilities may be supported.
- **Administration and access control:** The owner of a personal digital library always has unrestricted access to the owner's personal digital library content. In addition, the owner has the capability to grant other users with access to the owner's individual personal digital library.
- **Interoperability:** Interoperability with other personal library users and with other digital library systems using well-known interoperability protocols must be provided. Interoperability happens in PDLib with other systems by using the open archive initiative protocol OAI-PHM (OAI, 2006). However, users should be allowed to define their own document descriptors. It is also desirable to support direct interaction with digital content providers such as Web search engine, as well as to store the results from the Web search into a personal collection.
- **Data model:** Personal digital libraries must provide a simple and flexible data model where each user's library is composed of collections. Collections contain, in turn, other collections and/or documents. Users can interact with personal digital libraries by creating and deleting collections and submitting, moving, copying, or downloading documents. In addition, users can define the metadata set that will be used to describe the contents of each collection. These interactions allow the user to customize a personal library as desired

ARCHITECTURE OF PERSONAL DIGITAL LIBRARY

An overview of the PDLib system is shown in Figure 1. The PDLib software architecture consists of three layers:

Figure 1. PDLib system overview



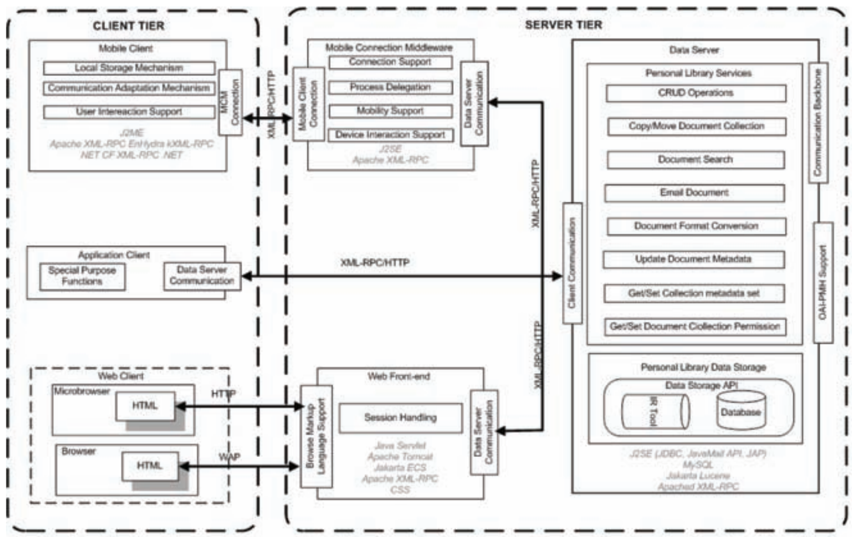
1. **The client tier** includes the variety of devices with which a user can interact with PDLib. Clients can be classified depending of their mobility and client-side architecture into: mobile thin client, mobile thick clients, fixed thin clients, and fixed thin clients. In thin clients, the application is delivered on a browser or microbrowser, while in thick clients both code and data may reside in the client device. Mobile thick clients are especially important to achieve off-line operations possible, therefore mobile applications should be based in this type of clients. Web applications typically focus on fixed thin clients.
2. **The server tier** includes the server system infrastructure that provides services to clients: (a) data server, (b) mobile connection middleware (MCM), and the (c) Web front-end. These components are addressed in a further section within this chapter.
3. **The interoperability tier** which allows the connection to other (PDLib) data servers and/or to OAI-PMH (OAI, 2006) compliant digital library systems.

The devices of the client tier communicate with the server tier to access PDLib digital library services. The access type of the client tier with the server tier varies according to the client device's capabilities: *middleware access* supports mobile devices, especially those with limited computing resources; *Web access* provides hypertext transfer protocol (HTTP) access to any device that includes a Web browser (WML/hypertext markup language [HTML]); and *direct access* for applications with very particular requirements can access the data server directly. PDLib architecture (Figure 2) is supported in two main components: 1) mobile connection middleware and 2) data server.

Mobile Connection Middleware

One of the main problems to solve in order to provide the data server services is the fact that the data server has been designed to be used by a wide range of devices and not just mobile devices. However, there is a clear difference in computing resources between mobile and fixed devices. This computing resource disparity makes it difficult to adapt the data server to the capabilities of mobile devices and signals the need of a middleware component to mediate the interaction of the mobile device and the data server. We call this middleware the mobile connection middleware (MCM), which provides the following functionality:

Figure 2. PDLib architecture



- **Connection support:** It is required by mobile clients in order to perform adaptation to the high bandwidth variability of the mobile environment and to cope with the frequent disconnections of mobile devices.
- **Process delegation:** Execute functions that would demand an excessive (or unavailable) amount of computing resources to the mobile device.
- **Mobility support:** Operations such as prefetching can be performed to speed up the retrieval of documents from the data server and store them in cache servers that are closer to the user. When the user changes location, it would be necessary to support migration of the information between different instances of the MCM.
- **Device interaction support:** Performs adaptation of content according to the characteristics of the device on which it is desired to show the information.

Data Server

The data server provides the services of a personal digital library, stores, indexes, and classifies digital documents. It supports interoperability with other digital libraries and helps users to organize their collections. The data server provides the following:

- **Personal library services:** The data server offers creation, retrieval, update, and deletion operations over the library objects stored in the personal data storage (collections, documents and metadata). The data server also provides services to copy and move documents or collections search for documents in a personal library, and send documents to the personal library of other users.
- **Data model:** The digital library data model in PDLib establishes that a library contains one or more collections. A collection contains documents or more collections and is associated with a metadata set. The metadata set is composed by one

or more metadata definitions. The fields that compose document metadata are determined by the metadata set of the collection. The metadata set of a collection defaults to the metadata set of the parent collection and can be redefined by the user on a per collection basis. Both collections and documents have an associated permission. Permissions are particularized in the following access rights: (a) personal, where access is restricted to library owner; and (b) incoming, where other users are allowed to create documents and collections. This access right applies only to collections.

- **Information retrieval:** One of the most interesting challenges in personal systems such as PDLIb is the retrieval of information based on metadata, where the metadata set for describing documents within the library may be quite different. Some work has been initiated (Saavedra, 2007), considering that different representations and labels may exist for a single concept.
- **Personal data storage:** It stores the data of the personal digital libraries. A text search engine is used to index the content of the personal digital libraries. A database is used to store the objects of the personal digital libraries. The use of a text search engine and a database in the data server permit to combined text-based queries and SQL queries, supporting the hierarchical classification of personal library content.
- **OAI-MHP support:** The data server exposes the metadata of the personal digital library documents via the OAI-MHP. In addition, the data server harvests metadata of other OAI-MHP compliant library systems to provide users with a subset of the personal digital library services to interact with other (OAIMHP compliant) library systems.

PDLib services allow users to collaborate by sharing documents and collections of documents of different types. Documents and collections are indexed and stored for further user navigation and accessing. Collections act as a collaborative memory. The main services that we provide as a means of collaboration are:

- **Public/Private access control:** Any collection or document can be made public or private by the owner. When a user has at least one public element as part of the user's library, then any user can browse and retrieve such public collections and documents.
- **Document sharing:** When a PDLib user wants to share a private copy of a document with another user, there are two services available for this purpose. 1) If the target user has a PDLib repository, the "send to PDLib user" service places the document into the target user's special collection named "unfilled documents." This is a very fast and efficient way of sharing the information since no actual network bandwidth is used for this purpose. 2) For non-PDLib users, the send library content via e-mail service is available.
- **RSS support:** RSS (RSS, 2006) is supported for collections and queries. At the collection level, any user with an aggregator can subscribe to any user's PDLib public collection. Any time that the PDLib user adds a new document to the user's collection, the feed is updated. PDLib supports the retrieval, storage. and indexing of syndicated information from any RSS source and allows users to have collections of feeds as part of their own personal space.
- **Collection creation from external search engines results:** Search engines offer an excellent list of initial resources (documents including Web pages) while looking for a unknown topic. Usually results from Web search engines are relevant to user

interest in the first few hits. Those results may be consulted immediately, but a very useful service should be to store them for further reference in a collection instead of click and saving bookmarks one by one. PDLib offers the service for creation of collections based on results of external Web search engines such as Google or Yahoo!.

- **Mobility support:** In order to enhance the possibilities for social interactions, personal digital libraries services have to be available wherever the user needs it. The mobile environment challenges are addressed by the PDLib's mobile clients. Our current PDLib's mobile client implementation supports two platforms, one based on CLDC/MIDP J2ME and other based on .Net technology

CONCLUSION

This chapter presented an overview of the PDLib system and the services it provides. PDLib services not only facilitate the management of user's personal documents, but also help users to increase interactions among colleagues and friends. In this way, a personal digital library system can be seen as an approach for supporting social computing. The current version of PDLib supports all the functionality described here.

Digital libraries are systems that have much to offer to social computing (Schuler, 1994). Even though the focus of both areas may seem to be initially quite different, on one hand, social computing is working with system informality and spontaneous communication to enable people collaboration and interconnection, and on the other hand, the digital library community has focused its efforts towards classification services and content structuring within centralized documents repositories. However, personal digital libraries support perfectly the management of personal information and the notion of collaborative/cooperative work by sharing collections of documents among individuals, making available to groups interesting findings, and consulting several sources of information from a single entry point.

As future areas of research and development we envision the incorporation of off-line operations and a synchronization mechanism from personal digital libraries mobile clients. Creation of ad hoc networks for the sharing of documents in small groups is also an area of opportunity for enhancing the user experience.

Currently we are developing a voice-processing capability that makes it possible to capture voice conversations, to convert them to text, and to store them into the system. Another development in progress is the creation of a peer-to-peer network of PDLib library servers. There are other issues such as scalability of the collections, consistency of information, and optimal document management that need to be addressed not only in PDLib, but also in personal information systems.

KEY TERMS

Digital Document: Any document in a digital format. A digital document can be text, image, video, or any combination of these formats.

Middleware: Any software component that mediates between an application server and a set of mobile clients.

PDLib: The personal digital library project developed at Monterrey Tech. Information and product available at http://copernico.mty.itesm.mx/pdlib.

Personal Collection: A set of digital documents that belongs to a specific user.

Social Computing: The ways of using computer applications to enhance and influence forms of social relations. The term "social computing" also refers to the social and ethical implications that software professionals have in an increasing "computerized" society

Thick Client: Software product that request information to a central information server. Thick clients have both application code and data residing on the client device (e.g., desktop, laptop, PDA, or cell phone)

Thin Client: Software product that request information to a central information server. In thin clients, the application is delivered on a browser (for large or middle size devices) or microbrowser (for a more restrictive device such as a PDA). Thick and thin clients can coexist in a single device.

ABSTRACT

The aim of this chapter is to overview the ways in which knowledge media technologies create opportunities for social learning. The Open Content movement has been growing rapidly, opening up new opportunities for widening participation. One of the Open Educational Resources (OER) initiatives is the OpenLearn project, launched by the Open University, which integrates three knowledge media technologies: Compendium, FM and MSG. In this chapter, the authors analyse some examples, which show how these tools can be used to foster open sensemaking communities by mapping knowledge, location and virtual interactions. At the end, they present some questions and future horizons related to this research.

DOI: 10.4018/978-1-60566-208-4.ch024

INTRODUCTION

Due to the widespread use of new technologies, people have greater access to information, interaction at distance and knowledge reconstruction than ever before. Open learning materials, online libraries, electronic journals and collective repositories are part of a larger movement to create a public online space providing open high-quality content in different formats such as hypertext, image, sound and video. The Open Educational Resources (OER) movement has also been opening up new opportunities for widening participation (Willinsky, 2006; Dholakia, King & Baraniuk, 2006; Downes, 2006; O'Mahony & Ferraro, 2003; Open Source Initiative, 2007).

The Open University UK´s OpenLearn Project, for instance, is a large scale project that makes a selection of higher education learning resources freely available on the internet. OpenLearn, which is supported by William and Flora Hewlett Foundation, was launched in October 2006 and in eighteen months released over 5,400 learning hours of the OU's distance learning resources for free access and modification by learners and educators under the Creative Commons license (OpenLearn, 2006). OpenLearn also offers three knowledge media tools: Compendium (knowledge mapping software), MSG (instant messaging application with geolocation maps) and FM (Web-based videoconferencing application).

This chapter introduces these three OpenLearn technologies and presents examples about the use and integration of these tools to promote social learning. During its first year and a half there are 50,000 registered users in OpenLearn, over 1,000,000 unique visitors to the site, over 1,000 video meetings booked, 1,377 Compendium Knowledge Map downloads and 17,000 MSG users.

Our current work is to investigate how these tools can be applied to foster open sensemaking communities (Buckingham Shum, 2005a) around the OERs, that is, the interpretative work that must take place around any resource for learning to take place. How can these technologies be used to support this critical activity in an OER context when learners must find and engage with peers themselves, if they do not wish to study alone?

"Open sensemaking communities" refer to open and self-sustaining communities that construct knowledge together from an array of environmental inputs (Buckingham Shum, 2005a; Weick, 1995). Thousands of open communities can be found on Facebook, MySpace, Orkut, Flickr, Yahoo groups, Google Groups, Moodle etc. However, there are some challenging issues for an "open community" (Reagle, 2004) to turn into an "open sensemaking community"(Buckigham Shum, 2005a). Participants must literally reflect upon information (Brooks & Scott, 2006) and "make" sense together by giving shape or modelling diverse ideas through significant representations (Buckingham Shum and Okada, 2008). They need transform their abstract thoughts about what is being learned into their personal framework - "knowledge objects" (Entwistle, 1995) and into "collective representations of knowledge" (Nonaka and Takeuchi, 1995). The term knowledge object is used *"to describe the essence of these quasi-sensory experiences of aspects of understanding*", through structures of thinking paths or summaries of integrated body of knowledge produced by a student (Entwistle, 1995:50). However, the "making" of a "shared artefact" to express the emerging, collective view of the problem/solution is an important distinction. Sensemaking is a "*mutually negotiated understanding*" (Weick, 1995:4). It means interpreting and representing plausible narratives about the world collectively. Through sensemaking, externalising one's understanding clarifies one's own grasp of the situation, as well as communicates it to others — literally, "*the making of sense*" (Weick, 1995: 4). An example of open sensemaking community is a community of open source software's developers. They learn with each other by representing and sharing understanding about the content, programming code, and also the process. They construct their set of principles and practices by themselves which facilitate access and quality to the design and production of their products and knowledge.

In higher education, how can knowledge media technologies be used by online learners interested in learning with their social network? How can they represent and share meanings together constructed from what they are studying? In the next sections, we present ways in which Compendium, FM and MSG have been used by participants of an OpenLearn Community. Based on these examples, we analyse some benefits and also their difficulties of using knowledge media tools for social learning and for fostering open sensemaking communities.

BACKGROUND

Information and Communication technologies have been promoting the rapid and flexible dissemination of open content and educational resources. There are currently many open content initiatives offering free access to learning materials on the Web. However, one of the main challenges for online learners is not only to be able to access free high quality content; they also need to be able to capture, organise, discuss and make sense of it including the deluge from search engines, news feeds, digital libraries, blogs and emails in order to construct meaning from this ocean of available information and opinions (Okada and Buckingham Shum, 2006).

The simple access to information does not necessarily mean understanding. In order to develop understanding, students need to be engaged in higher order thinking which operates beyond mere exposure to factual or conceptual information. Understanding means going beyond the information given to make inferences, connections and explanations. "*Understanding is not mere knowledge of facts but inference about why and how, with specific evidence and logic – insightful connections and illustrations*." (Wiggins and McTighe, 2005:86).

In contrast to "information technologies" whose purpose is to deliver data structured through different media and representations, "knowledge technologies" aim to support learners to interpret those representations and construct their understanding together (Buckingham Shum, 2005a). Interpretation means the process of assessing information to construct personal meaning. It is making an implicit idea "x", explicit as "y". (Jonassen, Beissner and Yacci,1993). Understanding involves being able to explain meanings and apply it in different contexts (Wiggins and McTighe, 2005).

The term "knowledge media tools" introduced by the Knowledge Media Institute KMi at the Open University UK means technologies to support the processes of generating, understanding and sharing knowledge using several different media, as well as understanding how the use of different media shape these processes. KMi considers that "media-rich learning experiences based on constructivist models of education are the key for ownership of understanding". Knowledge media technologies empower individuals - schoolchildren, adult learners, or corporate employees and their managers - to create their own content, to represent understanding and reconstruct their own knowledge. Learners need to develop their critical authorship rather than being merely recipients of information. Through these tools, users can research topics, collect information, discuss the content, manipulate digital media, categorise and structure meanings and publish their reconstructed thinking and knowledge on the Web (Eisenstadt and Vincent,1998:ii). Knowledge Media Tools are designed to assist users in giving form to their ideas as they evolve from ill-formed, inchoate structures to more formal, rigorously organised expressions and foster their own "open sensemaking communities" (Buckigham Shum, 2005b).

Contemporary approach on education consider learning as a process that is developed through dialogue (Vygotsky, 1962; Bakhtin, 1981). Learners construct their understanding through dialogic interactions with peers, teachers and learning materials. A critical discussion scaffolded by a learning community enables participants make sense of what they are learning. They internalise new meanings from significant dialogues developed interpersonally to form new understandings intrapersonally in their ZPD - zone of proximal development (Vygotsky, 1962).

Sensemaking is enacted through the interaction of explicit and tacit knowledge (Nonaka and Takeuchi, 1995) from individuals to groups (Cook and Brown, 1999). Tacit knowledge is highly personal and hard to communicate to others. "*We know more than we can tell*" Polanyi(1967:4). In contrast, explicit knowledge is easily stored, expressed and reused (Nonaka, 1991). Sensemaking is a process shaped not only by tacit knowledge - what people have in their mind, but also explicit knowledge – from interactions with their social and physical world (Cook and Brown, 1999).

The spiral of collective building of knowledge (Nonaka and Takeuchi, 1995) shows that, students need to learn to connect their own ideas with the other people's and knowledge from different domains to their own experiences (combination). They need to make sense of their own selected network of information, generate questions, critical arguments and pursue their reasoning to some coherent conclusion or outcome (internalisation). Students also need to know how to represent their insights, reflections, interpretations through images, sound, words, even maps, (externalisation) and share their thinking with their community (socialisation) using knowledge media tools.

Knowledge technologies have a role to play in this process, and the focus must move from simply capturing and storing knowledge to supporting learning and sharing understanding (Finerty, 1997; Ruggles, 1998; Sumner et al, 1998). Social tools designed for educational use support and engage individuals to learn together by eliciting their implicit knowledge based on their individual and collective needs (Anderson, 2007). In this context, knowledge media tools can be used to engage learners to (see Figure1):

1. Externalise their implicit knowledge by representing what they have in their minds through modelling, mapping and writing it down in forums, chats, Web videoconference or knowledge mapping tools.
2. Combine explicit knowledge by connecting different perspectives, adding new meanings, tagging or categorising best examples.
3. Internalise explicit knowledge by accessing, analysing, questioning and interpreting codified knowledge
4. Socialise implicit knowledge by sharing new experiences, observing, brainstorming and opening new opportunities for feedback.

Table 1, which is based on the examples presented in this chapter, summarises the role that some knowledge media technologies (Compen-

Figure 1. Spiral of the collective building of knowledge(Nonaka and Takeuchi, 1985)

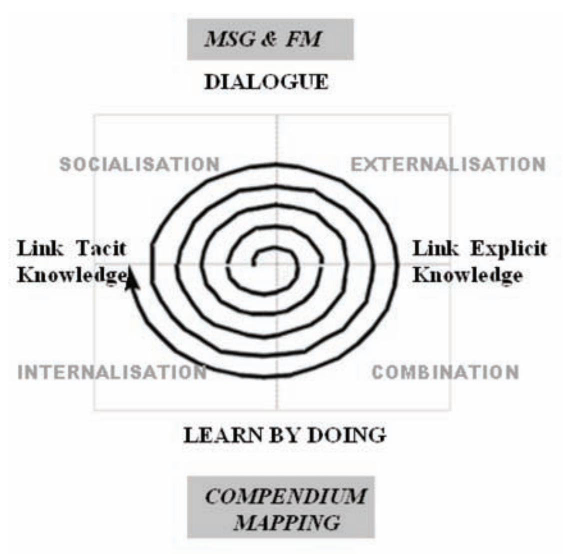

Table 1. Knowledge media tools integrated in the OpenLearn project

	Compendium a hypermedia mapping tool	FM a web videoconferencing application	MSG an instant messaging application
Externalisation	Represent reasoning through knowledge maps.	Present and discuss ideas through web video conferencing.	Point out opinions and feedback through instant messaging.
Combination	Connect ideas, concepts, argument, and web resources.	Connect questions, feedback, comments from different media (text, audio, urls, graphs).	Connect location, social presence and social awareness.
Internalisation	Visualise, reflect and analyse connections in order to develop better interpretation.	Replay the discussion in order to reflect on and analyse the content.	Access the chat history to recall answers, solutions and insights.
Socialisation	Share knowledge maps by downloading editing and uploading them again.	Share FM events, taxonomy system in order to search and find events.	Share relevant content from instant messages by copying and pasting it in a forum, a FM session or a knowledge map.

dium, FM and MSG) can play in order to construct knowledge collectively.

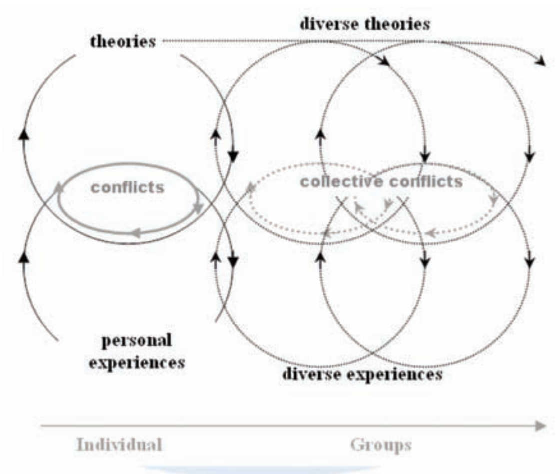
Compendium, FM and MSG can be used to externalise their ideas, combine different viewpoints, internalise new concepts and socialise new meanings. However, there are some challenges in order to leverage the spiral of knowledge to foster collective sensemaking from individual to groups.

- Could these tools help a learner identify and bridge a gap for sensemaking? "*Sensemaking moment is the point in time-space when a person experiences a gap while moving through time-space. (…) The person bridges this gap by experiencing questions and muddles that lead them to construct bridges consisting of ideas, thoughts, emotions, feelings, hunches and memories*" (Naumer, Fisher and Dervin, 2008:3).
- How do learners use these tools to create and share representations around some problem they need to understand? "*Sensemaking is the way people go about their process of collecting, organising and creating representations of complex information sets, all centered around some problem they need to understand*" (Russel, Jeffries and Irani, 2008:1).
- In what ways learners can apply these tools to identify common conflicts, clarify new concepts and negotiate a consensual understanding together in virtual learning environments? "*Learners are not naturally likely to argue spontaneously with each other, at least with respect to the subjects that they have not been in contact with yet and sometimes, interpersonal conflicts or individual contradictions are not sufficient to provoke the incidence of argumentation*" (Okada, 2005: 85). In order to make sense together by developing a consensual agreement through argumentative dialogue, learners need to identify a common problem (e.g. conflicts) by mastering concepts from theories that support their opinion and personal experiences (Figure 2).

CASE STUDY

"*CoLearn - Comunidade de Pesquisa sobre Aprendizagem Colaborativa* " (Community of research about Collaborative Learning) is a Community of OpenLearners from Portuguese-speaking Countries <http://colearn.open.ac.uk> in the OpenLearn – LabSpace. LabSpace is an open area in the OpenLearn for users creating and sharing mate-

Figure 2. Argumentative dialogue for sensemaking in collaborative learning environments (Okada, 2005: 88)



rials, and running their communities. CoLearn´s participants are educators and academic students whose interests focus on exploring knowledge media tools to facilitate collaborative learning. Based in different countries, they use FM to meet online, learn together and create OER. Their discussions are focused on diverse open learning issues such as game based environments, knowledge media and social software. Compendium Knowledge Maps are created on e-democracy, thinking skills and information literacy. Through MSG, they can see who is online, ask questions and get answers quickly. By exchanging instant messages, they can discuss problems with tools, share additional information on the Web, such as OER, knowledge maps, Web videoconferences and papers' URL about what they are studying.

Figure 3 shows the Labspace area of this community, and some information about one of its OpenLearners, "Lila" and her social learning network. On the left, there are three blocks: MSG Instant Messaging, FM and Knowledge Maps. In the MSG block, she can chat with 93 fellows from her list of 1419 contacts. She can also locate them in her MSG Google map. In this picture, we can see that she is one of the 17.041 OpenLearn users, in which 414 are online. Lila can access 11 FM Web-conferences for replaying. She can also browse or download a list of 62 knowledge maps.

On the right, in Lila´s Personal Profile, we can see that she is registered in six OpenLearn communities, and her interests are focused on information literacy, digital games applied to education, open learning,

Figure 3. CoLearn - Community of Portuguese Language Countries in the OpenLearn

culture, society and media, knowledge media tools and knowledge mapping for learning design. As an OpenLearn user, Lila can access all her forum posts, her learning journal and activity reports.

Whenever Lila is logged, she can chat with her peers through MSG, book a video meeting, manage and edit her events. She can download and install the Compendium software tool for knowledge mapping in order to create and share maps within her communities.

MAPPING KNOWLEDGE WITH COMPENDIUM

Compendium <http://www.compendiuminstitute.org> is a software tool for visual thinking, used to connect ideas, concepts, arguments, Websites and documents. The purpose of the Compendium application is to manage information, model problems, and map argumentation discussions. It can be used as an individual or group tool to develop new ideas, goals, logical concepts and collaborative scenarios. A key feature of Compendium is its ability to categorise information. It offers a set of different types of "nodes": question, idea, pro, con, reference, note, decision, list and maps views. This node classification allows one to better organise the structure of the map and understand the argumentation discussion more easily.

Figure 4 shows a map created by an OpenLearn user from the CoLearn community also interested in Information Literacy. It illustrates how to use Compendium to organise ideas and arguments:

1. Drag and drop a question-icon from the palette and type a question.
2. Create new nodes: for answers, concepts or data; for arguments, choices or possibilities; for supporting arguments; for counterarguments. If you want to make connections, by clicking the right button of the mouse over the icon, drag the arrow and drop it onto the other icon.
3. Pictures, sites and documents from the Web can be added into this map by dragging and dropping the media resource.
4. A number superimposed on a node (e.g. 2) means that it appears in more than one map. The same idea can play roles in multiple contexts and conversations which can be linked. When the mouse is over the number

Figure 4. Compendium's user interface for linking issues, ideas and documents

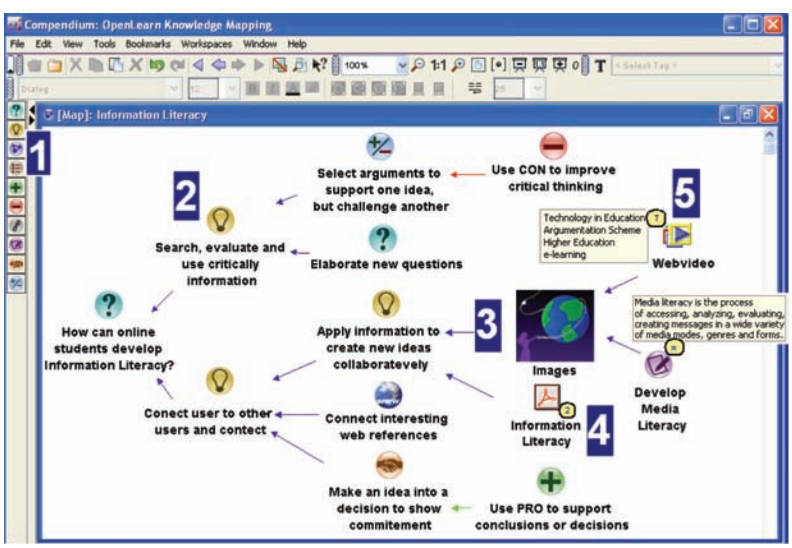


Figure 5. Compendium's user interface for linking issues, ideas and documents

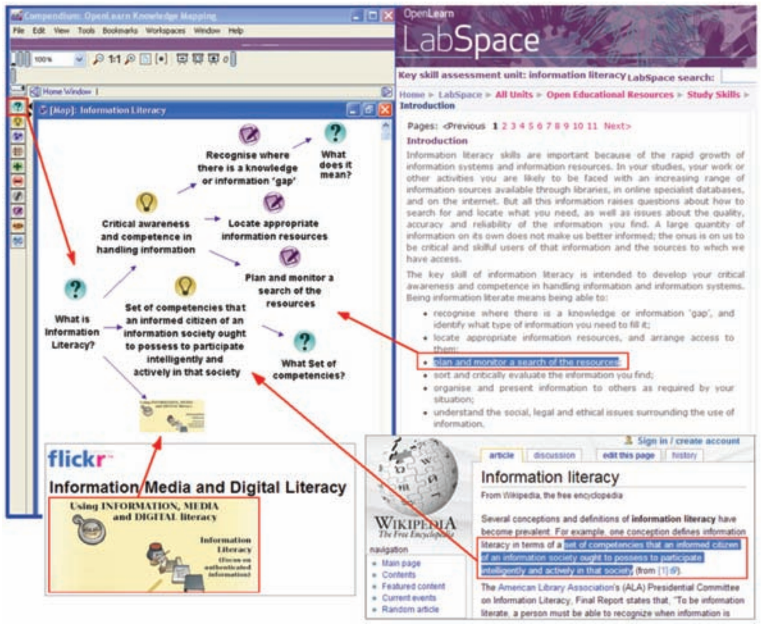

you will see all maps related to that node.

5. User-defined keyword tags [T] can be annotated onto nodes to help when searching for related material across multiple maps, and include comments [*].

CoLearn community has been using Compendium to create knowledge mapping applied to studying an OER together, sharing new references and describing the meaning of concepts.

Knowledge Maps as a Strategy for Studying an OER Together

Knowledge Mapping can be used as a strategy to study online learning materials (Buckingham Shum and Okada, 2008). Figure 5 shows an OpenLearn participant who used Compendium to select key sentences from the OpenLearn Unit "Information Literacy" in the LabSpace and from other Websites such as WikipediA and flickr. By dragging and dropping the content into their maps, she collected relevant pieces of information from different sources. She externalised her interpretation graphically by combining their own comments, bringing arguments and raising new questions. She could identify concepts that they did not understand (e.g. what does it mean?) and also "recognise where there is information gap" (e.g. what competencies are they talking about?).

By socialising a map within their communities, their fellows interested in the same topic can browse it, visualise and reinterpret keypoints, access Web resources, download it and combine new contributions in order to internalise new meanings. They can also discuss about its content (questions, ideas and arguments) in a video meeting, MSG or forum.

Knowledge Maps as a Strategy for Sharing New References

Figure 6 shows a Compendium map to collect and share relevant information source, which was created by another openlearner interested in "Media Literacy". It shows interesting Websites and offers complementary references related to "Information Literacy". This Webmap with nine online references was accessed by other participants for downloading, editing and new uploading. Participants interested in this topic used these references to compare Media Literacy in the UK and their countries. These references were used to support new ideas, answer questions related to Media Literacy and raise new issues, concepts and arguments. Web maps can be described as hybrid way of mapping in the sense that learners can integrate diverse objects of their own – concepts, links, personal documents, organizers - and progressively evolve these maps into concept maps (Zeiliger and Esnault, 2008).

Knowledge Maps as a Strategy for Describing the Meaning of Concepts

Figure 7 shows how Compendium was used to describe the meaning of a new concept. This concept map indicates several keywords that were collected from different sources and connected to explain what information literacy means. Other openlearners can access this map, visualise how the concept information literacy was interpreted and access the reference sources by clicking in the icons. They can also download this map to represent new viewpoint and new ways to make sense of this concept by adding examples, resources, case studies and new keywords.

Concept maps is an effective way to represent and contrast learners' understanding of various concepts by allowing they share and build knowledge individually or in groups (Canas and Novak 2008). Through concept mapping learners make sense of new concepts by structuring their thinking and connecting their prior knowledge (Novak, 1998).

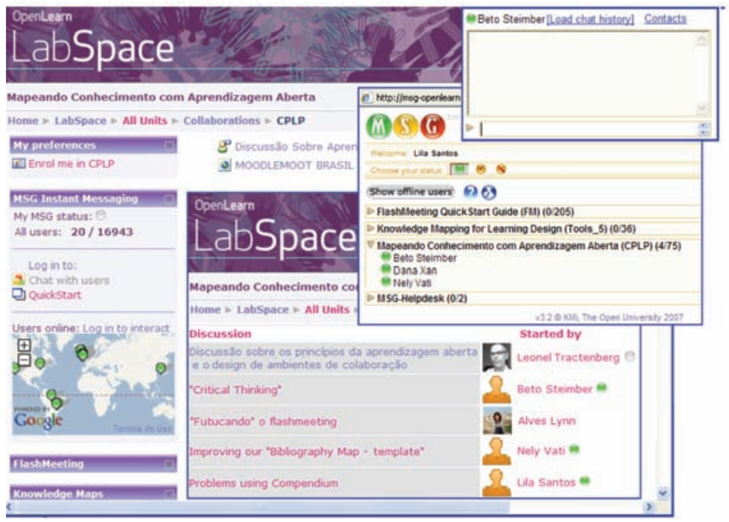
MSG: AN INSTANT MESSAGING APPLICATION WITH GEOLOCATION

Social presence can stimulate group awareness and the building of collective knowledge in online communities. Presence has evolved from just being 'online' or 'offline' to a range of preferences such as availability or location (Chakraborty, 2002). Websites, such as 'The World as a Blog', released in 2003, can provide real time blogging activity and the blogger's physical location, represented as a dot on the earth (Maron, 2003). This approach can be extended in communities of practice having a common knowledge objective, where members located in different parts of the world can support each other, and where knowledge use and reuse has a specific impact upon their evolution. Wenger (1998) described communities of practice as the interplay of four fundamental dualities: participation vs. reification, designed vs. emergent, identification vs. negotiability and local vs. global. Location and social presence display an aspect of the users' context, contributing to collective understanding.

MSG is a Web application for instant messaging that allows users to contact fellow OpenLearn users. It is an evolution of BuddySpace (Vogiazou, et al., 2005) that acts like a 'personal radar' that shows who is online and where. A key advantage of MSG over other instant messenger systems (e.g. MSN Messenger, AIM, GTalk etc) is the full integration into all OpenLearn units — meaning that throughout the site (e.g. in discussion forums) users can see who is currently online and can immediately 'click to chat' to the poster of a relevant forum message. Groups of contacts are automatically generated in MSG based on the courses users have enrolled on, enhancing in this way the creation of a sense of community with common knowledge goals and interests.

MSG also offers a presence map which allows users to find out where fellow users are located geographically and gives the same presence information and click-to-chat functionality as given in the OpenLearn units. The markers on the map are automatically clustered to avoid markers overlapping and obscuring each other. Clicking on a marker shows all the users at that location with their presence status and click to chat option if they are online. Additionally, users can easily search for users, update their own location and filter the map markers based on the groups and courses they have enrolled on.

Figure 8. The MSG block where you can click on contacts and chat with them



MSG, as Strategy for Finding Peers to Learn Together

Open learning can be sometimes a lonely experience. OpenLearners are located in different countries, access a course at different times and start from different areas. How can they find fellow students studying the same course when they are logged in the LabSpace? Figure 8 shows that Lila can contact her fellow students from the Google Map on the left bar (MSG Block) or from any Webpage in the Labspace such as the discussion. By keeping an eye out for the green and yellow 'presence status icons' throughout LabSpace, e.g. next to user names in a discussion forum, she can just click on it to chat directly to the person (e.g. Beto), even if she has not yet launched MSG.

If Lila, who lives in Rio, wants to find her peers who are in Sao Paulo and online, she can then access the MSG Presence Maps. Figure 11 shows that through the map, Lila can view who is currently online in Sao Paulo by clicking on the marker over Sao Paulo.

The box on the right in Figure 9 indicates that Lila is online, she received 8 new MSG messages and by clicking in this hyperlink she can read the

Figure 9. Multiple groups of MSG contacts

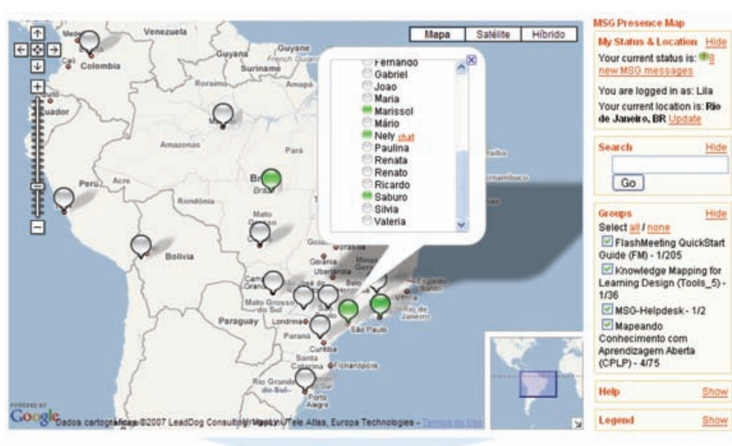


Figure 10. MSG displaying the availability of contacts of the same course worldwide

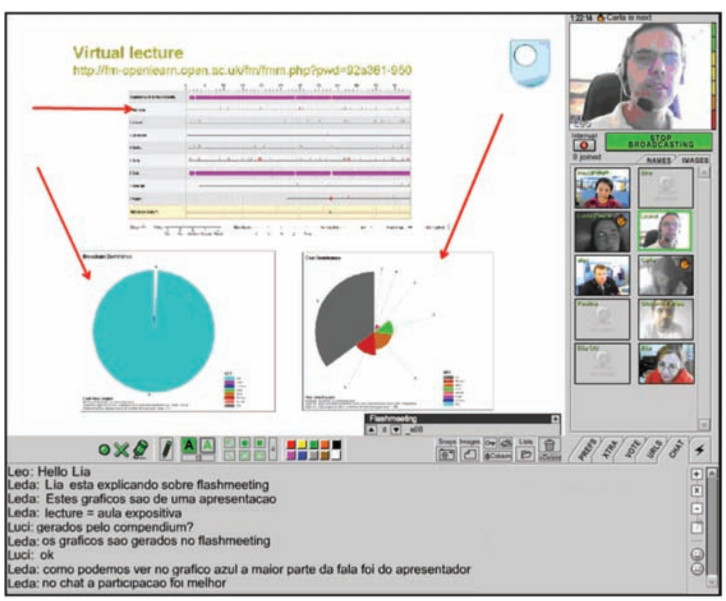
content. She can update her current location and also hide in case she does what to show it. She can search her fellows by name, locality or groups. Each group represents an OpenLearn course that she has enrolled on. She has 4 groups which shows the quantity of people logged in and online. For instance, in the group "FM QuickStart" there are 205 users and one is online. Lila can also contact people in Portugal and ask how they have been using knowledge media tools.

Figure 10 shows Lila from Rio de Janeiro chatting with Nely from Lisbon. Nely was searching the FM and used MSG to find a solution for her problem ("Hi Lila! I am looking for the FM Website…") and her fellow Lila helped her answering her question ("See this url http://fm-openlearn.open.ac.uk"). In this case MSG is useful to bridge quickly a gap that can be important in a more complex activity to develop understanding or foster the spiral of knowledge.

Figure 11. FM extract from CoLearn community



MSG, as Strategy for Mapping Social Presence

Presence is an indispensable social software function, featuring in instant messaging, video-conferencing and ambient video awareness tools. In Biocca et al (2001), presence is described as 'being there in other places' and 'being there with other people'. Mapping social presence in open sense making communities can give insights by providing geo-locations of the individuals who may be relevant with specific knowledge areas and can provide advice to others.

In instant messaging systems, a set of presence attributes may include time, context, availability, location, activity etc. A great variety of software supporting group interaction and location based social software applications, from providing awareness of friends being in vicinity to online community sites, helping users meet other users with similar interests. In the case of OpenLearn, MSG maps the location of members of the same community of practice, representing in this way the geo-location and impact of collective intelligence related to a specific course. In this way, the users can obtain a list of contacts, who may provide peer support during learning activities. Through MSG OpenLearners can identify the availability of contacts throughout the globe related to a specific learning resource.

FM: A WEB-BASED VIDEOCONFERENCING APPLICATION

FM (fm-openlearn.open.ac.uk) is a desktop videoconferencing tool, integrated in the OpenLearn environment. Any OpenLearn user can book an online video meeting and select the time, date, duration and number of attendees. The system generates a URL, which can then be circulated to the meeting attendees, who simply click on the link to gain access to the videoconference.

FM as Strategy for Social Learning through Group Discussion

The FM live communication tool allows learners to externalise their implicit knowledge into explicit knowledge by presenting their ideas during a video meeting either through the foreground communication channel (broadcast) or through the background channel (text chat). The application provides a 'push-to-talk', simplex audio system, allowing only one person to broadcast at any one time. Those who wish to talk can raise a symbolic hand and queue, whilst waiting for their turn to come, or click on the 'interrupt' button.

In the mock up example in Figure 11, Leo is broadcasting, while Luci is next and Carla is the last in the queue. Other communication channels in FM include a text chat function, URL sharing, a voting system, mood indicators, and a whiteboard which allows participants to upload slides, reflect on the content and annotate by drawing shapes or write text, visible to all participants. In this Web videoconferencing there are people from UK, Portugal and Brazil. While Lia from UK is explaining in English the graphics generated by FM, Leda is answering questions in the chat in Portuguese and translating important key ideas from English to Portuguese. All participants can visualise the graphs, interpret the content, ask questions and give feedback through different media: text, sound, audio, graphic and icons. In this way, users make sense by combining explicit knowledge from different media.

FM as Strategy for Individual Learning by Replaying the Discussion

FM events can be recorded and their replay, called FM Memo™, can be annotated, edited and discussed with their community or viewed by other people in the world. The replay is browsed by navigating through the names of the attendees on the right, or via the timeline on the bottom of the window, representing the length of each broadcast, with different colours to distinguish between participants. In this way, the FM Live Communication tool engages learners in internalising explicit knowledge through the replay function; users can replay the recording of the discussion in order to reflect upon it and analyse the content.

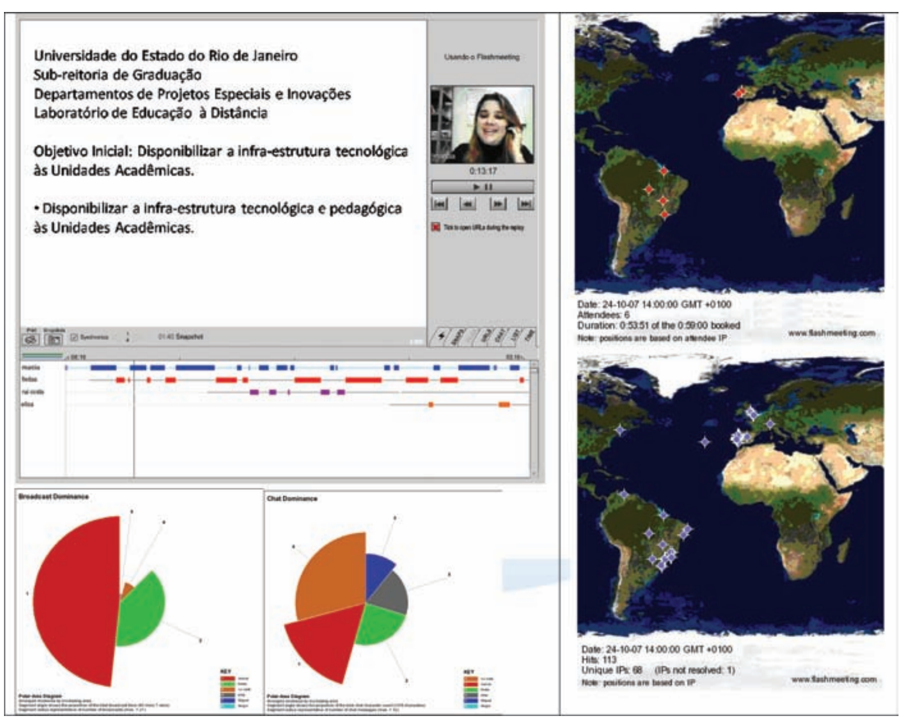
The example shown in Figure 12 portrays the replay of the broadcasts of 6 attendees from different cities in Brazil and Portugal. The whiteboard presents the purpose of their meeting, which is to discuss about technology and pedagogical methods applied to higher education. The time line below shows that the first two participants started to talk and the two following attendees in this list participated with their comments during the middle and at the end of this meeting. The other two attendees did not start broadcasting, they were probably only listening.

Automatically generated broadcast dominance diagrams (circle diameter=turns taken, circumference=total duration) and chat dominance diagrams (circle diameter=messages sent, circumference=characters typed) indicate the attendees' participation in the meeting (Scott et al, 2007). The first graph below, "broadcast dominance", confirms that there were two presenters, two active attendees and two listeners. The second graph, "chat dominance" presents almost similar participation among the six participants.

The meeting minutes are available online, providing different information in order to enhance the understanding of the event, remind attendees of what was discussed, or inform people who did not attend of the meeting content. The metadata generated after each meeting include the chat log, the number of attendees, a linear visualisation of individual broadcasts along the timeline of the event, the type of emoticons displayed, the time of raised hands, the URLs fired and others.

FM Memos can also be shared and made available through a publicly accessible Webpage for everyone who wishes to view and learn from them, enhancing in this way the collective knowl-

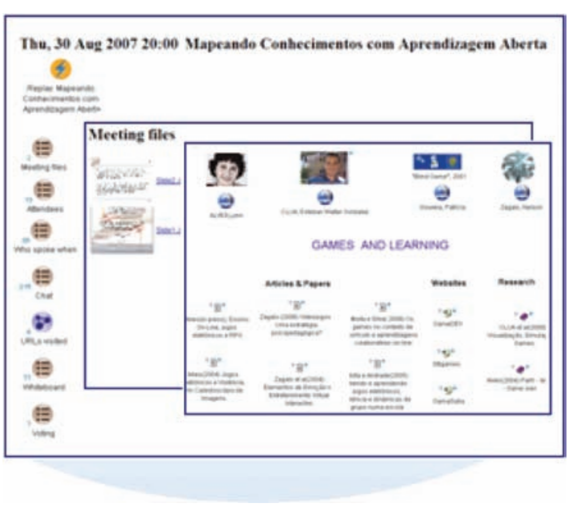
Figure 12. FM is a web videoconferencing application offering instant online meetings.



edge of new, reusable learning objects. In less than two years of existence, the FM-OpenLearn folksonomy hosts around 100 public events. In this perspective, the FM Live Communication encourages learners to socialise implicit knowledge by sharing their video meetings, allowing other learners to search and find events related to their interests and build knowledge through social awareness. Around 10 public events have been attended by the CoLearn community, such as series of interactive seminars held by experts on Moodle, video lectures on a variety of topics such as information literacy, elearning games and knowledge media tools. Amongst the rest of events, there are also Web-casts of conferences, interviews of e-learning experts, moderated project meetings, peer-to-peer student meetings and many others. These different kinds of events may contain different communication patterns, which can be interpreted in different sense-making representations, be it knowledge maps of the meeting or visualisations of the event shape.

In FM, the metadata produced after each meeting can be used to interpret the event in different ways. For example, the IP resolutions of FM users include information about the use of the

Figure 13. A FM map in Compendium representing Games webconference



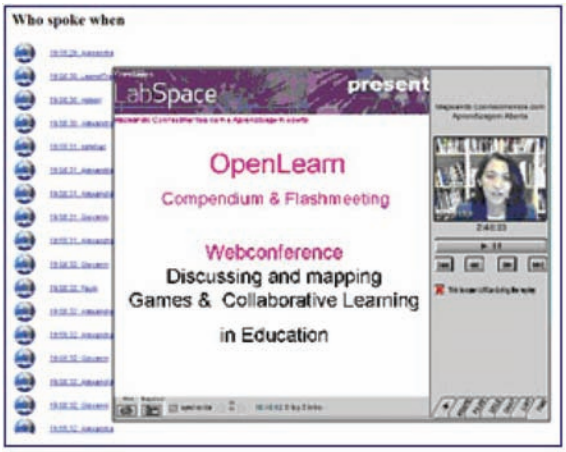
tool by different communities. Using people's IP addresses, their location can be plotted on a world map. In this way, maps can be generated to show the distributions of users for both the attendance of live meetings and replay access. For example, the IP resolution of the users connected to the live meetings shows how the tool is being used to connect people from the same social network or community of practice, while the IP resolution of the users viewing a public replay shows the learning impact of the event reuse in different parts of the world.

In Figure12 the map on the top shows 6 unique IP addresses from Brazil and Portugal that were connected to this live video meeting in the CoLearn community, while the map below shows the truly global use being made of FM recordings during the same month, with 113 unique IPs viewing FM recordings around the world, representing in this way the impact of the knowledge included in the replays of virtual events and transferred to hundreds of individuals around the world.

FM and Compendium as Strategy for Constructing Collective Knowledge

The FM Memos generate a set of metadata, available in XML format. This XML can be imported into Compendium and turned into knowledge maps as we can see in a virtual meeting about digital games applied to education. These maps can enhance the understanding of the event, as they include temporal and conceptual connections amongst all event elements, such as who attended the meeting and who spoke when (Figures 13 and 14), the URLs visited and the whiteboard images or interactions (Figures 15 and 16), text chat logs, annotations, votes and keywords. All these elements are nodes automatically linked in a knowledge map, which can be used to assist the replay users in structuring, acquiring and reconstructing the knowledge transferred during the discussions and argumentations in the meeting (Okada et al, 2008). In this way, learners can

Figure 14. Keeping track of who spoke when



internalise explicit knowledge of the community into implicit knowledge. The nodes are actually links back to the original replay as well; therefore a way of traversing the replay through different categories of indexed timestamps.

The knowledge maps of different kinds of FM events may differ in that they may present different map structures. For example, seminars can present richer maps in terms of URLs, broadcasts and chat logs, as they are more interactive events, involving the active participation of several attendees. Virtual lectures, on the other hand, with a main presenter broadcasting and her virtual audience interacting with chat, may include poorer argumentation between individual nodes. The structuring of the FM replay information in maps allows the users to browse the different parts of the event, based on the different event elements, such as individual broadcasts, annotations, URLs shared etc. Mapping the knowledge transferred in a virtual meeting enhances the combination of explicit knowledge in the form of questions, feedback and comments from different media.

DISCUSSION

In this initial study, the use of Compendium, FM and MSG was introduced around OERs, providing learners and educators with some strategies to foster open sensemaking communities. Table 2 shows a summary about how these knowledge media tools can be useful to develop understanding from individuals to groups.

Figure 15. Mapping the URLs visited along with their time during the event

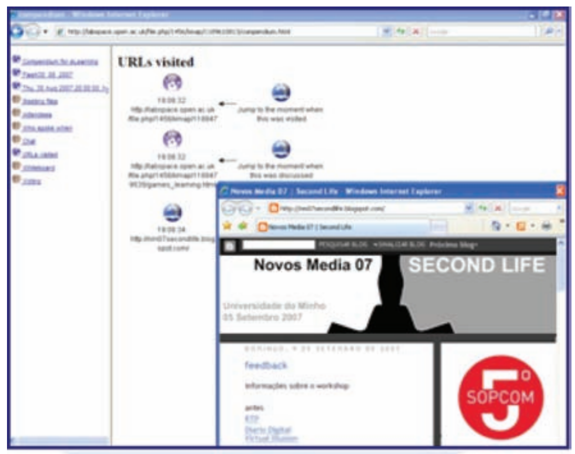


Figure 16. Mapping questions, ideas, pros and cons discussed on the webconference

Table 2. Knowledge media tools for open sensemaking communities

	How these tools help learners to	Compendium hypermedia mapping	FM a web videoconferencing	MSG Instant messaging
INDIVIDUAL GROUPS	identify a gap	Visualising questions not addressed and concept without connections	Raising questions through broadcasting, chat or Flashboard and unknown concepts	Raising simple questions through instant messaging.
	bridge a gap	Selecting relevant information resources	Getting peers' feedback through smiles, vote, chat or broadcasting E	Contacting who knows the answer for simple problems that need to be solved quickly
	develop and share representations around some problem	Bringing significant information in their maps and uploading the files in their community.	Preparing slides or Compendium maps and sharing them in WhiteBoard	Identifying simple problems that can be discussed in MSG
	identify common conflicts	Visualising questions and gaps in other's maps	Voting or highlighting in the WhiteBoard issues that the group are interested in	Meeting peers who are helpful to raise significant issues
	negotiate a consensual understanding	Mapping FM discussions representing the groups' argumentation around problems	Discussing Compendium Maps of previous meetings, which represents the groups' understanding, in the Whiteboard	Meeting participants who are helpful to solve problems

The combination of knowledge media tools for knowledge mapping, presence and live collaboration can assist learners in identifying and bridging gaps, developing and sharing representations around the same problem, tackling common problems and negotiating a consensual understanding. Learners can identify gaps by raising simple questions via instant messaging and visualising questions addressed for the first time and concepts without connections through hypermedia mapping. New questions can be raised during a live videoconferencing session.

Relevant resources organised in knowledge maps can help bridge gaps in sensemaking, while learners can locate and communicate with people who know the answer to simple problems via instant messaging and can get instant feedback in a videoconference through broadcasting, text chat, voting and emoticons.

Knowledge media tools can encourage the development and sharing of representations around a common problem. Learners can discuss simple problems via the MSG instant messaging tool and bring significant information in the knowledge maps, which can be accessed by their community, or prepare maps and slides to be shared in the whiteboard during a live video meeting.

Common conflicts can be tackled through visualising questions and gaps in fellow learners' maps, or finding contacts who may be helpful with the identifying problems via instant messaging, or through voting and highlighting issues in the whiteboard. The process of making sense is induced by issues that create discontinuity in the flow of experience engaging learners to collective interpretations (Weick, 1979).

Finally, consensual understanding can be negotiated by identifying contacts though MSG groups and maps, who may be able to solve problems. Moreover, the mapping of virtual discussions represent the groups' argumentation around problems and the discussion of Compendium maps of previous meetings via the FM whiteboard represent the group understanding.

In this case study, we analysed some examples, which show how these tools can be used to foster open sensemaking communities by mapping knowledge, location and virtual interaction. The sensemaking process in online environments can be developed by connecting sequences of enactment, selection and retention (Weick 1979) via knowledge media tools. In enactment, learners actively construct meaning by rearranging and labelling raw data into equivocal data to be interpreted in their maps or synchronous conversations . In selection, learners identify meanings that can clarify equivocal data by overlaying their prior knowledge or past interpretations as templates to the current experience. Compedium, FM and MSG can be used to provide explanations of what is going on. In retention, the community stores the products (maps, Webconferences and messages) of successful sensemaking that learners may retrieve in the future.

In this pilot study, it is important to stress this work will be extended through quantitative and qualitative research. A Web survey with follow-up interviews will soon be conducted about the uses of these knowledge media tools in the OpenLearn project. Although there are significant number of members registered, it is not yet possible to see widespread of open sensemaking communities around OER. Previous surveys indicated that individuals come to OpenLearn primarily for accessing the free OERs. It is not surprising that they do not as a rule share knowledge objects — or indeed, engage in a lot of collaborative learning activities. In order to start their communities, t**hey need to find peers with similar interests and have** social and intellectual commitment to learn content and tools together. Disseminating strategies and ways to apply these tools to foster open sensemaking communities may engage OpenLearn users in collaborative learning.

CONCLUSION AND FUTURE RESEARCH

Knowledge media technologies mark a profound shift in developing products, creating new strategies for learning, and sharing knowledge. Learners move from simply following information, instructions and tasks to discussing them, making sense of them, reconstructing and sharing meanings collectively with anyone in the world with similar interests. OpenLearn indicates a new way to interact and construct knowledge collaboratively from individual learners to social groups (Aigrain, 2003) and from global networks to local communities (Anderson, 2007). It offers an environment to actively support individual learners, educators and self-organising communities through the integration of Compendium, FM and MSG. In order to enhance social learning, these knowledge media tools can be used to:

- Create awareness that the user is part of a community
- Build new learning objects, leaving them open for sharing, reuse and remixing
- Manage personal or group information by dragging and dropping in any document or Website (a form of 'visual e-portfolio');
- Manage knowledge and learning by charting questions, ideas, and arguments as they arise;
- Share learning pathway maps over resources; to work through revision question templates;
- Browse or construct knowledge maps associated with learning resources and literatures, or dialogue maps which add value to online meetings.
- Identify social roles and improve individual behaviour and social interactions in open sense making communities
- Build knowledge through social awareness

The number of knowledge media technologies' users has been rising in this first year and a half of OpenLearn Project. During this period, the OpenLearn project has engaged a critical mass of over more than 1,000,000 users, taking advantage of the OER to learn at their pace and time. Our future research focuses on how students and educators can use the knowledge media tools as open sensemaking tools to foster their social learning networks and contribute to the open learning resources movement by developing their learning materials and new pedagogical strategies. Open Educational Resources, knowledge media tools and open sensemaking communities are essential to promote open learning mainly if OpenLearners can take part in this movement as active participants by valuing their authorship.

KEY TERMS AND DEFINITIONS

Knowledge Mapping: A technique for organising knowledge, which aims to facilitate the creation and communication of knowledge through graphical representations. Beyond the mere transfer of facts, knowledge mapping aims to further create or transfer insights, experiences, attitudes, values, interpretations, perspectives, understanding, and predictions by using various complementary visualisations.

Knowledge Media Technologies: Means tools to support the processes of generating, interpreting and sharing knowledge using several different media, as well as understanding how the use of different media shape these processes.

Open Educational Resources: Educational materials and resources offered freely and openly for anyone to use and under creative commons licenses, which allows users re-mix, improve and redistribute on the Web.

Open Learning: A learning method for the knowledge acquisition based on open educational resources, free technologies and online communities. Open learning aims to allow participants self-determined, independent and interest-guided learning. It has been also offering opportunities for collaborative study and social learning.

Open Sensemaking Communities: Refer to open and self-sustaining communities that construct knowledge together by interpreting, reconstruct their understanding together and literally "making of sense" from an array of environmental inputs.

Peer-to-Peer Networks: Typically used for connecting people via largely ad hoc connections. Such networks are useful for many purposes, such as social and open learning, sharing content files containing audio, video, data or anything in digital format and realtime data.

Social Learning: Refers to the acquisition of social competence that happens primarily in a social group, virtual learning environments or online communities. Social learning depends on group dynamics, people with similar interests and disposition for studying together.

Social Presence or Co-Presence: Terms used in virtual learning, which refer to the ability of learners to project their personal characteristics into the online community by presenting themselves as 'real people' through the media of communication: picture, profile and via the "sense" of being with others.

Chapter 3.15
Using Notification Systems to Create Social Places for Online Learning

James M. Laffey
University of Missouri-Columbia, USA

Christopher J. Amelung
Yale University, USA

ABSTRACT

Context-aware activity notification systems have potential to improve and support the social experience of online learning. The authors of this chapter have developed a context-aware activity notification system (CANS) that monitors online learning activities and represents relevant contextual information by providing notification and making the learning activity salient to other participants. The chapter describes previous efforts to develop and support online learning context awareness systems; it also defines the critical components and features of such a system. It is argued that notification systems can provide methods for using the context of activity to support members' understanding of the meaning of activity. When designed and implemented effectively, CANS can turn course management systems (CMS) into technologies of social interaction to support the social requirements of learning.

DOI: 10.4018/978-1-60566-368-5.ch016

INTRODUCTION

Online learning in its various forms plays an increasingly important role in how students learn, how faculties teach, and how higher education meets the needs of its constituents. However, while online learning plays a powerful role in broadening access within and beyond campus sites, there is a growing concern that it may be diminishing the quality of teaching and learning by forcing instructors and learners to view courses through the narrow lens afforded by contemporary software systems. Today's approach to online learning is encapsulated in course management systems (CMS) of which Blackboard, WebCT and Sakai represent most popular applications. The CMS provide fairly effective ways for instructors to give and control access to course information (syllabus, assignments, grades) and instructional resources. They also present some facilities for direct interaction through discussion boards and chat rooms. The CMS approach helps manage the course and related information but is limited in supporting the interaction, coordination and cooperation between students and instructors. The authors of this chapter have developed a Context-aware Activity Notification System (CANS) (Amelung, 2007; Laffey & Amelung, 2007) as a mechanism for improving social ability in online learning (Laffey, Lin, & Lin, 2006). CANS is a software system that monitors activity within an information system, represents relevant contextual information (such as where, when or under what conditions), and provides notification to other participants about the activity.

In traditional face-to-face courses instructors and students come to a physical place where they mutually act out the course activities. Coordination and cooperation are facilitated by cues and structures in the context: such as, a bell ringing to signify it is time to attend to the teacher, the clock on the wall providing a common marker for knowing how long an activity should last, or students passing completed work forward at the end of a class period. Seeing how others use these cues and structures also shapes interaction. However, in online learning the CMS is a black veil between the instructor and students and among the students. Faculty and students are limited in their knowledge about what is happening in the course to the "words" spoken. Students do not see other students working; nor for the most part do they see each other's products. Instructors do not see students working and can only influence them with words. Similarly, students do not see instructors working outside of the formal presentations and feedback prescribed by the instruction. Seeing that an instructor has read your discussion post or looked at the file you uploaded to share with the class may encourage participation and develop a sense of an interpersonal relationship with the instructor.

Evidence of high dropout rates in distance learning attests to the problems that students may have with this form of education. Chyung (2001) found that online learners who dropped out perceived that their online learning environment was not engaging, had low levels of confidence while learning at a distance, and had low satisfaction levels for the instructional processes used in the online learning environment. The incidental learning that happens through working together, the social navigation that happens through observing others, and the motivation to keep learning that happens because of a sense of shared social experience are possible in a traditional classroom because members see and experience activity in context, but in online learning these outcomes are greatly constrained. However, there is potential for new social interaction technologies to improve the social experience and social support of online learning. These same approaches and technologies that have potential for supporting the social nature of online learning may also be important to online collaborative work and leisure activity. The ability to turn an online space into a social place is a challenge to the design and implementation of all forms of online activity and interactivity. This chapter describes one such social interaction technology, context-aware activity notification systems. These systems have the potential to make the activity of other members salient and to enhance the social nature of learning in an online space, in this case a course. To the extent that these notifications are provided in ways that are meaningful to the social roles and interactive tasks of being in a course, then the members will experience the online environment as a social place for learning and activity.

BACKGROUND

The goal of transforming course management systems from information space to social place is in keeping with the recognition that education is a social activity and that information access and use has a social nature. In *The Social Life of Information*, Brown and Duguid (2000) summarized a growing recognition that information systems need to both support use in social contexts and represent the social nature of accessing and using information. For example, a tech support information system should be organized by the practices that people do which cause them to need tech support and include meta data about who has provided the information, how frequently it is used, and what other resources were used by the folks who used this one. In this way, the users do not simply have a static piece of information related to the problem they are solving; they can make attributions about the information, such as the likelihood of it being accurate or sufficient. Being able to make these attributions gives the information contextual meaning and helps the user have a sense of how that information fits into practices within a community, such as the importance and value of the information or perhaps peripheral status of the information. In this sense, having the relevant contextual information is seen as important or necessary for making decisions and solving problems effectively (Palumbo, 1990).

By having a goal of transforming CMS in to a social place, we mean that the online system becomes a medium that represents both the explicit and tacit information of social activity and that the forms and objects of the system communicate possibilities for action (Harrison & Dourish, 1996). This emphasis on creating "place" foreshadowed Web 2.0 by emphasizing the value of supporting social practices rather than simply enabling information access and exchange. As discussed earlier for face-to-face classes, the awareness of what others are doing is necessary for social practice. What others do and how they use the elements of their environments stimulate us to action, provide feedback to our own actions, and support social navigation. *Social navigation* refers to the phenomena of people using what other people do as a guide for what to do (Benford, Bowers, Fahlen, Greenhalgh, & Snowden 1995; Gutwin & Greenberg, 1996).

By *context aware*, we refer to how we use cues from our environment to make sense of the situation and decide what to do. In education many of these cues represent the social circumstances and include the physical and historical circumstances that may have a role in shaping activity. Early work on context awareness emphasized the need to design computer systems in ways that accounted for the social contexts of the environments in which they were being used (Moran, 1994): for example, how the computer activity fits into the broader scheme of activity in which the computer activity occurs, is but one of the processes that shapes the meaning of the computer activity for the participants. More recent work has shown the value and role of context awareness for ubiquitous and pervasive computing (Moran & Dourish, 2001; Kaptelinin & Czerwinski, 2007). The potential and new insights for context awareness for CMS is that there is social activity and a social context "within" the CMS, and that the appropriate use of notification systems can change the information spaces of CMS into social places for collaborative and social learning.

Carroll, Neale, Isenhour, Rosson, and McCrickard (2003) investigated the role of notification systems in supporting collaborative awareness in a virtual school context. Their study found that three types of awareness information contributed to the productivity of synchronous and asynchronous collaboration: social awareness ("who is around"), action awareness ("what is happening to objects"), and activity awareness ("how are things going on"). Unlike some types of notification systems that simply and straightforwardly provide information about events, Carroll and his collaborators found substantial complexity in maintaining awareness for the long-term activities of their educational site. They also found that in some cases the relevant information for maintaining context awareness can be provided as notes about discrete events while in other cases the notes should be snapshots that aggregate series of events. They conclude that to coordinate and effectively work in the online cooperative world of educational settings, users (teachers and students) need sets of tools for: (1) managing objects in the learning process, (2) knowing when someone does something to an object, and (3) keeping track of objects over a span of time and work practice. Their work suggests the need for notification systems that not only convey information, but also put that information into the context of work practices and social roles.

Yang (2006) and colleagues showed how matchmaking between learner and service ontologies enables interactive matchmaking in collaborative learning environments. Learner profiles consist of entities, such as student accessibility preferences, calendars, and locations. Service profiles consist of knowing such entities as who is online, how to get in touch with classmates, and how to find relevant course materials. The goal is to augment collaborative learning by providing the student user with information relevant to educational purposes, such as whether other authors of a collaborative work are online for discussion.

Our interest in context awareness emerged from our development and implementation of an online learning system back in the late 1990's. As we used and studied the system, we noticed that users (instructors and students) were using what we called activity information to navigate the system. Our online system had an "activity monitor" that displayed recent activity of others in the system on the home page. We noticed how we were drawn to using the monitor to click through to see what had been done rather than using the normal navigation tools of opening the library or discussion applications and then navigating to the target. It became clear that students were doing the same. However, as the semester marched on, the performance of our activity monitor slowed as it had to handle more and more activity. The architecture and mechanisms of the monitor needed to be reconsidered and redeveloped. Chris Amelung, a doctoral student at the time, took on the redevelopment for his dissertation work and the result was the first implementation of CANS (Amelung, 2005).

CANS has a vocabulary of activity and monitors those activity events in a CMS, such as when a discussion board item is read, a resource is uploaded or an announcement is posted. CANS also has a registry of preferences which it uses to distribute notifications. Instructors and students can create reporters to establish and manage notification. For example, an instructor could create a reporter for the time period of a course unit that would keep him abreast of how students are doing and if any are falling behind. Similarly students could create reporters for a work group to know when others in the group have contributed or reviewed work, thus facilitating coordination of activity and keeping a sense of group work even when members never see each other. Notifications are currently packaged as e-mail digests, widgets (small applications that stay resident on a computer desktop), or web pages within the CMS.

NOTIFICATION IN COURSE MANAGEMENT SYSTEMS

The above discussion shows that context in educational settings is quite complex, social, and important. A variety of notification and awareness services are potentially meaningful, but the constructs upon which researchers are building systems of awareness for collaborative and educational purposes are still in formation. This section will examine the components of notification systems and identify approaches to design for context awareness as well as issues in creating a sense of place associated with the various components. It should be noted that almost all CMS have some notification functionality tied to specific applications within the system with possible aggregation for notification, but the objective here is to identify a comprehensive framework that can apply to the full course experience and not simply augment a specific application.

Monitoring

The most straightforward way to monitor online activity is by recording all mouse clicks or keystrokes. This approach is sensible if there is no a priori schema for differences among these actions. However, in CMS almost all acts can be understood by application and function. For example, a specific mouse click in a discussion board can be recognized as opening a message for viewing or as starting a reply or new thread. Thus, similar to the ontology constructed by Yang (2006) or the vocabulary constructed by Amelung (2005), the monitor can create a specific set of events to monitor, based on a framework for what would be meaningful to members and impact behavior. In the case of CANS a listener was created and tuned to certain events and not others. The listener needs to record the event and appropriate context information which may include actor, time and application specific attributes, such as the name of the thread being read.

Building the ontology or vocabulary for the system is a substantial task of marrying the specific functionality of the CMS to a pedagogical schema for knowing what is relevant and important for teaching and learning behavior. It is also important to keep in mind that CMS's are growing and evolving systems that add and modify functionality over time. The monitoring mechanisms must adapt and be able to include new functionality as changes in the CMS dictate. CMS such as Sakai have numerous applications and an institution may choose to activate or disable some of this functionality. Because CANS systems are applied across a variety of institutions, they must be sensitive to the local implementation and accommodate new functionality as they become available. In all aspects of the development of monitoring mechanisms that are attuned to CMS functions and are adaptable to changing functions, a critical concern is that the monitoring process does not negatively impact the performance of the CMS.

Storage

Since almost all implementations of CMS are sensitive to system performance, how data are handled is a concern. One form of notification, streaming or tickertape type applications requires no substantial storage. The data is usually limited in scope and distributed as a stream to anyone who signs up for it. CMS usually require more complex forms of notification. As suggested by Carroll, there is a need to keep track of information over a span of time and for aggregation to answer complex questions, such as which students are behind on an expected activity during a particular unit of the course. The CANS system stores data on a secondary server to the CMS. This allows minimal impact on CMS performance, having data available for a variety of reporting functions and requests, and affording the opportunity to merge activity information across multiple online systems. However, for notification systems that seek to also enable dynamic interactivity with the notifications, such as comparing today's level of activity with that over the last three days, then hybrid storage forms may be required to accommodate both massive storage and quick retrieval within sets of data.

Processing

Processing refers to matching event information to requests for notifications. The simplest form of this is to program for all users to get the same information. Under some circumstances this may be reasonable, but in online learning there is considerable variety in user roles, how users want to work and the interdependency of information. Subsequently, customizing outputs to users and contexts seems necessary. In CANS administrators can establish what information will be monitored for their site, and instructors can establish what information within the set enabled by administrators will be monitored for their course. Users can then create reporters which allow one time requests for certain types of reports: such as, what was the activity level in my course for this past semester or subscriptions to information reports such as receiving an e-mail note each morning of the semester reporting on the activity of the previous day.

Representation

Representation has two considerations. First, what is the mechanism for delivering the notice? In many cases notification outside the CMS is desired or required. External notices can be provided via e-mail, external web pages, widgets or even phone calls. In some cases notice within the CMS is desired. Awareness information could be embedded within an application. For example, posts in a discussion board or files in a resource section can be labeled with frequency of reads. Additionally, within CMS awareness, information could be provided within a special application that allowed requests for custom reports of archived data as well as interaction with the data. For example an instructor may want to see when during the course of an assignment students actually used the resources made available to them, and then once the findings are available the instructor may want to sort by attributes of the data. The second consideration for representation is how the notice should be displayed. Figure 1 illustrates a text-based digest of information currently used in CANS. This form is effective for communicating both general information about the level of activity and detail about who did what. However, as the amount of information increases, the effectiveness and efficiency of this form decreases. Figure 2 shows a visual representation that provides a quick summary for a large amount of information but requires interactive capabilities for drilling down into the data for the user who wants more detail. Figure 3 uses social comparison for organizing the data and shows how the choice of representation impacts the meaning of the information. In this case users see how their activity level compares to the activity level of a high performer and to the class average.

We have discovered that an important issue in representation is identity. What identity does the notice represent? For example the representations can include names of the actors or not. Under some circumstances, having your name on a list that shows who has done the most activity can bring social pressure to motivate more activity. In teaching, this is a tool that an instructor can use to motivate students. However, students are likely to not want such a list and some may feel it is a violation of their privacy. Under some circumstances, university policies or government regulations may even be issues to consider. Additionally there is always the *law of unintended consequences* to

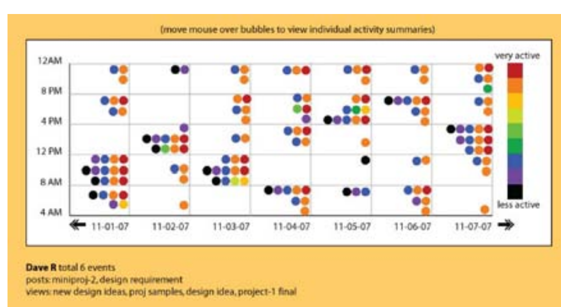

Figure 3. CANS social comparison digest

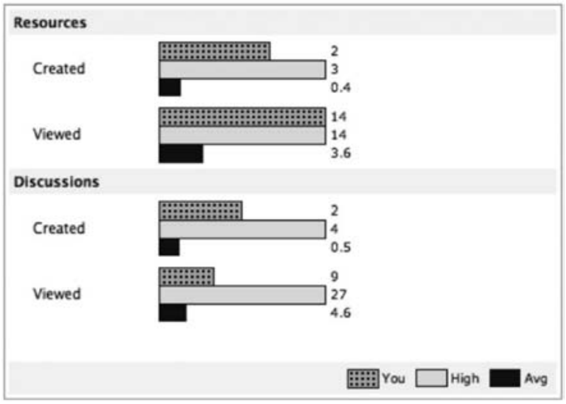

consider. An instructor may want to motivate students to further effort, but may engender activity that simply tries to cheat the notification system by opening items without reading them. Our best judgment is to provide a variety of ways to represent identity so that the circumstances of the institution and course and the pedagogical approaches of the instructor can determine the form taken. One approach as is illustrated in Figure 3 is to keep the members anonymous. Comparison information is provided but it preserves the privacy of the individual members. However, the form shown in Figure 3 requires an individual representation for each member, so the benefits of both comparison and privacy come at the cost of added design and processing. An alternative identity to basing notification on who has done what is to use system objects as the design center. For example, rather than pointing out who has read a discussion board message, the system can report that a particular message has been read 5 times. This approach may meet the need of supporting social navigation without risking privacy concerns, but may impact the social nature of the course differently than when the members are the design center for activity notification. As with many of the points discussed in this chapter, this is an issue for further research.

Management

Educational coursework and the participants in the coursework have great variety. No one size or form of notification will suit all types. For example, the type of notification system that fits a small enrollment graduate course being taught online is likely to be inappropriate for a large enrollment undergraduate on-campus course. The online graduate course may benefit from a high level of student-to-student awareness and personalization, but the same approach in the undergraduate class may be overwhelming with the amount and detail of information provided. Similarly, different institutions or instructors may wish to manage privacy concerns differently. For example, while in some cases knowing the name of who has read a discussion board post may benefit group interaction, in others it may be seen as a violation of one's privacy. Thus the capabilities of the system must be customizable by those who implement the system and then again by those who use the system.

CANS allows management in a tiered fashion. The CANS implementation for a site or multiple sites allows the course management administrator to set permissions for monitoring and notification functionality. Within this set of permissions an instructor or course manager can set permissions for how the course will work. These permissions then provide the functionality that members use to create reporters and notification representations. Figure 4 is a prototype for how permissions may be managed in the Sakai implementation of CANS. Within Sakai, members have roles that correspond to having access or having rights to maintain sites and collections. The system administrator can set the permissions that will be the default for the roles in each course. Instructors can reduce permissions within their courses but not add those restricted by the administrator. Items such as id.open prescribe whether a member in the role can see the personal identifier for the actor opening an object in Sakai. With this schema members could be given permis-

Figure 4. Setting monitoring and notification permissions in CANS for a Sakai implementation

sion to know who posted something but not who read it or vice versa.

FUTURE TRENDS

A few years ago the dominant experience of being online was accessing information or making transactions. Today, especially for youth, being online is a social experience. Taken from another perspective, social activity is increasingly mediated by technology and the Internet. We interact with colleagues, friends, family and absolute strangers through e-mail, chat rooms, shared documents, video conferencing, and 3D virtual environments. As we become socially networked via technology, we will also need forms of social information that fit these new environments and relationships.

Attending to the behavior of others and using that behavior to help shape our own behavior and serve as a basis for the types and levels of relationships we form with others is a natural part of human everyday experience. Context awareness and notification tools for online environments can facilitate the attention and sense making that happens rather intuitively in natural settings. But, how to make this happen in ways that resonate with us when we are online constitutes a design challenge and an area in need of further research. Our experience suggests that these tools are likely to come in many forms that are appropriate for the nature of the communities or relationships being formed in online spaces.

For example, online auctions such as eBay provide mechanisms to keep track of the status of your bid in an auction based on what others are doing. The designers of eBay recognized that what motivates a person to place a higher bid in a traditional auction is hearing another person make a bid higher than your last one. Similarly, the pace of bidding and other contextual factors influences bidders. Designing a user experience that makes these circumstances of one's auction activity salient in an online space has substantially impacted the use and ways of using eBay and other online transaction systems. The task then is to design context awareness and notification that are appropriate to the task, community, and individuals involved in online spaces.

One of the key challenges we see for our design efforts for context awareness in teaching and learning was foreshadowed by Carroll, Neale, Isenhour, Rosson, and McCrickard (2003) when they discussed the need to keep track of objects over time. Most events are not just moments in time. They have a past and a future as well as a present. When the stock market ticker shows the current price, it also shows the change from the last price. For most activity this sense of trajectory is also a key part of making sense of the information and being able to use the activity information to make choices about one's own behaviors. One way of addressing this need is to provide more and more data so that users can use what is relevant in their eyes. For example, the e-mail digest of Figure 1 can become more verbose about each event and show more events. However, this method rapidly runs into diminishing returns as the data fairly quickly overwhelm us and become noise. Visualization as in Figures 2 and 3 are part of the solution to making more information available and valuable.

Our experience suggests that there are two aspects of visualizing data in context awareness that have potential for making information more salient for users and their choices. The first is having visualizations that fit the context. In a sense we mean context aware representation. For example Figure 2 is a useful way of representing information for a large class but may be irrelevant to the needs of a smaller class. Our second key aspect is interactivity. We want the ability to ask questions of our data representations, such as sorting and filtering information. Similarly we want the ability to compare information. For example, an instructor may look at a display of yesterday's activity that shows 2 or 3 students with a very low level of activity. The instructor may want to then see what happened over the last week to see if the same pattern is evident.

The CANS project faces challenges of integrating activity information into the core teaching and learning activities of CMS. Current capabilities allow notification through e-mail digests. The next steps include embedding information into the CMS home pages and applications so that notifications can provide both peripheral awareness and be embedded in learning tasks. Embedding information into the CMS is of course a technical challenge that will require innovative solutions; but if we truly hope to move from information space to social place, the embedding will require that we understand how the activity information relates to teaching and learning practices. This requires a socio-technical solution for connecting a member to his or her group and points to the need for improved methods of designing systems. Similarly, institutions of higher education are concerned with regulations about releasing information about students, and students are concerned about maintaining a sense of privacy and security in their work. These issues require political-technical solutions for connecting members to their community.

While the future of notification systems promise ubiquity, rich media representations, integration across systems, and customization to improve meaning and salience, the future also demands technical solutions that fit social customs, motives and regulations. It is important to remember that just because information can be provided and may be useful does not mean it should be provided. The application of context awareness in the service of making information systems more social requires interdisciplinary thinking and research across social psychology, organizational development, learning technologies and computer science.

CONCLUSION

The preceding discussion has briefly presented a rationale and framework from prior work that shows the value of making online learning more social and the potential for using social interaction technologies, such as context-aware activity notification systems. The authors identified the components of such a system and highlighted some of the design and implementation complexities and issues. The chapter has also highlighted that while context awareness is a natural and necessary part of human activity and human learning, there is much work to be done to make it a powerful and integral part of course management systems.

Although making social information available, salient, and meaningful in online systems and for online learning seems a natural progression of system capabilities in a Web 2.0 and beyond world, little is known about how to do so in ways that provide the information as natural components of a social place for activity, optimize the beneficial effects on teaching and learning, and maintain comfort levels of institutions and individuals for privacy and security. Efforts such as the research and development underway for the CANS project are needed to identify the best fit of information to the social nature of online learning and to identify the best technical solutions for efficiency and useful features for processing, representation, and management of activity information. The challenge is clear, however, as the online lives of students outside of their courses become ever richer and more social with new interaction technologies. If the online experience of courses through CMS fail to keep up with the increasing sociality of being networked, online learning will miss its potential both as a medium for learning and as a transformation of society that can increase access to higher education.

KEY TERMS AND DEFINITIONS

Context-Aware Activity Notification System (CANS): A software system that monitors activity within an information system and represents relevant contextual information, such as where or when or under what conditions, and provides notification to other participants about the activity.

Context Awareness: In a general sense, it means the salience of physical, social, historical or other circumstances that may have a role in shaping activity. The term has been appropriated within a movement toward ubiquitous computing (moving computing beyond the desktop and into the world of activity) to indicate awareness within the computing system of physical conditions outside the system, such as location or user attributes.

Course Management System (CMS): A software system that simplifies the tasks of managing course content and interaction to help teachers organize and facilitate instruction. Typically systems provide security and some process support for teacher and student work.

Online Learning: Multiple terms including e-learning, networked learning and cyber learning, as well as online learning, are used to refer to educational practice that takes place via networked computers. The general benefit is to allow learners to learn from any place (at a distance) and anytime (asynchronously).

Social Ability: A person's capacity to associate with fellows and to use the members, resources and tools of the social context to achieve something of value. Used to represent a sense of competence for social interaction in online environments

Social Navigation: A construct that represents being aware of what others are doing as a primary guide for one's own actions. Research on social navigation has shown that people move in an information space based on where other people are, what they have done, or what they have looked at.

Social Place: A construct used in human-computing interaction to refer to designing the information space to represent cues and markers for social practices.

ABSTRACT

This chapter analyzes how the development and use of mobile and Web technologies are changing the way to search information, to plan, to buy, and to travel. The new technologies are changing several aspects of our life, such as the way in which people work, buy, learn, travel, and how they relate to each other, and so on. The tourist sector certainly represents one of the most dynamic markets, able to capture innovations and opportunities provided by the Web, in such a way that gets to be an out-and-out model of e-business. Internet access now is not restricted to personal computer. In fact the use of mobile devices is becoming increasingly important. The chapter's goal is to analyze social implications of Web applications and mobile devices and how they are improving the attitude of the customers both the fruition of tourism services and to development of sustainable tourism.

DOI: 10.4018/978-1-60566-156-8.ch027

INTRODUCTION

The widespread use of Internet and Web technology in every aspect of our daily life has brought great change in the consumers habits in any field but mainly in the tourism sector. Every year, million of tourists approach to Internet in order to find tourist information: vacations, flights, guides, last minute, cruises, destinations and routes. This situation is changing the concept of tourism. In particular, tourism was defined by the World Tourism Organisation as "the activities of persons travelling to and staying in places outside their usual environment for not more than one consecutive year for leisure, holidays, business, health treatment, religion and other purposes".

A new concept of "intelligent tourism" is spreading, based on all those innovative technological solutions offered by Web that allows achieving information on cultural, artistic and other kinds of natural interest.

The Web imposes itself more and more as relevant reference and indispensable resource in the tourism sector both for customers and tourism companies, thanks to undisputed advantages such as:

- Speed for information exchange,
- Improvement of interaction among people located in different places,
- Improvement of information sharing, knowledge and services availability for all the users.

These above three aspects are very important because they are producing the markets globalisation and the spatial and of temporal boundaries break down. Moreover the information and knowledge production and sharing improves both quality development of social inclusion. Moreover, the success of the Web and mobile technologies in the tourism sector is given by very competitive prices, but also by the ability to differentiate the offer, by the improvement of possibility to reach the market niches and by proposing new services with a good usability degree. The user is not a passive subject and when s/he visits a business site s/he knows that s/he will not be able to find negative aspects of a choice. This has brought to the creation of virtual communities where users share their own travel experiences with other tourists and where the potential tourist consumer finds relevant information. The tourist seems in fact to prefer descriptions and testimonies of other people that have already visited that place.

In the next sections we introduce the passage from the old economy to the new economy in tourism sector, in particular we describe how the advent of e-commerce has marked the passage from traditional travel agencies to Internet. In succession we describe the different tools tourist used for Web and mobile and their social aspects. Finally we describe the new scenarios of tourism using the new technologies and how the mobile devices can develop the sustainable tourism, increasing both tourism demand and tourism supply.

FROM TRAVEL AGENCIES TO ONLINE TOURISM E-COMMERCE

The tourism initially involved an elite activity. In the last years it has beenbecoming a mass phenomenon shared by million of people all over the world, and it has been becoming one of most relevant economic sector of most countries. Data provided by World Tourism Council (1997), in fact talk of seven hundred million of arrivals of tourists all over the world. The tourism represents the 7% of the total occupied people and the 2% of global gross domestic product. It is a dynamic phenomenon, mutable and complex, it can be defined as a "social fact", it changes with transition of tendencies, of orientations, of necessities and needs of society.

In the past tourists had to go to the travel agencies, i.e. in the physicals commercial places where to plan and buy a travel. These agencies execute activities of reservation and selling of single tourism services or services packages confectioned by Tour Operators. This means that people, have to go to a physical place to use such services. The choice of the agency can be limited by the physical distance. Moreover services obtained depended by operators, by their personal skills and by their limited information.

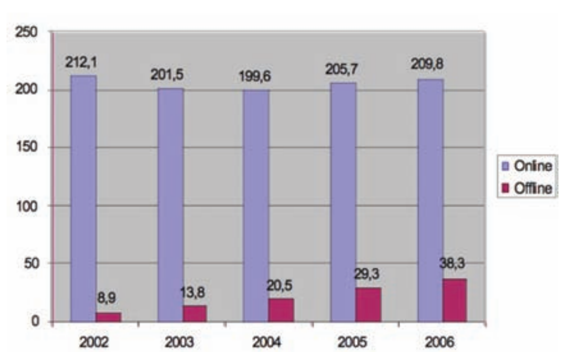
When tourists visit different locations guidebook can be very useful. The paper guidebooks more frequency used by tourist in the old economy. Even if they are still now the principal tool used by travellers, because it is easy to consult and information is well structured, they have a lot of limits. Information in tourist paper guidebooks can be outdated because items written many years before could not be updated, hotels and other tourist activities could be ceased (Schwabe, 2005). Actually the new Web and mobile technologies can provide more timely and complete information than paper guidebooks. In fact user can obtain an updated answer to her/his question, more than a paper guidebook and improve the information quality and consequently the travel quality.

Thanks to technology innovation of the last thirty years, not only users have obtained several advantages but also the tourist companies. The most innovative ones in fact, can actually be able to redefine their own organization structure and relationship with partners, optimising the operating costs and improving the quality of services.

Information and Communication Technologies (ICT) have allowed tourism companies to increase their efficiency and their market value. In fact ICT offer the chance to share data-bases with other organizations and other customers' information resources and services. Besides ICT allow to optimize other internal functions, either lowering costs and by expanding services to offer (Poon, 1993).

In latest three decades the tourism sector has been characterized by three technological phases: Computer Reservation System in the 70s, Global Distribution System in the 80s and Internet Revolution since the second half of 90s. (Buhalis, 1998). The first two have allowed to create, to develop and to globalize availability of services by travel agencies, who have exclusive access to automatic booking systems. The last phase has allowed the customer to perform bookings by themselves, redefining the entire business tourism system, modifying the same tourism fruition and improving the tourist experience. (Stipanuk, 1993).

Figure 1. Value of tourism European market: Comparison online offline (Reference: Mele, 2007)



The first change registered in tourism market according to these technological evolutions is a great increase of e-commerce. On-line tourism is one of the most meaningful achievement cases of the e-commerce in the world. The tourism products in fact have ideal characteristics for e-commerce, they can be represented in Web site utilizing potentiality of multimedia and hypertextual communication. Some studious, such as Werthner and Klein, assert in fact, that tourism is considered as one of more important field of application in the World Wide Web.

Some statistic data can help to understand the Internet impact on tourism sector. According to research of Eyefor Travel Research (2007), the tourism e-commerce field represents about the 30% of Web purchases. In 2005 the on-line booking represented the 33,6% of the worldwide tourism market, in 2006 the market quote of travel agencies is of 36,6%, it goes over with the 37,5% by on-line market. However the United States remains on the top of e-commerce for tourism services creating a gap with other countries.

In Figure 1 it is possible to see how the online market is very important and relevant respect to offline market. In Europe the off-line canal is traditionally the one preferred by consumers but it is loosing more and more market quote to vantage of on-line tourism, the online selling since 2002 to 2006 are increased constantly of 43% per annum. Data in the next table is showing the Internet relevance to improve relation between demand and supply operating on promotion and vending of tourism services to consumers. The trend of on-line tourism market (Figure 2), in fact,

Figure 2. Trend in European online travel market (Reference: Mele, 2007)

YEAR	TOURISM MARKET (SELLING)	ONLINE SELLING %	ONLINE % SELLING INCREASE
2002	221.036	4,04	77
2003	215.303	6,4	54
2004	220.094	9,3	48
2005	235.017	12,4	43
2006	247.16	15,5	30
2007	253.506	18,4	22
2008	259.723	21,1	17

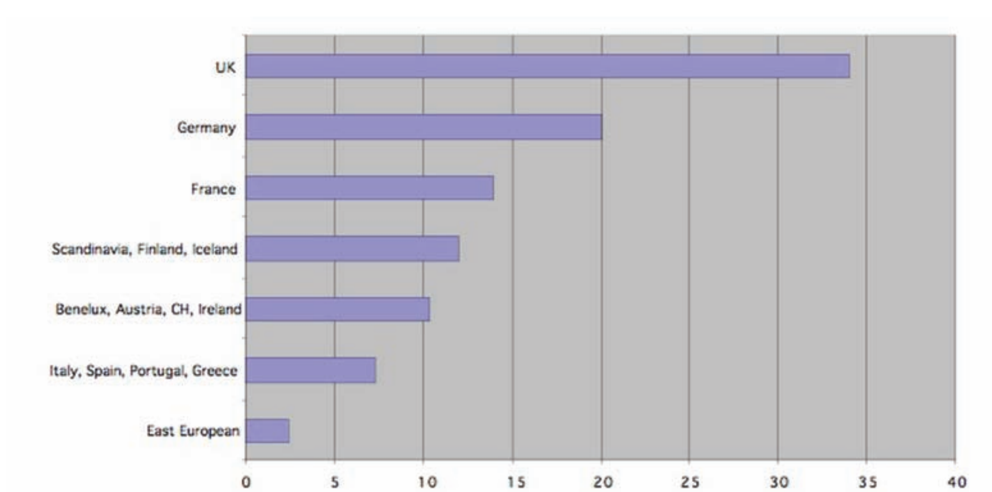
shows an yearly increase on-going ascent of 30% in 2006 respect to 2005. Among reasons of this increase there are different factors; first of all the raise of Internet utilise, then the coming of low cost companies and last the expansion of large band-width and of electronic credit card.

Analysing the European countries scenario of on-line travel market, United Kingdom is the best one with 34% thanks mainly to large presence of low-cost flight. In the second position there is Germany with 20% of on-line travel market. On the bottom of it there is the Southern Europe, the reason of this gap is also due to socio-cultural factors. The UK consumers in fact, are used to buy everything on the Web, thanks to wide presence of large band-width and frequent usage of electronic credit card. In Southern Europe there is distrust to buy in Internet especially by people more traditionalists. There is a cultural distaste to use credit card because they fear to be deceived. Moreover, there is a short access to the large band-width. It's noticeable that the Web diffusion depends on structural and cultural factors linked to countries' policies and economies. In Figure 3 is represented the European scenario of on-line travel market 2006.

Regarding the service typologies the purchases more frequent on the Web in the European online market are occupied by: Air travel 56%, following booking hotel and travel packages 16%, train 8%, car renting 3% and finally car ferry 1%. Increasing also others segments as holiday houses and cruises. Another data about European scenario is about selling channel: in 2006 the direct sellers accounted for 69% of online sale and intermediaries the 31%. This is way low-coast companies sells flight tickets directly to consumers by their sites, avoiding intermediaries actions.

The new trend of tourism is also influenced by duration and kind of holiday. In particular short trips, especially in the weekend, are growing. The Online Travel Agencies (OTA) have understood (exploited) this tendency and created the Dynamic Packaging, that allow travellers to organize the travel about their needs.

Figure 3. Geographic status of the European online travel market 2006 (Reference: Mele, 2007)



As reported by travel weekly (www.travelweekly.co.uk) "Dynamic Packaging is the practice of selling holiday components separately rather than in a single package." OTA have to create the Dynamic Packaging to compete with the prices and flexibility offered by online retailers. In general, we can affirm that tourist behaviour shows the wish to adapt vacation to his/her own needs, adopting consequently travel solutions.

The business travel are the most purchased on Internet due to several advantages: convenience, best prices, speed and availability of tools to search travel and services, possibility to change default packages for personal needs, possibility to choice the hotel franchising, the renting society, possibility to read on one page all options about flight and so on.

After to have analysed the transition from offline to online market tourism, in the next section we will describe the new online tools for Web and mobile that improve the quality of tourism services fruition.

NEW TOOLS FOR WEB AND MOBILE INTERACTION

New technologies in hand (at disposal) of tourists have deeply enhanced the tourism information quality. We know that Internet usage is still increasing dramatically, mainly through personal computers and mobile devices. So far, much of this growth has come from new Internet users. Another aspect to consider is that in the short to medium future, users will be accessing the Internet more frequently using a variety of other mobile devices for different purposes and some of these will be quite surprising.

Users can use advanced tools such as wikis, blog, personal spaces, mush-up and their own passage to mobile devices to organise their travels and relate to each others.

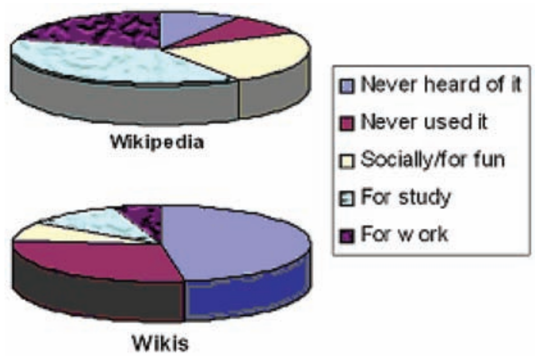
Wiki is a Web-based application that allows users to add content and also to edit content supporting collaborative writing, opening discussions, interaction and Web-authoring (Desitlets 2005). At the same time it also allows to delete every content of a new page or another already written by others, to restore an old version, to avoid risks of damages by hackers or non-collaborative members. Thanks to wiki everybody can write everything about a place, a city or a country, and can read everything, or improve what is already written.

Wiki is the most important example of collaborative online community, and applied to a tourism site give to every traveller the chance to share their own experience and to collaborate with other members, activeness and loyalty to the site is guaranteed. The Web site www.wikitravel.org represents an example of a collaborative and updated online global travel guide.

Another kind of Web application important for tourism is represented by personal pages (that can be part of a social network). Technically they are more simple than wikis, in fact they only represent a page created and modified by only its owner. But their technical ease allows users to concentrate on their own contents, and besides they can also build their own buddy network by adding other user's personal pages to their "friend list". Every page becomes in this way an host joint to a bigger network, and every user can discover new paths by starting from the page of a friend. A personal space usually includes blogs: diaries of text or pictures in chronological order (such as Blogspot), personal pages where the contents are more static and includes every kind of multimedia items (such as MySpace) or every other thematic social content (list of Web links, list of news, musical tastes, and so on).

It is easy to understand that Internet promotes the making of thematic sub-network such as travel blogs. In the blog every author talks about her/his own favourite topics, and it's easy to quote other's news or opinions in this way; for example, a list of travel blogs links each other to compose a thematic travel network. In fact, new Internet users do not

Figure 4. Different types of usage of wikis and wikipedia (Reference: White, 2007)



utilize only one tool at time. They use a wide set of Web tools: they write their daily thoughts on a blog, post their best pictures on a photo blog, collect their favourite Web sites on social bookmarks, and so on.. Every kind of new Web application has one special feature that makes the difference among the infinite offer of Internet; however there is the necessity to do not neglect the role of the "pass the word" in the choices of potential tourists. After the vacation, contacts are kept by email and messenger, different opinions are compared on forum, suggestions before leaving are read online, the best offers and discounts are accessible everywhere and every time. In fact, the advanced tools do not swap tools such as emails or forums.

It is important to have an idea about how Internet users relate to wikis and blogs. (Fig. 3-4). About wikis, David White (2007) reports in his research, that most users not know what they are, but when talking about Wikipedia (the famous free encyclopaedia created and continually updated by its users) he reports that nearly the 80% have used it for study, work or simply for fun (see fig. 3). Instead about blogs, users have been asked about their own blogs, other blogs and institutional blogs. What emerged is that only the 20% write their own blog and nearly the 75% read other's blog to work, to study but the most of them is for fun; but if we talk about blogs run by institutions or company the percentage decrease to 45%.

We can easily see that blogs are more used than wikis for fun because they are easier to use and similar to personal diaries then more appropriated to socialise, they are more used by young target under 18 then from 18 to 34 years, less by adult public. Instead Wiky are more complex and reference target is heterogeneous, they are in fact more used for study and for work.

The question is: what does make new Web tools really powerful? This question find its answer in the fact that one of the main goals of Web operator is actually of giving to every content a real meaning; this is the goal of the semantic Web (also called Web 2.0). The simple text of any content over the Internet can always be misconceived by search engine and other Web applications; the goal of semantic Web is giving every object (a picture, a paper, a clip and also papers) a real meaning, and this is possible by linking one or more keywords to that particular object. In this way it is possible for every user to find e.g. pictures of a "puma" without obtaining sport wear brand "Puma" images. The same text, can now have two or more meanings! That's the reason of users' vitality for social networks and new collaborative Web tools, which represent the first step to give texts, pictures, video clip or every other object a real meaning. Moreover, tagging is a new emerging way to categorise, share and search information based on meaning of keywords that facilitate tourists in their choices.

Once contents of every kind are meaningful, becomes important accessing these information and the Web tool that helps user to do that is: RSS (Really Simple Syndication). RSS is a new file format used to communicate information by following a syntax. It is used to spread news, new blog posts and new multimedia object, and it is read by software (Web based or not and also called "aggregator"). Thanks to RSS provided by almost every kind of site, users can read news about their favourite site without visiting every single site. Users can also rearrange their own subscribed feeds to obtain thematic news, by adding labels or tags, the same kind of keywords we talked about Web 2.0. It is easy to understand that the use of RSS allows everybody to improve their own information needs, besides it represents a tool available by every kind of technological device, from a desktop computer or even a small cell phone or a palmtop.

This technology has several positive impacts also for tourism supply. Many companies have adopted RSS feeds in their Web sites to keep a communication with their customers and enhance their search engines optimisation. It is difficult keep update offers and purposes because they are short life. This technology is characterized as a demand-pull rather than a supply push model. (Sigala, 2007). Furthermore, information flows about travels, special offers or more interesting places are real time provided on computer's monitor by a special software (Web-based or not) called "aggregator".

We have already talked about sites that offer the chance to upload pictures, tagging them with keywords (giving these pictures a real meaning), organizing them by creating albums or slideshows; but now the new scenario is about people, or travellers, who can take pictures with digital camera and/or smart phones and immediately send to these to online services. For travellers this means they can prove their skills and their travel experience; for all the other Internet users means to have the chance to find pictures from all over the world, especially when some special happening occurs. This new trend allows old media such as newspaper and television news to report flash news by showing images or video clip, taken from (respectively from Flickr or YouTube).

Another very important field on mobile devices applications for social activities (and consequently for tourists) are organizers and planning sites. They allow to set a calendar of events (to be shared with other users or customers) that can be subscribed, edited and shared. For example Google Calendar allows a hypothetic travel or service agency, to set a special calendar of event about new destinations, prices updates or happy-hour promotion. The users and customers can subscribe this particular calendar, and they can even receive on their own cellular phones SMS reminders that advice about expiring offers or new item added in that particular moment. These mobile technologies make available tools to plan the complete travel and the localization of the places of interest. Among these technologies we find the Internet mapping: the digital interactive maps that supply information on the hotel proximity, restaurants, stores, services, monuments, situated historians, archaeological sites. It is also possible to know the territory classified in different topics (sport, well-being, wine and food, information on traffic, weather forecast). The customer can generate personalized itineraries, search useful services and visualize more specific information on places of interest.

Newer technologies also allow mixing different applications (usually Web-based applications) to each other, to obtain a completely new one with new different functions. These are called "mash-ups", and they represent the newest scenarios in new Web technologies. The most famous mashups are those regarding Google; the Mountain View company in fact, has built a global system of satellite maps covering the whole world, and thanks to GPS devices, users can add new information such as pictures, short videos or information of any kind, exactly relating to a place on the map. In this way tourists can share information of any kind, in a very simple and funny way. Tourists can create their own path by describing with words, by drawing the route on a digital map, by adding digital pictures relating to a special point on the map. So they can create thematic itinerary and share for other tourist, just as every other digital tool we previously described.

Almost every Web 2.0 site involves the chance to interact with the site itself and other users too. The whole Web based application (and so, also online tourism market) is going towards Web 2.0 and so called Mobile2.0, this means that collaboration among users and participation is fundamental for the content site. The future of the e-commerce plays a very important role in the field of the collaboration and sharing: friendships, fellow traveller, socialization are carrying elements of each kind of travel. The main use of mobile devices by tourists is photo and video sharing whit others by personal blog or site.

Portable mp3 devices also give another chance for the tourists. In fact, they allow tourists to bring with them, in a very low weight, a large amount of video or audio files, such as thematic guides. Some operators have also started to provide their customers, with mp3 devices already filled by guides about the subject of the travel (a museum tour, a walk in the historical centre of a town, and so on).

The main reason that allows to tourism to benefit from the use of mobile technologies is the new services to travellers on the move. An example of this technology is the location – based Services.

The term *location-based services* (LBS) refers to information services that are accessible through a mobile handset and based on the current geographic location of the mobile device (Antikainen, H., 2006). The most commonly used is the satellite-based Global Positioning System (GPS). The conventional application areas of LBS include mapping, tracking, routing and logistic, electronic yellow pages, data collection and public safety (Beaulieu & Cooper 2001, Maguire 2001, Veijalainen et al. 2001, Zipf & Malaka 2001).

The primary functions of LBS for tourism are usually regarded as being the localization of persons, objects, and places, search of restaurants, shops, hotels, or points of interest in proximity and information about traveling conditions. Currently, mobile services facilitate the reservation of last-minute trips, rental cars, and hotels; and they provide information about changes and delays of flights and trains, offer guides on restaurants, events, and sightseeing opportunities at the destination (Berger *et al.* 2003, Eriksson 2002).

In the last years mobile devices such as mobile phones with embedded camera, palmtop, notebook and last but not the least GPS systems, have enhanced the use and the production of personal sites and blogs. In fact they allow everybody to post, not only reviews of a new bed & breakfast but also the pictures of the rooms or a short movie showing the landscape.

This brings to birth of the mobile virtual communities. In the next section will be analyse the social aspect of virtual communities.

SOCIAL ASPECTS OF VIRTUAL TRAVEL COMMUNITY

All these new tools that we have described are changing the way of people to interact and to communicate among them. In fact, the users can use these tools and meet new people in a virtual community that is a virtual place where people can speak (textual chat), can meet (video chat), can discuss about different matters (newsgroup and forum), can play and can exhibit themselves (personal home page and free Web).

The first sociological definition of "virtual community" was given from Rheingold in 1993 where he defined the virtual communities as: "…social aggregation that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form Webs of personal relationship in cyberspace. A virtual community is a group of people who may or may not meet one another face to face, and who exchange words and ideas through the mediation of computer bulletin boards and networks".

The first element of a virtual community is the absence of territorial boundaries due to its missing physical dimension; it changes for anyone the perspective to interact with other people according to their own needs and interests enhancing the real interaction and communication possibility. Whatever reason motivates a user to join network, sooner or later, s/he will need or curiosity to interact with other.

The advantage of Web is that it encourages humans to establish "weak" relationship with unknown people; this enables the communication also among persons that have different social characteristics. Moreover the on-line communication usually is uninhibited favouring sincerity in the discussion. The impact in the real social life is not decried but reinforced. The networks represent an aggregation form similar to society in which we live: weak and strong relationship, need comparison and exchange.

This form of social aggregation is not ground on politic, ethnic, linguistic, religious affiliation but volunteer cooperation between individuals that share the same interests, hobbies and goals.

It is easy to understand that Web community has become a term who involves any group of people who communicate online. These people can share different goals, interests or hedonistic pleasures. The term "online community" is also used to mean community network. One of the fields where all these concepts are successfully applied is the online travel community. This is a virtual community where backpackers, globetrotters, and other adventurers from all over the world to join together at different online platforms to exchange information, experiences, and plans in their favorite pursuit travel. In fact, in the travel and tourist industry, Internet encouraged more and more people to join into virtual communities to satisfy their needs, to fulfil their asking tips and suggestion before having a "real" travel.

Recently also travel organizations have realized the power of the new technologies for the core of their activity and the importance of virtual travel communities for their own marketing actions, by broadening their borders.

The travel and tourism virtual communities represent an ideal place without space and time, where people can meet experiences and different worlds. The travel is in its own nature delocalised in respect to point in which oneself is; for this reason it needs a strong communications and information exchange.

The travel experience is rich of emotional and relational contents that for this nature can be shared in the community. A person accesses a virtual community for different reasons: to search information and services, to contact different kind persons, to find partners to share experiences, amuse (oneself). All that is very compatible with tourism that is an "experience reality" and that needs of aggregation places.

Wang, Yu and Fesenmaier (2001) study, analysed needs of online tourists communities related to tourism organization marketing.

They have identified three main classes of needs: functional, social and psychological one. Functional needs include: transaction, information, entertainment, convenience and value. Social ones include: relationship, interactivity, trust, communication and escape among humans. Finally, psychological needs are include: identification, engagement, and sense of belonging, relatedness and creativity. In their work they pointed that since tourism is traditionally studied referring to geography location and space, it is noticeable that tourism-market organizations lack skill in how an online community can be used as a marketing tool. In fact, we cannot forget technological evolution about Internet since the last 15 years. They also predict growing of community concept as the Internet becomes more and more widespread with the new global economy. The network technology has allowed people to be more connected to each other.

People can obtain a lot benefits by joining themselves to the community depending on the different nature of communities and the various characteristics of community members (i.e. many people want to make efficient business transactions and interact with others people; many other rather want to have fun, meet fellow traveller and to express their own opinions; many other still want to develop a sense of belonging, to express their cultural and economic interests and establish relationships).

In 2004 Wang and Fesenmaier expanded their theory with a further study on modelling participation in an online travel community. In particular, were examined the relationship between members' needs and their level of participation in a virtual travel community. In their work they added to the user's needs identified in their previous papers, a hedonic need (including entertainment, enjoyment, amusement and fun). According to them, members participate in on line travel communities to satisfy four fundamental needs: functional needs, social needs, psychological needs and hedonic needs. In this latter work the authors also analyse the role of demographic differences in the behaving of tourism online consumer. It was hypothesized that users' needs in a VTC are not constant but can change with demographic characteristics such as gender, age, education and so on. For example female members usually attach more relevance to hedonic needs, while male members are more significant to membership duration. Other important results of their analysis are about differences according to different ages. For example they observed that groups who are aged 56 or more, versus young members are less attached to functional needs. The aged 20 or younger attribute greater importance than the older groups to social and psychological needs. Differences are also found between members with different education level and their respective needs.

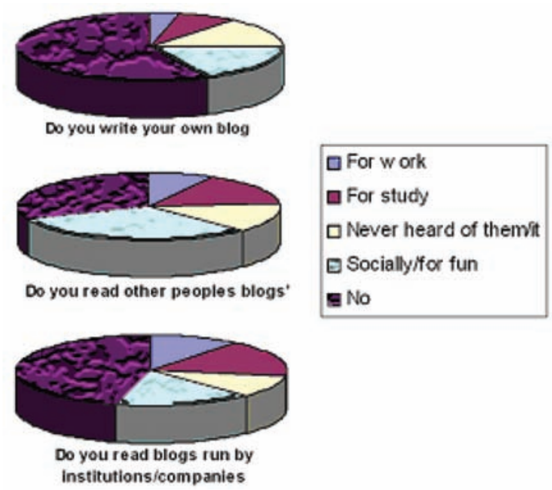
All virtual travel communities have some common features. Communities mostly provide a warm, trusting, and supportive atmosphere. When members share information, they do it with great care and responsibility. They rely on each other more than they do on outdated travel guidebooks or on second-hand and static information from conventional travel literature. They also have to attract a lot of members and give them benefits and satisfactions to be successful. This aspect is very important for tourists because they need to solve a wide range of problems, starting from the pre-visit, the post-visit and of course the travel itself. Before the new technological and digital tools, the traveller could only trust a travel agency operator, but now s/he can find help to choose her/his destination, to solve the most common problems during the planning of the travel (medical suggestions or documents needed), and obviously buying the cheapest flight rate; every question asked by the traveller finds an answer from a user already experienced in that way. But not only, virtual communities are also widely used by tourists to enhance their journey; in fact as seen before, mobile devices allow users to access the infinite Web without sitting in front of the computer at their home, and heavy guidebooks are now substituted by light mp3 reader or other mobile devices. Finally, tourism virtual communities are important after the travel itself, in fact if a traveller has made use of others' resources, it is now the time to contribute with his own by uploading pictures, writing a review or an itinerary, answering to other's questions, or by simply writing his personal blog to share with friends, but sooner or later someone will find his writing and they will find it useful.

Every user approach a community to search something for himself. This usually is the first step in a lot of other cases, and it is important because the user identifies himself with the community; after this first step her/his loyalty is guaranteed, and it is very easy that s/he will become also a content creator contributing to the growth of the community.

NEW SCENARIOS ABOUT TOURISM AND NEW TECHNOLOGIES

In the early section we analyse the technological and cultural changes trigged by Internet in the tourism fruition and the motivations that encourage the users to belong to a virtual community. All the different modalities used by tourists to plan, buy and do their own vacations, can be classified in off-line, on-line and mobile approach; we can represent them in a pyramid (fig. 5).

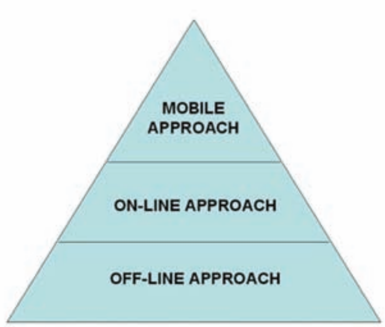
Figure 5. Different types of usage of blog (Reference: White, 2007)



The bottom of pyramid is occupied by off line approach; they firstly appeared in chronological order and are the most used by people because they are largely widespread and accessible to the large part of the tourists. Moving upward we find the online technologies more powerful but less widespread and less accessible to users. On the top of the pyramid there are very advanced technological tools (such as mobile devices) but fewer diffused than the other, in fact the pyramid tightens.

It's easy to imagine that in the future this pyramid will probably completely reversed. The traditional paper guidebooks will probably be

Figure 6. Tourism technology evolution



less utilized and available to tourists while online tools on advanced mobile devices will be largely accessible and commonly used.

The objects in the pyramid of Figure 6 are sorted to help us to simply keep in mind evolution of tourism tools. The basis of the pyramid contains "old economy tools" such as paper guidebook and travel agency. Indeed, they are the most common tools used by travellers, and are concrete objects based on an economy made of selling of products (the paper book itself) or services (travel agency). The next step is represented by the rising of the Web technology; in fact Internet has deeply changed everything, and of course economy too. Everything was concrete in the old economy has now become immaterial and "made of bits". People have Web pages to browse using a computer instead of such a book to read in several contexts. They contain forums, blogs, personal pages and wikis. Then, over the Web era, the top of the pyramid contains technological mobile devices. They are obviously the most advanced tools among the all previously described, and we also have to point that they have to be used jointly with the previous one. In fact, all Web applications will use mobile device so users will have access to information from anyplace and anytime.

In this way, what we have hypothesized about the future of this evolution (the previously described rotation bottom up) is already in progress, because mobile devices of every kind are used much more than other Web tools. This is causing tourism to benefit from use of mobile technologies about new services to travellers on the move.

Every new technology that we described, can be used to enhance tourist's experience, and they can also be a great chance for local administrations or local tourist promotion organizations to improve their tourism appeal and promotion between appropriate operators.

Mobile technologies give great opportunity to increase the value of territory and to develop sustainable tourism. The virtual community is in fact one of the most effective business models and provides great opportunities for both tourism organizations and customers. (Armstrong & Hagel, 1996).

Users more and more approach to mobile virtual communities to search new and unique contents, uncontaminated places, not commercials and far from mass-tourism. The new tools can allow promoting a sustainable tourism with respect of people and places.

People are searching more and more a high quality environment, but environmental resources on which tourism is based are limited. That's why it is very important to invest in a sustainable tourism. This kind of tourism is defined by the World Tourism Organisation as "tourism which meets the needs of the present tourists and host regions while protecting and enhancing opportunities for the future." A fundamental characteristic of sustainable tourism is that it creates safeguard and respect for the environment and local traditional culture. Moreover it recognizes the centrality of hospitality.

Tourism is a worldwide phenomenon that is very important for the socio-economic development of a lot of countries. It can contribute to the progress of a country but there is the risk it causes environmental degradation and loss of local cultural heritage.

Through digital mobile communication, the natural and cultural heritage that characterize the geographical area, could be communicated in an integrated way to tourist to guide him/her, also by geo-referenced information, toward their own fruition and knowledge with the other purpose, to contribute, through tourism, to the developing of minor tourist centres and their own neighbouring zones. The tourist communication can be made using a Personal Digital Assistant (PDA) or a Smart Phone and thanks to GPS system, it is so possible not only to localize the tourist on the territory, but also the cultural heritage of the location, by sending to users, on their wireless devices, the geo-referenced information with geographic route to reach that particular cultural heritage. The information sent to tourists can be personalized, integrated, complete, clear and multimedia: it can be communicated by text, but also map, video clip, 3D images and audio files.

Social innovations consist of tourists that can reach also places that are not necessarily promoted by tourist book guides or catalogues and they can be reached by messages concerning particular events at the particular time in that place.

Local administrations will have the opportunity, to promote and improve their own territory, to reinforce the sense of belonging and share memories and experiences. The promotion of these cultural aspects of a country will give the chance to have a positive impact on local economies and particularly on the tourism sector.

Promotion of a territory can produce added value to the economy of a place. To promote the local typical products, the local artisan products, to characterize thematic itineraries, fairs, that distinguish a country, is very important to improve the productivity, to create new job and new opportunities and to stimulate the development and innovation. The promotion of a territory is an important moment in the economic development of a community.

Thanks to the use of virtual communities, moreover, local people can enter in contact with people from all over the world and can attract tourists interested in culture and nature of their country.

The use of mobile technologies for sustainable tourism will remove the risk of cultural marginality or isolation because they represent an opportunity for cultural exchange and a possibility to integrate local knowledge into social, economic and cultural development. The importance of natural and cultural safeguarding is confirmed by increased demand of tourism, that joints attention for nature with the interest for intangible culture.

The intangible culture refers to a set of non-physical characteristics, practices, representations, expressions and skills that characterizes cultures, people and places.

The protection and safeguarding of cultural tradition: social practices, typical products, performing arts, rituals and festive events, language, knowledge and practices concerning landscape, has played an important role in the cultural politics and programmes at all levels (local, regional, national, European and international) in recent years. Furthermore people's interest to knowledge and their research of tourism that improves these aspects will remove the risk that a large number of cultural traditions can be lost.

Mobile technologies in the tourism sector represent an important opportunity to improve the vitality of a community. Its bring economic, environmental, image benefits. For example it can stimulate performing of traditional events and festivals that otherwise could be lost. Moreover mobile technologies can stimulate the development of the tourism in marginal regions and can reduce emigration from local areas. They can improve job and earning perspectives of the local population and improve the quality of the tourism activities and the related skills. Moreover they can improve the quality of life of the local population due to the creation of facilities and services, upgraded infrastructure, health and transport improvement, restaurants, food, and so on.

CONCLUSION

In this chapter we explained how mobile technologies have modified tourism sector and how they became important for the tourists themselves and for the global economy.

We have provided a description of the main social implications of the Web technologies earlier, and mobile later. We have analysed how users approach tourism Web applications; they firstly use (for example) Internet to buy low cost flight or to plan trips, later they start writing their blog, sharing their pictures or reviewing their trips, and in this way they start contributing to build a virtual community that will be used by other users for advices to buy their tickets, to plan or share their trip or just for fun. That's why all this, is now called social network.

The next step we have analysed is the coming of mobile devices that have revolutionized the way that tourists enjoyed their experiences. In fact, it is obvious that Internet, as described above, helps tourists before and after their trips, but now, thanks to mobile devices, the high potential of Internet is brought straight to their hands to facilitate the fruition of tourism. Mobile technologies can improve accessibility, information and service provisioning and safety for both tourists and tourism resorts.

Then we have hypothesized a pyramid representing on the bottom the old economy of a travel agency or a paper guidebook, in the centre all the new economy tools belonging to the Internet world, and on the top the mobile devices. Anyway analysing the future scenario we have also described the rotation of the pyramid because in the near future mobile devices will be more accessed and utilised than old economy tools, and what was rarely diffused in the past, will be commonly used.

Finally we focused on the issue of sustainable tourism a new way to travel respecting environment and traditions, by merging information sharing and new technological devices.

Thanks mobile devices several small places and particular events far from commercial routes can be promoted by local administrations and discovered by tourist, contributing both sustainable tourism and development of small place's economy.

KEY TERMS

Mobile Interaction: The relation between users using mobile devices, it allows users to communicate and to access Web applications from any place.

Mobile Technologies: A parent category for mobile telephony, mobile computing, and miscellaneous portable electronic devices, systems, and networks.

Online Tourism: The purchases, the selling or the consultation about services tourism on Internet, both Web and mobile technologies.

Social Network: A community of people who share interests and activities, or who are interested in exploring the interests and activities of others. Each user create contents and uses others' contents.

Sustainable Tourism: A tourism which meets the needs of the present tourists and host regions while protecting and enhancing opportunities for the future.

Virtual Travel Community: A group of people that primarily interact via communication media such as forum, blog, chat room, instant messaging and that are interested in sharing information about tourism or travel.

Web Interaction: The relation between users and Web applications in order to search information about their own needs or for fun.

Chapter 3.17
Cityware:
Urban Computing to Bridge Online and Real-World Social Networks

Vassilis Kostakos
University of Bath, UK

Eamonn O'Neill
University of Bath, UK

ABSTRACT

In this paper, we describe a platform that enables us to systematically study online social networks alongside their real-world counterparts. Our system, entitled Cityware, merges users' online social data, made available through Facebook, with mobility traces captured via Bluetooth scanning. Furthermore, our system enables users to contribute their own mobility traces, thus allowing users to form and participate in a community. In addition to describing Cityware's architecture, we discuss the type of data we are collecting, and the analyses our platform enables, as well as users' reactions and thoughts.

INTRODUCTION

The formalised study of network graphs is considered to have begun by Euler's famous solution to the Seven Bridges of Königsberg problem in 1736 (Biggs et al., 1986). In his solution, Euler represented the four landmasses and seven bridges of Königsberg, now Kaliningrad, as four nodes and seven links respectively. Thus, he was able to prove that no route crosses each bridge only once. Graph theory has greatly advanced every since, mostly focusing on mathematical proofs and theorems on graph topology, trees and cycles.

While graphs have been used to explore relationships between social entities for over a century, it was not until the 1950's that this became a systematic, and ultimately scientific process. Some of the first studies to engage in social network analysis are the kinship studies of Elizabeth Bott (Bott, 1957) and the urbanisation studies pioneered by Max Gluckman in Zambia (Gluckman & Aronoff, 1976). Similarly, Granovetter's work (1973) lay the foundations for the small world hypothesis, suggesting that everyone is within six degrees of separation, while Wellman's work gave some evidence of how large-scale social changes have affected the nature of personal communities and the support they provide (1979). Since then, social network analysis has moved from being a suggestive metaphor to becoming an analytic approach, with its own theories and research methods.

DOI: 10.4018/978-1-60566-152-0.ch013

In the 1970's, Freeman developed a multitude of metrics for analysing social and communication networks (e.g. 2004), thus boosting commercial interest in the area due to companies aiming to optimise their procedures and operations. In the last decade, the identification of mathematical principles such as the small-world and scaling phenomena (Barabasi & Albert, 1999; Watts & Strogatz, 1998), underpinning many natural and man-made systems, have sparked further interest in the study of networks.

The systems design community has also been interested in the study of social networks as well as online social networks. Typical research topics in the area include the effect of social engagement on behaviour (e.g. Millen & Patterson, 2002), the issue of identity and projected identity (Lee & Nass, 2003), as well as the design of socio-technical systems (Herrmann et al., 2004). The recent proliferation of online social networking system such as Facebook, Dodgeball and MySpace, has provided researchers with platforms for carrying out research into online social behaviour, and a journal devoted to this topic (http://www.elsevier.com/locate/socnet). In the Urban Computing domain, such studies have looked at the effect of social incentives and contextual information on the use of public transportation (Booher et al., 2007), the relationship between users' online profiles and their online behaviour (Lampe et al., 2007), the various trust issues that emerge from using such systems (Riegelsberber & Vasalou, 2007), how such systems can help strengthen neighbourhoods (Foth, 2006), and the development of systematic grounds to base our designs (Kostakos et al., 2006).

To make inferences from online behaviour datasets, researchers still have to collect data from the real world and relate it to the online data. Thus, while social networking websites make it easy to capture large amounts of data, researchers still need to employ interviews, focus groups, questionnaires, or any other method that enables them to relate online with real world data.

In this paper we describe the development of the Cityware platform, which aims to bridge the gap between online and physical social networks. It allows users and researchers to explore an amalgamation of online and physical social networks. The key strength of our platform is that it allows the collection of vast amounts of quantitative data, both from the online and real worlds, which is immediately linked, synchronised, and available for further analysis. Furthermore, our platform enables both end users and researchers to gain a better understanding of the relationship between online and urban social networks. Here we describe the architecture of our platform, the types of data it makes available to users and researchers, the typical user-oriented scenarios that are beginning to emerge, and our planned research-oriented scenarios.

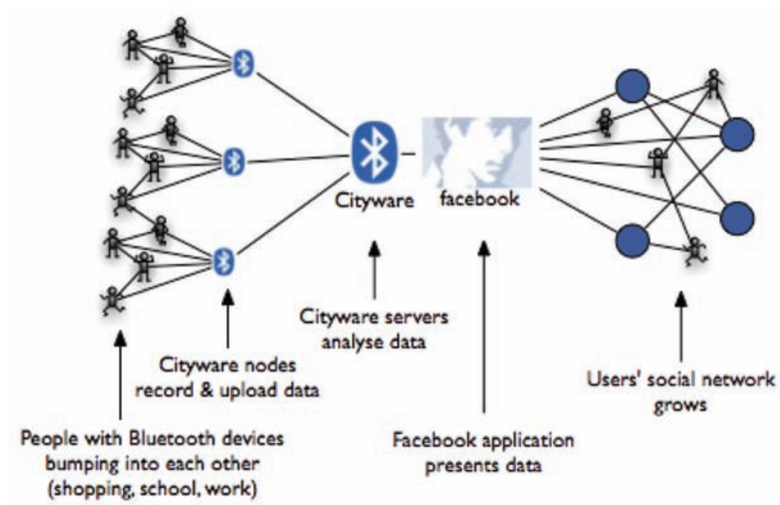
CITYWARE

Our platform is a massively distributed system, spanning both the online and physical worlds. Its architecture uniquely allows it to expand and contract in real time, while also enabling live data analysis. The main components of the platform are: people's Bluetooth-enabled devices, Cityware nodes, Cityware servers, Facebook servers, Facebook application. An overview of this architecture is shown in Figure 1.

Infrastructure

In many ways the most vital element of our platform is people's Bluetooth enabled mobile devices, such as mobile phones, PDAs or laptops. For any data to be collected, users must have switched on their Bluetooth devices, and set them to "discoverable" mode. From empirical observations, we know that, at least in certain cities in the UK, about 7.5% of observed pedestrians had Bluetooth switched on and set to discoverable (O'Neil et al., 2006). More crucially, however, Bluetooth

Figure 1. Overview of the cityware platform



matches very closely to people's movement, as it typically has a short range (10 or 100 meters).

The presence of discoverable Bluetooth devices is captured via the deployment of Cityware nodes. These nodes are computers that carry out constant scanning for the unique identifier of Bluetooth devices, thus recording details about the devices in the immediate vicinity. The advantage of this approach is that the users' mobile devices do not need to run any special software; simply enabling Bluetooth is adequate.

Initially, we deployed a small number of nodes as part of a pilot study. However, we also released open-source software that allows users to turn their Windows, Linux, and Mac OS X computers into nodes. Additionally, we modified the open-source application WirelessRope (Nicolai et al., 2005) to make it compatible with our platform, thus enabling mobile phones themselves to become Cityware nodes. So far, our platform has attracted nearly a thousand individuals for Europe, America, Asia and Australia who have set up their own nodes and are uploading data to our servers.

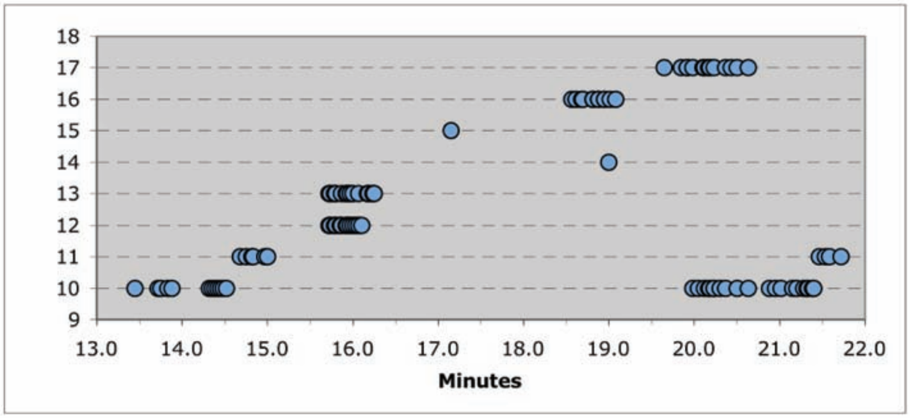
Analysis

The method we use to scan for Bluetooth devices generates discrete data about the presence of devices in the environment. A visualisation of our data, which we have termed timeline, can be seen in Figure 2. Here, the graph represent a specific scanning site, and each dot represents a discovery event, i.e. a point in time (x-axis) when the Bluetooth scanner picked up a specific device in the environment. By applying filters, we can see that, for example, device 16 was present in the environment between approximately 18.5 minutes and 19.5 minutes.

To study the patterns social interaction in our data, we first need to identify instances where two or more devices were present at the same place and the same time. For example, in Figure 2 we see that devices 12 and 13 encountered each other. Such encounters are effectively opportunities for networking, both social and wireless. We developed filters that analyse our data and give us instances of devices encountering each other at each Cityware node location. These results take the form of records:

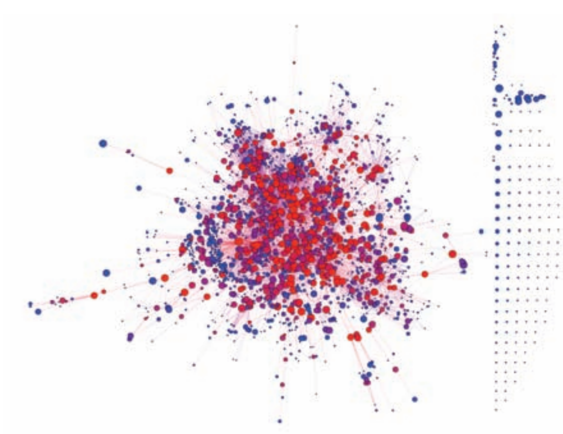
device1_id, device2_id, date, time, duration, Cityware node location

Figure 2. A timeline visualisation of our Bluetooth gatecounts. Each device is given its own timeline (dashed lines) and each discovery event is plotted as a circle on the timeline



At this stage in our analysis we have a long list of such records, describing which devices encountered each other and by which scanner. For example, in Figure 2 we see that devices 12 and 13 encountered each other at 15.5 minutes and were together for approximately 1 minute. This list of encounters is a textual representation of the patterns of encounters across the scanning locations. To further study the patterns and structure hidden within this list, we transform it into a social network graph as follows: assuming that each device from our dataset becomes a node in the social graph, then the list of encounters indicates which nodes are connected. Proceeding in this manner, we are able to generate a social graph per Cityware node, as well as a social graph containing data from all Cityware nodes.

Figure 3. A graph visualisation of the encounters that we recorded by one Cityware node



For illustration purposes, in Figure 3 we show the graph generated from one node's scan data, located inside a pub. In this graph, each observed Bluetooth device is represented as a node in the graph, and connected nodes indicate devices that encountered each other at some point. We note that the scanner (i.e. Cityware node) is not represented in this graph. By visual inspection we can verify that most devices are linked to the main core, whilst some devices are islands. The latter indicates cases where a device has never encountered any other device. Additionally, the size of nodes represents the total amount of time that a device has spend in this location, while the colour of the nodes (blue to red) indicates the betweenness of a node (from 0 to 1 respectively).

One of our initial observations is that due to the sheer number of nodes in the graphs, the visualisations themselves help little in analysing our data because of the visual clutter. However, by transforming our data into graph form, we are able to run a number of well-established analysis algorithms (e.g. centrality measures, community detection, etc.) using existing software such as

Pajek, Ucinet, and iGraph. It is the results of these analyses that we present users through our Facebook application.

User Interface

Our platform relies on the Facebook system (http://www.facebok.com) to present data to users. Facebook is an online social networking website, where people upload profiles and explicitly link themselves to others via annotated links (e.g. flatmate, work-mate, went to school together, etc.) Our user interface has been deeply integrated with the Facebook system itself, matching its look and feel and using a number of Facebook's capabilities, such as the ability to display a list of the user's established friends, and the ability to send notifications using the Facebook mechanisms. A screen-shot of our user interface is shown in Figure 4.

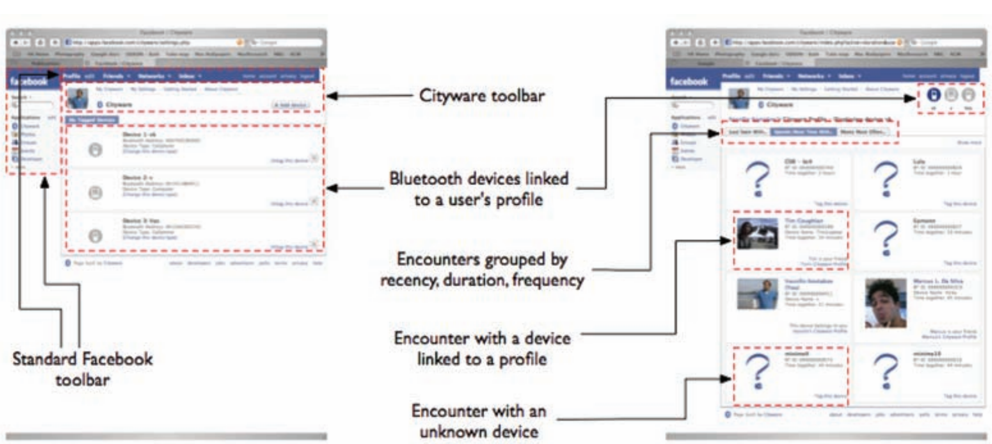
To use our system, users must have a Facebook account, and additionally they must decide to add the Cityware application to their Facebook profile. This can only be done by logging on to Facebook and ticking the Cityware application from the list of available applications. The next step in using our application is for users to register their devices. This involves typing into our system the Bluetooth identifier of their device. Users may associate more than one Bluetooth device with their Facebook profile.

Once this link has been established between Bluetooth data and a users' Facebook profile, our system is able to display the user's encounters, sorted either by recency, duration, or frequency. These encounters represent an ego-centric textual representation of the social network captured by the scanners (e.g. Figure 3). Given that each user represents a node in this graph, our Facebook application enables users to see their graph "neighbours", and their "neighbours neighbours" in three distinct ways: who they met most recently, who they spent most time with, and who they meet most frequently.

For each encounter, our system displays the Bluetooth name of the device (as recorded by the Cityware nodes). If a user recognises a device as belonging to someone they know, they are able to "tag" that device, thus linking it to a Facebook account and to that account's owner. If this happens, the owner of the newly tagged device is notified via Facebook's own built-in mechanisms.

The end result is that users are presented with a list of encounters that have taken place in the real world, with some of those encountered devices being linked to Facebook profiles. For such devices

Figure 4. Screen-shot of the Cityware user interface



our system can display the owner's picture as a well as link to that person's profile.

Our platform's distinctive characteristic is that it provides information that both end-users and researchers can use. This is because end-users see and explore data that is directly related to them (i.e. who they meet, and related statistics), while researchers have access to the "big picture", thus being able to explore and understand aggregated behaviour. Additionally, the self-registration and tagging mechanisms provide the crucial links between online and real-world networks. Effectively, our system enables users to annotate our dataset, thus enriching it with all the information that users make available via their Facebook profiles.

USER FEEDBACK

Facebook has its own built-in discussion board mechanisms to facilitate public and private conversations. These are accessible only by logging on to Facebook. These mechanisms have proven to be invaluable for collecting and categorising user feedback. A community has begun to form around our platform, with members using the discussion board to help other users with technical difficulties, suggesting design ideas, and holding debates. The size of this community is about 4000 people, including those who are running Cityware nodes and those who have added the Cityware application.

Prominent amongst the discussion topics is troubleshooting. Many users have posted questions in relation to the node software installation, making sure the software runs constantly, how bluetooth works, as well as how Cityware works. Fellow users have responded to these queries, suggesting that a peer-support community is being formed around Cityware.

While Cityware was officially released in late July 2007, it was not until mid-August that it became widely popular, mostly due to a web article published by the BBC (Waters, 2007). Since then, we have observed an interesting phenomenon amongst users of Cityware. As if feeling somehow "connected" or part of the same social group, our users are eager in establishing new nodes all over the world. A big part of the online discussion evolves around users proudly stating that they have established "yet another node", thus making their town or city part of Cityware. Additionally, users are eagerly posting messages requesting to know if there are any nodes near where they live. This enthusiasm is not different from what has been observed in other recent social phenomena (c.f. Rheingold, 2002).

A further interesting aspect of the feedback we have collected has to do with the context in which users are setting up nodes. While some users have reported establishing nodes in their homes, others have done so in their workplaces. Furthermore, some users of our application own shops and establishments (such as nighclubs) in which they have installed Cityware nodes. A feature that was heavily requested by users was the use of a map to visually locate Cityware nodes. Since we had not developed such functionality, we instructed users to mark their nodes on the public website http://www.wikimapia.com. This enables users all over the world to locate, as well as mark, Cityware nodes, post comments about them, or even attach pictures.

Privacy is a much-debated topic amongst users of Cityware. While some users are being critical of Cityware's privacy implications, many are supportive. We should note that the discussion board is not public, but rather only for self-selected users of Cityware, and as such may not be representative of the general public. Certain users have expressed concern about people being tracked about a city, and having their preferences and routines being inferred by a malicious party. In response, other users commented that anyone can at any time opt-out of Cityware by switching Bluetooth to "invisible". Additionally, it was highlighted that authorities can track people who simply own a mobile phone, regardless of Cityware. Furthermore, users commented that location is not being made available by our system, but nevertheless could be inferred. Another user noted that people are already disclosing information about themselves via their Facebook profile, and that Cityware can expose only that information. A good synopsis was offered by a user who wrote: "There are two groups of people here – one group that willingly submits to this, and the other group, that are totally opposed to any tracking/recording." This comment very well reflects our understanding of user's reactions towards our system. We feel that the reactions are mixed, with some feeling very positive and others very negative towards our systems, but no consensus having been reached at the moment.

RESEARCH POTENTIAL

While end users of Cityware are enjoying the functionality of our system, we are quite interested in the research possibilities that our platform has enabled. To quickly summarise some properties of our system as of late 2008: 3000 people have added Cityware to their Facebook profile, 450 nodes have been registered, while roughly 100,000 unique Bluetooth devices have been recorded by all Cityware nodes over a period of 4 months.

The dataset being collected by Cityware nodes is extremely rich as it describes people's visiting and encounter patterns across space and time. While comparable datasets, such as the Crawdad project (Crawdad, 2007), are available to the scientific community, it is only when such quantitative data can be linked to qualitative data that interesting research possibilities open up. While Cityware collects large amounts of quantitative data on people's movement and encounters, it also has access to the extremely rich qualitative data that people make available through their Facebook profiles.

Typically, Facebook users provide a wealth of information on their profile, including their demographics and preferences. More crucially, however, users annotate their relationships with people they know. Friends can be marked, for example, as colleagues, house-mates, or relatives. Additionally, a relationship can be annotated with dates, locations or organisations that may be relevant.

By combining the wealth of user-supplied qualitative data with the large amounts of quantitative data collected by Cityware nodes, we can begin to explore new research approaches to social metrics, system design, security, and even epidemiology. The logical next step for our research would be to compare people's movement and encounters with the qualitative data provided by users. For example, we can begin to empirically understand how people spend their time: with friends, family, or colleagues? Do these patterns change over time, seasons, or countries? Additionally, we want to explore if "friendship", "house-mate", or any other type of relationship systematically manifests the same Bluetooth patterns. This would lead the way for developing context-aware systems that can automatically classify a user's social network into friends, colleagues, etc.

Furthermore, such systems can make use of increased amounts of implicit, rather than explicit user input, which can enable them to adapt their behaviour appropriately and in certain cases understand and predict user needs. Hence, another area we are exploring related to making use of such data to make predictions about the users' behaviour, and accordingly adapt any software they may be using. At the moment we have distributed node software that runs on mobile phones. This software could act upon predictions about user behaviour and adapt any of the phone's functionality. Crucially, user feedback about the validity of predictions can easily be related back to our servers for further analysis.

A further research strategy is to explore the usefulness of our system for enhancing the security and privacy of users. We can conceptualise our dataset as a world map of relationships between users, annotated by users. This map may be used to inform users of security-related decisions they face (such as making a wireless payment) when entering a new context, such as a restaurant in a city they are visiting for the first time. Our servers can identify user comments about such a place, but more importantly assign weight to such comments based on the user's "social proximity" to the authors of these comment.

Finally, the data collected by Cityware is an invaluable source for understanding how mobility and encounter patterns can help in the diffusion of ideas, innovations and viruses (Kostakos et al., 2007). This could be achieved by exploring aggregate diffusion patterns over time, and exploring how different types of information (e.g 1Kb vs 1Mb) or viruses (biological / digital) would spread through the network of encounters and people. We note that this data is a result of public observation, hence we argue that the data can be readily used by the observers. Thus, local or national governments can use such data to develop and evaluate immunisation strategies to combat biological viruses. Similarly, telecoms operators and handset manufacturers can assess the effectiveness of their infrastructure against digital viruses that can spread via the Internet, GPRS, SMS/MMS, and Bluetooth.

CONCLUSION AND ONGOING WORK

In this paper we have described the Cityware platform, how users have reacted to it, and the potential for research strategies that it has enabled. As part of our ongoing work we are developing visualisations that both end users and researchers can utilise for better understanding the various patterns and properties of our dataset. We are also considering the development of software that will allow users to automatically geo-tag their data if they have a compatible GPS receiver. Furthermore, we are in the process of correlating aggregate encounter patterns with user-specified properties of those encounters. Finally we are examining the potential viral spread through users' encounters, and relating viral spread to user-specified qualitative data.

KEY TERMS AND DEFINITIONS

Aggregate Patterns of [Behaviour/Encounter/Diffusion]: On an individual level each person behaves in distinct and unique ways, having specific objectives in mind. Yet, when analysed at an aggregate level, communities and cities exhibit non-random patterns that emerge from the combination of each distinct person's activities. Such patterns are known as aggregate patterns, and can describe how people encounter each other, or how information is diffused and spread through the community.

Bluetooth Identifier: A unique 12-digit hexadecimal number used by Bluetooth components for identification.

Massively Distributed System: A real-time computer system with large numbers of physical and logical components spanning great geographic distances.

Social Network: A structure that represents social relationships. The strutter typically consists of nodes and links between the nodes, and the nodes represent people while the links represent a specific type of relationship such as friendship, marriage, or financial relationship.

Urban Computing: A research field focused on the development of computer systems that are to be used in urban space. Typically, such systems entail fixed, mobile and embedded components.

This work was previously published in Handbook of Research on Urban Informatics: The Practice and Promise of the Real-Time City, edited by M. Foth, pp. 196-205, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 3.18
Improving the User Experience of a Mobile Photo Gallery by Supporting Social Interaction

Elina Vartiainen
Nokia Research Center, Finland

ABSTRACT

Today, image gallery applications on mobile devices tend to be stand-alone and offline. For people who want to share photos with others, many add-on tools have been developed to connect the gallery applications to Internet services to enable photo-sharing. The authors argue that photo-centric social interaction is best supported when the gallery application is fully integrated with an Internet service. In this case, no additional tools are needed and the user's image content is fully synchronized with the service. They designed and implemented a service-integrated mobile gallery application with a corresponding Internet service. Moreover, they conducted a field study with 10 participants to compare our application with a state-of-the-art gallery application combined with an add-on photo-sharing tool. Their application was preferred by most participants and it was especially appreciated because of the user experience. Above all, the results show that social activity increased amongst the participants while using our application.

INTRODUCTION

People are starting to use their mobile devices as their primary cameras because the quality of mobile cameras is improving (Nokia, 2008). As most mobile devices are also capable of connecting to the Internet, they can be used to publish photos to photo sharing Internet services and also browse and comment the photos hosted by those services. However, photo sharing on mobile devices still tends to be a laborious task and on that account users might not be able to share their mobile photos at all.

Nowadays, users are able to share their photos on their mobile devices by using applications that are essentially upload tools for certain Internet services (Kodak EasyShare Gallery, 2008; Meaning, 2008; Pictavision, 2008; Radar, 2008; Share Online, 2008; ShoZu, 2008; Yahoo! Go, 2008). The upload tool applications are usually add-ons to existing gallery applications offering functionalities for separately uploading and downloading images and their data. However, the image gallery application and the user's image collection are not fully integrated and synchronized with the service. Also, the upload tool applications require account creation and configuration of settings before they can be used. In the mobile context, users who might be on the move and have only a limited and possibly fragmented time to spend on a task is unable to use a mobile application that is hard and slow to use and configure. Furthermore, the upload tools might be developed by a different party than the developers of the gallery application or the corresponding Internet service. This might result in a mismatch between the available functions and features on the mobile gallery application and the Internet service. Thus, the upload tool applications cannot guarantee a deep integration of the gallery application and the service.

Mobile image gallery applications continue to be stand-alone and offline, even though many mobile devices today are connected to the Internet with a flat-fee, always-on network connection. The gallery applications have not yet utilized the opportunity of integrating directly with a corresponding Internet service and having user's images in sync with the service. If the gallery application was deeply integrated to the service, it would enable users to share images in real-time on the go in an easy and fun way. Users would not need to configure or separately synchronize their image collection when they want to communicate using images. Hence, we argue that as the overall user experience improves via the deep integration of a mobile gallery application and a corresponding Internet service, it also facilitates the social interaction among the users of the Internet service.

In this article, we introduce a mobile gallery application that aims at offering great user experience by being fully integrated to a corresponding Internet service. The application provides an easy and fun way for users to share and interact with photos in real-time. We tested the application in a field study of 1+1 weeks (a test period of 1 week for each application) by comparing it to a state-of-the-art mobile image gallery application combined with an Internet service upload tool. The goal was to investigate whether the social interaction is best encouraged when users are using a mobile service-integrated gallery application compared to state-of-the-art applications and tools existing on the market today.

RELATED RESEARCH

Mobile image sharing has been an important topic in the research literature. Many imaging application have been developed around the topic of mobile image management and sharing process, but we are not aware of any research on seamlessly integrating personal image management and photo sharing between a mobile device and a corresponding Internet service and how that would affect the user experience and social interaction. Instead, the previous research on mobile imaging applications can be divided into two groups: studies on the usage and management of personal images and studies on sharing images. The studies on personal images have revealed many ways to help users to organize and locate their photos (Ames & Naaman, 2007; Bentley et. al., 2006; Frohlich et. al., 2002; Gurrin et. al., 2005; Jacucci et. al., 2006; Naaman et. al., 2004; Wilhelm et. al., 2004). They have also shown how to enable image browsing (Harada et. al., 2004; Khella & Bederson, 2004; Pauty et. al., 2005; Wang et. al., 2003) or displaying (Liu et. al., 2003) in an effective way on a mobile device in terms of user's personal image collection. The research on mobile image sharing has been focusing on how to improve the image sharing process (Ahern et. al, 2007; Ahern et. al., 2005; Counts & Fellheimer, 2004; Sarvas et. al., 2005). The mGroup project (Jacucci et. al., 2006) studied the collective creation of mobile media in terms of instantaneous messaging, while the Zurfer project (Naaman et. al., 2008) concentrated on consuming and viewing shared mobile images.

However, earlier studies have emphasized the importance of ensuring that the basic features of a system for managing photos should be efficient, reliable, and well-designed (Ahern et. al., 2007; Cooper et. al., 2005; Cui et. al., 2007; Frohlich et. al., 2002; Kirk et al., 2006; Kuchinsky et al., 1999; Rodden & Wood, 2003; Shneiderman et. al, 2006). The user interface of a digital photo album demands more than using a file manager type of solution derived from a PC. Nonetheless, most of the earlier research has not been focusing on improving the user experience but to include "easy to use" functions on mobile devices, in other words, enhancing the usability. Users' emotional satisfaction should be a key part of enhancing the user experience of digital photo albums (Balabanovic et. al., 2000; Harada et. al., 2004; Jin et. al., 2004). Indeed, there are a couple of projects that considered user experience also an important aspect. In the Flipper project (Counts & Fellheimer, 2004), one of their design goals was to provide a minimal set of features, but maintain focus on photo content. In the Zurfer project (Naaman et. al., 2008) their design goals included enabling simple and easy access to the user's own photos and their contacts' photos. The design also aimed for intuitive and playful interaction with the content. Our focus was also to design a mobile application and photo sharing service in such a manner that the enjoyment aspects of use and the whole user experience were the first priorities.

Earlier studies in the human-computer interaction community have developed definitions and models for user experience that have incorporated such aspects as pleasure, beauty and hedonism (Forlizzi & Battarbee, 2004; Hassenzahl & Tractinsky, 2006; Jordan, 2000; Norman, 2004). Hassenzahl (2003) has presented a model that takes into account both pragmatic (individuals' behavioural goals) and hedonic (individuals' psychological well-being) attributes of a product. This model defines aspects of user experience such as the subjective nature of experience per se, perception of a product, and emotional responses to products in varying situations. Roto and Rautava (2008) built on the earlier studies on user experience definitions and defined user experience elements that take into consideration the brand promise of Nokia. They defined user experience elements to be utility, usability, social value and enjoyment, which can be used when evaluating user experience. We have taken these aspects into account in the user evaluations.

PHOTO SHARING APPLICATION

To create a mobile gallery application that would be fully integrated with a corresponding Internet service, we defined the requirements for the application and implemented a functional prototype of the system.

Requirements

The requirements for a mobile photo sharing application were derived from our user studies and evaluations of current mobile photo sharing applications (Vartiainen et. al., 2008). They were also in line with previous research (Naaman et. al., 2008):

1. An easy way to register to a photo-sharing Internet service
2. An automatic uploading and backing up images to the Internet service
3. An easy way to browse images from the user's own collection or other users' collection
4. An easy way to publish images
5. An easy way to add and modify titles and

descriptions of images
6. An easy way to add and view comments

To meet the first requirement of simplifying and facilitating the registration process, we investigated ways to minimize the registration effort. After several brainstorming sessions, the identification number of the device was decided to be used as an initial user name. Thus, a user account (including the user name and password) would be created to the service without any user input except from asking the permission to use network connection. Afterwards, the user would be notified of the successful registration. Typing text with a mobile device can be a laborious task, especially when some users may not use any dictionary, or if the task requires text entry without any typographical errors. That is why by removing the need for any input, we would lower the entry barrier for the user to start using the application. The user could easily change their user name into something more descriptive by using the Internet service from a PC later on.

The captured images would be transparently transferred without requiring any user interaction to fulfill the second requirement of backing up users' images. As a result, a user would have a feeling of having his image collection always present on the device and in the service. The application would not only be an offline gallery or a tool for uploading images to a online photo sharing service, but a fully integrated photo sharing application that is always in sync with the corresponding service.

To satisfy the third requirement of browsing images, the photo sharing application would have two modes: one for browsing local (user's own images) and another for online (published by others) images. When the user would start the application, a main menu would immediately indicate the two modes for local and online browsing. We wanted to minimize the amount of steps that would be required to show the latest image in both modes full-screen: The first selectable item in the main menu would be "Latest" in both modes. As the first item in the menu would be selected when the application was started, the user would be one click away from his latest image and two clicks away from the latest public image. After clicking on a menu item, the user would be taken to an image browsing view, where he could browse his/public images with the left and right arrow keys.

Finally, an image menu was defined to meet the fourth, fifth and sixth requirements of letting users to publish and add/view titles, descriptions and comments of images. This menu would be accessible when browsing the images and would show the options that were relevant for a particular image. The title, description and comments of an image would be in sync with the corresponding Internet service: Whenever the user decides to change a title or description or add a comment either on the mobile device or in the service, the changes would also appear in the other end. This would in turn improve the user's perception that the application was fully integrated to the service and the content appeared to be common in both ends.

Implementation

The photo sharing application was implemented on the Nokia N95 mobile device using the Symbian S60 platform. The device had a display with a resolution of 320x240 pixels and hardware graphics acceleration with OpenGL ES. The N95 device also worked in the High-Speed Downlink Packet Access (HSDPA) network, where the data transfer speed can be up to 3.6 Mbit/s.

Figure 1 shows a screenshot of the main menu of the application. The left side of the view displays all the options that were available in the current mode. On the top, the text "My Images" explains that the current menu relates to the local, user's own images. The arrow beside the text indicates that by pressing the right arrow key, the user moves to the other mode of the main menu used for accessing "Public Images", namely online

Figure 1. The main menu

photos published by other users of the service. The background image was the current image in the selected photo set. When the application was started, the last captured image was shown as the background image.

For local images, we decided to create screen-size thumbnails to make image browsing faster and decrease memory consumption. For online images, we used the Web service to fetch the latest images published by other users of the service and cache them to the device memory. The service would also send only screen-size thumbnails of the images to make the transfer fast and save network bandwidth. As our target device supported HSDPA and we had a cache implemented, fetching the online images could be done in real-time without any disturbing waiting periods.

The image browsing view is shown in Figure 2, which shows the image full-screen. The left and right arrow keys were used to browse to the next and previous image, respectively. Figure 3 shows the image menu that was used to show functions that were available for the selected image. The image menu was activated with a joystick press in the image browsing view. When the user selected to publish an image, modify the title or the description or add a comment, the changes were sent to the service automatically. The synchronization also worked the other way around: the service notified the mobile application of changes on the service-side. The update messages only contained textual data, not the image itself. The commenting view is shown in Figure 4. The commenting view was activated from the image menu. Comments were always up-to-date with the service.

Figure 2. The image browsing view

Figure 3. The image menu

The second part of the implementation was the Internet service that included a Web user interface that users could use to access the same information as with their mobile devices. The Web user interface also offered the same functionality as the mobile application: the user could view and publish his images, add and modify titles and descriptions of images, browse images published by other users, and view and add comments.

USER STUDY

We conducted a field study of 1+1 weeks to compare our service-integrated mobile gallery application with a state-of-the-art gallery application combined with an add-on tool for photo sharing. The study included two groups each containing five participants who used our application and the combination of the gallery application and the upload tool for seven days each. The focus of the study was on the overall user experience of implemented features and how that would affect the social activity within the group during the testing periods.

Application for Comparison

The state-of-the-art gallery application used for comparison was the default Gallery application in the Nokia N95 mobile device. The upload tool used with the Gallery application was a mobile Symbian S60 application developed for posting images from a mobile device to a photo sharing Internet service. It was available on the market and used with the Flickr service (2008) during the study. We will later refer to the combination of the Gallery application and the upload tool as the “Gallery application”.

Figure 4. The commenting view

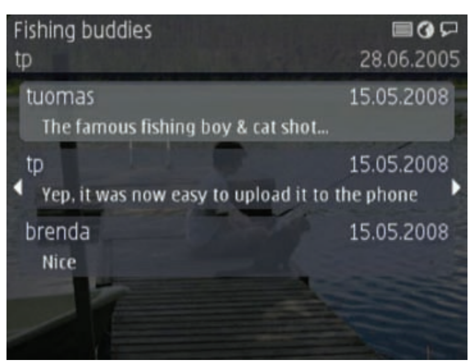

Figure 5. The upload tool used for the comparison

The upload tool was a stand-alone application that offered a way for user to browse, upload and publish images (Figure 5). The user could also view images published by others. The upload tool also included functionality to view and add titles, descriptions and comments. The commands were accessible via a tool bar that was visible when browsing images. Furthermore, the upload tool enabled publishing of images directly from the Gallery application by adding a command to the application.

The upload tool needed to be configured to use the Flickr Internet service for publishing images. If a user did not have an account to Flickr before starting to use the service, he needed to create the account by using a Web browser. After the configuration, the upload tool was ready to be taken into use. The user could set the upload tool to automatically poll Flickr at certain intervals and download the latest public images from his contacts and all other users of the service. The updating could also be done manually.

While our application was a prototype, the Gallery application was a more feature complete product. Especially, the tool was able to show a list for user's contacts in the Flickr service and the user could directly access the contacts' images using the list. Our application did not yet have this functionality implemented. The participants were asked to ignore the features (especially the feature for having contacts in the service) that were available in the upload tool and Flickr but not in our prototype application. However, this did not always happen as seen in the results of the user study.

Participants

We used two groups in the field study both including five participants that were friends with each other and daily in contact. The target was to follow social interaction in a group of friends who all use the same mobile application and corresponding photo sharing Internet service. The participants were students from university ages ranging 19-25 years. Two of the participants were female and eight of them were male. We decided to recruit students as they belong to the target group of social Internet services and are already actively using such services.

The participants did not have technical background, but some had interest towards technology and considerable IT skills. Seven of the participants described themselves as PC power users while the rest were basic users. Half of the participants had a smart phone, the other half a basic phone. Nine participants owned a digital camera, and five used their phone also as a camera. None of the participants were users of the upload tool application used for comparison nor the Flickr Web service, but they mainly used Facebook (2008) and e-mail to share images.

The participants were paid a small reward after the test period and they did not have to pay the data costs during the test period. We did not reveal the origin of either application during the study.

Procedure

Group 1 used the Gallery application first and switched to our mobile photo sharing application after seven days. Group 2 used the applications in the opposite order. We chose to conduct the field study in this way to ensure that the testing order of the applications did not affect the results. The participants were not given instructions on how to use the applications, because we wanted to simulate the situation where real users take a mobile photo sharing application into use for the first time. The participants were given Nokia N95 devices, which had both applications pre-installed.

We sent one or two tasks to the participants by text message every morning. Together with the message, we sent a multiple-choice question, which they had to answer before the next morning. The questions formed a set to evaluate the usability aspects of the applications. Below, you can find an example of a task:

Discuss about images and add comments to images that other users of the service have published.

How easy was it to comment images on a mobile device? 1=Very hard .. 5=Very easy

We selected 6 goal-oriented tasks for each period. The tasks included basic use cases for a photo sharing application: Registration, uploading an image to the service, publishing images, browsing published images, commenting and replying to comments. The tasks were the same for both periods.

In addition to the daily task feedback, the users were asked to keep a diary about their experiences with the applications during the test period. This was to gather their insights during the whole test period as well as experiences about their own use cases and challenges. We also logged data on the service-side including the number of published images and comments made by a user to measure the social activity within the participant groups.

After testing each application, we asked the participants to fill out a Web questionnaire including closed and open questions about the application. The Web questionnaire included three parts: In the first section, we asked rating questions about the general use; in the second section, we had rating questions about other aspects of user experience than usability; utility, social value and enjoyment (Roto & Rautava, 2008); and the third section included open questions, where we asked the participants to list three best and worst things in the application and improvement ideas.

After both periods, we asked the participants to choose which application they preferred to use for photo sharing in the future. We also organized a 2-hour focus group session separately with each of the two groups to discuss about their experiences during the testing periods.

RESULTS AND DISCUSSION

As described in the previous section, we collected various types of feedback from the study participants. In the following sections, we discuss the results related to the user experience and social activity. To analyze the statistical differences between the means of the ratings, we used a two-tailed T-test, with alpha = 0.05.

Preference

After using both applications for 7 days each, we asked the participants to evaluate which application they would prefer to use in the future to publish images with their mobile devices. We used a 7-point scale, 3 meaning strong preference for either application and 0 meaning no preference. 7 out of 10 participants preferred our application very strongly and 8 participants in

Figure 6. The preference of the application

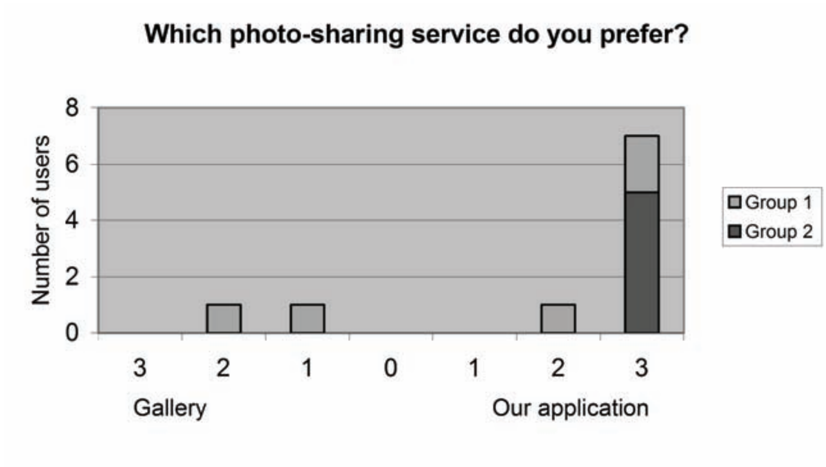

Figure 7. The overall evaluation with standard deviation

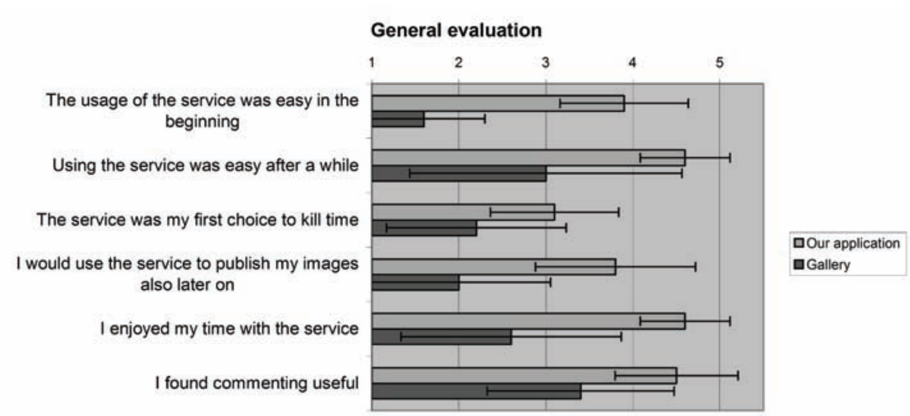


total (Figure 6).

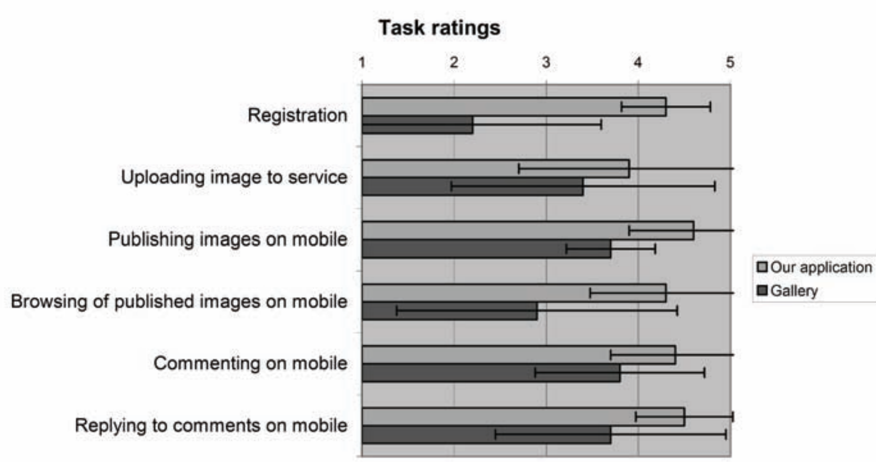
All users who first used our application (Group 2) clearly preferred it, whereas the preference distribution of the group, which started with the Gallery application (Group 1), varied more. The reason is that the Gallery application had a feature for adding contacts to a list, and the participants could easily check the latest images from their contacts. Our application did not have this feature yet implemented as it was still a prototype. The participants, who used the Gallery application first, had used this feature right from the start and missed it in our application. One participant commented that he chose the Gallery application because the lack of this feature in our application but otherwise he would have preferred our application.

Overall Evaluation

The results of the overall evaluations are shown in Figure 7. We used a 5-point Likert scale, 1 meaning that a user disagrees with the statement and 5 that he or she agrees. The questions aim at evaluating the overall experience of the applications.

The results show that our application was preferred in all questions. Especially, the start

Figure 8. The results of the task ratings with standard deviation



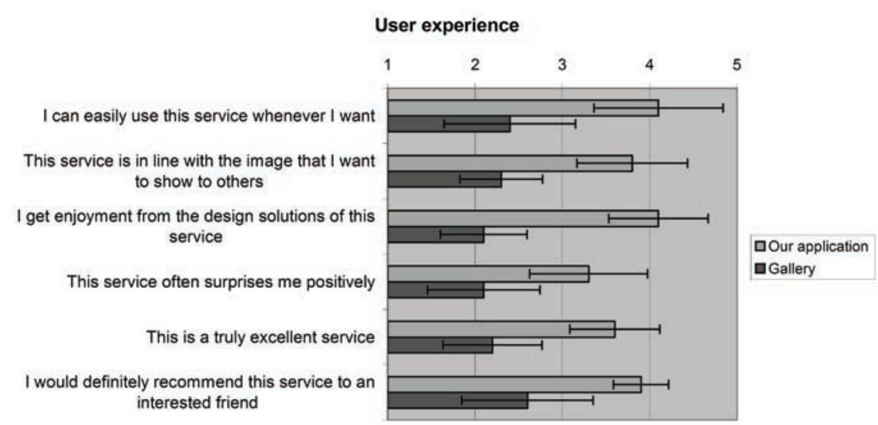
of use was significantly easier in our application (p=0.00001): The automatic registration was very easy and the instructions were helpful. In regard to the Gallery application, the participants commented that the registration to Flickr was too laborious to do on a mobile device. Most of the participants spent 1-2 hours to complete the registration on their mobile devices.

Compared to the Gallery application our application also scored significantly better in the questions "Using the service was easy after a while" (p=0.011), "I would use the service to publish images also later on" (p=0.0005), and "I enjoyed my time with the service" (p=0.0003). As the participants enjoyed their time with our application, they would gladly continue using it also in the future. The participants commented that they were pleased with the fast uploading of images, although it surprised some of them that all images were transferred to the service and not only the ones that they will publish. Image browsing, both with own and online images, felt very fast and commenting also proved to be more useful in our application as indicated by the significant difference in the score to the question "I found commenting useful" (p=0.001).

Although the Gallery application was very hard to configure in the beginning, the basic usage afterwards was quite simple and easy. However, as the image collection was not in sync in between the Gallery application and Flickr, the participants commented that they needed to manually upload all the images that they were going to publish. In addition, when they wanted to check the latest photos that other users had published, the online image collection was not always up-to-date since it is dependent on when the automatic update was done. If the automatic update was done only occasionally or not on at all, the participants needed to manually update the online image collection. The manual update sometimes took too long for the participants to actually view the latest images if one had only a couple of minutes when, for example, waiting for a bus. This irritated the participants and lowered the scores of the Gallery application in the overall evaluation. The same applies also for commenting. Even though the comments were easily accessible, the hassle with updating the content lowered the usefulness of commenting.

The question "The service was my first choice to kill time" indicates that photo sharing is still not the main use case for the participants to kill time. This is quite natural as the participants commented that they were not normally using such services with their mobile devices. Still,

Figure 9. The results of the user experience evaluation with standard deviation



our application scored significantly better in this question as well (p=0.029).

Usability Evaluation

After executing one of the daily tasks, the participants gave their ratings about how easy it was to complete the task indicating the usability factors related to the task. The results of the task ratings are shown in Figure 8. A sample rating question was presented in the Procedure chapter.

Our application scored significantly better in two tasks: "Registration" (p=0.002) and "Browsing of published images on phone" (p=0.039). As explained in the previous chapter, the registration in our application was simple and completed with one click while in the Gallery application, the registration process was complex. The participants highly appreciated the easiness of our solution and rated it high. The browsing of published imaged on the phone scored well in our application because the online image collection was always up-to-date when the user accessed it. In the Gallery application, the user needed to check, if the collection was recently updated. In the worst case, he needed to do the updating manually and wait for several minutes to see the latest online images.

Also, the task "Publishing images on mobile" (p=0.004) scored clearly better in our application as the image collection was always in sync between the mobile application and the service. There was no need for separately uploading an image before it could be published but the user could just publish it immediately. However, some participants had problems with uploading due to network problems, which in turn lowered the score for the task "Uploading image to service" (p=0.244, not significant).

On the contrary, the Gallery application did not offer any information whether the image was already uploaded to the service. Many times the sending was interrupted and had to be reinitiated, as there was no automatic resending. Furthermore, the participants commented that the uploading was quite easy but irritatingly slow. The participants needed to update every section manually if they wanted to get up-to-date information. In addition, comments were not always up-to-date as the updating occurred at certain intervals or only manually. This resulted in the participants adding comments to a discussion, which was not up-to-date, and the comments ended up being in a "zigzag" order in the discussion. In our application, the participants felt that they could trust that the discussion was always up-to-date with the service, and they could immediately reply to a comment. However, our application had limitations regarding the commenting view: It was sometimes slow to view comments and there was not any notification about new comments. This affected the scores for "Commenting on mobile" (p=0.140, not significant) and "Replying to comments on mobile" (p=0.137, not significant).

User Experience Evaluation

The results of the user experience evaluation are shown in Figure 9, where the ratings evaluated the social, utility, and enjoyment aspects of user experience. The results show that our application scored significantly better in 5 out of 6 questions. Even though our application also scored better in the task ratings measuring the usability of the main features, a clearer difference is shown in the ratings and participants' comments related to user experience.

Particularly, the easiness of use ("I can easily use this service whenever I want", p=0.016) and the design solutions of our application ("I get enjoyment from the design solutions of this service", p=0.0004) attracted the participants as clearly indicated by the results. The participants listed the ease of use and simplicity as one of the key design solutions of our application. They would rather have less well-designed features than many that are hard to use. The participants enjoyed the use so much that they would even recommend it to an interested friend ("I would definitely recommend this service to an interested friend", p=0.018). This seems to be an important aspect in social Internet services as the participants commented that it is important to have their friends using the service.

Furthermore, the participants considered our application and service to be rather excellent ("This is a truly excellent service", p=0.013) and support the image that they want to show to the others ("This service is in line with the image that I want to show to others", p=0.003). The participants explained that they highly appreciated the visual looks of our application and they described it as "stylish", "modern" and "beautiful". Our application also managed to surprise the participants positively from time to time ("This service often surprises me positively") and they commented that our application was fun to use but the difference was not significant in this question (p=0.066).

On the contrary, the Gallery application did not score well in these questions: Although it was quite simple and usable after a while, it did not manage to attract the participants or get them excited. The participants commented that it had unnecessary features and the essential functions were sometimes cumbersome and slow to use. They had problems of figuring out how the Gallery application works as a whole and what was needed to be done to carry out a task. The participants wanted a mobile application to be fast and smooth to use, as they might not have many minutes to accomplish a task on the go.

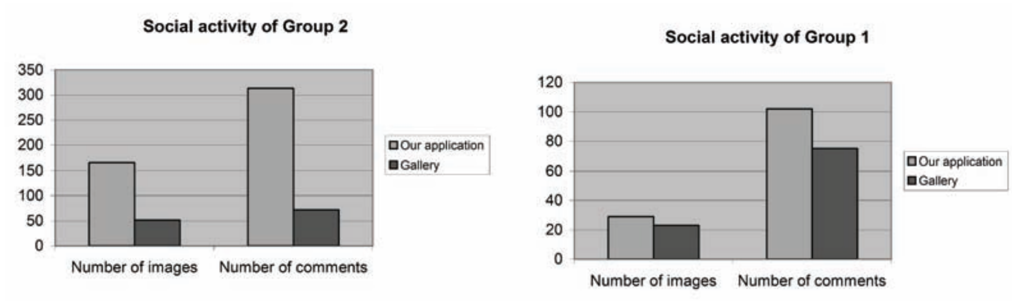
The user experience evaluation also explains why our application was strongly preferred by the participants compared to the Gallery application, which was not evident in the general or usability evaluation. The participants took pleasure in using our application even though they also got things done with the Gallery application. Our application enabled the participants to enjoyably interact with each other in real-time on the go, while the Gallery application still required the participants to take care of many tasks (e.g. uploading an image, syncing the image data) before they could concentrate on the actual communication.

Social Activity

Lastly, the results of the social activity within the participant groups are shown in Figure 10. The figure shows the number of published images during the test periods. It also indicates the number of comments that the participants added to the images. The number includes new comments and replies to existing comments.

The results reveal that both of the groups were more active when using our application. Group 1 which switched from the Gallery application to

Figure 10. The results of the social activity



our application published 26% more images when using our application. Also, the group added more comments to images when using our application: the number of comments increased 36%. The figures for Group 2 are even more convincing: Their activity when using our application for publishing images was 325% higher than when they used the Gallery application. Group 2 also added 420% more comments when using our application.

The activity figures show that the groups had different dynamics: Group 2 was clearly more socially active than Group 1. However, the results show that the activity was higher within both groups while using our application. In addition, the social activity was not dependent on the order in which participants used the applications and services. This is an interesting aspect as usually people might first become very enthusiastic about a new service or application but the excitement subsides over time. In this study, the usage of a photo sharing service on a mobile device was a relatively new method for the participants, which means that they were excited about it during the first period. Still, Group 1 increased their activity after switching from the Gallery application to our application.

CONCLUSION

In this article, we introduced a mobile photo sharing application that is fully integrated to a corresponding Internet service; thus, offering an easy and fun way to share and interact with images. In particular, we put special attention on making the user experience of the implemented features as positive as possible. The research goal was to find out whether social interaction is best nourished when users are using a gallery application that is deeply integrated to the Internet service compared to a solution existing on the market today, which uses an add-on tool to enable photo-sharing.

To evaluate our application, we conducted a field study with 10 participants to compare a state-of-the-art gallery application with an Internet service upload tool to our solution. The results of the study show that 8 out of 10 participants preferred our application and it also scored better in more detailed usability and user experience ratings. Our mobile application was especially appreciated because of user experience and speed. The gallery application used for comparison scored reasonably well in general and usability related questions but not in the user experience evaluation. This means that the usability or general evaluation did not reveal how satisfied the participants were with the service nor did they explain the participants' application preference. The state-of-the-art gallery application combined with the upload tool was missing the enjoyment aspects of use, which are essential for a mobile application used for social communication. The participants of the study were more socially active when using our application, which indicates that better user experience encourages users to use social Internet services more actively.

ACKNOWLEDGMENT

I would like to thank Davin Wong, Janne Kaasalainen, Toni Strandell, Timo Pakkala, and Tuomas Tammi for their support in authoring this article. Financial support from Nokia Foundation is also gratefully acknowledged.

Chapter 3.19
Social Support for Ontological Mediation and Data Integration

Gianluca Correndo
University of Southampton, UK

Harith Alani
University of Southampton, UK

Manuel Salvadores
University of Southampton, UK

ABSTRACT

Most organisations store their data in several databases with no flexible mechanism for integration and access, and with no common vocabulary in place. Maintaining local vocabularies while realising distributed access is a challenge that most organisations face regularly. For several years, the Semantic Web community has been developing algorithms for mapping data models (ontologies). Nevertheless, ontology mapping remains to be a great challenge, and humans are always expected to verify the results of existing automatic mapping tools. The spread of social web demonstrate the possibility of using collaborative techniques for reaching consensus and fostering user participation. While a number of prototypes for collaborative ontology construction are being developed, collaborative ontology mapping is not yet well investigated. In this article, the authors describe an approach that combines off-the-shelf ontology mapping tools with social software techniques to enable users to collaborate on mapping ontologies.

INTRODUCTION

Most public and private organisations own a vast capital of information, stored in many distributed databases, using various departmental vocabularies, and are usually subject to frequent change and update. Realising a persistent integration and access to such data is usually a major challenge, especially when there is a need to integrate with external data sources, such as in coalition forces scenarios, or in government.

The UK, in its e-Government agenda, has identified Ontologies and sharing as crucial issues, and recommended the Semantic Web as an enabler technology (Alani et al. 2007). B2B is another example of cross organization scenario that would benefit from data integration. Traders can in fact achieve a higher level of exposure of their businesses by sharing structured data and SW research initiatives are helping in delivering ontologies for defining offerings, services and products (Hepp, 2008).

In the academic domain, the Linked Data initiative (Bizer et al. 2007) has been very successful so far in guiding the exposure and sharing of data in semantic formats. Over 17 billions of triples are currently available as Linked Data, covering a wide range of domains, such as Wikipedia, FOAF files, census data, scientific publications, social websites data, and much more (Hausenblas et al. 2008). However, this growing community has little support for mapping the data it is publishing and sharing.

Enhancing information sharing and reuse requires providing communities with common spaces, tools and technologies for the dissemination and integration of structured information from different sources. There are many cases where organisations invested in building monolithic data models to subsume their entire information asset. However, such top-down models are very costly and time consuming to build. Furthermore, they are often hard to deploy and impose on data owners for various reasons, such as difference in coverage, inflexibility of the model, and its disproportionate scale (Alani et al., 2008).

The Semantic Web (SW) brings hope to easing the above problems by providing the technology to develop and share ontologies to represent data sources, and to map them together to facilitate integration and access, without the need to adhere to a common terminology. The Semantic Web offers hope to solve a number of problems that have been haunting the digital information world for many decades. Problems such as lack of shared understanding, differences in terminology, lack of machine understandable information, difficulty in integrating distributed information sources, high reuse costs, are all quite common problems.

Using the web as a common framework for data publishing helps in providing communities with a worldwide shared information space, and adopting standards from the SW (Berners-Lee, 2007) enabled the process of data exposure and linking. Ontologies provide a formal interpretation of data semantics that can be used for supporting information exploitation.

Defining an ontology or a knowledge base and mapping it properly to related resources is usually a costly and time consuming task. If ontologies are meant to reflect the views of a specific community over a specific domain and support their knowledge sharing tasks, then the community itself should be empowered to express, agree, bridge and formalise their definition by social means in order to support such tasks (Shadbolt et al. 2006).

There is currently an increasing interest in exploring new methods for constructing such knowledge in more social and collaborative ways, and several tools have recently been developed for this purpose (Noy, Chugh, and Alani, 2008). These tools tend to focus on supporting communities to create instance data or to build domain ontologies collaboratively. However, generic tools for collaboratively mapping these shared resources are not widely available.

In this article we describe OntoMediate, a system for supporting communities in sharing, mapping, and extending their ontologies and knowledge bases. More specifically, OntoMediate allows the following: **align** local ontologies to shared ones; **exploit** social interaction and collaboration to improve alignment quality; **reuse** user ontology alignment information for enhancing future automated alignments and **query** heterogeneous data sources.

In the following section we will briefly explain ontology mapping and existing automatic techniques for producing mapping results. In section 3 we will describe a number of tools for collaborative knowledge construction, highlighting their goals and main characteristics. Section 4 is dedicated to describing OntoMediate; our tool for community-driven ontology mapping. OntoMediate is briefly compared with other related tools in section 5. A small-scale evaluation of the system is described in section 6. Various remaining issues and challenges are discussed in section 7, followed by future work and conclusions in sections 8 and 9 respectively.

ONTOLOGY MAPPING

Previous to the Semantic Web and ontologies, data integration efforts focused on the physical and syntactical levels. Such integration lacked semantics and meaning (Uschold and Gruninger, 2004). Ontologies offer to make this tight physical bridging between systems much more flexible.

A key step towards semantic integration is ontology mapping (Kalfoglou and Schorlemmer, 2003). Other names for ontology mapping include alignment, fusion, merging, integrations, etc. All these names refer to the action of bridging between the representations (i.e. concepts, relations) of one ontology to another, to enable knowledge communication and sharing across the two.

Goh identified three main sources of semantic heterogeneity (Goh, 1997): **confounding conflicts**, where information items seem to mean the same things, but they are actually different; **scaling conflicts**, where different standards or references are used to describe the same thing and finally **naming conflicts**, where it is possible to use synonymous or broader names for the same thing.

Ontologies provide a framework to encode conceptualisations of domains that, once created, help to create a shared understanding, enabling communication between computer (or even human) agents. One common use of ontologies is to bridge between different data stores to facilitate data exchanging supporting therefore inter-operability that can be done at different scopes and levels. Inter-operability can also be used to integrate ontologies that represent different domain, to enable communicating inter-disciplinary information.

Ontology Mapping Techniques

The three main approaches for automatic ontology mapping be summarised as follow: instance based (Isaac et al. 2007), lexical based (Magnini et al. 2002) and structure based (Euzenat and Valtchev, 2004). Instance based approaches requires that a set of instances are classified with both the two ontologies to map. Then, using such coverage information, alignments are proposed using the probability of two concepts to include the same set of instances. Lexical methods analyse the lexical labels and descriptions of ontology entities and compute a similarity measure based on string similarity. Lexicons and thesauri can help such methods to take into accounts synonyms but hey are bounded to map ontologies whose textual documentation is in the same language. Finally, structural methods rely on structural similarity of the lattices of the two ontologies to map for computing an ontological similarity between entities.

Although many efforts have been devoted to propose robust and precise methods to solve the issue of automatic mapping of ontologies, so far no solutions have been found and such task still remain heavily driven by users.

COLLABORATIVE SW TOOLS

In this section we will describe a number of prominent tools for community-driven construction of knowledge, in the form of ontologies, taxonomies, or knowledge bases.

Investigations into enhancing user knowledge through collaboration and sharing go back to the early nineties (Patil et al. 1992). SW has taken this approach further by providing the tools and languages to construct networked semantic representational layers to increase understanding, integration, and reuse of information. The rise of Web 2.0 approaches demonstrate the effectiveness and popularity of collaborative knowledge construction and sharing environments that adopted a lighter version of ontologies, where the emphasis is put on the easiness of sharing knowledge rather than on creating or adopting static formal ontologies (Correndo and Alani, 2007). Harnessing Web 2.0 features to facilitate the construction, curation, and sharing of knowledge is currently pursued by different communities.

Collaborative Protégé (Tudorache and Noy, 2007) is an extension of the Protégé ontology editor from Stanford Medical Informatics department for supporting collaborative editing of ontologies. Collaborative Protégé provides some features for collaborative ontology editing, supporting discussions and conflict resolution by capturing changes, proposals, votes, ratings, and comments in annotation properties. Recently, Noy and colleagues (Noy, Griffth, and Musen, 2008) extended a repository of biomedical ontologies (**BioPortal**) to allow users to submit and share mappings between any of the ontologies in this library. Their system focus on capturing metadata information about the mappings: who created them, when, which mapping algorithm was used, comments about quality, etc. OntoMediate however, is more concerned with providing a generic tool for collaboratively mapping any ontology. It also provides the community with discussions and voting facilities, as well as querying services for the mapped resources.

Hozo (Kozaki et al. 2007) is a server based tool developed by the University of Osaka for supporting the development of networked ontologies in a distributed environment. The main focus of the tool is to ensure consistency among interdependent ontologies when they are simultaneously developed by different users. The tool allows then to lock ontologies for editing, broadcasting ontology modifications and the possibility for a user to accept or reject such modification.

OntoWiki (Auer et al. 2007) is a web based tool for collaborative editing of information maps that supports a number of visualisation widgets for different kind of instance data. The aim of OntoWiki is to provide an intuitive and collaborative tool for the editing of RDF content that supports knowledge engineering in a distributed (web based) environment. The user can browse the taxonomy tree of the concepts and freely adding or editing concepts' instances. OntoWiki also provides a number of typical Wiki features for enhancing social interaction. These include change tracking, commenting, access logging to estimate popularity, and provenance capturing.

DBin (Tummarello et al. 2006) is an application that allows a group of users to share structured content using RDF as a content language and a P2P network as a content provisioning infrastructure. The tool provides a set of reusable widgets that handle RDF data (e.g. for visualising maps or URLs) and is supported by a framework for RDF data sharing in a P2P network.

BibSonomy (Hotho et al. 2006) is a social tagging system developed by the University of Kassel and the L3S research institute of Hannover. BibSonomy helps in organising and sharing resources such as bookmarks and publications. BibSonomy introduced the possibility to add an informal notion of *isa* relation between tags in order to provide a taxonomic structure that can be helpful when retrieving information. Bookmarked resources can be made private or shared among the whole community. When shared, the bookmark and all associated tags can be searched by others and used by the system for future tag recommendations.

SOBOLEO (Zacharias et al. 2007) is a web based collaborative tool for the engineering of taxonomies developed by the Research Center for Information Technologies of the University of Karlsruhe. The tool allows users to maintain a shared taxonomy, using SKOS concepts[2], and to use such concepts for tagging internet resources. The tool has a collaborative taxonomy editor for changing the hierarchical definition of the concepts.

There are few approaches similar to OntoMediate that address ontology mapping within communities. Zhadanova and Shvaiko (Zhdanova and Shvaiko, 2006) proposed to use similarity of user and group profiles as a driver for suggesting the reuse of ontology alignments. The focus of that work was on building such profiles to personalise reuse.

In OntoMediate, we are exploring the use of collaborative features (discussions, voting, and change proposals) to facilitate the curation and reuse of ontological mappings by the community, to facilitate a social and dynamic integration of distributed knowledge bases. The use of collaboration for achieving consensus on terms' semantics is largely justified because of the social nature of ontologies. In order to mediate possibly conflicting description of concepts, user feedback is taken into account and discussion within the community is therefore fostered. Our approach is novel in the way it addresses the task of mapping ontologies, by extending and enhancing automatic mapping tools with a more comprehensive community support. In our approach, mappings are seen as a resource, built and shared by a community. The community is able to investigate, argue, and correct the individual mappings, using various supporting services provided in OntoMediate.

ONTOMEDIATE

In OntoMediate we are studying how social interactions, collaboration and user feedback can be used in a community to ease the task of producing and sharing ontology mappings (Correndo et al. 2008). The system is a Web application developed with J2EE and AJAX technologies; it manages RDF ontologies that are parsed using the Jena API[3] while the persistence of system entities is assured by Java Persistence API (JPA). The system is composed of four main subsystems:

- Ontologies and datasets manager: provides services for managing users' ontologies and data sources;
- Ontology mapping environment: provides services for automatically mapping ontologies (extendible APIs for integrating different algorithms);
- Social interaction environment: provides services for creating, discussing, and voting on mapping proposals;
- Data integration support: provides a service of query translation using mappings managed by the community.

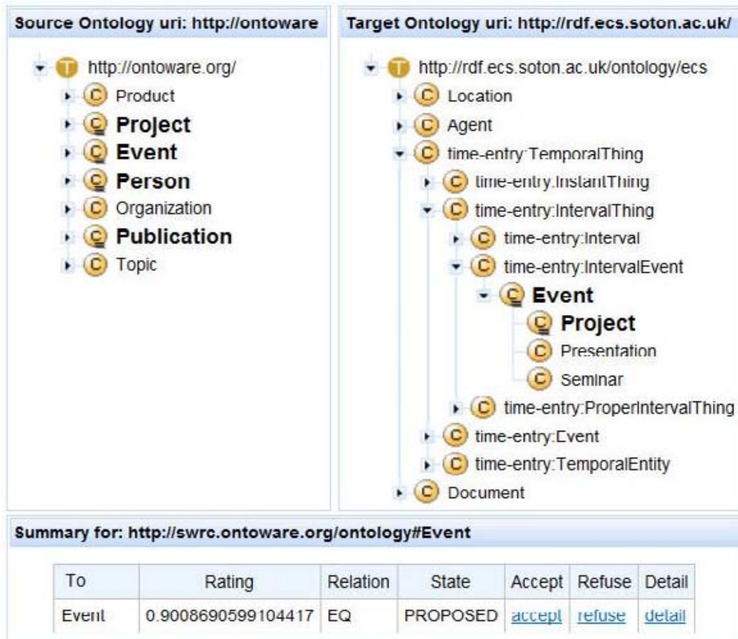
Ontologies and Datasets Manager

This component is responsible for receiving ontologies and managing their storage. Users can submit and remove ontologies and knowledge bases and choose whether to share them with the community or not. Sharing them will allow others to browse, map, and query these submissions. If they are not shared, then they are kept hidden from the community, and only their owner can use them. The system currently supports different storage types for the ontologies and datasets:

- **URL:** only the URL is stored and the ontology is accessed (read only) remotely;
- **Cached file:** the file is uploaded to the system and stored on a file server;
- **Jena RDBMS:** the file is uploaded to the system and stored in a relational database using the Jena database back-end;

Once an ontology is registered with the system, it will be added to the list of available resources, and its owner (and everyone else if the ontology is shared) can browse using a flexible frame-like interface. The browser shows the hierarchy of concepts, as well as detailed information for the focused concept (selected concept). The detailed

Figure 1. Ontology alignment environment



information includes: labels, superconcepts, subconcepts, equivalent concepts, concept description (from the *rdfs:comment* annotations), properties and their constraints.

Ontology Alignment Environment

Networked data environments require that different data vocabularies are mapped as well as the underlying data they represent. That is why OntoMediate allows users to align personal ontologies to models that have been shared within the community. Full automation of ontology mapping is hard to achieve (Kalfoglou et al. 2004), which is why OntoMediate extends automatic mapping tools with community support. This component of OntoMediate caters for the processes of submitting, sharing, and mapping of ontologies. It also provides functionalities for browsing the ontologies and their mappings.

Our system provides an API that enables automated ontology alignment tools to be plugged into an underpinning infrastructure. It also maintains a data structure for storing any parameters needed by a particular mapping tool (e.g. threshold values or tool options). The API allows for easy integration of new mapping tools, when they become available, by means of wrappers. Some tools have been already integrated with our system (e.g. INRIA Align (Euzenat, 2004) and Falcon OA (Jian et al. 2005)). These tools allow the system to support the alignment task by proposing some initial candidate mappings to the user.

Once the automated mapping tools are activated, the results are presented to the user for review. The ontology mapping interface is split into three main panels (Figure 1). The left panel is for showing the source ontology, and the right panel is for the target ontology. A smaller third panel at the bottom is used for summarising the mappings found for the focused source concept. Users can click on any mapping to display a more detailed view with a description of the mapped concepts shown side by side. This should aid us-

Figure 2. Ontology view showing an ontology hierarchy and related user feedback

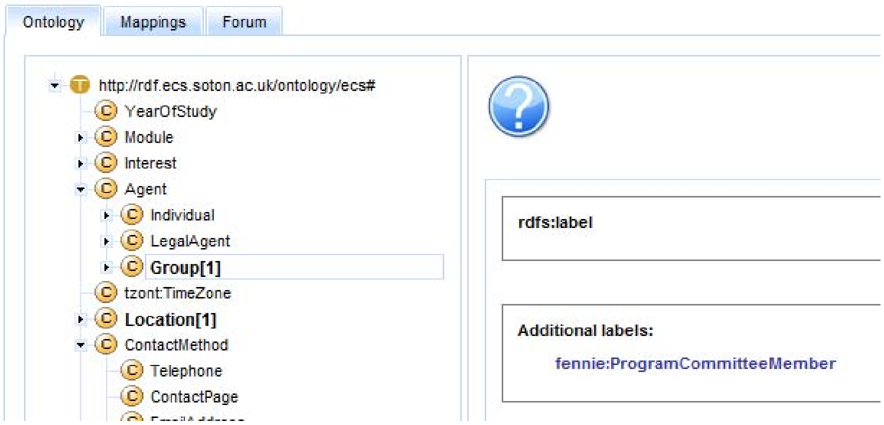


Figure 3. Forum view showing an ontology hierarchy and a change proposal

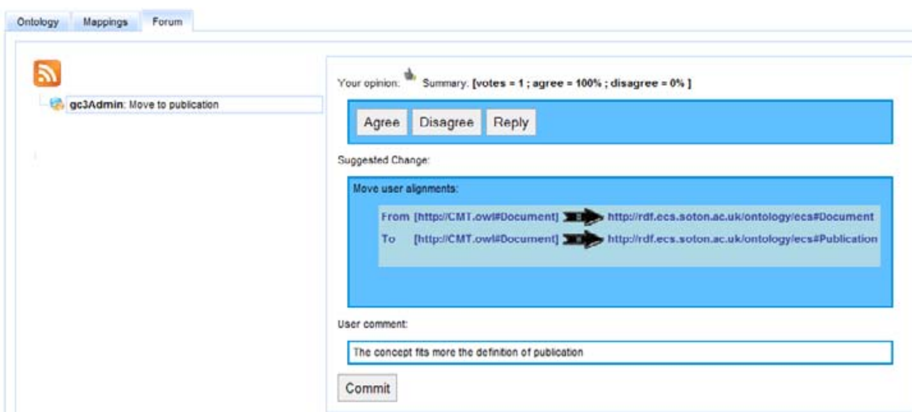


ers in their review of such mappings. Users can then review and create new mappings between properties and concepts by using a drag and drop technique.

Social Interaction Environment

This component allows community members to interact with each other to improve the quality and quantity of mappings. Users with similar data or interests can participate in such collaborative efforts and benefit by creating a better linked knowledge network.

The aim of this social interaction is to exploit community feedback in order to enhance the overall quality of ontology mapping and to reach agreement. The Social Interaction Environment displays three views to the user: an **Ontology** view (Figure 2); a **Mappings** view and a **Forum** (Figure 3).

The Ontology view displays the hierarchy of the selected ontology. In this visualisation, the number of incoming mappings, and the number of related messages or posts in the forum, is displayed in brackets next to relevant concepts.

Users can switch to the **Mappings** view to see more information about the mappings to a concept when that concept is clicked. Users can then inspect a summarised description (i.e. sub-concepts, superconcepts, properties, etc.) of the two focused concepts and decide if they should be mapped or not. Alternatively they can initiate a discussion thread in order to change this mapping. Any change proposal is composed of a thread post that describes in natural language the content of the proposal, and a formal description of the operation to discuss. The proposed change may affect a number of mappings and thus may lead, if the proposal is accepted, to the relocation of such mappings to a different target concept.

The **Forum** view is dedicated to the discussion of the users' proposals (see Figure 3). Each time a user proposes a change using the mappings view or the user view, a new thread is created in the forum and other users are free to debate the proposal, *reply* to the proposal with a new one or simply *agree* or *disagree* with it. Once a proposal reaches a critical mass (e.g. when the majority of users affected by the change have expressed their opinion) it will be endorsed, or submitted to an administrator in order to assess it and take a final decision.

Data Integration Support

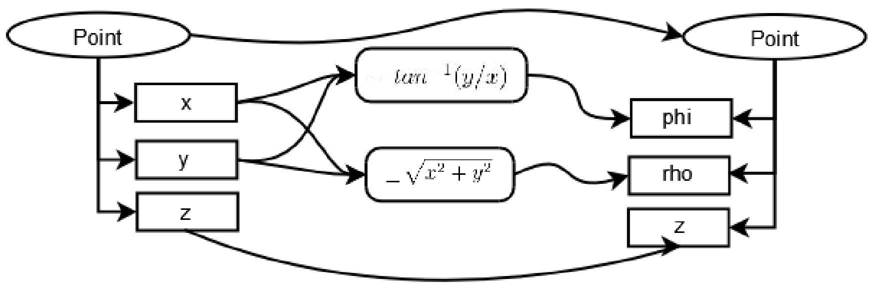
The features described above allow a community to maintain a network of ontologies, data sources and their mappings. In order to integrate data from sources described by different ontologies, the collaboratively maintained mappings must be exploited for translating queries and data. For this reason we developed a *Data Integration* service for the translation of RDF data and queries. The provided service takes a SPARQL query and a set of dataset's URIs as input, and then runs queries against those datasets, translating the queries whenever needed. The results obtained from the separate datasets are then merged together in a single homogeneous result set.

In OntoMediate the ontological mediation is achieved by means of query translation. Similarly to the approach adopted by Euzenat and colleagues (Euzenat et al. 2008), the alignments managed by the users and the topology of the data network are both exploited to translate queries and results from one ontology to another. In the case of OntoMediate, the shared ontologies are used to define the SPARQL queries that translate between the terms of one or more local ontologies for accessing the user data. Moreover, since the results need to be described with the same ontology used for the query in order to be understood by the issuer of the query, the translation mechanism developed enables the results to be translated back into the source ontology.

Currently, ontological relations are used to define equivalence among concepts and object properties. Mappings among datatype properties make it possible to define *n:1* relations and complex value transformations, by means of scripts, needed to bridge different encoding systems. A typical example where such complex transformations are needed is when different information systems decide to encode point coordinates with two different expressions (e.g. is_1 with Cartesian and is_2 with cylindrical coordinates). The notion of *Point* is easily mappable between the two ontologies (i.e. $is_1{:}Point \equiv is_2{:}Point$, see Figure 4) but the information described within the two concepts are not always directly mappable. In order to be able to translate a point from a Cartesian system (x, y, z) to a cylindrical system (ρ, φ, z) we need to be able to describe value transformations (i.e. $\rho = f(x, y) = \sqrt{x_2 + y_2}$) as well as multiple dependencies between entities. For representing such mappings, the usual representation by quadruple (Euzenat, 2005) $\langle e, e', R, n \rangle$ has been extended: the source entity e is replaced by an ordered set of entities E and a scripting function s is associated with the mappings. The representation of a mapping in our system is therefore a quintuple: $\langle E, e', R, n, s \rangle$.

Our translation algorithm visits and rewrites the algebraic description of a SPARQL query. This implementation exploits the features provided by Jena API for: rewriting the RDF triple patterns present in the original query; obtaining a query that matches the target ontology; retrieving the required instance set; and rearranging the result set to fit the source ontology. Such query translation functionality is then used to offer a service, accessible as a standard SPARQL endpoint.

Figure 4. Complex mapping between entities



COMPARISON

As already described in section 3, there exists a number of tools for involving a community in authoring an ontology, populating a knowledge bases, sharing knowledge, etc. The major difference between those tools and OntoMediate is that the latter is focused on ontology mapping. However, some of these tools are complementary to each other, and all have roles to play in the cycle of knowledge creation and sharing. For example, Collaborative Protégé or OntoWiki can be used to author the ontologies, or use Hozo if the ontologies are being built up from joining existing, and possibly conflicting, ontology parts. These ontologies can then be populated with instances in DBin, or used by Bibsonomy or Soboleo for annotating web pages with tags. Once such ontologies and knowledge bases are created, they can be mapped inside OntoMediate. Mappings produced in OntoMediate can be uploaded into BioPortal[4].

Table 1 summarises the main similarities and difference between OntoMediate and the above tools.

USER EVALUATION

An initial small scale user evaluation held within our university has provided some feedback about the usability of the system. Four users, knowledgeable about academic domain and SW technologies, have used OntoMediate to align four different ontologies about conference domain to the ECS ontology[5] about academic domain. The chosen source ontologies are relevant to the conference domain and are part of the data sets provided by the OntoFarm project.[6] They were: CMS; ConfTool; Crs and Ekaw. The domain is not exactly the same in order to allow users to issue ontology mappings as well as edit the ontologies.

One positive remark on the evaluation is that the ontology alignment editor interface has been found usable and effective although the process of alignment in this scenario should be supported by a wizard based interface that can guide the user trough the needed steps. The social interaction environment has been underused, mostly because the interface, focused on the ontology hierarchy and not to the items of interest (alignments, posts, proposals) failed to ease the access to the needed information. Such design decision didn't help users to review the relevant items, forcing them to browse the hierarchy for retrieving them. It is noteworthy that the possibility to use the RSS channels associated with forums for an offline access to their content have not been used. On the other hand, social tools like Facebook,[7]usually provide such channels along with the reader in a common interface minimising the adoption effort by users. A feature that has been requested by the evaluators was to express dis/agreement on alignments without being forced to provide healing actions.

Table 1. Comparison of tools

	Collaborative Protégé	BioPortal	Hozo	OntoWiki	DBin	BibSonomy	SOBOLEO	OntoMediate
Automatic mapping Does the tool map ontologies automatically?								✓
Manual ontology mapping Can users issue mappings between ontologies manually within the system, and share them with the community?								✓
Personal space Does the tool distinguish between personal spaces (only accessible to their owners) and public spaces shared by the community?			✓			✓		✓
Ontology editing Does the system support collaborative editing of ontologies or taxonomies?	✓		✓	✓	✓	✓	✓	✓
Discussion Is there support for the community to discuss any relevant issues?	✓	✓					✓	✓
Voting Can users flag their agreement or disagreement with proposals?	✓			✓				✓
Distributed data querying Does the tool provide an engine for querying distributed datasets?								✓
Query translation Are ontology mappings, if they exist, taken into account when querying? are the queries rewritten in accordance to these mappings to enable cross-ontology querying?								✓
Importing/exporting mapping Can users import or export mapping results?		✓						✓
Web interface Is the tool accessible online through a web browser or does it need to be installed?		✓		✓		✓	✓	✓
Instant messaging Does the tool support instant messaging between community members?	✓						✓	
Change history Is the history logged and made accessible to the community to trace back changes?	✓		✓	✓	✓			✓
Concept annotation Can users associate ontology concepts or properties with annotations?	✓			✓	✓			

DISCUSSION

Collaborative ontology mapping has a great potential in enhancing data retrieval quality and in sharing results of automatic mapping tools. The system presented in this article supports users in their ontology mapping activities by giving them access to automatic mapping tools, allowing them to review, correct, and extend mapping results and issue new ones manually, share mappings with the community, discuss and vote on various issues, etc. Collaborative ontology mapping is a brand new domain, and it lays out various new challenges to be overcome.

- **Context:** Ontology mapping is inherently difficult, and can be influenced by various issues. For example, some mappings can be user or context dependent, in which case a mapping that has been approved by some users may not necessarily suit others. Also, the community might fail to reach a consensus on certain mapping suggestions. It is necessary to allow for conflicting or contradictory mappings to co-exist (Noy, Griffth and Musen, 2008). In such a case it will be useful to provide users or application developers with filters to help them choose which mappings to use, for example based on authorship, source, mapping tools, etc. (Noy, Griffth and Musen, 2008).
  Mapping popularity can be used to weight each ontology alignment. The degree of popularity of a specific alignment can be taken into account when displaying alignment suggestions to the user. Storing user profiles to personalise mappings has been proposed elsewhere (Zhdanova and Shvaiko 2006).
- **Error propagation:** When reusing mapping results, it is important to prevent error propagation. It is important to build a user interface in such a way to discourage blind reuse of mappings. OntoMediate allows the community to flag, discuss, and democratically change incorrect mappings, but this is of course dependent on users spotting erroneous mappings. If a mapping is reverted, it will be important to readjust its popularity accordingly.
  In addition, mappings that receive repeated change proposals or become subject to long and intense discussions may be regarded as controversial or debatable mappings. Such mappings may also need to be handled with care when used or reused suggesting that administrators should create appropriate ontological descriptions to better characterize those particular local concepts.
- **Complex Mappings:** OntoMediate uses off the shelf automatic ontology mapping tools, and hence the complexity of its mappings is largely based on those of the mapping tools. The current implementation of OntoMediate allows users to manually map entities expressing simple one to one mapping. More complex mappings, such as mapping a union of classes or linking properties by means of transforming functions, is not currently supported. However, it has been reported that when engineering ontologies collaboratively, complex OWL constructs are often not required (Noy, Chugh and Alani, 2008).
- **Alerting the community:** When loading a new ontology to the network, or changing some existing mappings, it will be important to inform interested users of such change. Rather than flooding the community with messages and alerts, a more personalised communication approach can be adopted. Sending RSS feeds or alerts can be restricted to only the users who have mapped to, voted for, or recently discussed or queried a particular mapping.
- **Added value:** Ontology mapping is a not an easy task, and hence users will not expected to link their ontologies without a clear added value. The ultimate goal of OntoMediate is to facilitate distributed querying and integration of knowledge bases within a community. Therefore, in addition to displaying concept mappings, it will be important to also display contextual information regarding the knowledge that each ontology brings to the community, in order to encourage users in extending their mapping asset.
- **Scale:** The approach we focused on in OntoMediate is based on a small to medium size

community, sharing interests and goals that can benefit from integrating their data. In OntoMediate, it is presumed that an overall administrator can act as the ultimate curator of the system. For such an approach to scale up to the Web as a whole, the wisdom of the community will have to be the final ruler. Wikipedia is a fine example of how this can work, and the Linked Data initiative is a first step to creating a wide network of linked semantic data (Bizer et al., 2007). However, demonstrating added value will be more difficult once the community grows large and diverse, and hence it will probably breakup into sub-communities with similar requirements.

- **Versioning**: Noy and colleagues (Noy, Griffth and Musen, 2008) highlight the problem of managing ontology mappings when new versions of those ontologies are uploaded in collaborative ontology mapping environments. They argue that some mechanism must be put in place to associate mappings with ontology versions, and to notify users of such version-dependencies.

FUTURE WORK

Next we plan to provide OntoMediate as a tool for supporting ontology mapping within the Linked Data community. This will give the system a large user base, and will thus help us to launch a much larger user experiment to further test the validity of the approach, and the usability of the services and features that it provides. Additionally, we will next focus on building the capability to allow users to perceive, and query, the integrated knowledge bases, thus increasing added value.

CONCLUSION

In this article we presented OntoMediate; a prototype for supporting ontology mapping and data integration with community interactions, where users can collaborate on mapping their ontologies, and manually-driven mapping can be stored and shared across the community, and used for distributive querying. To the best of our knowledge, OntoMediate is the first tool of its kind that is entirely designed for supporting communities to map and integrate their ontologies and datasets.

ABSTRACT

This chapter presents results from an ongoing social television project, in the context of other research in the field. The authors give a detailed description of the STV prototype used in their research, and summarize their studies, which provide the findings explained in the rest of the chapter. Three major research focuses are identified, namely evaluation and validation of Social TV systems, communication modality comparison, and detailed observation of user behaviors. Based on the findings in these areas, the authors list three major open questions and challenges for the field: multi-user support, new equipment requirements, and the creation of distinct and unique social television experiences. Finally, the chapter suggests that the emphasis within social television may be moving from research to design, implementation and deployment.

DOI: 10.4018/978-1-60566-656-3.ch010

INTRODUCTION

Over the course of this decade, social television has gone from a marginal idea to a major focus area within the field of interactive TV (ITV). As members of an ongoing Social TV project in Motorola's applied research division, we have studied the issues around the subject extensively. In this chapter, we aim to discuss some of the things we have learned about social television, point out a few major unanswered questions and unsolved problems with social television, and offer a perspective on where social television is headed. Throughout, our own research and experiences are used as a jumping-off point, complemented by findings from the growing literature on the topic.

The main part of this chapter is devoted to three big questions that have attracted much attention. We look at attempts to evaluate the effectiveness and appeal of social television experiences, and find that their potential has been largely validated, although some important misgivings remain around privacy, disruptions, and systems that do not offer full freeform communication. We next examine comparisons of different communication modalities, primarily text, voice and video. Our findings indicate that contrary to previous, inconclusive studies, text is a better communication option than voice in the context of in-home social television, while video does not appear to be a suitable option. Finally, we describe the observed usage patterns of Social TV systems. We find that in naturalistic use, conversations are not as closely tied to the TV content as has previously been thought. On the other hand, television presence provides an important link between viewing behaviors and social interactions.

Because each topic draws widely on results from all our different studies as well as from the literature, the chapter is not broken up by individual study. Instead, to provide the necessary background for the reader to assess the findings we present, and explain where we are coming from, we first describe the prototype system used in our research, followed by a summary of the research we have conducted, before we start talking about what we have learned.

STV: A SOCIAL TELEVISION SYSTEM

At Motorola, we have explored several different kinds of social experiences around the TV. One of the experiences that has received most attention is to allow a small group of friends or relatives to share a feeling of contact or togetherness while watching TV; a "virtual couch." As part of this research, we have developed a series of prototypes, collectively known as STV, for use in lab and field trials (Table 1). The first iteration, STV1, consisted of a simple, single-session audio link between households, which allowed users to communicate via open room-microphones and hear their conversation partners through their television speakers, mixed with the TV audio (Harboe, Massey, Metcalf, Wheatley, & Romano, 2008a). There was no visual user interface, and the only control given to users was the ability to adjust the relative volumes of the TV audio and the voice audio using a remote control.

Later prototypes have been more elaborate, providing fully integrated Social TV systems that could be deployed in the field for extended periods of time. Since their features largely overlap (the biggest difference being an evolution in communication capabilities), we will describe them together in more detail. The main features of these prototypes are television presence (provided in the form of a buddy list and an ambient display), program suggestions, communication (including at various times graphical emoticons, pre-defined text messages, text chat and voice communication) and historical information such as viewing habits.

Table 1. Versions of the STV social television prototype.

Version	Presence	Suggestions	Communication
STV1	No	No	Voice
STV2a	Yes	Live, Future	Emoticons
STV2b	Yes	Live, Future	Emoticons, pre-defined text-messages
STV3	Yes	Live	Emoticons, text chat, voice

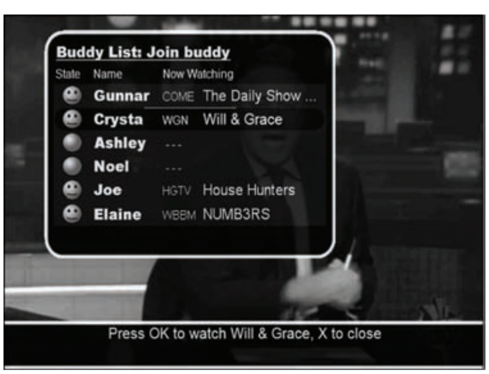
Presence

Presence information provides users with awareness of other users' current state, particularly their availability or whether they are currently active on the system. It can also include other information about their context. Television presence information, for example, lets users know about their buddies' current TV viewing. In STV, the two most important presence features are the buddy list and the ambient display.

Buddy List

The buddy list displays the user's contacts ("buddies") on the STV network, and shows their current status (Figure 1). Buddies who are not currently watching TV, or who have logged off in order to watch in private, show up in the list as unavailable. The STV buddy list is similar to buddy lists in instant messaging (IM) applications such as Windows Live Messenger[1] or AIM[2],but provides additional television-specific context, showing the station and program each buddy is watching. The user can tune directly to those stations by highlighting the buddy and pressing Select on the remote, joining whatever channel the buddy is watching.

Figure 1. Screenshot of the STV buddy list.



Ambient Display

The ambient display provides a way for users to be aware of their buddies' presence status even when the TV is turned off. An Ambient Orb[3] (Figure 2) displays aggregate presence information by glowing in different colors depending on how many buddies are currently active watching TV on the system, with separate states for no buddies, one buddy, and multiple buddies active. The ambient display is described in more detail in Harboe et al. (2008b).

Program Suggestions

In addition to the ability to join what a buddy is watching through the buddy list, it is also possible to actively ask buddies to watch something. Program suggestions help users let each other know about specific shows, and arrange to watch them together. Upon receiving such a program suggestion, a user can accept and automatically tune to the program, or close the suggestion without accepting (Figure 3).

STV2a and STV2b also let users send suggestions for upcoming shows. If the recipient accepted the suggestion, the show was scheduled so that a notification would remind them when it was about to start. STV has no DVR capability, so there was no option to record the show. Perhaps because of this limitation, suggestions for upcoming shows were rarely used, and the feature was removed in STV3 to simplify the user interface.

Communication

Different iterations of STV have included different forms of communication. Although STV1 supported voice, this function was not included in the STV2 prototypes, which instead tested more limited, closed-form communication options: emoticons and pre-defined text messages. When these features proved unsatisfactory, STV3 restored voice support, and also added text chat, providing a choice of freeform communication options.

Closed-Form Communication

Two forms of simple, closed-form communication have been tested in STV, both of them restricted to users watching the same program. Graphical emoticons, present in all versions since STV2a, are meant as a quick way to comment on the program or exchange greetings without necessarily getting engaged in further conversation. Currently, this takes the form of "thumbs up" and "thumbs down" smileys (Figure 4, Figure 4b), which can be sent using dedicated remote control buttons. A third smiley, called "shoutout" and representing a generic greeting or exclamation, was included in STV2a, but proved redundant and was removed from later versions.

In STV2b, the shoutout was replaced with a set of around 20 fixed, pre-written text messages and responses, with phrases such as "How is this show?", "This sucks!", and "Call me" (Figure 4a). The content of the messages was picked based on input from study participants so as to express the most important things users might want to say to each other. After poor participant response in the field trial of this version, the pre-written messages were scrapped, and replaced in STV3 by full freeform communication in the form of voice and text chat.

Figure 2. Ambient "orb" display sitting next to the television.

Text Chat

The text chat feature of STV3 is similar to IM, in that users select a buddy from their list (the buddy must be active, but can be watching a different channel), type them a message, and that message then immediately appears on the buddy's screen, initiating a conversation. The chat window can easily be hidden so as not to obscure the TV program while waiting for a response. Users can be in multiple text chats at the same time, switching between them (Figure 5), but in our current system

Figure 3. Screenshot of incoming program suggestion.

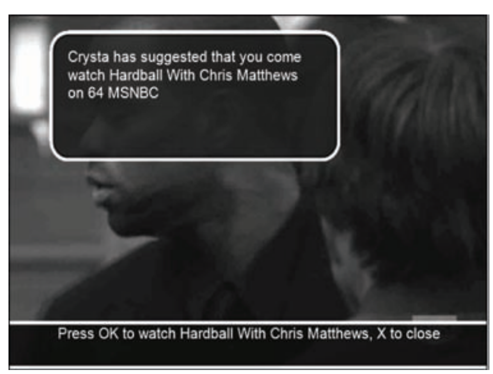


Figure 4. Closed-form communication in STV. (a) Pre-defined text messages. (b) Emoticons.

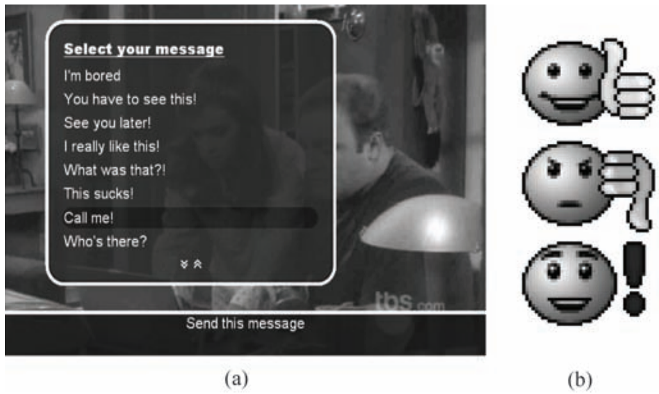

each conversation is one-to-one; we do not support group chat for text. Text entry is through a wireless Bluetooth keyboard, for ease of typing.

Voice Chat

In STV3, as in STV1, voice communication is made possible by establishing an audio link with one or more buddies. This is done in STV3 by selecting them from the buddy list and calling them. If any of the buddies accepts the incoming call, the audio link is set up and the call starts directly. Group calls are possible; a call can be set up with multiple people from the start, or more can be invited to an ongoing call (Figure 6). There is no particular ownership of a call; any participant can invite more people to join, and the call lasts for as long as any two participants remain. It is only possible to join a call by invitation, and each user can only be in one call at a time. While in a voice conversation, or when invited to a voice call, users can see a list of all the current participants in the call.

For voice communication, users have an echo-cancelling room microphone placed somewhere central in the room, for example on the coffee table. The voices of the remote participants are transmitted through the television speakers, mixed in with the audio from the TV program. The microphone sensitivity and the volumes of the voices and the television program audio can

be muted and adjusted independently.

Users can start and maintain voice conversations with their buddies whether or not they are watching the same TV station or program. It is also possible to take part in both a voice and text conversations simultaneously, either with the same participants (e.g. using text as a backchannel in a voice conversation), or in different conversations with different people.

Historical Information

In order to make the TV content more socially meaningful, STV provides users with some awareness of their buddies' viewing habits. There is a viewing history which lists the programs each buddy has watched. Users can also see a list of favorite (most frequently watched) shows for each user, and for their buddy list as a whole (Figure 7a). These shows are also marked in the Program Guide grid with a little buddy icon (Figure 7b). Finally, another option allows users to view a list of shows they have in common with another buddy, meaning shows they have both watched.

A program only counts as having been watched if the user watched at least ten minutes in total of a single broadcast of that program. Programs that a user watches while logged off are not counted, and users can remove programs from their own viewing history.

OUR RESEARCH

The social television research in Motorola originated in several studies that we conducted on family communication and use of media. These found that "people who want to build/maintain relationships but live far apart can use mediated communication technologies to develop 'close' relationships through a virtual experience of being 'physically' close," and that sharing the experience of commercially created content is an important way to maintain a personal connection (Bentley, Metcalf, & Harboe, 2006). In one study in particular, we noticed people calling each other during a TV show they were both watching, so that they could watch it "together." This led us to explore the concept of social television.

Our research to date has included paper prototyping tests, lab tests, usability studies, participatory design sessions and technical studies. However, the results presented here are drawn from four main studies (Table 2). Initial concepts were evaluated in a focus group study. The different STV prototypes were then tested in a series of in-home field trials. We will describe the methods used in each study in detail, followed by a summary of our data analysis methods, before going into our actual findings.

Table 2. Overview of Motorola Social TV studies. Publications referenced: (1) Harboe., Massey, Metcalf, Wheatley, and Romano, 2007; (2) Harboe et al., 2008a; (3) Harboe et al., 2008b; (4) Metcalf et al., 2009; (5) Tullio, Harboe, and Massey, 2008; (6) Huang et al., 2009.

Study	System	Method	Participants	Publication
Concept Study	[N/A]	2-hour focus groups	7 groups, 53 participants	(1), (2)
STV1 trial	STV1	1-hour field trials	4 groups, 8 (+1) households	(1), (2)
STV2 trial	STV2a STV2b	2-week field trials	2 groups, 10 households	(3), (4)
STV3 trial	STV3	1,3-week field trials	2 groups, 9 households	(5), (6)

Focus Group Concept Study

We ran a concept study to test the appeal of communication and interaction through the TV, as well as four other, more advanced, concepts (which will not be addressed in this chapter). The primary purpose was to guide the future course of the project. The study consisted of seven focus groups (and a pilot group) followed by a data analysis workshop. In the focus groups, which lasted for two hours, participants were shown a number of storyboards depicting possible Social TV scenarios and were asked to discuss them with respect to their own needs and lifestyles. They also individually filled in worksheets with quantitative ratings (using Likert scales) and other information.

In all, 53 people participated in the focus groups. We had 6 groups of 8 participants, representing teens (17 to 19); young adults (25 to 35); and baby boomers (42 to 61), split into separate male and female groups. Finally, a group of 5 male Xbox Live gamers (18 to 25) was included. The groups were selected to include people with and without children, and for other demographic characteristics considered relevant. The concept study was run by an independent consultancy, with researchers from Motorola involved at each step of the design and execution.

STV1 Prototype Field Trials

For these field trials, we used the STV1 voice-only prototype (described above). The prototype was set up in the participants' own homes for a live TV show of their own choosing. We ran four trials with STV1. Each trial lasted for one hour, and the participants watched live programming that had been agreed upon in advance. Participants were recruited from our social networks using the friend-of-a-friend method. In all, there were 11 males and 8 females participating in 9 different households, and all were non-engineers (Table 3). The programs consisted of a basketball game, an American football game, an animated comedy followed by a sitcom, and a home decorating show. The participating households were connected to friends and their friends' families, except in the second trial which brought together a family by connecting a woman with her son, daughter-in-law and grandchildren. In the first trial, one of the 3 participating households was that of a Motorola employee familiar with the project, and data from this household was not used in the analysis. The participants were video-taped during the trial (the researchers were not present), and interviewed immediately afterwards. We also recorded the programs they watched.

Table 3. STV1 field trial sessions

Trial	Households	Participants	Programming
1	2 (+1)	5-10 (varying)	Basketball
2	2	5	American football
3	2	2	*Family Guy, Full House*
4	2	2	*Trading Spaces*

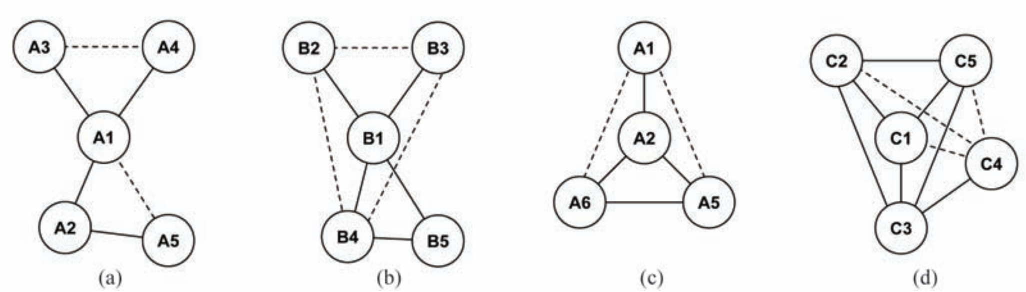
STV2 Prototype Field Trials

We ran two separate in-home trials of STV2, using slightly different versions of the prototype (STV2a and STV2b). The focus in this iteration was on the presence awareness, with limited capabilities for communication through suggestions, emoticons, and (in the second half of the study) pre-defined text messages. Five households were recruited for each trial, and each trial was conducted over a two-week span. Participants were recruited using an independent recruiting agency. Its instructions were to find social groups in which the various household members were mutual friends, and all had strong ties with one another. A number of different kinds of relationships were represented in the two social groups, but neither group was completely tight-knit (Figure 8a, b). All the recruited participants were women. However, other family members such as husbands, fiancés, and children also used the system, and were secondary participants of the study.

We used multiple methods for data collection, including semi-structured interviews, automated usage logs, and voice mail diaries. Each household was interviewed three times. The initial interview lasted about half an hour and was used to collect background information about viewing habits, communication routines, and social relations between the participants. In a phone interview after the first week, lasting between 15 and 30 minutes, we gathered data about the participants' use of and reactions to the prototype in the first week. The final interview, lasting from an hour to an hour and half, was structured to collect more detailed information on their use of and reactions to the prototype.

We logged all interactions with the system, including when the TV turned on and off, and all button presses during system use. Voice mail diaries were used to collect information on behaviors surrounding the ambient presence features and other communication with other people in the study, since these did not appear in our logs.

Figure 8. Social network graphs of relationships between households in our field trials. The solid lines represent friendships and close kinships (siblings), and the dashed lines represent more casual acquaintances.



STV3 Prototype Field Trials

This study, which used the STV3 prototype, was run in two stages: first a preliminary one-week trial with four households participating, then a more elaborate three-week trial with five households.

For the preliminary trial, we contacted three participants from the first group of the STV2 study (A1, A2, and A5) who formed a tight-knit group. A fourth participant, A6 (the sister of A2 and A5) was also added (Figure 8c). The participants were between the ages of 25 and 35. The system was deployed in their households for a period of one week. As in the STV2 study, an initial interview was used to gather background data, a phone interview was conducted mid-week to investigate participants' experiences with the system during the first half of the week, and a final interview was conducted at the end of the week to examine their experiences in-depth. We also logged all interactions and all text chats, and recorded all voice conversations held through the system.

For the longer trial, a recruiting agency recruited five participants, all of whom were males between 30 and 36. All were sports fans, and most were old friends (Figure 8d). The study was run during "March Madness," the American college basketball playoff series. For one week, the participants used the system without being able to connect to use the social features, in order for us to gather baseline data and to populate their viewing histories. After that, the social features were turned on, and they could use the system to communicate for two weeks, until the end of the study. The data gathering was as in the preliminary trial.

Analysis

In each study, we used a form of grounded theory analysis to interpret the data, applied as an affinity diagram technique (Bernard, 1998; Beyer & Holtzblatt, 1998). We reviewed the interview data, and (when available) the observed or recorded data from the usage sessions. We pulled out direct quotes and observations from the sessions and interviews that addressed the research questions. These items were grouped using the affinity method. Insights were drawn from the patterns that emerged, and the resulting organization of the data surveyed to answer the research questions.

For the focus groups and the STV2 and STV3 trials, we also performed statistical analyses of the data (ratings and usage logs, respectively). This quantitative data is mainly descriptive, especially for the field trials, since the small scale, non-experimental setup and numerous confounding variables don't permit us to draw statistically sound conclusions about any effects.

The results produced by our analysis, based on data from all the separate studies, form the material for the following section.

WHAT DO WE KNOW ABOUT SOCIAL TELEVISION?

In addition to the primary research just described, we have been able to draw on a growing social television literature. Research around social television has mainly clustered around a few big questions. We can sum these up as: validating the effectiveness and appeal of social features around video; exploring and comparing specific features and communication modalities to produce more optimal designs; and studying the behaviors around use of social television systems. Through the studies detailed above, we have made important contributions to answering each of these questions, which we will deal with in order.

Effectiveness and Appeal

As a concept that has never been widely deployed, social television requires some validation to test whether it is actually something people want or would enjoy, and whether it is useful or has other positive effects. The flipside of this question is the need to identify the concerns it causes and any potential negative effects it could have. This section will describe attempts to quantify the social and psychological effects of social television use, as well as people's response to it. We will then look at qualitative studies that describe people's first reactions to the idea without having used it, and compare these to studies of people's actual experiences with different Social TV systems. Finally, we examine the issue of privacy, which is crucial to the acceptability of social television.

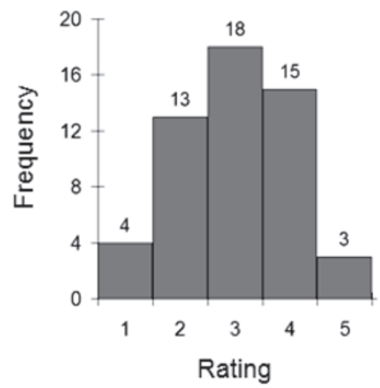
Quantitative Measures: Ambivalence

A fundamental question to ask about social television is whether it really does provide a social experience. A number of researchers have studied the problem using quantitative methods.

Baillie, Fröhlich, and Schatz (2007) compared the "joint TV experience" and "social presence" of watching TV in the same room to watching together through the AmigoTV system. They found that using audio chat did not differ significantly on these measures from actually being in the same room, but communicating only through graphical symbols was significantly lower on both. Similarly, de Ruyter, Huijnen, Markopoulos, and IJsselstein (2003) found that group attraction was significantly higher for participants watching TV when they had a live video view of their friends watching the same thing than when they only had a sketch visualization or no view at all. Along the same lines, Weisz et al. (2007) found that the ability to text chat while watching video on the computer significantly increased feelings of closeness with and liking of other participants. Finally, participants in a 9-week trial of ConnecTV felt significantly more connected when using the ConnecTV system than when watching regular TV in a control condition (Boertjes, Klok, & Schultz, 2007). Plainly, there are social television features that increase television sociability, at least when compared to solitary viewing.

As reassuring as it is that social television clears this fairly low bar, the last study, the ConnecTV trial, deserves a second look. In addition to measuring connectedness, the researchers collected four other ratings from participants, on the scales pleasant–unpleasant, activated–calm, satisfied–irritated, and inspired–bored. On all scales, ConnecTV scored worse than just watching television. Participants were less pleased, less calm, more irritated and more bored. After the trial, only slightly over half of respondents (17, N = 31) regarded the system as an interesting addition to watching TV (Boertjes et al., 2007). Frustration over technical difficulties may have depressed ratings in this particular study, but the question remains: is Social TV something people even want?

Figure 9. Focus group participant ratings of their interest in a generic social television concept. Likert scale from 1 (least interested) to 5 (most interested).



In our own concept study, focus group participants rated their response to the ideas presented in storyboard scenarios on a 5-point Likert scale. The ratings showed a response that can best be described as lukewarm, falling mostly near the middle of the scale (M = 3.0, SD = 1.04, N = 53) (Figure 9). Weisz et al. (2007) report a similar result for watching films while chatting on the computer; enjoyment was moderate (M = 4.3, SD = 1.6, N = 15, on a 7-point scale).

In contrast, Regan and Todd (2004a; 2004b) report that 93% of participants in their study (N

= 32) answered that they would like to IM with others while watching TV, and Baillie et al. (2007) also found that 93% (N = 30) of their participants would like to use a Social TV application. Harrison and Amento (2007) got a somewhat weaker, but still positive, response to their CollaboraTV system, with 69% of participants saying they would use the system, and most agreeing that it made watching TV more enjoyable (M = 3.56, N = 32, on a 5-point scale). Results from a later CollaboraTV study by Nathan et al. (2008) were similar (M = 3.57, SD = 0.65, N = 16).

A lot of this variation can be attributed to differences between systems and study conditions, especially the recruiting. Both Regan and Todd and Baillie et al. specifically recruited participants believed to be receptive to buying this kind of product, while Harrison and Amento recruited employees of, and Nathan et al. former interns at, a corporate research lab. The participants in the other studies, on the other hand, were recruited from the general public, or from particular communities without a predictable bias. This may indicate that social television appeals primarily to certain demographics, and does not currently inspire widespread interest.

First Impressions: Wariness

In addition to responses measured quantitatively on Likert scales, there is a wealth of qualitative data on people's reactions. This information helps to paint a richer picture of the aspects of social television that excite people, and the things that concern them about the idea. Three similar studies all point towards the same concerns.

In our focus groups, the mixed reactions to the concept were expressed in words such as "intriguing," "interesting" and even "wonderful," on the one hand, but, "weird," "unnecessary" and "pointless" on the other. Matching descriptions were elicited by Ali-Hasan (2008) in a participatory design exercise and by Hess (2008) in a user forum. In each case, the concerns of skeptical participants soon turned to privacy. The focus group participants worried about others being able to see what they were watching at any given time. Most argued that this social transparency overstepped the boundaries of acceptability, and several invoked "Big Brother," perhaps recognizing in STV the telescreen from *Nineteen Eighty-Four* (Orwell, 1949/1990). As in the studies by Regan and Todd (2004b) and Ali-Hasan (2008), participants articulated their discomfort in variations of, "I don't watch porn, but if I was…"; except for a few male participants who were more worried about getting caught watching programs targeted at women. The more general point expressed in these examples is that people worry about being embarrassed about their TV viewing. After all, many popular TV shows, as well as television viewing in general, are held in low regard critically and culturally. These "guilty pleasures" may therefore not reflect well on the viewer: "If someone was watching stupid shows all the time, I would think, 'God, what a moron are *they*!' to be watching these dumb shows."

Some of our focus group participants could see no value in linking personal communication to broadcast content. They felt that a television program would be an irrelevant distraction from their interaction with other people, for which existing communication technologies (telephone, email, IM, etc.) or face-to-face meetings were sufficient. The lack of perceived utility was captured in the words "toy" or "novelty," terms also heard in other studies (Metcalf et al., 2009; Ali-Hasan, 2008).

Experiences: Interest and Appetite

While user panels and focus groups are cautious in their response to social television, field studies where people get a chance to use it reveal a different and far more positive reception. The enthusiasm is apparent in the testimonials about Zync, the video sharing IM plugin, collected by Shamma et al. (2008) "Let me start by saying, I absolutely love Zync, currently myself and my wife are about 2000 miles apart but we love to watch movies together and it allows us to talk and watch together and its the closest thing we have to actually being together."

The participants in the STV1 trials were similarly very positive, on the whole, towards the concept and their experience with the prototype. We consistently found evidence that social television added value over and above watching alone, in a number of different ways. It helped to relieve boredom, allowed the participants to share their interests, gave them someone to ask questions of and show off their knowledge to, relieved loneliness, and heightened the intensity of exciting moments (cf. Weisz et al., 2007). In some cases it came close to the experience of actually being together: "I kind of forgot I was talking through the television at some point. I just was talking and could hear Mom." "It felt like she was in the room."

Participants in the trial of the STV2 presence-oriented prototype expressed frustration about the lack of communication options (a reaction shared by participants in the Boertjes et al. (2007) pilot study of the similarly restricted ConnecTV system), and their overall reaction was more negative. When some of them had a chance to try STV3, which incorporated voice and text communication, they all agreed that it was a significant improvement, describing it as "a lot more fun." Other participants in the STV3 study said the same thing: "I certainly liked it. It was a nice means to communicate and interact with my friends who share some of the same interests." "It opens and creates new avenues and communication experiences that I didn't have with a normal TV."

Other questions find less clear-cut answers. Some focus group members were concerned being in communication with others would interrupt and disrupt their viewing, causing them to miss parts of the show they were watching. They argued that television was their "down time," the only chance they had to relax and unwind. In the tests of STV1, however, voice conversations generally did not prove to be greatly disruptive. This agrees with the findings by PARC researchers (Oehlberg et al., 2006; Ducheneaut et al., 2008) in a similar experimental setup. In our later prototypes, some participants expressed impatience with the amount of on-screen notifications and messages, calling it "a chore" to deal with, while others enjoyed the fact that they could use their downtime to stay in touch with friends. Weisz et al. (2007) found that text chat during video viewing is distracting, and their participants reported this as their main dislike, and Weisz and Kiesler (2008) again demonstrated a distraction effect. On the other hand, when Regan and Todd (2004b) asked participants to rate how much incoming IMs interfered with the enjoyment of the TV content, average ratings were uniformly low.

Just like the response of participants in our field trials was generally more positive than that of members of the focus groups, several of those people were more enthusiastic after having had hands-on experience with it than they were beforehand: "Before going into this I thought 'What would I ever use this for?' But it was a totally different experience actually doing it. Because I totally changed my mind: […] I would totally use it!" Supporting this observation, Abreu and Almeida (2008) found that the proportion of subjects expressing high interest in a Social TV application rose from 27% before use to 67% after having tried it. (Baillie et al. (2007), on the other hand, found that participant reactions after having used the system were consistent with advance expectations. However, in that study, initial attitudes were already overwhelmingly positive.) To us, this underlines the value of practical testing in the study of new experiences. It is hard for people to predict their reactions to a hypothetical scenario. That is not to say that prototype tests are without their own biases; in all our field trials, as well as in the ConnecTV pilot study, technical problems (including degradation of TV image quality) were among the top complaints, and appear to have affected participants' overall reactions negatively.

People seem to respond more positively to social television when they try it than when it is only explained to them, and those who like it are a lot more enthusiastic. Some of the concerns people have when the concept is presented are not as serious as they imagine.

Effects on Privacy

As in the various user panels, aspects of privacy were also an important issue in our field studies. Although some participants expressed worry about government surveillance ("Can you imagine, like, back in the fifties, if they were Big Brother watching what we were watching? I would hope the government now doesn't want to come and… I mean, we don't have anything on our TV that's so…"), spammers, hackers, the possibility of strangers stalking them through the system, and the safety implications for their children, the gravest privacy concerns were in relation to their friends and family, both those on the system and those with whom they shared the home.

In practice the concerns were somewhat different from those anticipated by the focus group participants. The live television presence, which participants without direct experience worried about, did not prove to be a problem, perhaps because participants were able to log off if they wished to watch something in private. However, many felt that the viewing history feature, which logs all the TV programs watched publicly by a buddy, was too intrusive: "It's not really personal information, but it's not information required for anyone else to know. […] I don't think people would feel comfortable knowing what other people have watched." When the information was presented in summarized and aggregated form in STV3, participants had fewer objections.

STV3 also exposed another problem: the confidentiality of—and the confidence participants could have in—communications via the system. In the trials, there were numerous instances of participants being impersonated by other members of their households when using text chat. In some cases they were quickly found out ("it was the way [her husband] said 'Hey dude,' and my sister doesn't talk to me that way"), while in other instances the other person never realized the deception. Once people recognized this potential, reactions were strong: "Oh wow, that's scary... Heavens no! I'd be, like, angry if I knew that that happened. […] That's just, like, a violation of just, like, normal goodness!" "If she just pries a little bit, […] [my girlfriend] might find out something she doesn't necessarily need to know."

Everyone did not share this reaction. One participant was generally unconcerned about divulging information to the wrong person, because he felt that the conversations generally centered on topics that were not particularly sensitive: "What I was saying, even if it wasn't the person I [thought I] was talking to, I didn't feel like it was going to hurt anything. It wasn't anything that was sensitive information… so I wasn't too concerned about that." "I wasn't giving out my social security number."

Nevertheless, the overall trend is clear. When it comes to Social TV the primary threat to privacy is not Big Brother. It is people's actual big and little brothers, as well as their sisters, significant others, and other close kin.

Effectiveness and Appeal: Discussion

Evaluations of social television concepts and systems turn again and again to questions of sociability. The ability of the technology to provide a social experience is well established. When users talk about the benefits of having social television, nearly everything they say is about how it makes them feel closer to the other users: "It kept us more in touch with each other." Observations of their usage show that they take advantage of the social nature of the experience to engage in a rich set of behaviors.

Despite this alignment of potential capabilities with desired outcomes, and enthusiastic reception in certain studies, reactions to Social TV have not been uniformly positive. While some participant reservations could be caused by unfamiliarity with the concept (in focus groups, participatory design sessions and user panels) or technical problems (in prototype tests), two misgivings are not so easily dismissed: People worry about their privacy, although precisely what worries them is refined after experience with the system; and they are unhappy about disruptions that distract them from the TV viewing. These are problems that need to be addressed in the design of Social TV systems.

A final cause of dissatisfaction with some social television systems is that they are not social *enough*. Prototypes such as STV2 and ConnecTV, which do not allow freeform communication between users, cause much frustration. This frustration is satisfied in systems like STV3, which offers full text and voice chat support. It is therefore necessary to look at which features do satisfy people's social needs around television, and how they compare to each other.

Communication Modality Alternatives

The social television systems in the literature differ in the capabilities they offer for sharing a viewing experience. As pointed out above, merely offering presence awareness, or limited communication in the form of emoticons or pre-defined text messages to choose from, is not a satisfactory solution for users (Metcalf et al., 2009; Tullio et al., 2008; Boertjes et al., 2008; Baillie et al., 2007; However, see Schatz, Baillie, Fröhlich, & Egger, 2008). There is a need for more expressive communication. In existing systems, solutions to this have mainly taken the form of text chat (e.g. CollaboraTV) (Harrison & Amento, 2007), audio links (e.g. AmigoTV) (Coppens, Trappeniers, & Godon, 2004; Coppens, Vanparijs, & Handekyen, 2005), and occasionally video links (e.g. Reflexion) (Agamanolis, 2008), generally according to the designers' beliefs as to what will provide the most satisfying experience for users. A number of studies have sought to compare these different modalities.

Text vs. Voice

Geerts (2006) looked at voice chat and text chat in two separate systems, AmigoTV and Windows Media Center with Window Messenger. After using both systems in the lab, nine out of seventeen participants preferred the voice chat of AmigoTV, five preferred the text chat of Windows Messenger, and three had no preference. While voice was the more popular choice and was considered more natural, younger users and those with experience with IM text chatting tended to prefer text.

In a 144-person between-subjects lab experiment, Weisz and Kiesler (2008) compared communicating using text chat, voice chat, and both while watching streaming videos. Their results show that all options were enjoyable, and do not point to any of them as clearly preferable. Participants tended to prefer the option they personally experienced to other alternatives presented. Overall, text chat did slightly better both on enjoyment ratings and preference rankings, but on the other hand, users who had both voice and text available used voice almost three times as much. On the whole, the authors interpret the findings as support for adding voice.

In our focus group, participants were uniform in their opinion that communication should be by voice, and that talking should be made as natural as possible. They rejected out of hand the idea of texting for communication. Participants in the field tests of the voice-only STV1 system agreed, while those in trials of STV2, which had no freeform communication, were split on which they would prefer. Some talked about the benefits of voice: "A microphone or something to turn on would be cool. I wouldn't take the time to be typing in stuff back and forth; I'd pick up the phone and call them." Others strongly preferred text: "There's no way I want somebody talking to me during a TV show. Let the damn letters pop up. If I want to ignore them I'll close the window. I would never want someone talking to me during a TV show."

Text and Voice in Practice

In an attempt to resolve these conflicting views and inconclusive studies, we included both voice and text communication in the STV3 field trials. The results were unambiguous, based both on people's subjective opinions and on their actual use of the system. In the first, one-week trial, we counted 6 separate conversations, made up of combinations of 4 voice calls and 12 text chats. Of the 6 conversations, 3 involved voice, and all involved text. In the second trial, where participants had two weeks to use the communication tools, we counted 43 conversations, 6 of which involved voice, and all of them involving text.

Text was clearly the more frequent communication choice, and all the participants except one stated that they preferred it to voice. Their reasons for this choice varied. Some simply gravitated to what they were most familiar and comfortable with: "I guess that's a technology I'm used to, because I text-message a lot, and that's all I do at work." Other explanations were exactly the opposite: "[At work] I'm constantly on the phone, and you get burned out and it's just easier to text."

A number of participants felt it was easier to use and interfered less with watching TV: "Texting is what I think I'm more comfortable with, and you can pay attention more with the program, doing that. And when the voice worked, it was still fine, 'cause I could hear the program and hear the person. But it seemed like it took a little bit more of your attention or focus to make sure that you're hearing them and responding."

There was also a widespread feeling that contacting people over text was less intrusive and disruptive than trying to contact them over voice. "I don't want to inconvenience somebody by calling them or vice versa." Text was also seen as less intrusive to the rest of the household. "There's no sound or anything, so it's not disruptive," especially at night after children's bed time. The reluctance to use voice was closely tied to a sense of a social obligation being imposed. "I think the calling feature can be kind of tough to determine whether or not they're up for chatting. […] Let's say you want to [text] first instead of just popping into a call, and so they don't have to turn you down and kind of feel bad about it or whatever." Considering this problem of initiating the conversation, it is interesting to note that all but one of the voice conversations started out with a text chat first. As one participant put it: "Texting sets up the conversation, 'Hey, I'll give you a call' or whatever… then I'll know to call."

Text may have been seen as less intrusive than voice because of the semi-asynchronous flow of a text conversation. While the back-and-forth in voice sessions was essentially instantaneous, text chats often included long pauses—many minutes, sometimes even hours—between a statement and the response. Participants felt that this offered more control over the rhythm of the conversation. "You don't feel like you have to be waiting on the other person's response." "I think you're more in a control in a conversation where you can text, where[as] when you talk, you're all in, you're in that conversation, and you can't just at the end of a sentence… you can't just walk away and then get back to them ten minutes later, like in a text." "So the same reason why you would send a friend a text, because they can answer it when they get to it, is the same reason you would text somebody on the TV. When you're on a voice call with them, you can't do anything else, you can't talk to anyone else, you don't feel like you can just get up and leave."

Video Communication

While there is now a substantial amount of data on text vs. voice, social television with video link communication has been less thoroughly studied. Agamanolis (2008) found that watching TV programs or movies together was "one of the most satisfying ways" to use the "magic mirror"-style video conferencing system Reflexion. And as already mentioned, de Ruyter et al. (2003) found that group attraction was significantly higher while watching TV with a video visualization of a remote group of users than when watching with a sketch visualization or without any visualization.

In our focus groups, many participants said that they would like for social television to include a video link, so they could see each other while talking. However, the field trials indicated that adding video to the voice connection would be problematic. When our participants were relaxing in their living rooms, they were very unselfconscious, which didn't always mean visually presentable. In the STV1 tests, all of our participants were barefoot, and most put their legs on a table or on the couch. In a more extreme example, a child walked naked into the living room during one of the sessions. "Good thing it's not live video! [My kid] has got no bottoms on." They joke about it—"That's just sick! (Laughter)"—but it is clear that it would be a genuine concern to them. One participant told us that "the best part is [that] it's not picture in picture, where you're talking to someone and they see you." "[People] don't want anybody seeing you." Mostly, having video just seemed unnecessary. "Visually you don't see them but it did feel like there was this big sense of camaraderie. But outside of the optical sensation of [not] seeing them it did seem like they were here. It was strange."

Communication Modality Alternatives: Discussion

In none of our studies did participants actually have a chance to try a video-mediated Social TV experience, so our findings on this issue cannot be conclusive. The difference between the opinions solicited in focus groups, the results of lab experiments, and the observations made in field trials demonstrate that we should be cautious in drawing firm conclusions from limited data. In addition, our findings on voice and text chat are themselves based only on two small groups of users, and may not be widely generalizable. However, if the results hold up, it would seem that text is the preferred mode of freeform communication for social television, followed by voice, followed by video (which surely faces all the same problems as voice, and others in addition).

Even this conclusion is not the full answer, however. Each communication modality can be provided in a number of different ways. For example, text chat can be enabled with a QWERTY keyboard or using other text entry methods and input devices, and voice communication can be open-microphone/open-speaker, or using personal headsets. The effects of such design variations remain mostly unexplored. Schatz et al. (2008) have found that they have substantial impact on the user experience of Social TV, observing that the method of text entry often determined participants' feelings about the text messaging features. The same authors also compared four ways to control voice conversations, and found significant differences in the experience of watching TV together and in the overall preference (Baillie et al., 2007). Additionally, they report that 50% of their participants preferred an open table microphone, 30% the headsets, and 20% had no preference.

The Uses of Social Television

Some of the most fascinating insights about social television have come from the detailed observation and description of the behaviors of people using it. Two main approaches have been used: observations in a laboratory, and observations in system field trials. Lab studies can be run on a large scale and allow close monitoring of participants, but sessions are typically short in duration, and the lab setting and experimental conditions can affect people's behaviors. Field trials can be much longer in duration and observe participants in their natural environment, performing natural tasks, but the ecological validity comes at a price: because they are time-consuming and difficult to set up they are typically smaller-scale, and rely more on interview data and records of actions than on high-fidelity monitoring. There are also studies with aspects of both approaches. We will first present an overview of the findings of a number of lab studies, then discuss two main themes identified in field trials: the content and style of conversations and the pattern of behaviors leading up to conversations. Finally, we touch on some of the ways social television can be harmful to social relationships.

Like Being There (In the Lab)

Lab studies are the most common method used to observe groups using social television. The key exemplar of this line of research is PARC's Social TV study (Oehlberg et al., 2006; Ducheneaut et al., 2008). In that study, the researchers compared the speech acts of a group of people watching TV in the same room to those of groups watching in two different rooms, connected via an audio link. Analysis showed that the nature and structure of the conversations were surprisingly similar in the two conditions. Participant interactions were tightly interwoven with the structure of the show, with conversations taking on a rhythm to minimize disruption of the programming.

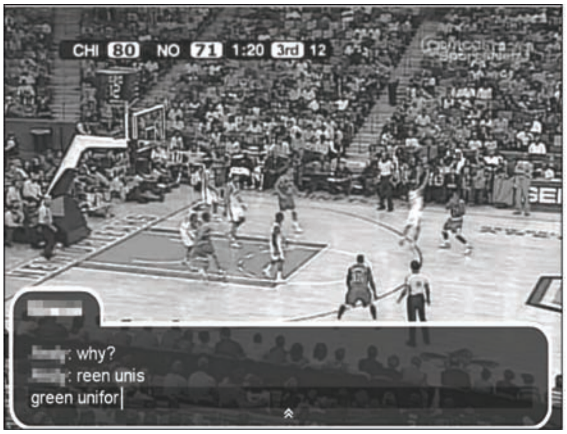
In our field trials of STV1, we observed many of the same things. The flow of the conversations was remarkably natural, much more like a face-to-face conversation than a phone call. People would leave and come back, chime in from another room, fall silent when they were paying attention to the show, and chat with each other when nothing interesting was happening. In the bigger groups we often saw several conversations going on in parallel, and collocated groups frequently had side-conversations among themselves while still taking part in the larger, connected group.

Adding support to these results, Baillie et al. (2007) found that conversations over AmigoTV audio chat had characteristics similar to face-to-face conversations, and Geerts (2006) concluded that Social TV voice chat is more natural than text chat. Weisz et al. (2007) coded the content of text chats during video watching in the lab, using categories similar to ones identified by Oehlberg et al. (2006). In their data set, 55.3% of all statements were related to the content in some way, with 22.8% consisting of personal conversation. In a later lab study, Weisz and Kiesler (2008) found that 48.1% of the conversation concerned the video and 9.9% was personal. In a field study by Nathan et al. (2008), the numbers were 42.3% and 18.9%, respectively. When seen alongside the observational studies, these results point to social television experiences that are natural, unforced, but adapted to the rhythm of the concurrent content, which also provides the primary topic of conversation.

Just Talk

Although the above studies point in the same direction, it is important to recognize that none of them observed behaviors under natural conditions. In each, researchers arranged the viewing sessions, set up the communication link ahead of time, and, in several cases, selected the content. (With one slight exception: In the Nathan et al. study the researchers selected the content and gave participants viewing assignments, but did not otherwise interfere.) Because the initiative to watch and interact did not come from the participants, the way they do these things may be

Figure 10. C1 in a text chat with C3, commenting in passing on the team's green St. Patrick's Day uniforms.



different from how they would act if the decision to engage was spontaneous.

In fact, when we examined these behaviors under less artificial conditions in the STV3 field trials, the results were very different. We found that personal conversation was far more common than conversation about television content. In the second group, for example, only eleven of the 43 text chats and three of the six voice chats contained any references to the current TV content. As one participant put it, "A lot of the text chats I had were more just general, 'Hey. How's your day? I haven't talked to you in a while. What are you up to?' It wasn't necessarily focused actually on the program. Which I thought was interesting, myself, 'cause I was thinking at the start that that's what we're gonna be focused on, we'll be talking about the programs." The following excerpt from the beginning of a voice conversation serves as an example:C3: [C3].C1: Hello. What's up?C3: [C1], what's up buddy?C1: How are you? You sound funny.C3: Ha-ha, I'm just exhausted dude, Monday just eats me up.C1: It does, huh? It's the first day of the week. You should be at your strongest. C3: Na, I think it's just from really enjoying the weekend and come Sunday at night you're finally feeling decompressed. You know? And then it's like you go back to the grind.

In cases where conversations did touch on the concurrent programming, the comments were in passing. The conversation structure did not seem to be tightly interwoven with the structure of the programs. "We touched on watching it, but [our conversations] were separate from what we were watching." (Figure 10)

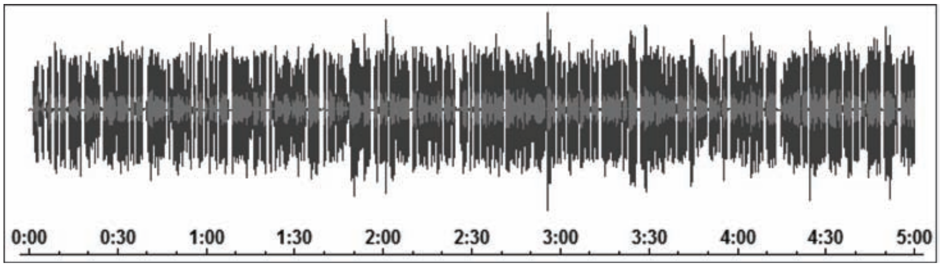
In fact, conversations were on a wide variety of topics. Participants reported that the topics and tone of their conversations bore resemblance to their face-to-face conversations. Participants often engaged in small talk and banter, as in this text chat:C5: does [C1] always text about food?C3: he must..i heard he sleeps with a bag of doritos under his pillowC3: if [C1] were president, free zingers 4 everyoneC5: for sureC5: time to take the dogto dumpoutC3: yeah, you have a good night broC3: sweet dreamsC3: sweet dreams on chocolate creams

However, participants also used the system to engage in more serious conversation. In one text chat, one participant inquires about how the other is doing after a recent move:C2: How are you enjoying the burbs?C5: we love itC5: nice and quietC2: It is a change from the city. Like the quiet too.C2: Only thing is a good night out is going to Bennigans.haha

In another example from a text chat, participants used STV3 to provide live context updates about themselves and their families, and to set up face-to-face meetings:A2: i'm backA2: whats [your son] doing?A1: being a pain in my butt. I am going oA1: to put him to sleep soonA2: but hes so cuteA2: sounds goodA1: yea he isA2: i miss himA2: we should get together really soonA1: he gets his looks from his dad...

Just like the content of the STV3 conversations was largely independent of the TV programming, participants did not fit the rhythm of their speech in the audio conversations to the TV content. Unlike the long silences between statements that

Figure 11. The waveform of the first five minutes of a typical audio session. Participants are talking continuously, and pauses are short (<3 s).



we observed in the STV1 trials whenever participants were paying attention to the program, here conversation was constant, with the longest pauses between utterances less than 5 seconds in length (except at times when users had technical difficulties with the system), and most no longer than a second or two (Figure 11). As a result, each audio session generally corresponded to a single, unbroken conversation. The data shows no indication of participants ever pausing to listen to the TV, and they generally kept the program volume low (but not off) during their conversations.

Overall, despite the coupling of communication with television and the fact that participants could only communicate with others who were also watching television, television content was generally not the main focus of conversation. Participants in the STV3 trials did enjoy the opportunity to communicate through the television. However, the voice and text chat features were not primarily used to create a social television experience of "watching together," but rather as another communication medium that had little to do with the television content.

Usage Patterns

As touched on above, one explanation for the different patterns of use found with STV3 compared to previous studies is that the social dynamics of communication are to a large extent determined by when and how conversations are initiated, as well as how they are terminated. If social television designers wish to encourage different types of social experiences, they need to understand the steps that lead up to the actual conversations. We investigated this issue in our studies of STV2 and STV3.

STV2 and STV3 both incorporated an ambient display, intended to help participants establish contact with each other. We saw evidence that the ambient information did help to engage them in the social television experience. Many of our participants told us of occasions when they turned on the TV because the orb indicated that others were watching. For example, one participant told us "as soon as I come into the house or I wake up or come into the room, that's the first thing. It draws my attention, and the first thing I do is turn on the TV." Another said that the orb "has made me a little bit more aware, makes me want to, when it does change colors, to see which of my buddies are on."

Once their TV was on and participants could see not only who was watching but what was being watched, their curiosity was stimulated further: they would often take a peek at the shows their buddies were watching. Said one participant, "If they're watching it, then maybe it's a good episode or something." Some participants used what their friends were watching as a sort of menu of program options to choose from. No one needed to suggest a show; they would simply be curious and join them. One participant described that

Figure 12. Different stages of interaction with the system, along with some notable characteristics.

Interaction	Presence specificity	Context detail	What others experience	Degree of participation
Noticing ambient display	Aggregate buddy list (+inferences)	TV is on/off	No presence info	Peripheral awareness
Viewing buddy list	Aggregate household (+inferences)	The program(s) being watched	TV is on/watching program	↓
Co-viewing program		Shared viewing context (common ground)	Sharing the viewing experience	
Message probes		Reactions to show, responses to messages	In contact, communicating	
Full two-way communication	Individual	User-provided context (+ background audio)	Rich conversation	Full involvement

she would turn on the TV "just to see who's on, and then most of the time we would all end up watching the same thing."

In the STV2 trials, participants often used lightweight messages like thumbs-up as greetings and to acknowledge others watching the same thing. For example, one said she sent messages to express "'Hey! You're watching the same show. Good show!' Kind of… acknowledging." In other instances, suggestions were used in a similar way, as a way to greet someone who just came on. Lightweight messages were also taken as a signal of availability to communicate. Sometimes this would culminate in a phone call:

"I noticed the orb was blue, so I knew somebody had their television on, and sure enough, it was [B2's household]. And I knew that her husband's at work and her kids were at school, so I deduced it was [B2]. And so without even saying 'Who's there?' I immediately went to her channel, which was Oprah, and I sent her a thumbs-up. And then she thumbs-upped me, and then two seconds later I said [to myself], 'This is dumb!' And then [I called her, and] we had a whole conversation." (B1)

When freeform communication was integrated in the system with STV3, we saw a similar pattern. The orb would alert participants that a buddy was available, and they would then test the buddy's interest in communicating:

"I sit down, and then I see the light go blue or whatever color, that means someone else is on there; and I go look and see, and then if I'm in the mood… I think if people are in the mood they'll type a line or two, and if they're not interested and just want to have a quiet night without having the keyboard in front of them in the family room, [they'll] just ignore it." (C5)

As an indication of how important this gauging of interest is, we can observe that with only one exception, all voice conversations were preceded by a text chat.

To generalize the steps reported: the participants become aware of their friends' availability through the ambient display, turn on their TV (thereby themselves showing up as available to the other participants), look at their buddy list, and often either join what one of their friends were watching or suggest that their friend join them. Once they were viewing together, they would usually send messages or emoticons. From this idealized flow, we can define different stages of interaction (Figure 12).

Moving through the stages, the user becomes progressively more engaged with the experience, going from peripheral presence awareness to immersive participation through a number of intermediate levels. Part of the reason for this is that at each stage, the user has access to more detailed social information. However, the most interesting thing to note may be the two-way dynamic at work. As users become more deeply engaged, they also become increasingly present to and connected to their buddies, which tends to nudge their buddies to become more deeply engaged. In this way, the system encourages more social interaction and communication at every level.

Anti-Social Television

Although the purpose of STV is to connect people and strengthen social bonds, we have always been on the lookout for possible negative effects social television could have on sociability. In our focus groups, some participants were concerned about the risk that easy communication through Social TV could be a substitute for face-to-face socializing. Similarly, there have been concerns that it might increase TV viewing, making people less active and less social.

In our field trials, we saw little evidence of either of these effects. Although STV3 participants reported that the system substituted for some phone calls or text messages, they did not get together any less frequently in person. In fact, our results suggest that STV3 may have encouraged increased face-to-face interaction. Participants reported extending and receiving opportunistic invitations or suggestions to meet in person through STV3 that would otherwise not have occurred:

"There was one time that we started texting on the system and he's like, 'Hey, we're going out for dinner. Do you guys wanna join us?' First of all, we probably wouldn't have talked to him that night [without STV3] but since we did it was pretty neat. It was something that opens communication between everybody." (C1)

In the STV2 trials, several participants felt that the system made them watch more TV, while with STV3 all agreed that they did not watch more television. Our usage logs do not indicate an increase in viewing.

Another concern about a system like STV is that the awareness it provides will not lead to feelings of closeness, but instead emphasize differences and cause alienation. The ability to observe friends' viewing habits may lead to the realization that you have less in common with them than you thought. In fact, while many participants told us in the initial interviews that they thought they had similar tastes to the others in their group, they in fact learned that their interests differed significantly. As one participant expressed it, "I have noticed that for the most part we don't watch a lot of the same shows." Several people commented that one particular household watched what they variously called "weird shows" or "crazy movies." That participant in turn observed, "they watch something totally different from what I watch."

Similarly, a presence indicator can also be an absence indicator. There were many occasions on which only one participant was watching TV, so that there was no one to talk to over the system: "The oddest thing, it's a nice night to be in… and not one person is on Social TV tonight!" Some participants would repeatedly check their buddy list, and sometimes try to contact people who were offline before giving up.

Even when other buddies showed up as being on the system, attempts to contact them were not always answered. "We were sending suggestions and nobody was answering us back, and it was like, 'Are these people just leaving their TV's on?'" Some participants felt like they were being ignored: "I thought, 'OK, maybe she just doesn't feel like responding.'" One participant speculated that her friends "just wanted to watch their show, and they were ignoring you."

Participants never explicitly stated that they felt rejected or were hurt by such non-responses, or that being the only person on the system made them feel lonely. However, turning the question around, they *were* concerned about how others would take it if *they* didn't answer. Accordingly, there was a social pressure to respond. For example, one participant felt "obliged to send something back" when she received a message, because "it just felt like they're doing something, so should I do something back…"

Another potentially disturbing problem which we saw scattered evidence of in the field trials was a displacement of sociability. In the STV1 sessions, one of our participants confided that because he was interacting with his friends, he was paying less attention to his son than he would have done otherwise. By bringing outsiders into the family room, social television can intrude on important "quality time," and weaken the closest ties even as it builds relationships with more distant people.

As stated by a participant in the STV3 trials, evenings are traditionally "our time with our significant others that we live with." By effectively bringing other people into the living room, social television challenges the home sphere. In some cases, this can literally drive away the ones who are closest: "My wife would probably just look at it, see something ridiculous [my friend] would write and say, 'Oh, you guys are stupid,' and she'd go out and leave the room." Taken to its ultimate consequence, this could lead to a situation like that reported by Quico (2003): "I left my wife because I am in love with the TV set."

The Uses of Social Television: Discussion

Earlier studies have tended to portray the conversation experience of social television as very much an aspect of the viewing experience, with both the structure and the content of the communications tightly linked to the program content. In contrast, the STV3 field trial reveals a communication system that goes beyond simply being a tool for communicating about television.

That is not to say that integrating voice and text communication with the TV is irrelevant. Through the presence mechanism, TV viewing influences the set-up of conversations in a number of ways, most of them positive. Although there is always a risk of causing harm to existing social relationships, so far the overall effect has been to strengthen social ties and even cause new ones to form.

WHAT DON'T WE KNOW ABOUT SOCIAL TELEVISION?

Many of the important unanswered questions about social television arise from what we have learned so far. Research into the appeal of social television has uncovered challenges around privacy and disruption that need to be resolved. Evaluations of different types of communication modalities have indicated high-level preferences, but left details unanswered. And finally, studies of social television behaviors have found that the process of initiating contact, and the way remote communication interacts with collocated relationships, require further investigation. Here, we will look at these questions from a slightly different angle, organizing them under three big questions: how the challenges raised by the fact that TV is often a shared device and a shared activity can be resolved; which missing technical pieces are necessary to realize social television; and which direction social television should go in to provide a distinct and particularized social experience.

How Do We Support Multiple Users within the Home?

In households with more than one person, the main television is usually a shared device, what we might call "public within the home." It is used by multiple different people, both separately at different times and in groups at the same time. This fact has a major impact on social television.

Of all the privacy concerns surrounding social television, the ones most manifest in the field are those over how to protect communication from other people in the household. Let us call this the "Little Brother" problem. At different times and in different situations, Little Brother could be a sibling, a girlfriend, boyfriend or spouse, a parent, a child, or a roommate. Little Brother complicates social television in a number of ways:

- Little Brother is nosy, and particularly interested in the private matters and personal relationships of his family. He listens in on family members' conversations unannounced. He impersonates them on text chat with their friends. He sometimes conspires with the real person to fool others, sometimes with that person's buddies, and sometimes he acts by himself.
- Little Brother is (at least sometimes) a child, and it is important to his parents that he is protected from inappropriate messages like swearing and adult conversations, kept safe from strangers, and that they can restrict and control how he uses the system.
- However, Little Brother does not want to be monitored.

In addition to these privacy issues, Little Brother faces another two problems of television sociability:

- Little Brother has his own friends. Most of the time he wants to talk only to them and see only what they are doing, and doesn't care about his other household members' friends.
- Little Brother is (usually) a family member, and watching TV is traditionally his quality time with the others in the household. Social television makes it easier for outsiders to intrude on these family moments.

In order to address these problems, a way to manage the multiple identities within the household is needed. This may include separate accounts for each user, with a logon process to verify identity. Since multiple users may be watching at the same time, the presence states needs to be flexible enough to represent this, and the interface needs to bridge or merge separate buddy lists and allow interaction from different user accounts. To date, Media Center Buddies is the only documented social television system with explicit support for multiple users (Regan & Todd, 2004b). For the most part, the design requirements for such capabilities remain unexplored, although ideas from the general interactive TV field may come into play (e.g. Farré, 2006).

Several approaches could be taken to limit the increase of intrusion and reduction of intimacy caused by social television. One avenue could be social television applications that support collocated sociability, socializing within the home, as suggested by comments by Chorianopolous (2007). In another direction, the shared nature of the TV makes it a potentially more inclusive social device. We have seen several instances where STV helped make other family members part of a relationship, such as when the girlfriend of one participant for the first time had a real conversation with one of his friends, or as the husband of another participant said about his wife's relationship with her sisters: "Usually I wouldn't know what they talk about. Here I get more involved, probably more than I wanted to." It remains to be seen if this involvement can be maintained once each household member can contact *their own* friends.

If, then, multiple users want to use social television individually at the same time, there are some scarce resources that need to be managed. Two of the most important ones are screen real-estate and system control. TV's have traditionally only had one remote control, which limits direct input to a single user at any one time. Similarly, only a limited amount of information can be displayed on the television screen, and will always interfere with the TV programming. Potential solutions to these problems include appropriating other devices, such as cell phones, for use as control and input mechanisms (Lin & Chen, 2005; Cesar, Bulterman, & Jansen, 2006), and employing secondary screens to display supplementary and personalized information (Fink, Covell, & Baluja, 2006; Cesar et al., 2008). This brings us to the issue of equipment.

What Equipment Do We Need?

Even if social television proves itself viable in field trials and pilot deployments, significant barriers to mainstream adoption remain. One of the main bottlenecks for deployment is the requirement of specific hardware. For this pragmatic reason, determining the necessary hardware components of a social television system is important. From the point of view of social television, current hardware is limited in terms of processing power, middleware support and networking ability, in the availability of input devices for communication (including text, voice, video and other forms), and in the use of peripheral and secondary displays.

We found an ambient display to be a popular addition to the STV system, and an important part of the experience. Because such displays are rare in the home, the question becomes whether the functionality can be provided through other equipment. One candidate are the secondary screens mentioned above. As already pointed out, the more important function of secondary screens is to move the display of (and often interactions with) advanced and personalized features off the TV. The effects of such a separation between TV content and social application on how social television is perceived and used are not well understood.

The most important hardware requirement, however, is very likely the choice of input device, or input devices. This choice is primarily driven by the communication modality. For text chat, a text input device is needed; for voice chat, a microphone; and for video communication, a video camera. A pointing device is desirable for on-screen drawing; closed-form communication (like emoticons and multiple-choice messages) can make do with a regular remote; while a game controller is ideal for rich avatar interactions.

Current findings point to text as the preferred communication modality over voice, and seem to show that video communication is not suited for social television. Nevertheless, efforts are likely to continue with all of these means of communication, and others. In any case, the demonstrated inadequacy of closed-form communication indicates that regular remote controls are insufficient for input.

We can predict, then, that a flood of different input devices is heading for the living room, if people are willing to let them in. However, the details remain open. For voice, what are the merits and drawbacks of a room microphone compared to headsets? For text, are any entry methods other than a full QWERTY keyboard acceptable? We know that these choices affect the experience, but the exact effects are unknown.

The numerous complicating factors with deploying social television for the TV, and the restricted capabilities of most current set-top boxes, raise the possibility that social experiences can more easily make a breakthrough as part of the burgeoning TV and video offerings on the Internet and on mobile platforms (Schatz, Wagner, Egger, & Jordan, 2007). The chance that widespread deployment may happen through systems and devices already primarily used for communication only makes the question more acute: in what way can Social TV differentiate itself, so that it offers a communication experience that is not interchangeable with existing offerings?

Where Should Social Television Be Going?

From the original definitions of social television (whether narrow or broad), both research results and system developments have tended to blur the line between Social TV and other social network and communication technologies. As online video becomes increasingly integrated with chat (e.g. Zync) (Shamma, Bastea-Forte, Joubert, & Liu, 2008), the distance between text chat over social television and over IM becomes smaller. Findings that show that most communication over social television is not content related make such systems seem less distinct. And with the prospect of using a cell phone or computer for the interaction, it becomes hard to separate social television interaction from any other form of communication.

For social television to become merely an extension of existing communication systems would be mildly disappointing, given some of stated ambitions of the field. We believe that the potential for social television to contribute unique and powerful user experiences exists. In order to achieve it, two goals should be pursued: close integration with the activity of television viewing, and close integration with the television content.

Our studies have shown that television presence information influences communication initiation. Presence awareness as part of a frequent and extended laid-back, recreational activity provides a spur to striking up conversation. At the same time, the degree of contact and transparency imposes social pressure, not just to communicate, but also around the patterns of TV viewing. Social television systems should seek to harness these forces positively (cf. Consolvo, Everitt, Smith, & Landay, 2006), for example by improving the mechanism of word-of-mouth recommendations of high-quality programming, and be designed to minimize the risk of alienation (Sokoler & Svensson, 2008). Future research should continue to explore the social effects of exposing TV viewing to public scrutiny.

Alongside these efforts, communication modes that are more directly focused on the content deserve more attention. These include shared program tags, exchanging clips, and social bookmarks that point to moments of interest within a program. Previous studies have shown that commercial content such as music is appropriated by people for their personal and social uses (Bentley et al., 2006), and one could take the perspective that social television is about using television content as a resource for personal and social interaction. Even more promising is the creation of social television experiences tailored to specific programs, such as multiplayer competition within quiz shows (Luyten, Thys, Huypens, & Coninx, 2006), fact checking or commentary during political debates, or a gossip channel as part of entertainment news. Enabling third-party creation of these custom experiences requires standardized protocols and a social television API. The ability to define interaction formats could allow a wide variety of structured social experiences for the television (van den Bergh et al., 2007).

Social TV systems can certainly provide generic text and voice communication experiences over the television. Much of the research and development to date has been explicitly of implicitly aimed at reaching and validating this capability, and most of the major questions have now been answered. Moving on from this early achievement, social television should set its sights on making a difference and creating an independent identity for itself.

CONCLUSION

Several years ago we embarked on a project with a simple idea: to create a "virtual couch" that would let people watch TV together even when apart. We quickly found ourselves on a lengthy exploration of a much bigger topic; an exploration that has involved extensive prototyping, reading, and primary research. We have made some surprising discoveries, and on at least one occasion had to change our course.

In that time, the uncharted waters of the topic have been mapped, at least to some extent, by ourselves and others. On three big questions about social television we have at least partial, tentative answers. The exploration is not yet complete, and there may be major discoveries yet to be made in the further reaches of the subject area. However, according to our bearings, some of the emphasis is moving from research to more practical concerns of design, implementation and deployment. Future advancements in social television are likely to come from new products as much as from dedicated research.

ACKNOWLEDGMENT

We would like to thank all the other people who have worked on or been involved with the Social TV project, including Vernell Chapman, Ambiga Dhiraj, Frank Bentley, Dave Wheatley, Josh Hurwitz, Larry Marturano, Seonyoung Park, Timothy Sohn, and many others. Thank you.

Section IV
Utilization and Application

This section introduces and discusses the utilization and application of social computing technologies. These particular selections highlight, among other topics, the many applications of social networking technology, social software, and social marketing strategies. Contributions included in this section provide coverage of the ways in which technology increasingly becomes part of our daily lives as it enables the creation of new forms of interaction among individuals and across organizations.

Chapter 4.1
Social Networking, Adult Learning Success and Moodle

Margaret Martinez

Sheila Jagannathan
World Bank Institute in Washington DC, USA

ABSTRACT

We know that technology is rapidly changing the world and it is hard to keep up. Social networking is the latest online trend we need to learn about. This chapter will consider the enormous changes that impact learners of all ages and offer some insights and resources for those professionals who want to provide more than just another lonely online learning experience. Social networking activities – including sites, blogs, chats, forums and wikis - are emerging to facilitate collaboration and knowledge sharing among adult online learners. The loneliness of the Web 1.0 is passé and the read-only, passive mode of adult learning is fading away. The term Web 2.0 has been used to describe all the new applications useful for a new collaborative or social approach to sharing and repurposing Web content to learn. Just as communities were important in prehistoric times, today online communities are an inherent and critical part of the Web learning experience. Implicit in most Web 2.0+ applications are social activities which help users network, share, create content, seek or research information, or contribute and interact with others. Youthful online learners are a driving force in this new social change, a change that adults can learn from and embrace. Our young Web users find technology is second nature and are unconsciously changing the paradigm of online learning as they communicate and socialize in a variety of new ways on the Web. Many adults are already following this trend. However, these ways of learning can only become mainstream only when many more adults who are responsible for adult learners learn to use the host of networking tools available. Moodle is an example of a popular open source application used successfully by many around the world. Understanding how to support collaborative online learning activities successfully can offer a huge leap towards greater online learning confidence, contribution and achievement. More is yet to come to change the paradigm of online learning and social networking in the future.

DOI: 10.4018/978-1-60566-828-4.ch007

SOCIAL NETWORKING, ADULT LEARNING SUCCESS AND MOODLE

Social networking is not really a new trend. The idea of learning through communication and collaboration is an old one. From the very beginning, humans have always gathered in groups to learn, communicate and socialize in communities with common goals, needs and interests. It is no surprise then that we humans, as the technology evolves, are similarly developing the Web with the same driving, evolutionary forces. Today, this process is enhanced by new online learning technologies supporting what is the next step in the evolution of the Web, commonly known as Web 2.0 or higher. The previous Web 1.0 phase, which was about finding and reading information, has passed—we have evolved. Users everywhere who have Web access are now collaborating passionately on a variety of social networking sites. Web 2.0 users are searching, creating and interacting with others with common interests to fulfill intrinsic needs to self-improve, learn new information and collaborate with others who are enjoying common likes and experiences. An important difference is that today's collaborative, online activities encourage others to engage and participate actively, continually and happily in the creation and use of new knowledge, artifacts and performance. This trend is in contrast to passive acceptance of what others know and pass on without collaboration or retention.

WHAT HAPPENING ON THE WEB? SOCIAL NETWORKING, SOCIAL MEDIA AND WEB 2.0+

There is a huge curiosity about the social networking phenomena. This is a groundswell of using technology to revolutionize learning and communication, especially among young people. More and more users really want to know how all this stuff works, who's doing it and how. Adults are equally becoming more enticed by the new opportunities to collaborate and be part of groups with common goals and interests. Social networking activities – including sites, blogs, chats, forums and wikis - are emerging to support online collaboration and sharing between users/learners more than ever before. Children are eagerly leading the way for adults in this latest fascinating and evolutionary technology trend. The loneliness of the Web 1.0 is over. Web 2.0 is about using new applications offering a social approach to work in collaboration to generate, share and reuse content. These new kinds of social activities and networks spark passions and help users find information, interact, self-improve and contribute. A description appears in the Wikipedia. Retrieved July 15, 2009, from http://en.wikipedia.org/wiki/Web_2.0.

Social networking activities can offer many advantages towards greater more successful online learning. Educators need to understand the opportunities supported by the new Web 2.0 tools and resources, which help harness the power to interact, create and contribute. Social networking websites are used by millions of people to connect with others with common, passionate interests and goals.

Researchers are also curious about social networking. It comes as no surprise that social networking offers other various benefits or influences. For examples, researchers at Harvard Medical School and the University at California, San Diego found that positive social networking relationships can make us happier. Such moods (e.g., happiness) can spread among those connected socially. "Everyday interactions we have with other people are definitely contagious, in terms of happiness," says Nicholas Christakis, a professor at Harvard Medical School and an author of the study (2008).Retrieved July 15, 2009, from http://www.npr.org/templates/story/story.php?storyId=97831171 and http://christakis.med.harvard.edu/

In North America, young adults are especially fascinated with collaborative sites, such as MySpace.com and Facebook.com. Adults are joining online communities too. For example, adults who may want to join charitable social networks that focus on giving back can join the Care2 non-profit foundation at http://www.care2.com/. Other examples are social networks that support families, health, longevity, hobbies, business or educational interests. Classmates.com and LinkedIn.com are examples of two social networking sites that have quickly grown in the last few years to accommodate those with passionate, related interests who want to network to accomplish common goals.

Federal governments and the military are equally involved in social networking to exchange information and interests behind heavily secured networks. In other examples, it is likely that social networking will have an even bigger impact in upcoming years in direct democracy, especially in how citizens involve themselves, voice opinions about how they are governed--nationally and globally. Already in the 2008 election, we experienced the powerful influence that social networking has on politics.

In the past few years, we have seen significant growth in seeing how companies and organizations are deploying consumer Web 2.0+ social networking tools to reach their customer base, e.g., online learning about products. This is a trend that will gain momentum as today's young people join the workforce and get involved in global concerns. Most corporate strategies will be adding social networking features on their site letting their users create profiles and offering opportunities to connect with people with common interests. They will want to support their workforce who are used to online collaboration. Many believe that social networking will have enormous potential for changing organizations, e.g., talent management effectiveness.

According to Awareness Networks, a social media solution provider, the "number of organizations that allow social networking for business purposes has increased, it says, to 69 percent in 2008-up from 37 percent in last year's survey." Retrieved July 15, 2009, from http://www.wipplaw.com/business-social-networking.html

You can find a list of international social networking sites on the Wikipedia web site. Retrieved July 15, 2009, from http://en.wikipedia.org/wiki/List_of_social_networking_websites

Individual Differences Impact Successful Online Learning

An especially important aspect of social networking and the successful acceptance and use of Web 2.0+-style tools is how individuals may need to learn, communicate and socialize differently. In other words, each of us a learning orientation, depending on a different set of genetics and body of experiences that influence how each of us will use our brain differently in different circumstances. Each of us have differences that will impact how we learn and use the Web differently—different abilities, goals, interests, needs and expectations will impact the success of each social networking and learning experience.

Recent advances in the neurosciences in the last ten years have revealed the extraordinary and fundamental impact of emotions on the brain. Emotions impact how we learn, communicate, socialize and set goals to live our lives. Theories about how emotions impact cognition, learning, memory and intention integrate biology with the more traditional psychological and educational aspects. Such neuroscientific theories propose new research foundations and explanations for individual differences and the important impact of emotions, values, intentions, and social factors on measuring and improving learning skills. These new theories will also help us understand how social networking technologies are changing our brain, especially our abilities to communicate, learn and innovate more successfully.

You can find examples of this research in Art of Changing the Brain: Enriching the Practice of Teaching by Exploring the Biology of Learning (Zull, 2002). Another example is Synaptic Self:

How Our Brains Become Who We Are (Ledoux, 2002). Newer books that echo this same research are: Brain Rules: 12 Principles for Surviving and Thriving at Work, Home, and School by John Medina and The Brain That Changes Itself: Stories of Personal Triumph from the Frontiers of Brain Science (James H. Silberman Books) by Norman Doidge.

Based on these recent advances in the neurosciences, Martinez' learning orientation research (2001a, 2001b) provides information about individual learner differences. This research describes how learners think, socialize and approach life differently (learning, goal-setting, risk-taking, setting expectations, etc.) and uses three attributes to suggest reasons why, including independence or autonomy, self-motivation and strategic effort. Retrieved July 15, 2009, from http://www.trainingplace.com/source/research/. The neurosciences help to describe a comprehensive set of neurotransmitters in the nervous system that influence or alter these states to influence choices, learning, communication and social networking. Martinez' research demonstrates how some individuals may find it difficult and stressful to even use a computer for online learning much less sign on to a social networking site without an effective guidance and support system. Others may be good at using one type of collaborative tool but may find it overwhelming or frustrating to have to learn to use a wide variety of resources. Others might get angry if they have to do too much work in a site that does not interest them. The neurosciences and the learning orientation research can help educators understand individual differences and the reasons why some interventions and instructional strategies work better than others in social networking or online learning situations.

Unfortunately, too few educational studies explore how people interact with the Web and use online collaborative tools differently. However in areas such as Neuromarketing (a way to study the brain's responses to marketing stimuli), you will find much more research about individual Web use. Neuromarketing strategies explore how individual users create content, join communities and choose transactions, products and activities. Neuromarketing is a hot topic. An example is how Carnegie Mellon used brain scan research to study how consumers buy products. Retrieved July 15, 2009, from http://www.cmu.edu/news/archive/2007/January/jan3_brainscans.shtml.

Similarly in education and social networking, we need to explore the triggers that influence how learners anticipate, learn, commit and persist. We need to identify and better understand emotions, learning dynamics, relationships, and instructional strategies that provide more personalized, supportive solutions in a more social online learning experience. Tapping into emotions will help individuals make the connections that translate into improvement, progress and achievement. There is a growing body of neuroscientific research and evidence that suggests that each of us are differently influenced by various factors, such as maturity, gender, brain agility, learning, memory and communication ability, exposure to technology, life experiences, facilitation. Such factors are also influenced by an individual's ability to set goals, embrace change and take risks. Working against each of us are negative states, such stress, anxiety and frustration, which are detrimental to the learning and social networking experience. The neuromodulation research demonstrates how these negative emotions act as barriers to learning and communication and can impede progress to communicate, network and strive for self-improvement. Fortunately, these same negative states can shift into more positive states, such as anticipation, exhilaration and satisfaction, with sufficient guidance and support (e.g., using social networking tools and facilitation).

Not all educators embrace social networking tools. Many think such tools are a distraction and not supportive of academic goals. However, the growth of social networking technology demonstrates that many young people are very adept at embracing the innovative social changes introduced by technology. While education might have traditionally underestimated or ignored emotional and social aspects of learning, many young people today seem to be enthusiastic about getting it right. Put an interested kid on the Web with a MySpace account and you will probably not have to worry if he/she will learn how to use the computer or the social networking site. With the combination of enthusiasm, reward and social networking, his/her positive states are aimed at learning very quickly. Educators who can expertly tap into happy, engaged emotions in a supportive social networking environment have a powerful advantage, especially in addressing the individual needs of the learner and helping them with lifelong successful learning experiences.

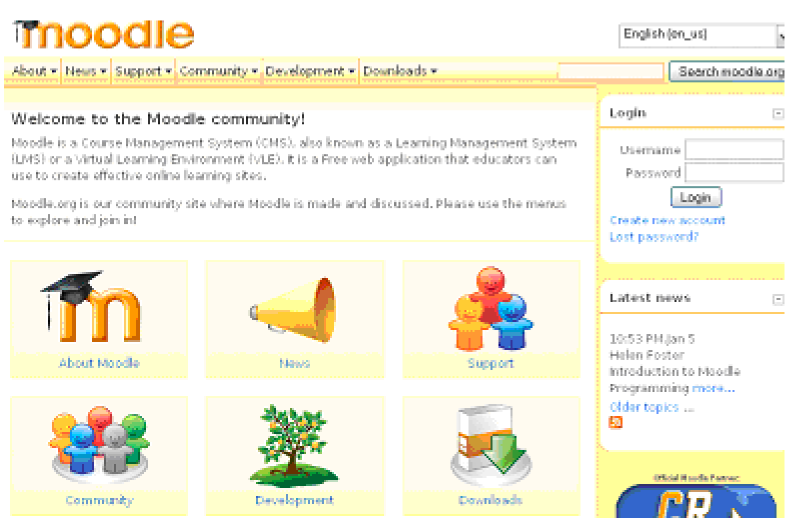
Fortunately in education, Moodle is just one of the social networking applications that has already changed online learning as we know it today. Moodle helps educators create, deliver and manage online courses. Moodle (Modular Object-Oriented Dynamic Learning Environment) offers many social networking tools, resources and activities to support opportunities for rich interaction and especially how people want and intend to learn differently.

Learning and Social Networking with Moodle

Moodle creator Martin Dougiamas, a WebCT administrator at Curtin University, Australia, began working on Moodle to support his dissertation about using "open source software to support a social constructionist epistemology of teaching and learning within Web-based communities of reflective inquiry" (Dougiamas, n.d.). While the dissertation remains unfinished, this research has strongly influenced the development of Moodle. Of particular importance, Moodle supports pedagogical aspects and constructivist and social constructionist activities. These types of considerations are often missing from similar learning and course management applications. The Moodle approach emphasizes that learners and teachers alike can contribute and experience learning using a variety of social networking resources and activities.

Moodle is an open source (free) course management system supported by a global community of developers, professionals and educators who are very passionate to improve the interactive online learning experience based on sound pedagogical

Figure 1. Moodle site at http://www.moodle.org



principles. Also often called a Learning Management System or Virtual Learning Environment, Moodle's open source license means that anyone can develop additional functionality and offer the new solutions back to the international Moodle community.

Increasingly, many schools, organizations and businesses around the world are meeting their online learning and social networking needs with Moodle. The Moodle community is global, rapidly-growing and eager to help with development, implementation, use and course creation. Introduced in 1999, Moodle has deeply penetrated K-12 and higher education and is now supporting the needs of corporations, especially small businesses. In 2006, the Moodle community reported over 22,000 registered web sites offering close to 900,000 courses to over 9 million users.

In less than 3 years, Moodle has multipled its user base with 35,437 registered sites with 24,396,163 users. Retrieved July 15, 2009, from http://moodle.org/stats/. It is easy to see that Moodle has enjoyed tremendous growth in the past few years. Moodle's international appeal is that it helps users create cost-effective online learning and social networking communities in different languages throughout the world; in rich and poor countries alike. Moodle's popularity also stems from the academic community's values of freedom, peer review, and knowledge sharing.

Typically in large organizations, institutions and corporations, Moodle use is restricted to departmental, divisional, or experimental use, particularly because of the lack of IT acceptance and Moodle's non-support of ERP, HR and other business processes. However, Moodle Partners (http://www.moodle.com) suggest that Web Services and W3C standards (e.g., SOAP and XML-RPC) strategies are successfully able to support the enterprise-wide needs of larger organizations. Many Moodle partners are available to offer a variety of corporate features to enhance Moodle capabilities. Whether you work in education, government, or the corporate sector, you cannot ignore Moodle's penetration into the LMS market. While Moodle isn't about to replace the more expensive proprietary enterprise-wide products like Saba's Enterprise or SumTotal's TotalLMS, the global community is using and enjoying Moodle a lot.

Worldwide institutions are deploying Moodle sites on a very large scale. A good example of a large Moodle implementation site is the Open Polytechnic in New Zealand. They have deployed Moodle across eleven polytechnics and three universities, along with several Government departments and a growing number of schools. In 2007, the Open Polytechnic of New Zealand won a prestigious $100,000 award from the United States-based Andrew W. Mellon Foundation. "The annual Mellon Awards for Technology Collaboration recognizes the work done by not-for-profit organisations globally in the field of open source software development and collaboration." Retrieved July 15, 2009, from http://www.icde.org/oslo/icde.nsf/id/DE27144682EDC2AEC1 2573A0003B8C71?OpenDocument. Their site appears at: http://campus.openpolytechnic.ac.nz/moodle/.

In the UK, according to government-funded 2006 OSS Watch Survey, Moodle was the LMS of choice for 56% of UK institutions. Retrieved July 15, 2009, from http://www.oss-watch.ac.uk/studies/survey2006/. Recently the Open University has announced a $7.39 million OpenLearn initiative that offers 900 hours of e-Learning available on their new Moodle platform for over 180,000 learners. Canada's Open University, Athabasca University has switched to Moodle for developing an effective learning management system that serves over 30,000 users for eleven undergraduate and graduate courses.

Similar developments have taken place in several countries ranging from New Zealand to Iceland, from China to Spain as a means of minimizing costs while maximizing reach. Developers, especially at large sites, are very adept at integrating Web 2.0 components into Moodle and expanding the platform to incorporate a larger variety of potential learning activities and learner engagement.

MOODLE'S 'SOCIAL CONSTRUCTIVIST PEDAGOGY' ENHANCES TEACHING AND LEARNING FOR ADULTS

Moodle's online learning innovations excite innovative educators. At its core, Moodle is educational software grounded in a philosophy of collaborative learning, often referred to as social constructionist pedagogy. In this approach, learning is viewed as much a creative, social process as it is an individual one, where people learn together by investigating, analyzing, collaborating, sharing, reflecting and drawing lessons. Perhaps this is a key reason why it has such a rapid uptake among the educational community.

Moodle developers put in core elements (e.g., tasks, activities, resources and tools) that encourage people to learn and develop understanding together by embodying pedagogical principles, including:

- Effective learning takes place when learners are actively engaged in constructing knowledge (i.e., creating or doing), rather than passively reading, memorizing or viewing
- An inquiry- and discovery-based approach is an effective way to learn
- Learners learn better when knowledge is chunked and structured according to a predefined segmentation, e.g. required and optional readings, key messages and in-depth content.
- Observing and interacting with our peers and the community is also crucial for learning and retention
- Collaborative environments encourage participants to be both teachers and learners at the same time
- Learning environments need to be flexible and adapt quickly to satisfy often rapidly changing learner needs
- Creativity and innovations are sparked (emotional appeal) when everyone has an opportunity to engage, contribute and exercise voice and participate

The organization and design of Moodle's interface is to support the learner and the online learning tasks and not technology and the tools. As an organizing framework, Moodle offers a choice of three different course formats to cater to a variety of eLearning experiences. For example, you can organize your course materials using the traditional Topic format, or a Weekly format, in which you organize content chronologically week-by-week, or even a Social format, which is less formal and more discussion-focused.

In terms of features, Moodle has all the standard features of LMSs that support a content-driven learning model (i.e., tools for course structuring, presenting text and multimedia, interactivity, quizzes, and assessments). Figure 2 shows a partial list of available collaborative activities. In addition, Moodle provides a suite of tools to promote interaction and social networking among people by sharing ideas, collaborating in small groups, discussing, and reflecting on experiences (and thereby meets the pedagogical principles summarized in the earlier paragraph). Discussions and dialogs are at the heart of effective online courses, and Moodle supports these through three standard channels of communication: Discussion forums (an asynchronous, public way of sharing thoughts), Chats (a more immediate and simultaneous conversation with groups) and Dialogues (a private channel between two or more people). Research indicates that learners remember only 10% of what they read, and about 50% of what they discuss, proving that these are more effective forms of learning.

In addition, Moodle offers teachers and course designers a toolbox full of powerful, interactive online teaching tools based on Web 2.0 collaborative technologies. A few of these tools that promote new channels of communication, and collaboration are described below.

- The use of online journals encourages participants to reflect on the course and content, to experiment in a safe haven, and to stimulate deep thinking and learning.
- Blogs are relatively new in Moodle and therefore is not as feature-rich when compared with other blogging platforms. However, since blogs for learning are growing in importance, you will definitely see major improvements to blogs in future versions of Moodle. Even in its current form, there is plenty of room for creative applications for blogging in Moodle. Some ways learners can use blogs include: to reflect on new learning, to express opinions, comments on topics, and to share and discuss course related resources, activities, projects. Teachers also find blogs useful to post course information, examples of student work, build a class newsletter, link to another class worldwide, and even to reflect on teaching experiences and offer insights.
- The simple, flexible nature of Moodle wikis makes them a powerful tool for collaborative work. Wiki, which means quick in Hawaiian, is a type of free, on-line writing space where content can be created, edited and viewed by a community of users. The best example of wikis is the Wikipedia (www.wikipedia.org) which is a free, multilingual web-based encyclopedia with over 12 million articles written collaboratively by volunteers. Moodle wikis offer a quick way for learners to collaborate and share ideas textually, while creating a content rich web site. Here the knowledge of the group is greater than an individual, and the end product is the result of the group's interactions. Learners can collaborate to summarize readings or lectures; brainstorm initial thoughts on new ideas, topics, or technology; investigate the authenticity of a topic, e.g., on Wikipedia; collaborate on group projects (where each person contributes a piece); create e-portfolios; and participate in group authoring of presentations, reports, papers and research papers. Computer-savvy users in the teaching community find wikis useful to collaborate on a syllabus or learning materials. Wikis offer huge potentials for building community collaboration and team solutions.
- Glossaries in Moodle help learners internalize the vocabulary of the field by creating definitions collaboratively and negotiating their meanings for common understanding and use. Beyond vocabulary, glossaries can also be used for other brief learning material, such as stories, tips, quotes, examples, and frequently asked questions. The key advantage of a Moodle glossary over a web page it is that its constant presence on the

Figure 2. A list of collaborative Moodle activities

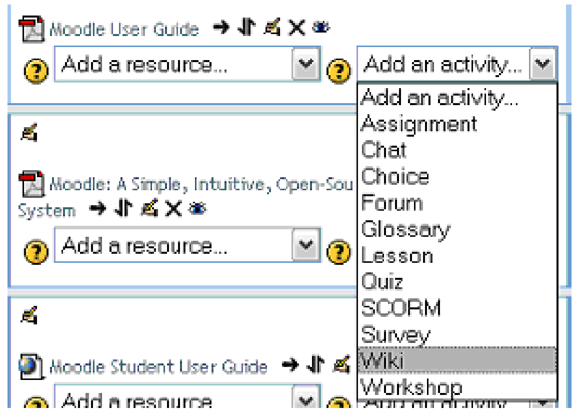


Figure 3. Largest WIKI – Collaborative encyclopedia edited by anyone in real-time

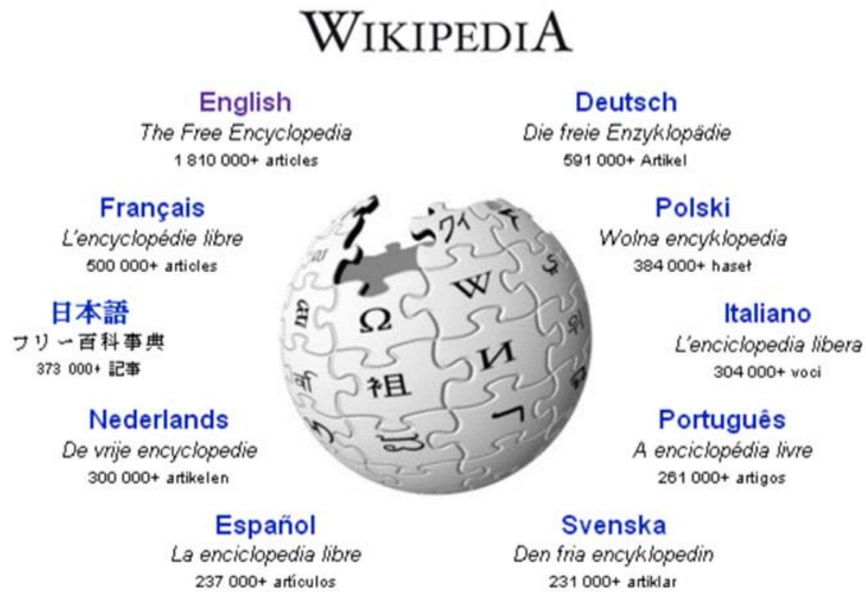


sidebar making it easily accessible from anywhere within the course.

By facilitating the use of various types of multimedia (such as audio, video clips, simulations) as well as a learner-centered approach, Moodle caters to adults with different learning preferences. Also, providing timely feedback and responses to adult learners is important to improve the effectiveness of learning. Moodle allows teachers and learners to provide both quantitative (via grades and reports) and qualitative (via scales that can be customized) feedback for nearly all activities and modules. Moodle features that support reflection address an important criticism of e-Learning compared to traditional face-to-face classrooms. For example, the Assignment module (in which learners can upload their work in any file format), allows the instructor to provide detailed comments in text as well as audio formats. This is true of Discussions, Journal and many other modules, in which feedback and reflection can be encouraged, restricted or made accessible to all participants.

In summary, via the tools and functionality described above, Moodle capably support adult learners. This fits Malcolm Knowles (http://en.wikipedia.org/wiki/Malcolm_Knowles) theory of andragogy, which suggests that adult learners are more autonomous and need the freedom and resources to direct themselves. They know their goals and abilities and they need to be able to connect to their own experience. Typically, adults must see a reason for learning something and then apply new knowledge that relates to their life, e.g., work life.

If you want to learn more about how to use social networking tools in Moodle, you can explore the following links resources for educators:

- Moodle Teaching Techniques, William H. Rice, Packt Publishing, 2007
- Using Moodle, Teaching with the Popular Open Source Course Management System,

Jason Cole, Helen Foster, O'Reilly Community Press, 2007.
- Useful Resources for Moodle Users. Retrieved July 15, 2009, from http://www.ibritt.com/resources/moodlethings.htm

Moodle, like most Web 2.0 tools, are not without some limitations. Some key concerns are described below:

- Vandalism and spam concerns could reduce credibility
- Culture of collaboration needs to be passionately promoted by champions offering incentives in support of common interests
- Inherent intention between control of content vs. freedom to collaborate and innovate
- Privacy issues
- Participants may potentially create legal complications by failing to respect intellectual property rights

Moodle and New Literacies for 21st Century Education

The increasing importance of collaboration for learning in the 21st century can be seen in the recent update to Bloom's taxonomy which factors in the new collaborative behaviors, literacies and new online learning opportunities that arise out of the advances to educational technologies (especially those associated with Web 2.0). As illustrated below, the updated Blooms taxonomy by Arthur Churches includes a digital component that maps out cognitive elements as well as the methods and tools that a teacher would use in the classroom. Such collaborative experiences that facilitate higher-order cognitive process are often facilitated by a variety of digital media increasingly available in Moodle and other CMSs/LMSs/LCMS.

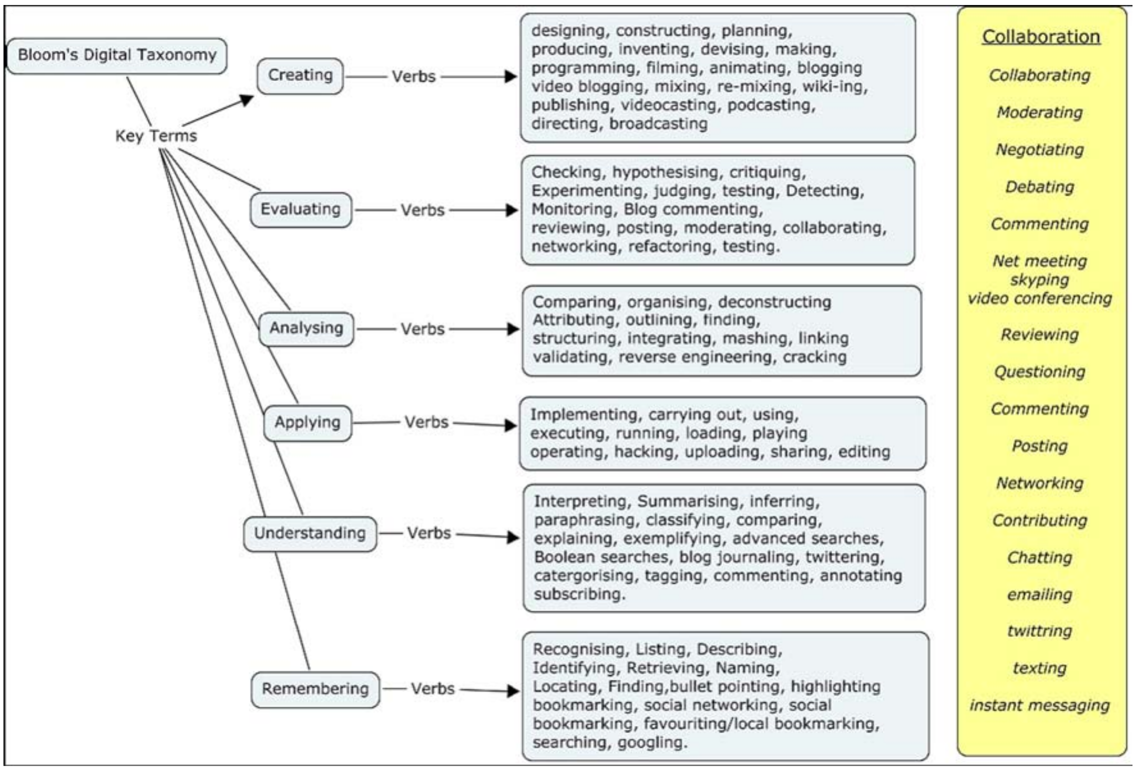
The impact of these Web 2.0 collaborative technologies on adult education is going to be huge, especially for the next generation. In addition to Moodle, just about every new software application that is available today has such tools built in –often free, open source and easy to use. As Will Richardson (2006) puts it "teachers will be using Web 2.0 tools like blogs and wikis and the like in ways that are transforming the curriculum and are allowing learning to continue long after the class ends. They are tapping into the potential of the Web that is a conversation and not a lecture, where knowledge is shaped and acquired through a social process, and where ideas are presented as a starting point for dialogue, not an ending point" (pp. 126). What we have now is a read/write/collaborate Web, which will continue to evolve and grow in the coming years (Richardson, 2006, pp. 126). As educators, we must use the new tools creatively to enhance teaching and learning for future success. To be effective, the role and abilities of adult learners too will need to change to include the new literacies. Learners must learn to be active consumers of information on the Web, be able to articulate and publish their ideas and thoughts online, be adept at working collaboratively with others in virtual environments and also be able to manage vast amounts of information. For adult learners this is a challenge.

FUTURE TRENDS FOR MOODLE

Work is now ongoing for Moodle version 2.0 (Expected late 2009). Follow Moodle's roadmap. Retrieved July 15, 2009, from http://docs.moodle.org/en/Roadmap and Moodle news at: http://moodle.org/mod/forum/view.php?id=82 to monitor upcoming changes. Some changes expected very early in 2009 are:

- File handling improvements
- Conditional activities - allows dependencies and forced paths through activities, e.g., "You can't do this thing until that thing is completed"

Figure 4. Blooms digital taxonomy - Drawing by a churches created using C-Map Tools (© 2008 Andrew Churches. Used with Permission)



- Learner plans and competencies - individuals can have learning plans which are updated when courses are completed
- Improved HTML editor 2.0
- Community hub interfaces – makes it easy for users to find and navigate other systems and external Moodle repositories, leveraging the Moodle Network in various ways. Unit tests (mock db), and remove the need for slashes in user space.
- Feedback module – cleaned up and included as a core module.
- Improved Wiki module (nwiki) - cleaned up and included as a core module. Nwiki is a wiki engine designed to be part of a LMS.

As a supportive adult learning and social networking environment, Moodle seems to be meeting the needs of a very diverse international group whose members depend on sophisticated activities and resources to change education to a more active, social networking and collaborative experience. They see using Moodle to focus on learners and how they learn. It will be fun to sit back and watch the future unfold. Will the number of Moodle sites again double by this time next year or will Moodle be just another passing trend? And, will Moodle keep pace with the trend for a more intelligent, learner or user-centered Semantic Web?

CONCLUSION

Kids are leading the way with the new social networking and technology changes. Our younger generation is having a huge impact as they indulge in the very natural human need to share, collaborate, learn and contribute together as a group with common needs, interests and experiences. Young people are not only familiar with virtual worlds but will expect to access their information and develop their relationships with Web 3D environments.

As a result, adult online learning is also rapidly changing as the technology and trends are changing. Discussions about social networking and Web 2.0 tools are already evolving into Web 3.0 or the Semantic Web discussions. Terms like business and student intelligence and new literacies are also commonly accepted terms. These new developments will "collectively comprise what might be called 'the intelligent Web'—such as those using semantic web, microformats, natural language search, data-mining, machine learning, recommendation agents, and intelligent tutoring using artificial intelligence technologies—which emphasize machine-facilitated understanding of information in order to provide a more productive, intuitive and more personalized or individualized user experience." Retrieved July 15, 2009, from http://computer.howstuffworks.com/web-302.htm.

And already, futurists are discussing Web 4.0. Web 4.0 is still a hazy vision about personal intelligent agents. Retrieved July 15, 2009, from http://blogs.zdnet.com/BTL/?p=4499. "The Semantic Web is an evolving extension of the World Wide Web in which the semantics of information and services on the web is defined, making it possible for the web to understand and satisfy the requests of people and machines to use the web content. It derives from World Wide Web Consortium director Sir Tim Berners-Lee's vision of the Web as a universal medium for data, information, and knowledge exchange. Retrieved July 15, 2009, from http://en.wikipedia.org/wiki/Semantic_Web. It is important to note that these more sophisticated Web technologies have another important impact. As the technologies evolve, complex security threats and privacy, legal and ethical issues will emerge and need to be addressed.

Predicting what the Web will be like in ten years is very difficult. What is clear is that the Web will continue to change the way we teach, learn, work and socialize. More importantly, there is a rapidly growing understanding that the many behaviors are being influenced by social networks and other evolving technology in ways that we have not fully researched or addressed. Social networking is an area where researchers in many disciplines need to ramp up quickly to keep pace with our younger generation. There is less than a ten-year window where universities and corporations will need to develop more intelligent Web 3D learning environments. Environments that are personalized and reactive to individual needs of users and groups of users will become an essential part of the technological learning infrastructure. Within the next five to ten years, a corporation without an intelligent technology, and virtual world presence will be losing market share rapidly.

Chapter 4.2
Use of Social Software in Education: A Multiple Intelligences Perspective

Filiz Kalelioglu
Baskent University, Turkey

Yasemin Gulbahar
Baskent University, Turkey

ABSTRACT

In this chapter, numerous educational activities are presented for instructors in order to address each type of multiple intelligences. Most probably, these educational activities are those which are already being experienced by many instructors. The key point here is that although students are exposed to many educational activities, instructors generally don't have any idea or rather don't consider the learning outcomes in terms of multiple intelligences. In general, assessment activities are based only on the chunk of knowledge that the student gains after any particular activity. In fact, instructors should deal with the effects and improvements in students other than just the knowledge, after engagement in educational activities. Thus, instructors should base their instructional plans on a theoretical basis, especially when integrating technology into their courses. Hence, the development and changing activities and other tasks of social software according to the multiple intelligences that underline individual differences were discussed briefly in this chapter.

INTRODUCTION

Innovations in technology have lead to the transformation of face to face interaction to online environments in past two decades. Many virtual communities have been constituted, for realizing different purposes by means of various technologies. Starting with the oldest and inevitably used technology, which we call e-mail, communication patterns and thus technologies have changed into discussion lists, forums, chat rooms and more recently blogs and wikis. These technologies are primarily used in

DOI: 10.4018/978-1-60566-826-0.ch004

business, nevertheless they have swiftly entered into and extended education. Hence, the latest technologies are used widely in most educational institutions today. The three common approaches for using of technology are to support to traditional instruction, blended learning, and e-learning. Among these alternatives, blended learning is the most prevailing as it has much more advantages than traditional instruction and e-learning (Horton, 2000). Blended learning takes the advantages of the strengths of classroom techniques together with web based training. Thus, the teaching-learning process occurs both in the classroom setting and the virtual environment, and all stakeholders can communicate both face-to-face and online.

Together with integration of the popular approaches, the usage of educational social software has moved forward greatly in distance education and e-learning at first. Afterwards, traditional learning and e-learning have begun to be used together - under the title of blended learning - by possessing the different benefits of both traditional learning and e-learning. In that process research studies have begun to be conducted in order to find out how effective all existing technologies are? Since the emergence of communication tools, many research studies have been conducted to maintain the effectiveness of these tools. Moreover, the results of these research studies have brought about the existence of the field known as computer-mediated communication (CMC).

In order to determine the success of these platforms, studies about students' and instructors' preferences and opinions about social software, content analysis of written posts or logs from the systems, interaction patterns and levels, which point out the usage of these social tools were conducted. Although the effectiveness of communication tools has been investigated from multiple perspectives by using different research methods in various settings, these studies currently do not contain the necessary theoretical framework. Nevertheless a number of conceptual frameworks, such as individual differences, social learning, collaborative learning and constructivism, frequently seemed to be used by many studies for establishing the theoretical foundation. However, the effectiveness of learning is a major concern in these environments since online environments are social platforms. It is necessary to make different theories for clarifying available communication patterns or educational activities in order to reach a more generalized and reliable result.

Under the lights of discussions, educational activities and tasks in these platforms must be constructed according to the theoretical framework. Thus, this chapter aims to discuss the development and changing activities and other tasks of social software according to the multiple intelligences that underline individual differences.

MULTIPLE INTELLIGENCES THEORY

"Multiple Intelligences Theory", proposed by Gardner (1993), approaches learning and instruction from a different perspective. Some researchers have claimed that our intelligence or ability to understand the world around us is a changing process, where people show diversity in terms of understanding and learning. Abilities in performing different skills may differ from individual to individual. One person may be good at playing a musical instrument; one individual may be good at playing football and another maybe good at writing poems. These differences among people are addressed in the multiple intelligences theory. To give an example, if an individual has strong spatial or musical intelligences, instructors should encourage those students to develop these abilities. Gardner points out that the different intelligences represent not only different content domains but also learning modalities.

Howard Gardner viewed intelligence as the capacity to solve problems or to fashion products that are valued in one or more cultural setting (Gardner & Hatch, 1989). Although Gardner initially proposed a list of seven intelligences, he

Table 1. Multiple intelligences

Type of Intelligence	Description
Verbal-Linguistic intelligence (Word Smart)	Interested in spoken and written language, the ability to learn languages, and the ability to use language to accomplish certain goals like effectively use language to express ideas.
Logical-mathematical intelligence (Number Smart)	Addresses the capacity to analyze problems logically, solve mathematical operations, and investigate issues scientifically. Examples maybe detecting patterns, reasoning deductively and thinking logically.
Visual-Spatial intelligence (Picture Smart)	Involves the potential to visualize graphics such as three-dimensional objects, imagine the details of an object mentally and draw visually appealing graphics and arts.
Bodily-kinesthetic intelligence (Body Smart)	Includes the potential to use one's whole body or parts of the body mentally and physically in harmony. The coordination of bodily movements in a rhythm, balanced and flexible way is the core of this type of intelligence.
Musical-Rhythmic intelligence (Music Smart)	Involves skills in the performance, composition, and appreciation of musical patterns. The ability of recognition and composition of musical pitches, tones, and rhythms are also among the important tasks of this type of intelligence.
Interpersonal intelligence (People Smart)	Deals with the abilities to understand and interpret the intentions, motivations and desires of other people emphatically. Effective communication and collaboration is also covered in this type of intelligence.
Intrapersonal intelligence (Myself Smart)	Involves an individuals' ability to recognize herself / himself in terms of trust, problems, feelings, fears and motivations. Knowing one's own capacity and deciding on what to achieve is also among the properties of this type of intelligence.
Naturalist intelligence (Nature Smart)	Deals with sensing patterns in and making connections to features and elements in environment and nature. It also enables individuals to recognize, categorize and draw upon certain features of the earth.

later made additions to this list. For this chapter, eight intelligences are taken into consideration: Verbal-Linguistic (Word Smart), Logical-Mathematical (Number Smart), Visual-Spatial (Picture Smart), Bodily-Kinesthetic (Body Smart), Musical-Rhythmic (Music Smart), Interpersonal (People Smart), Intrapersonal (Myself Smart) and Naturalistic (Nature Smart) (Smith, 2002, 2008; Brualdi, 1996; Gardner, 1993, 2006; Gardner & Hatch, 1989; White, 1998).

In the light of these facts, educational social software can be investigated in terms of different intelligence types. Furthermore, the tasks given to students may be organized in a way that addresses multiple intelligences. In this way, not only will technology be integrated into teaching-learning processes in an effective manner, but students will also have the opportunity for improvement in the different multiple intelligences. As also suggested by McCoog (2007), one of the best ways to make students acquire 21st century skills such as global awareness and social responsibility, is to differentiate instruction through the use of Gardner's multiple intelligence and technology.

For this chapter, blogs, wikis, instant messaging, forums and e-mail technologies have been selected for investigation from a multiple intelligences perspective. Before going any further, it will be useful to understand these technologies in more detail.

BLOGS

Blogs are called as a method of effective communication in online environments, and innovative ways to use them in education are frequently appearing nowadays. Originally, a blog was an online diary posted on the web that included the publication of personal thoughts, feelings, hobbies, and experiences in a chronological order.

Blogs can also be defined as online writing tools that help their users to keep track of their own online records (Hsu & Lin, 2008). Anyone who doesn't have advanced computer and Internet usage skills can still create such web pages, and express their feelings to others with the help of blogs. Furthermore, blog users and non-blog users can post their comments on the written issues easily. Depending on the authors' preferences, these online writing tools can include features such as links to other blogs, the author's detailed profile, and most importantly feedback from readers (Ellison & Wu, 2008). Blogs can be used for many purposes, but when they are used for educational goals, they can enrich the classroom environment and facilitate social interaction among students. Instructors can integrate blogs in blended and online learning to facilitate specific strategies: posting student work, exchanging hyperlinks, fostering reflective approaches to educational genres, forming and maintaining knowledge communities (Oravec, 2003).

Moreover, usage of blogs can address some of the theoretical underpinnings that are summarized below (Glogoff, 2005):

- In instructional blogging, as a knowledge-centered instructional tool, the instructor designs research activities that engage students in discussions with practitioners, and lead them through developmental concepts of the discipline's knowledge domain.
- In learner-centered blogging (that acknowledges the important attributes of learners as individuals and as a group), the instructor gives positive feedback to students regarding their comments and by posting comments for discussion. In this way, learner-centered blogging offers particularly useful opportunities for learner-centered feedback and dialogue.
- For providing community-centered instruction, blogging supports the importance of social and peer interaction.
- As a receptive learning tool, blogging can encourage students to acquire information from resources and reflect on what they have gathered.
- In a directive learning environment, blogs provide students with equal access to information, to expand students' understanding of specific issues, and to direct students to explore additional material.
- As a guided discovery and knowledge construction, blogs can also be used to present information architecture and explore more from web sites for other content.

To briefly summarize their many purposes, blogs can easily be used in educational environments. Publication of any materials, course notes, reflections may lead others to review, comment or study. At the same time, blogging not only supports individual sharing, but also allows other visitors to interact with the archived content, blog readers and the owner.

WIKIS

A wiki is a collection of web pages linked to each other which reflect the collaborative effort of many students working together. "Although it is not known as content management systems, wiki systems are another approach to publishing on-line information and a different way to collaborate" (Pereira & Soares, 2007, p. 88). Unlike blogs, which are chronologically reverse-organized, wiki pages are loosely structured but are linked in different ways (Beldarrain, 2006). Namely, "a wiki is a web site in which users can create and collaboratively view, edit, track changes, and save information by means of web browser" (Butcher & Taylor, 2008, p. 34). In these wiki pages, the instructor can also assess, edit or delete the information posted by the students, while students in a team can revise-edit, comment, contribute, reference or study.

Table 2. General information on blogs (adapted from Hsu, 2007)

BLOGS	
Description	A technology that allows a sequence of entries to be posted and published online
Advantages	Reflection and critical thinking Authenticity through publication Social presence Development of a learning community Active learning Ability to receive and respond to feedback
Disadvantages	Controlled primarily by blog author Editing/modifications not open as in a wiki
Educational applications	Online learning journal Problem solving/manipulation space Online gallery space (writings, portfolio, other work) Peer review exercises
Course/ subject suitability	Writing courses Foreign language courses Research seminars
Theoretical foundations	Activity theory Guided discovery Cognitive scaffolding Receptive learning Social cognition Community practice Communities of inquiry

One of the most well known examples of a wiki is Wikipedia, an online encyclopedia with entries authored and edited by different people from around the world. Wikis are very useful tools for educational purposes, since they encourage student participation and also a sense of group community. "Indeed, an important element of this is the relaxed sense of control over the content, allowing students to have a greater role in managing its focus and direction" (Hsu, 2007, p. 80).

The attractive characteristics of wikis can be summarized as follows by Shih, Tseng and Yang (2008).

- **Rapidity:** The wiki pages can be rapidly constructed, accessed and modified, in hypertext form.
- **Easy:** A simple markup scheme (usually a simplified version of HTML) is used to format the wiki pages, instead of the complicated HTML.
- **Convenience:** Links to other pages, external sites, and images can be conveniently established by keywords. Moreover, the targets of the keywords, links, need not exist when the links are built. They can be appended later.
- **Open source:** Each member can create, modify and delete the wiki pages. Wiki content is not reviewed by anyone before publication, and is updated upon being saved.
- **Maintainability:** Wiki maintains a version database, which records its historical revision and content, thus enabling version management.

In summary, a tool for collaboration and a form of groupware, wikis can be used for courses and activities where there is a document, text, or other project to be worked on jointly by a class or group. The compilation of a class or group report

Table 3. General information on wikis (adapted from Hsu, 2007)

WIKIS	
Description	A technology that allows for material to be easily published online, and also allows open editing and inputs by a group
Advantages	Contributions and editing by a group Open access to all users Collaborative
Disadvantages	Lack of organization and structure may result in an unmanageable wiki Tracking of contributions and modifications can be difficult Quality control
Educational Applications	Collaborative writing/authoring Group project management Brainstorming activities Knowledge management
Course/ subject suitability	Knowledge management Writing Group work in courses
Theoretical foundations	Conversational technology Constructivist learning tool

or project, the creation of a knowledge base, or brainstorming sessions appear to be viable applications (Hsu, 2007).

INSTANT MESSAGING (CHAT)

Synchronous discussion, or chat or instant messaging, refers to online dialogue occurring in real time. In chat sessions, there is no time delay between the sender's transmission and the receiver's receipt of the message unlike asynchronous communication (Borowicz, 2004).

Instant messaging engages geographically-distanced students in synchronous dialogues and offers a flexible platform for knowledge construction. Moreover, chat can be used to enhance out-of class learning activities by supporting collaborative learning and improving communication (McCreary & Ehrich, 2001).

Chat can be used in educational settings for many purposes. For example, in distance education it can be used for meeting with students once a week or twice a week, thus facilitating regular meetings, since online discussion lies at the core of distance courses. Moreover, in a blended environment, other activities can be arranged in which all students from a variety of locations are given a problem to solve collaboratively, meaning virtual problem solving groups. Students can invite people such as expert in various fields, community leaders, and others to their chat sessions. Furthermore, it is possible to communicate other people to practice language skills with the help of chat programs (Ingram, Hathorn & Evans, 2000).

For effective usage of instant messaging in courses, and to affect the quality of educational discussions, Ingram, Hathorn, and Evans (2000) identify a number of critical issues for instructors:

- **Environment:** As the graphical environment of the chat rooms is important, it is advised to use a chat program supporting graphical-based programs instead of text-based ones.
- **Task:** A clear discussion topic or detailed description of the expected product at the end of the discussion should be offered to the students. A second important issue for

Table 4. General information on instant messaging (adapted from Hsu, 2007)

INSTANT MESSAGING	
Description	Synchronous communications that allow for informal communications to be conducted easily and quickly
Advantages	Availability and acceptance by students Social presence Synchronous communications Encouraging collaboration Reduces formality in communications
Disadvantages	Distracted attention Expectations of 24-7 instructor access Can be time consuming for instructors Benefits are uncertain in classroom settings
Educational applications	Virtual office hours Collaboration on group projects Synchronous class discussions Mentoring
Course/ subject suitability	Courses with group projects and assignments Distance learning support
Theoretical foundations	Active learning Dual (verbal and visual) processing

offering task is type of task, i.e. tasks that require research and review of other materials would not be appropriate for this type of synchronous online discussion tool.

- **Rules:** A clear set of rules is useful for controlling and directing discussions in the chat sessions. It is also important for students to know when to write and when to read.
- **Group-size:** Synchronous online discussion tools usually work best with small groups of three to five students. When group size is larger than this range, it is advisable to divide discussion groups into separate groups in different chat rooms.
- **Identity:** To prevent a student from hiding their own identity, it is advised for students use their own name and not to mislead the rest of the group and the teacher with nick names.
- **Moderation:** According to factors such as large group size, task type or level of students, the instructor may prefer to find a moderator to lead the discussion and keep it on track.

Instant messaging, which is a synchronous tool mostly used to communicate, can also be used to support distance and blended learning to enhance learning activities by supporting collaborative learning. Possible activities may be performed by using chat programs in educational settings in a way of short discussions individually or as a group. Some activities may consist of role playing, conversation in different languages, word games in different languages, grammar games in different languages, brainstorming, summary of a subject taught previously, problem solving activities, case studies and peer review/editing.

FORUMS

A forum is an asynchronous platform where students can communicate by posting messages and responding to them for collaboration or discussion. If it is used for academic discussions or

Table 5. General information on forums

FORUM	
Description	Asynchronous communications that allow for communication and discussion to be conducted easily
Advantages	Availability and acceptance by students Social presence Asynchronous communication Encouraging collaboration Reducing formality in communication
Disadvantages	Distracted attention
Educational applications	Collaboration on group projects Asynchronous class discussions Mentoring Peer review exercises
Course/ subject suitability	Courses with group projects and assignments Distance learning support
Theoretical foundations	Active learning Dual (verbal and visual) processing

out-of class activities, online forums can enhance learning processes (Chen & Chiu, 2008). The most useful educational advantage of online discussion forums is to provide the time available for reading a message and think about a response, which can help to improve reflection upon and development of a topic (Guiller & Durndell, 2007).

Discussion forums can be used for many different purposes in different educational environments. The forums may be used as a support to distance or blended learning for social interaction, for discussion of topics towards answering the frequently asked questions, and for individual homework or group projects as a collaborative tool. Differentiated according to the purpose of the forum, instructors may:

- "limit discussions to one or more instructor-initiated themes,
- lead more general discussions,
- assume the role of answering most of the questions from students,
- moderate the discussions but maintain a low profile in them, or even be entirely absent from the discussions" (Mazzolini & Maddison, 2003, p. 238),
- assign a student as a moderator, and
- support discussion and motive to join non-participants into debate.

The discussion in the forum can often be carried out easily within small groups, which made up of four to eight students for learning sets or medium sized group with 20 to 30 students for discussions. If the forum is supposed to set up for very large groups, there may be disappointment with the levels of participation and there may be disorder of posted messages, so that it becomes unmanageable. Conversely, in small groups it is easy to control and follow the messages and information and also the participation level of the students. The participation in the discussion is not only important in face to face environments, but also it is an important concern within any small group in an online environment (Hammond, 2000).

E-MAIL

E-mail (electronic mail), which is a service for sending messages electronically, allows communication among people regardless of the status of

Table 6. General information on e-mail

E-MAIL	
Description	Asynchronous communications that allow for communications and discussion to be conducted and send messages electronically
Advantages	Asynchronous communications Encouraging writing and communication skills Reducing formality in communications Sending messaging to more than one person
Disadvantages	Distracted attention Time consuming for answering complicated questions
Educational applications	Asynchronous class discussions Peer review exercises
Course/ subject suitability	Courses with group or individual projects and assignments Distance learning support
Theoretical foundations	Active learning Dual (verbal and visual) processing

people, i.e. whether they are online or not. Moreover, the exchange of electronic text messages and computer file attachments between computers requires people to have a mail account, which is a place where someone can contact another person. Furthermore, an e-mail address is a unique name that identifies an e-mail recipient for the transfer of information from one computer to another. It is possible to store, send, compose, forward and receive messages over electronic communication systems by means of the using e-mail.

E-mail can also be used for many purposes. These purposes may be mainly for communication and the transformation of information. Palmer (2000) illustrated internet usage in education, noting that the WWW (for the delivery of multimedia content) and e-mail (for basic electronic communication) are the two important Internet services for teaching and learning. If the students and instructors cannot easily arrange face-to-face meetings, it is important to use e-mail communication (Lightfoot, 2006; Le & Le, 2002).

Martin (1996) chose the e-mail method in his courses in a research study because "student assessment was through requiring students to summarize, comment or discuss the content of each lecture", and "most of the students were part time, visiting the campus only for the scheduled classes" (p. 823).

Being an easy method to send messages, information or other kind of materials by just a few mouse clicks, the instructor want to take into consideration some issues. Instructors can:

- choose a topic for which individualized communication can take place and create links outside of regular space, time,
- support detailed analysis and reflection,
- give participants insight into others' perspectives, and
- keep records of the dialogues and messages (Cook-Sather, 2007).

CREATIVE IDEAS TO USE SOCIAL SOFTWARE IN EDUCATIONAL SETTINGS FROM MI PERSPECTIVE

Considering the advantages, opportunities and educational applications, social software can be integrated into many courses in various ways. Differentiating among intelligence types, social software can be used to create, modify, share, publish, and store course content while also offering communication flexibility. A list of educational activities addressing multiple intelligence types are presented in table 7. The concept and subject can be varied according to the type of intelligence and activities can be enhanced in this way.

For example, if students are required to complete a brochure with a word processor, the tasks and requirements should include steps such as: download a brochure template from the web site, modify the style and formatting of the template, choose a place to introduce or create a place never seen, search for images and information for that place, place images and information into the brochure template, and save and share this product via appropriate educational software. Adding details not only makes educational activities more extensive, but also addresses more than one type of intelligence. In this example, it is thought that Verbal-Linguistic, Bodily-Kinesthetic, Visual-Spatial, Intrapersonal and Naturalist intelligence types are emphasized through the completion of this kind of brochure.

For the effective integration of educational social software into existing curricula and courses, instructors should take into consideration the following suggestions. These suggestions will lead instructors to being able to achieve two major goals. The first goal is the improvement of the ICT skills of students through proper use of recent technologies. Use of the latest technologies to communicate and share resources will provide students the chance of having or improving their ICT skills and become lifelong learners which is expected of them as 21st century students. The second goal addresses the improvement of multiple intelligences. Performing tasks addressing different multiple intelligences will not only yield the manifestation of the dominant intelligent types but also provide opportunities for improving the less dominant intelligence types. In order to enhance students' ICT skills by addressing various types of multiple intelligences, instructors should be aware of the capabilities and opportunities that the software provides.

As previously mentioned, blogs provide users with a platform where people can post messages and others may view and respond to these posts. Moreover, the blog users can upload files, images, sounds, video, etc. to create more amusing content for their viewers. All the content elements are kept in a certain section or category named by owner. Distinct from blogs, a wiki is a type of web site which enables the students to add, remove, and edit the available content and includes the collaboration of work from many different author that is wikis can be seen as a community for collaborative documentation. Discussion forums, applications allow users to post messages and replies, also the linking of images, videos, sounds or other types of files with the help of other web sites offering opportunities to upload files. Chat programs and e-mail provide the opportunity for sharing all types of file with attachments. Transmission of information is sent in real-time in chat programs, whereas there is a little time delay in the e-mail method according to the status of servers.

Moreover, after realizing the potential benefits of the software, an instructor should take into consideration which multiple intelligence domains is mostly covered by the selected software. Hence, as also suggested by Nelson (1998), instructors can design their lessons including new learning activities fitting the individual strengths of all their students by using internet and web tools. Thus, the list in table 8 is provided to serve as a guide for instructors while addressing multiple intelligence types.

In the light of these facts, some suggestions for instructors in order to support courses with the use of social software for improving multiple intelligences of students are listed as follows. For each type of intelligence, possible computer software, educational tasks and activities have been explained separately.

Suggestions for Verbal-Linguistic Intelligence (Word Smart)

Students may prepare a composition, a story, a poem, a report (on a film, a theatre play...), a summary report, a newspaper, a brochure or a scenario through word processors. Using audio editing tools, students create recordings of a sketch, a composition, a poem, storytelling, news program, interview, scripting, choral reading and retelling. Through audio-video conferencing, students make discussions on a previously given topic. Using presentation software, students may design a narrated presentation on a given topic.

Suggestions for Logical-Mathematical Intelligence (Number Smart)

Students may create scoring pages by using spreadsheets. With the help of puzzle maker programs, students may prepare puzzles. Through mathematical and scientific software, it is possible to solve equations and draw graphs and moreover, students may report causes and effects of solutions. With the help of programming languages and database management programs, students may write codes to create databases. Playing strategic, logic and mind games and simulations is another type of activity to be completed according to lesson objectives.

Suggestions for Visual-Spatial Intelligence (Picture Smart)

By using a graphics/image editor, students can design graphics, cartoons, posters, and can create concept maps with concept map software, worksheets and flowcharts with word processing. Moreover, through 3D modeling programs, students may 'architecturize' real-life objects. It is also possible to integrate actual taken photos into animation programs to present a slide show or create a video in video editing programs. Through architecture software, students can create samples of buildings according to the given scale.

Suggestions for Bodily-Kinesthetic Intelligence (Body Smart)

Students may have the chance to drag and drop cards, elements, objects etc. in the computer-aided environment by using drill and practice software. Playing any games, simulations, strategy and card games, or any programs reinforce this type of intelligence.

Suggestions for Musical-Rhythmic Intelligence (Music Smart)

Audio editing software makes it possible for students to create audio clips by mixing sounds and adding effects. It is also easy to add sounds and audio clips to animations designed in multimedia software or authoring languages. Moreover, PowerPoint slides including sounds or sound effects can be produced. Besides these kinds of activities, it is easy to play virtual instruments with the help of musical software.

Suggestions for Interpersonal Intelligence (People Smart)

By playing video games that involve hundreds of players simultaneously, for example massive multiplayer online games, students can interact and communicate with others. Communication, consensus, and collaboration are the other main concepts underlined by group projects completed in any software in project-based learning. Likewise, the completion of a WebQuest requiring role playing enables students to empathize with one another in different situations. Moreover, joining a video conference, a type of connection of groups via satellite or codec technology, also can be recorded and shared via educational social software. By moderating a chat session or a discussion in a forum, students are able to follow the flow of discussion, communicate and interact with others in a more responsible manner.

Suggestions for Intrapersonal Intelligence (Myself Smart)

Through the usage of word processing, students can design curriculum vitae including the individuals' life history, job history, achievements and skills. With the help of virtual courseware, tutorials and drill and practice, students may study and repeat their lessons at their own pace. Through search engines, students can make research on a topic individually and prepare a reflection paper via word processor. To publish personal feelings, photographs, interests and hobbies, a personal web page can be created using web page development tools.

Suggestions for Naturalist Intelligence (Nature Smart)

Video editing programs provide students to create a documentary film covering possible environmental problems and solutions: i.e. environmental pollution, weather pollution, sea pollution and global warming. Through graphic/image editing software, students can design a poster that announces the issue of waterlessness and smart usage suggestions for it. Again in the same software, it is possible to create a banner that gives a message to stop forest fires for use at the top of web page. In animation programs, students can create season timelines to depict the differences between seasons.

DISCUSSION AND CONCLUSION

Today, all these tasks require technological literacy to some extent. Since the traditional curriculum does not promote the acquisition of contemporary technology skills, many attempts at integrating technology into the curriculum have been made and are still continuing. Being aware of the potential contributions of technology during and after graduation, instructors should use technology for its anticipated effects on students. Instructors should be aware of how children learn through technology, and should facilitate students' pursuit of inquiries, and their development of critical thinking and problem solving skills through the use of collaboration, communication and technology.

These issues notwithstanding, the method of integration of educational social software should be based on one or more of these learning theories. The answers to questions, "how do students learn with technology" and "how can the content be delivered through technology", which are related to educational practices and activities, should follow a learning theory. Moreover, the integration of social software should also meet basic learning needs and goals for students. Some technologies like internet and web tools supporting individual and collaborative learning, classroom presentation, discovery/exploration, synchronous and asynchronous communication and distance learning, provide environments for teaching that focuses on students' individual strengths (Nelson, 1998). Hence, instructors should effectively integrate social software into their courses, and should prepare their students for their future careers as lifelong learners, by providing a variety of activities promoting the development of the multiple intelligences.

A review of educational social software and multiple intelligences theory has shown that no single educational software and no single educational activity based on computer software may not address the expectations of all students. Thus, educational social software and activities which are to be performed by students should be carefully selected in order to meet the diverse needs of all students, and make them achieve expected learning outcomes. Moreover, the selected social software should also support the type of content to be shared with students.

In this chapter, many educational activities are presented for instructor use in order to address each type of multiple intelligences. Probably, these educational activities are those which are already being utilized and experienced by many instructors. The key point here is that although students are exposed to many educational activities, instructors generally don't have any great idea about, or don't consider the learning outcomes in terms of multiple intelligences. Generally, assessment activities are based only on the chunk of knowledge that the student has gained after the particular activity. In fact, instructors should be dealing with the effects and improvements in students other than their knowledge after engagement in educational activities. A curriculum that combines technology and some learning theories such as multiple intelligence supplements students' strengths and expands their possibilities (McCoog, 2007). Thus, instructors should base their instructional plans around a theoretical basis, especially when integrating technology into their courses.

Technology, especially computers, are multimedia tools which provide students with many attractive features such as sounds, pictures, animations, films, visual appeals, virtual field trips and three dimensional visions. When instructors encourage students to use their different intelligences creatively, students may have the opportunity of extending and enhancing their own capabilities and multiple intelligences. Noting that "technologies set out to be mobilized for better instruction" (Gardner, 2000, p. 33), we need to realize how various technologies can help students to develop different capabilities and skills. It is not the presumption that all technologies can help all students equally, but that certain technologies can help certain students (Veenema & Gardner, 1996).

Each type of multiple intelligences supports certain instructional strategies. The ultimate goal of instructional strategies is to meet the overall needs of each learner in the class and therefore might require designing multiple lessons (McCoog, 2007). In order to support a student who possesses strong verbal-linguistic intelligence; activities should be mainly in the scope of the world of words. These educational activities may for example include researching the origins and meanings of the words from online dictionaries, online encyclopedias or e-books, learning how to speak in other languages, learning the grammatical structures of other languages, playing word games such as hangman, puzzles etc, preparing an online book or e-book on a given subject, writing a composition, a story, a poem, a report, a newspaper, a brochure or a scenario via word processor, etc. These activities mainly address the improvement of the quality of the students' writing and expressing his/her feelings.

From the logical-mathematical perspective of the students, by means of educational software students can conduct an experiment and see its results, prepare a crossword or any type of puzzle, write scripts using programming languages, draw graphs, play strategic, logic and mind games and simulations, etc. These activities mainly help to improve the analytic, critical thinking and also problem solving skills.

For empowering students who have visual-spatial intelligence; activities should cover the 'visuals'. It is easy to hold this kind of students' attention on a topic by allowing them to prepare movie clips, timelines, posters, graphics, and cartoons, integrate photos into animation programs to present a slide show or create a video in video editing programs, etc. Moreover, through 3d modeling programs, students may 'architecturize' real-life objects. Also, publishing or sharing his/her products to the visitors via web pages, blogs and other types of educational software will encourage the student to produce more.

All the educational activities completed with the use of a computer-based environment support the usage of the skills of students with bodily-kinesthetic intelligence. The fact that computer applications are required to be used with a keyboard, joystick, mouse or other kind of hardware, students have to use these with physical skills, which is the scope of this intelligence. Therefore, using drill and practice software, playing any games, simulations, strategy and card games, and students may have to drag and drop cards, elements, objects, etc. in the computer-aided environment.

To support students with musical-rhythmic intelligence, educational activities should include activities based on music or musical forms. For example, activities may include adding sounds to presentations, animations, creating audio clips by mixing sounds and adding effects. Moreover, allowing students to play virtual instruments may keep interests in lessons alive.

For the students who have strong interpersonal skills, educational social software serves as a communication tool. It is easy to interact with other students by completing a project, playing video games with other players, joining a video conference, etc. Moderating a chat session or a discussion in a forum allows students to follow the flow of discussion, communicate and interact with others in a more responsible manner.

Individualized learning for the students possessing strong intrapersonal intelligence type is also applicable with all type of computer-based software. For example, tutorials, drill and practice software, simulations, web-based courses, educational games allow students to progress at their own pace. Through the usage of word processing, students can design curriculum vitae including the individuals' life history, job history, achievements and skills. Through search engines, students can conduct research studies on a given topic individually and prepare a reflection paper via word processor. To publish personal feelings, photographs, interests and hobbies, personal web pages can be created using web page development tools. Also, a self-improvement report with graphs prepared via word processing make this kind of student aware of their capacity, meaning things which are in the range of his/her ability and things which are not.

In order to support students with naturalistic intelligence, computers and the internet help them to explore the world as a virtual world. For example, virtual museums about dinosaurs, nature, or history offer a journey to the ancient times. Image galleries about underwater life, e-books about the environment, and videos including different scenes of the world may hold the attention of this type of student in educational applications. Moreover, some self-prepared activities will cover this kind of intelligence, such as creating a documentary film including global warming, a poster describing waterlessness and a banner giving a message to stop forest fires, etc.

The creation of educational applications underlining multiple intelligences and usage of a medium for delivering these via educational social software may motivate students to hold their attention on various topics. Moreover, it is possible to make them like the topics they may have previously disliked. Through a variety of intelligences, educational activities can be enhanced and attract the students' attention. Therefore, instructors try to use these technologies or explore new technologies in order to get an answer to the question as to how students learn best through technology. Furthermore, instructors should facilitate their students' sense of inquiry for their development of critical thinking and problem solving skills. Finally, instructors can keep in mind that technology-based activities enhance their intelligence, interest, and improve their communication and collaboration with each others.

CALL FOR RESEARCH

Some possible research studies can be conducted in order to discover answers to the following questions:

- What are the preferences and perceptions of the students about artifacts they produce in terms of sharing them in educational social software?
- What is the contribution of completed educational activities to the development of different type of intelligences?
- Which educational activity may lead students who have dominant or innate intelligence types to learn more easily?
- What are the suggestions of the instructors about the integration of these activities into the curriculum as an integration model according to their experience?

- How can educational activities addressing multiple intelligence be best assessed? What are alternative assessment types?
- How can an e-portfolio be used from multiple intelligence perspective?
- How to design courses where the communication and collaboration is based on educational social software from a multiple intelligences perspective?
- How can technology-based educational activities be differentiated according to levels of primary, secondary and high school students?

Chapter 4.3
Using the Social Web for Collaborations in Software Engineering Education

Pankaj Kamthan
Concordia University, Canada

ABSTRACT

The discipline of software engineering has been gaining significance in computer science and engineering education. The technological environment in which software engineering education (SEE) resides and thrives has also been changing over the past few years. A technological revitalization of SEE requires a considerate examination from human and social perspectives. This chapter studies the impact of integrating Social Web technologies and applications based on these technologies in collaborative activities pertaining to SEE. In particular, teacher–student and student–student collaborations, both inside and outside the classroom, are highlighted. In doing so, the feasibility issues in selection and adoption of technologies/applications are emphasized and the use of pedagogically-inclined patterns is made. The potential prospects of such an integration and related concerns are illustrated by practical examples

DOI: 10.4018/978-1-60566-368-5.ch048

INTRODUCTION

In the last decade, software engineering has been playing an increasingly prominent role in computer science and engineering undergraduate and graduate curricula of Universities around the world (Rezaei, 2005; Surakka, 2007). As software engineering matures, the question of how its body of knowledge is shared, communicated, and consumed arises. In particular, the role of collaboration is likely to remain crucial to software engineering in the foreseeable future (Whitehead, 2007).

Like other disciplines, software engineering education (SEE) is prone to evolution. To do that, it needs to be sensitive to the variations and evolution of the social and technical environment around it. In particular, any changes in the information technology (IT) environment need to be reflected in SEE, if it leads to viable opportunities and demonstrated benefits (Kamthan, 2008b).

The Social Web, or as it is more commonly referred to by the pseudonym Web 2.0 (O'Reilly, 2005), is the perceived evolution of the Web in a direction that is driven by 'collective intelligence,' realized by information technology, and characterized by user participation, openness, and network effects. In particular, the Social Web has enabled new avenues for collaborations (Coleman & Levine, 2008).

The aim of this chapter is to assess the implications of the Social Web for teacher–student and student–student collaborations in SEE, and underscore the prospects and concerns in doing so. It assumes a basic background in software engineering (Ghezzi, Jazayeri, & Mandrioli, 2003) on part of the reader. The terms Social Web and Web 2.0 are used interchangeably. For the sake of this chapter, it is also acknowledged that the notions of *coordination* and *cooperation* differ from the term collaboration and are subsumed by it.

The rest of the chapter is organized as follows. First, the background necessary for later discussion is provided and related work is presented. This is followed by a proposal for a systematic introduction of the Social Web technologies/applications for collaborations in SEE, labeled SW4CSE2 henceforth. The prospects of SW4CSE2 are illustrated using practical examples. The limitations of the underlying Social Web technologies/applications are highlighted. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

For the sake of this chapter, collaboration is defined as collective work to achieve common goals. In this section, motivation for collaboration in software engineering is provided and related work in the area is briefly highlighted.

Motivation for Collaboration in Software Engineering Education

The human and social aspect of software engineering has been known since for quite some time (Weinberg, 1998). There is a need to foster a collaborative environment in SEE at several different levels for a variety of different goals (Whitehead, 2007), which is discussed briefly in the rest of the section.

The development of large-scale software has reached a point that it is no longer possible for an individual to grasp its size and complexity. This has necessitated (1) the use of computer-aided software engineering (CASE) tools and (2) carrying out a software project in teams, both of which require dedicated collaboration. Indeed, currently deployed commercial CASE tools such as Microsoft Project, IBM/Eclipse, and IBM/Rational Method Composer, and non-commercial CASE tools such as Subversion need certain degree of collaboration among their users.

The need for collaboration is relevant to the situative/pragmatist–sociohistoric theory of learning (Bennedsen & Eriksen, 2006). Indeed, group assignments and team projects are two common approaches to induce collaboration among students.

It is often the case that a software engineering course is equipped with a team project intended to prepare students for a similar environment later in their careers, including industrial software development. In a team project, there is a need for collaboration *throughout* the duration of the project at two levels: (1) *internal*, that is, collaboration among participating students themselves and (2) *external*, that is, collaboration between students and the (individual(s) playing the role of a) client.

Collaborations in Software Process Environments

The software process environments with the client and user involvement have increasingly become collaborative (Williams, 2000). In particular, the movement in the past decade has been towards social flexibility of which agile methodologies and open source software (OSS) ecosystems are exemplars. Indeed, one of the agile principles is that "the most efficient and effective method of conveying information to and within a development team is face-to-face conversation."

The human aspect and indeed the social aspect of software process environments trickle down to process workflows. The following examples illustrate how collaboration permeates certain activities performed in process workflows.

To create an understanding of the problem domain of a software project, structural and behavioral models are constructed, both of which require collaboration among the project team members. For example, the terms and their definitions need to be agreed upon by the team as a whole. It has long been recognized that requirements elicitation is a social process (Macaulay, 1993) where the participants must work together for the most optimal outcome that may require making compromises in the process. The crucial design decisions, such as selection of views and viewpoints for software architecture and subsequent application of architectural styles or patterns, often depend upon close collaboration. Among the interaction design approaches, participatory design involves active collaboration between designers and end-users to ensure that the product is useful and usable. The Class-Responsibility-Collaborator (CRC) cards (Bellin & Simone, 1997) is an informal, high-level object-oriented design (OOD) approach that relies explicitly on the collaboration between the participants for identifying appropriate classes for the software system. The success of Pair Programming (Williams & Kessler, 2003), one of the core practices of Extreme Programming (XP) (Beck & Andres, 2005), strongly depends on the collaboration between the pair. Finally, usability evaluation methods such as card sorting, focus groups, and pluralistic walkthroughs involve moderated participation and collaboration of real users.

An Overview and Analysis of Related Work

The technologies/applications enabling the social component of software engineering and its education have taken time to get established. In the 1970s, the technologies/applications to support the social aspect of software engineering were not mature, and in the 1980s, they were largely limited to the use of electronic mail (e-mail). It was the 1990s, particularly the ascent of the Web, that opened new frontiers for people that were non-proximal to communicate in a variety of ways on a global scale.

Indeed, the use of Java applets in illustrating the *dynamics* of non-trivial algorithms in a classroom has been emphasized (Kamthan, 1999) and the benefits of hypertext for relating software artifacts and navigating through them have been shown (Bompani, Ciancarini, & Vitali, 2002). The use of instant messaging and the Web is made in a distributed software engineering course project that required collaboration at a global scale (Favela & Peña-Mora, 2001). The concerns related to the use of course management systems based on the Web have been pointed out (Wijekumar, 2001) and it has been concluded that the dynamics of group composition are critical for a successful collaborative learning. The benefits of collaborative learning in the construction and understanding of UML Class Diagrams have also been highlighted (Baghaei, Mitrovic, & Irwin, 2007). The use of Web to solicit feedback from stakeholders on requirements and bug information from users has become increasingly common (Whitehead, 2007).

Advantages and Limitations of Social Web Technologies/Applications

There are three primary factors that make the Social Web relevant to SEE:

1. The enablement of a many-to-many bidirectional communication paradigm in which the Web is (merely) the broker.
2. The maturation of the underlying technological infrastructure and the availability of its implementations as open source.
3. The awareness of the public followed by immense interest and large-scale participation.

These factors have made students 'first-class' active participants — rather than being mere passive observers — in the use of the Internet for education. By lowering the financial entry barrier, they have also helped level the playing field for students. It has been pointed out in surveys (Whitehead, 2007) that a heterogeneous combination of desktop- and Social Web-based technologies will be crucial for the future of collaborative software engineering.

However, there are evident side-effects of use of the Social Web for SEE. Unlike traditional commercial-off-the-shelf (COTS) desktop software, there are little or no a priori guarantees that a Social Web application will be available when accessed or provide the functionality as claimed. The open source Social Web applications inherit the issues pertaining to open source software (OSS) (Kamthan, 2007). For example, the legal realm in which these applications operate is currently unclear; technical support, if any, may not be assured; and technical documentation (such as a user manual or context-sensitive help), if any, may vary significantly.

Initiatives for Integrating Social Web Technologies/Applications in Education

There have been relatively few initiatives towards integrating Social Web technologies/applications in education. An overview of the potential of Social Web technologies/applications for education in general has been given (Anderson, 2007). However, the correspondence to any teaching strategy or learning theory is unclear, and the limitations in the deployment of Wikis have not been discussed. The uses of Wiki as a teaching tool in software engineering have been reported (Parker & Chao, 2007). In particular, it is pointed out (Parker & Chao, 2007) that Wikis can be used to publish and share course material and management of software process artifacts.

A learning process that is based on the socialization, externalization, combination, internalization (SECI) model of knowledge management and uses Social Web technologies/applications has been suggested (Chatti et al., 2007). However, the discussion is largely peripheral and one-sided: the precise advantages of the Social Web towards teaching and learning are not given and the corresponding limitations have not been pointed out.

In a recent work, the limitations of conventional computer-supported collaborative learning (CSCL) are pointed out and, via the introduction of an application, namely eLogbook, the usefulness of next generation of social software in engineering education has been demonstrated (Gillet et al., 2008). However, the treatment of Social Web technologies is largely one-sided, and eLogbook is not yet mature and its relationship to other social software and technologies is unclear. It has been reported that due to computer-mediated communications via Social Web, new social structures can emerge among students that in turn can help reduce the number of students leaving computer science programs prematurely (Jahnke, 2008).

In recent years, there has been an emergence of both commercial and non-commercial course management systems (CMS), such as Black-

board/WebCT, Moodle, and Sakai that enable some degree of collaboration using the Web and provide assistance towards learning. In particular, Moodle (Cole & Foster, 2008) integrates some of the Social Web technologies like blogs and Wikis as part of its system. However, CMS are modeled primarily after the needs of the teacher, not necessarily that of the students. For example, CMS may enable teacher–student collaboration but are not designed for use in course projects or for student–student collaboration.

TOWARDS COLLABORATIONS IN SOFTWARE ENGINEERING EDUCATION VIA SOCIAL WEB TECHNOLOGIES/APPLICATIONS

To be effective, the integration of any technological environment in SEE (Kamthan, 2008b) should be both disciplined and systematic, and the Social Web is no exception. SW4SE2 is a specialization is a methodology for integrating Social Web technologies/applications in SEE. It consists of a nonlinear and non-mutually exclusive sequence of steps as shown in Table 1.

The steps 1–3 in Table 1 are stated at a high-level and could be granularized further if necessary. They must also be feasible in order to be practical.

In a software engineering context, collaboration can be one of the following three types (Goldberg, 2002):

1. **Conceptual.** This type of collaboration is related to sharing information, sharing work products, as well as, sharing responsibility.
2. **Practical.** This type of collaboration is related to decomposition of work and allocation of tasks followed by integration of results.
3. **Educational.** This type of collaboration is related to help each other learn.

This chapter is primarily concerned with conceptual and educational collaborations that occur within the scope of SW4SE2 where the activities and artifacts (produced during some of those activities) are assisted by patterns. Figure 1 illustrates the underlying collaboration model for SW4CSE2. Since these collaborations result primarily from asynchronous communication, they are non-ad hoc (Cherry & Robillard, 2008).

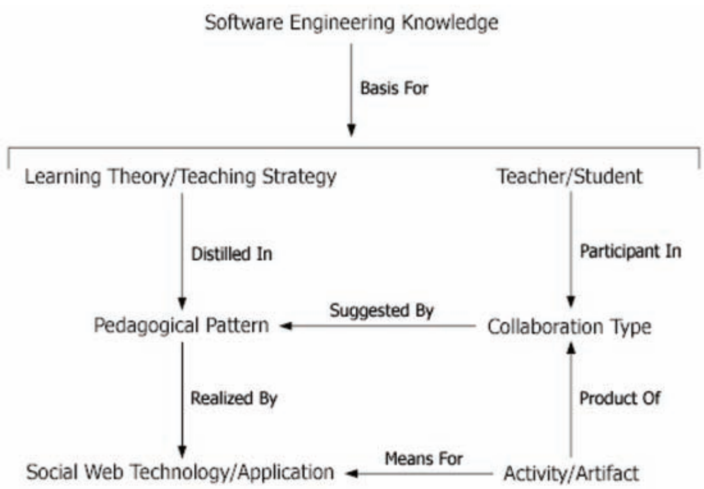
Step One: Deciding the Scope of Software Engineering Knowledge

The initial step in realizing SW4CSE2 is a characterization of software engineering knowledge. For that, the relevant software engineering topics could correspond to the knowledge areas of the Guide to the Software Engineering Body of Knowledge (SWEBOK) and the Software Engineering Education Knowledge (SEEK).

Step Two: Adopting a Learning Theory and a Teaching Strategy for Collaborative Software Engineering Education

The two theories of learning on which pedagogical strategies are being modeled today are *objectivism*

Figure 1. A model for collaborations enabled in software engineering education by the Social Web



and *constructivism* (Smith & Ragan, 1999). From an objectivist view, knowledge is external to an individual (and therefore objective), and therefore learning involves a 'transfer of knowledge' from the teacher to the student. From a constructivist view, knowledge is not external to an individual, and therefore learning involves constructing one's own knowledge from one's own experiences. In this case, it is a necessary that there are opportunities for social interaction among students. In recent years, constructivism has received attention in computer science education (Ben-Ari, 2001) in general, and SEE and OOD in particular (Hadjerrouit, 1999; Hadjerrouit, 2005). There has been much debate over the years in the educational community on the virtues and drawbacks of objectivism and constructivism. There are, however, signs of reconciliation (Cronjé, 2006).

Indeed, a classroom use of collaborative Social Web technologies/applications in SEE could be more objectivist than constructivist where the teacher plays the role of an 'instructor.' This could, for example, entail preparing Social Web technologies/applications-based lesson plans and lectures, and encouraging questions from students on a timely basis without severely interrupting the flow of the lectures. The teacher may also have to exercise some degree of discipline in the role of a 'manager' outside the classroom. For example, there may be need for a teacher to moderate a course mailing list, feedback to blog postings, a course Wiki, and so on, to maintain a level of decorum.

A project use of collaborative Social Web technologies/applications in SEE could be more socially constructivist than objectivist where the educator plays the role of a 'guide.' This could, for example, entail providing a balance between discipline and flexibility to the students in carrying out a software project with minimal guidance and timely feedback by the educator as and when needed: the crucial aspect being that the students play the primary role and the educator plays the secondary role.

From Theory to Practice

The reliance on the knowledge garnered from past experience and expertise is crucial for any endeavor. A pattern (Buschmann, Henney, & Schmidt, 2007b) is one such type of empirically proven and conceptually reusable knowledge.

Both objectivist and constructivist approach to collaborative SEE can be put into practice using pedagogical patterns. In particular, there are patterns for forming study groups (Sharp, Manns, & Eckstein, 2006), carrying out course projects (Hayes et al., 2006), and soliciting feedback from students (Bergin, 2006). These general high-level patterns can subsequently be supported by specialized low-level patterns for collaborative learning (DiGiano et al., 2002; Garzotto & Poggi, 2005; Hernandez-Leo, Asensio-Perez, & Dimitriadis, 2004) and patterns originally intended for computer-mediated communication (Schümmer & Lukosch, 2007). For example, APPLICATION SHARING, COLLABORATIVE SESSION, SHARED ANNOTATION, SHARED EDITING, and SHARED FILE REPOSITORY are patterns applicable to the Social Web context. As shown in the next step, solutions of these patterns manifest themselves in Social Web applications like blogging, social bookmarking, collaborative modeling, and so on.

Step Three: Selecting and Applying Suitable Social Web Technologies/Applications to Collaborative Software Engineering Educational Activities

Table 2 highlights the types of possible interaction between teachers and students in the context of SEE.

Table 2. A mapping between the types of possible interaction and educational contexts

Type of Interaction	Educational Context
Teacher–Student	Inside Classroom: Lecture Outside Classroom: Assessment Mode (Assignment, Project), Support
Student–Student	Outside Classroom: Assessment Mode (Assignment, Project)

Table 3. A mapping of student–student collaborations and corresponding Social Web technologies/applications

Collaborative Educational Activity	Social Web Technology/Application
Researching	Collaborative Annotation (Google Notebook, Microsoft OneNote)
Scheduling Events	Web Calendar (Google Calendar)
Brainstorming	Mind Map (bubbl.us)
Developing Software Process Artifacts	Collaborative Read/Write Application (Wiki, Google Docs)
Managing Software Source Files	Collaborative Source File Sharing (SourceForge)

Table 4. A mapping of teacher–student collaborations and corresponding Social Web technologies/applications

Collaborative Educational Activity	Social Web Technology/Application
Classroom Demonstrations, Audio/Video Interviews	Mashup, Podcast, Shared Presentation (YouTube, Google Video)
Dissemination of Lecture Material	Collaborative Note Taking (NoteMesh), Folksnomy, Wiki
Supplementary Course Material	Social Bookmarking (del.icio.us, Google Bookmarks, Yahoo! Bookmarks)
Notification and Syndication, Asynchronous Communication, Discussion	News Feed (RSS, Atom), Blog, Mailing List, News Group (Yahoo! Groups, Google Groups)

Tables 3 and 4 provide a relationship between common types of collaboration in SEE and Social Web technologies/applications.

For a given collaboration context, there may be multiple Social Web technologies/applications that are applicable. However, they may not necessarily be equally suitable.

The following criteria may be used for selection of a suitable technology or its application in SW4CSE2: nature of information (such as sensory modality) being communicated, alignment with teaching and learning goals, considerations for openness (commercial versus non-commercial), maturity, and feasibility. An objective third-party review of a candidate technology can also help in making the decision for adoption.

Examples of Collaborations in a Software Engineering Educational Context using Social Web Technologies/Applications

As evident from Tables 3 and 4, the Social Web lends various opportunities for collaboration and sharing. A sampling of these is considered next.

Collaborative Learning

The discipline of CSCL has a long history with origins in situated learning (Lave & Wenger, 1991). For the sake of this chapter, collaborative learning is a social interaction involving a community of teachers and students that acquire and/or share experience or knowledge.

In an objectivist approach to SEE, lectures and tutorials are still the norm where a teacher (or a teaching assistant) often makes use of black/white board or overhead projector for delivery. It is (theoretically) expected that each student will attend all of these lectures and tutorials from beginning to end, and be attentive all the time during the session. However, in practice, this need not be the case. The author has come across dedicated students who for one reason or another had to come in late, had to leave early, or for reasons of fatigue or otherwise, missed the essence of the session. A partial solution is to make the slides available for download. However, at times, there is implicit knowledge being communicated by the teacher that is not always made explicit. In such cases, students could benefit from their peers. NoteMesh is a Social Web application that allows students in the same courses to share notes with each other as well as edit each others notes. Its motto is 'collaborate to graduate.'

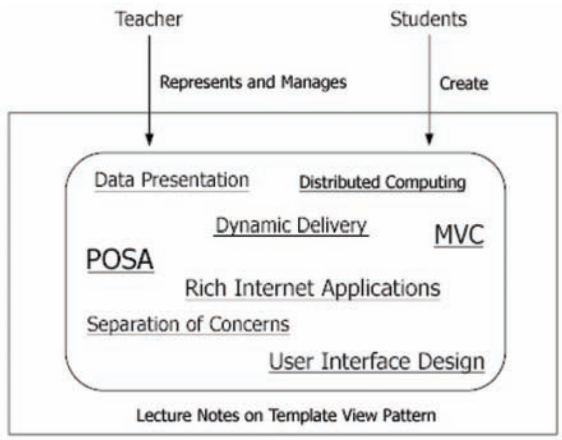
For the reason of time constraints or otherwise, the introduction of a topic during a lecture or tutorial is often relatively 'local' and from a single viewpoint. However, during assignments or tests, the students are expected to see the 'big picture.' Using the notion of folksonomy or social tagging (Smith, 2008), the students could associate other relationships with the lecture as they see fit. For example, phrases from past lecture(s) or the textbook could be candidates for tags.

A collection of tags can lead to the formation of a tag cloud. A tag cloud is set of related tags with associated weights that represent frequency of use of each tag. The frequency of use of each tag within a tag cloud is illustrated by visual cues, such as distinct font color and size.

The reliance on the knowledge garnered from past experience and expertise is important for any development, and a pattern is one such type of conceptually reusable knowledge. Figure 2 shows a tag cloud for the TEMPLATE VIEW pattern (Buschmann, Henney, & Schmidt, 2007a) used in the design of distributed software systems.

It should be noted that folksonomy (as opposed to taxonomy) is an uncontrolled vocabulary, and the lack of terminological control can have linguistic implications due to synonymy, homonymy, and polysemy. It is also not automatic that all tags that are created by the students may be relevant to the context. For example, a tag labeled 'template' or 'view' may not be related to the TEMPLATE VIEW pattern as depicted in Figure 1.

Figure 2. A tag cloud embedded in the lecture notes on the TEMPLATE VIEW pattern



In general, the success of collaborative learning may also depend on the students' background and past experience with technologies (Liaw, Chen, & Huang, 2008). For example, younger students may be more accustomed to technologies pertaining to the Web and are likely to have different attitudes than their older peers.

Collaborative Researching

The Social Web can be an indispensable source for students researching for information for assignments, or during the realization of a software project. There are Social Web applications that can assist in collaborative researching.

Social bookmarking goes beyond traditional bookmarking and enables management (for example, storage, organization, search, and sharing) of bookmarks residing remotely at third-party services. There are several social bookmarking services in use today including del.icio.us and Google Bookmarks. By unifying their knowledge base, social bookmarking can help both teachers and students to collaborate and share their links to resources.

The notion of social bookmarking can be extended to annotating the actual resources at the end of the hyperlinks. For example, applications such as Evernote, GoBinder, Google Notebook, Microsoft OneNote, and NoteScribe allow one to 'attach' notes to and clip text, graphics, and links during researching. Furthermore, the notebooks in Google Notebook can be exported to certain formats including Google Docs. The annotations associated with the resources found during researching can take various useful forms including comments on the relevance of the resource to the specifics of the software project, individual perceptions of the quality of the resource, reminders for comparing them with other resources, and so on. These notebooks can be saved, and can subsequently be used for collaboration and sharing with others. Furthermore, these notebooks persist once they have been created, and therefore can also be useful for future references.

Social Scheduling

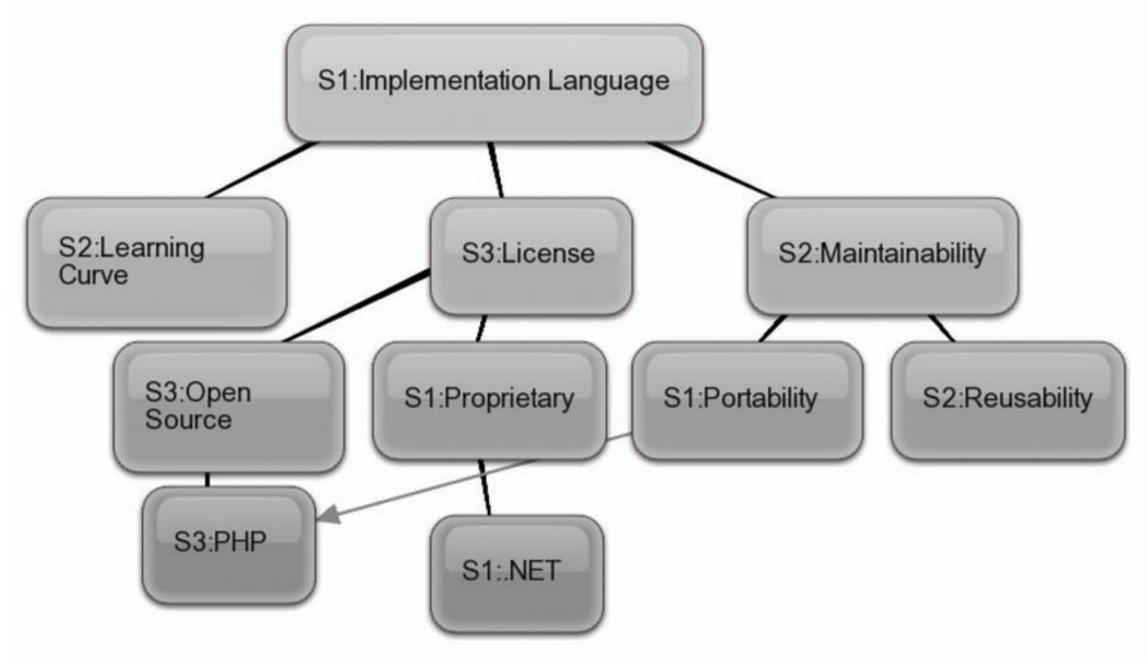
There is a need for meetings in a software project. For example, a team working on a software project has to schedule face-to-face meetings involving the members. An interview of representative members of the team with the client for the purpose of user requirements elicitation also requires meetings.

A schedule that is agreeable to all and is flexible (for example, due to frequent changes) can become difficult to manage, particularly as the number of persons involved increases. The use of Social Web applications that facilitate calendar sharing (such as the Google Calendar) can reduce some of the tedium involved in scheduling a meeting agenda.

Brainstorming

In a collaborative approach towards completing an assignment or formulating the details of a software project, students often need to engage in brainstorming. For example, for a given project, students may need to select a quality model, prioritize requirements, decide the best algorithm/data

Figure 3. An example of a partial mind map reflecting a brainstorming session on the viability of an implementation language



structure, or choose an implementation language, all of which necessitate brainstorming.

One way to brainstorm is through visualization, and mind mapping is a graphically-oriented approach to realize it. The authors can share these mind maps over the Web and, depending on the permissions, read and/or edit others' maps.

Figure 3 illustrates a snapshot in time (work in progress) of a mind map using bubbl.us. In it, three students, namely S1, S2, and S3 are in a brainstorming session on the feasibility of a proposed implementation language. The 'bubbles' in the figure reflect respective inputs by students.

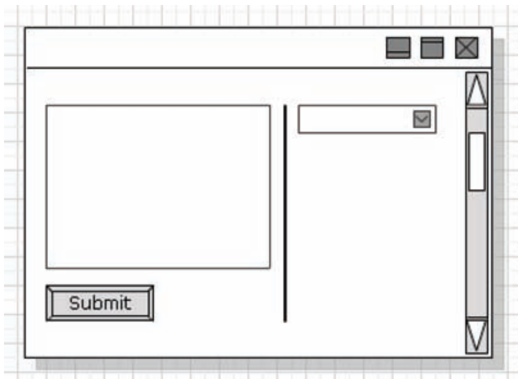
There are evidently other instances in which brainstorming is imperative. For example, the Goal/Question/Metric (GQM) (Van Solingen & Berghout, 1999) approach to software measurement necessitates formulation of recursively granular questions and assignment of corresponding metrics, both of which require brainstorming by the participants involved.

Collaborative Modeling and Prototyping

The activities of conceptual modeling and prototyping are critical to the success of software projects. They are becoming increasingly common in SEE (Cowling, 2005), particularly in model-driven approaches to software development (Völter et al., 2006) and interaction design (Beaudouin-Lafon & Mackay, 2008), respectively. They also should be carried out collaboratively. For example, the task of creating a large and complex model can be decomposed, and parts of it could be created by different students. Then, a conceptual model such as a domain model or a use case model being created by one student could benefit from informal inspections and feedback by another.

Figure 4 illustrates a snapshot of Gliffy, a Social Web application that allows collaborative modeling and sharing of diagrams. However, it should also be noted that Gliffy has limited capabilities compared to its desktop counterparts like

Figure 4. The construction in progress of a low fidelity prototype with six user interface elements



Microsoft Visio or IBM Rational Rose XDE. For example, support for the Unified Modeling Language (UML), a standard language for modeling object-oriented software systems, is partial. It is also currently not possible for users to extend a given template.

Collaborative Authoring

The Social Web presents a suitable environment for collaborative authoring of software process artifacts using various means including Google Docs and Wiki.

Google Docs is a Social Web application that provides capability to create word processing documents, spreadsheets, and presentations, as well as their import and export in various commonly-used formats. It also allows real-time collaboration and sharing of these resources using the Web. However, Google Docs has yet to completely replace a conventional office suite. The support is limited to certain user agents and there are currently physical limits on files sizes and designated storage space that may be constraining.

The concept of Wiki was invented in the mid-1990s as a group communication utility. It allowed open editing of information as well as the organization of the contributions and, with various enhancements, continues to serve well in that vein (Spinellis & Louridas, 2008). Wikis can be used, for example, for distributed collaborative authoring and multi-versioning of software process documents, recording design alternatives decision rationales, and feedback threads. The construction of knowledge takes places by the mutual influence of the social processes facilitated by a Wiki and the cognitive processes of the students (Cress & Kimmerle, 2008).

There are several, opens source flavors of Wiki available today addressing different target groups and organizational needs. Most flavors of Wiki, including MediaWiki and TinyWiki, can be easily acquired, installed, and administered under commonly-deployed computing platforms (Ebersbach, Glaser, & Heigl, 2006).

The Wiki environment can be used in a software project in various ways. For example, as shown in Figure 5, students could use Wiki to produce software process documents. These documents can be developed collaboratively and maintained independently, and can be hyperlinked for traceability and other purposes.

In software process documents, the key terms that are directly related to the domain of the project should be defined in a self-contained glossary. As shown in Figure 6, the terms that are not directly related to the domain of the project could point to resources from the projects of the Wikipedia Foundation (such as Wikibooks, Wikipedia, Wiktionary, and so on) for definitions and/or further details.

There are a few challenges in adopting a Wiki for SEE. It appears that the acceptance and use of Wikis varies significantly across education systems and countries (Gotel et al., 2007), and so their adoption may not be automatic. Since only some of the students may be extrovert in nature and may be prolific writers, others may not be, and therefore the participation of students is not guaranteed. Indeed, the personality traits of participants of Wiki may not be all that different from those involved in blogging (Guadagno,

Figure 5. A collection of software process documents using the Wiki environment

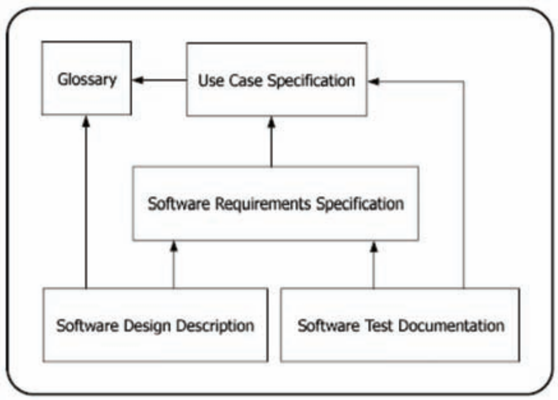


Figure 6. A software design document using external resources in the Wiki environment

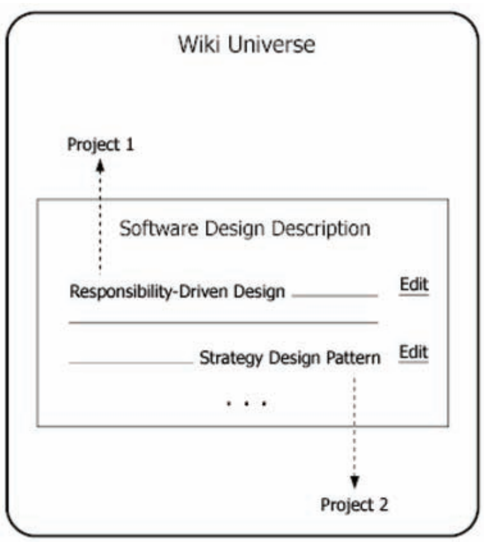

Okdie, & Eno, 2008). Wikis are also known for 'noise' (impertinent information), 'casual writing' (presence of phonetic and 1337 style of writing), and 'editing wars' (discussions that have morphed into endless debates). These, however, can be attributed to human usage rather than to inherent limitations of the underlying technology. Also, the incidence of errors introduced by end-users involved in the development but not sufficiently familiar with the computing environment can be high (Costabile et al., 2008). Therefore, some form of monitoring and control, perhaps initiated by the institution or the teacher, is essential.

Guidelines for Adoption of Social Web Technologies/Applications for Collaborations in Software Engineering Education

Even when it is clear that the benefits outweigh the associated costs, any novel undertaking comes with its own challenges, and the same is true for adoption of the Social Web as a platform for SEE. The following set of guidelines is presented to help prospective teachers in making an informed decision towards enhancing their collaborative activities in software engineering-related courses via the Social Web.

- **Administration.** It is needless to say that the teachers must be aware of the current policies of the institution pertaining to legal and privacy issues regarding students, and security issues regarding information and computing infrastructure. It can also be useful to keep the administration (such as the department Chair or the Dean) abreast of any new endeavors, and periodically inform them of successes and failures.
- **Students.** The students should be informed of any 'social experiments' being pursued as part of the course, made aware of their rights and responsibilities that comes with flexibility of Social Web technologies/applications, including any acceptable use policy (AUP) put forth by the institution, and introduced to the ethical issues in software engineering (Kamthan, 2008a) before they embark on a software project. The relation of collaborative work to assessment should also be made explicit in advance, say, at the beginning of the course.
- **Infrastructure.** The selection and adoption of Social Web technologies/applications

does not have to be a matter of 'all or nothing' and could be introduced progressively. Indeed, it may be useful initially to introduce technologies/applications in activities that can benefit most, select technologies/applications that are relatively stable, hopefully sustainable, and in which the teacher does not have to relinquish control completely, and the presence of technologies/applications is not apparent to students (that is, technologies/applications are transparent to and do not interfere with the learning goals). Then, based on a retrospective, the use of technologies/applications can be scaled appropriately.

FUTURE TRENDS

The work presented in this chapter can be extended in a few different directions. In the rest of the section, the significance of these directions is discussed briefly.

Management

The introduction of any new technology/application in education is susceptible to indirections. For example, a sustained integration of Social Web technologies/applications in SEE needs to address associated quality-related concerns that can outweigh the benefits of collaborating electronically. In particular, an assessment of the impact on the credibility of information emanating from relaxation of control and governance (from teacher's viewpoint) and emergence of privacy and reliability issues (from student's viewpoint) is of research interest.

The hardware and software demands of Social Web technologies/applications on both server-side and client-side can not be ignored. For example, the file sizes of podcasts that are not streamed but are available only as download could be prohibitive to those on low bandwidth. It is also not automatic that educational institutions will simply abandon the resources to which they may have invested in past years and embrace the Social Web. Therefore, an investigation into a cost estimation model for integrating Social Web technologies/applications in SEE would be of interest.

Evolution

The focus of this chapter is on software projects being carried out by students registered at the same institution. It would be interesting to examine the challenges of a global software engineering project that is carried out in a distributed environment by students from multiple institutions and the role of Social Web technologies/applications in overcoming those challenges.

This chapter does not discuss teacher–teacher collaboration, an issue that has received little attention. The courses in a software engineering program (such as at the author's institution) are usually not isolated from each other. It may even be necessary and/or mutually beneficial for teachers for courses software requirements, software design, and software testing to collaborate with each other during the semester. For example, the software requirements produced iteratively and incrementally in one course could serve as input to software design in another course. Indeed, many of the aforementioned Social Web technologies/applications can assist teacher–teacher collaboration as well.

This chapter does not discuss the suitability of computing environments for collaboration. While certain technologies and their applications may be targeted for stationary devices, others may be generic. Further investigations into this mapping could help identify and channel appropriate services to requesting clients.

Maturation

It is still early to predict the outcome of the Social Web phenomenon in general and its impact on SEE in particular. Although certain benefits of integration are evident, studies of the impact on the changes to the learning model and further evaluation based on actual teaching experience followed by surveys are indispensable. It would be useful to distill this experience and subsequently present it in the form of 'best practices.'

Finally, it is evident that the level of adoption of (Social Web) technologies in software engineering programs will vary across educational institutions. It may be useful to devise a *Technology Maturity Model (TMM)* that an institution could use to assess and improve its technological awareness, capability, and support. It is anticipated that TMM would include a finite number of levels, definition of those levels, and a rationale for the assignment of a technology to a level. TMM could be 'instantiated' for different areas, including collaboration. The requirements for an institution to qualify at higher levels will be more stringent than at lower levels. For example, a software engineering program that allows the use of mailing lists only would be at a lower level compared to another program that provides explicit support for real-time streaming media that can be annotated and shared, and has policies in place for its practical realization.

CONCLUSION

This chapter highlights the collaborative disposition of software engineering in general and SEE in particular, and the role of the Social Web in enabling it. It is evident that the perception, realization, and manifestation of collaboration outlined here are likely to change with the evolution of software engineering as a discipline and with the societal views of education. For example, the needs for global software engineering projects, say, conducted and shared by multiple educational institutions may require modifications to the Wiki model (Hohman, & Saiedian, 2008).

The challenges facing the practice of software engineering today are as much technical as they are organizational and social in nature. The social and organic aspects of software engineering not only need to be acknowledged by teachers but also made explicit to the students in a feasible manner. In doing so, there is a need to communicate the significance of and help develop the necessity of a *collaborative culture* (Tabaka, 2006) in which the students, individually or as a team, can thrive.

The technological infrastructure underlying the Social Web provides an avenue for teachers and students to collaborate and share information both inside and outside the classroom. This departure from the current status quo can open vistas for teachers to convey to students in an educational setting some of the dynamism and excitement of IT the students they may be exposed to in their daily lives. It can also help form a 'bridge' between academia and the real-world, and thereby demonstrate, particularly to undergraduate students, that software engineering is indeed 'alive' and constantly evolving discipline. At the same time, the promise of the Social Web must be kept in perspective with the associated costs.

ACKNOWLEDGMENT

The author would like to thank his students for their commitment and dedicated participation in course projects over the years, many of which involved implicit and explicit use of the Social Web technologies/applications.

KEY TERMS AND DEFINITIONS

Constructivism: A theory of learning that views learning as a process in which the learner actively constructs or builds new ideas or concepts based upon current and past knowledge. It is based on the premise that learning involves constructing one's own knowledge from one's own experiences.

Information Technology: Technology for activities related to information, such as acquisition, creation, communication, dissemination, processing, archival, retrieval, transformation, and so on, within the context of the Internet and the Web.

Mind Map: A diagram that represents goals, tasks, or other concepts linked to and arranged radially around a central theme or an idea. It is used to generate, visualize, and organize ideas, and as an aid to understanding, problem solving, and decision making.

Objectivism: A theory of learning that views knowledge as some entity existing independent of the mind of individuals. The goal of instruction is to communicate or transfer knowledge to learners in the most effective manner possible.

Open Source Software: A single encompassing term for software that satisfies the following conditions: (1) non-time delimited, complete software whose source is publicly available for (re) distribution without cost to the user, (2) imposes minimal, non-restrictive licensing conditions, and (3) is itself either based on non-proprietary technologies or on proprietary technologies that conform to (1) and (2).

Software Engineering: A discipline that advocates a systematic approach of developing high-quality software on a large-scale while taking into account the factors of sustainability and longevity, as well as, organizational constraints of resources.

Software Process: A set of activities, methods, and transformations that are used to develop and maintain software and its associated products.

Web 2.0: A set of economic, social, and technological trends that collectively form the basis for the future Web as a medium characterized by user participation, openness, and network effects.

Chapter 4.4
Exploring the Role of Social Software in Higher Education

Yoni Ryan
Australian Catholic University, Australia

Robert Fitzgerald
University of Canberra, Australia

ABSTRACT

This chapter considers the potential of social software to support learning in higher education. It outlines a current project funded by the then Australian Carrick Institute for Learning and Teaching in Higher Education, now the Australian Learning and Teaching COuncil (ALTC) (http://www.altc.edu.au/carrick/go) to explore the role of social software in supporting peer engagement and group learning. The project has established a series of pilot projects that examine ways in which social software can provide students with opportunities to engage with their peers in a discourse that explores, interrogates and provides a supplementary social ground for their in-class learning. Finding creative ways of using technology to expand and enrich the social base of learning in higher education will become increasingly important to lecturers and instructional designers alike. This project represents one small step in testing the applicability of social software to these contexts. While many of our students are already using various technologies to maintain and develop their personal networks, it remains to be seen if these offer viable uses in more scholarly settings.

DOI: 10.4018/978-1-60566-208-4.ch012

INTRODUCTION

The evolution of the Web in the 1990s saw a parallel development of commercial Learning Management Systems (LMS) and, by 2001, the widespread adoption of the latter in Australian universities, in response to growing demands for flexibility or convenience for students. Yet much of the research indicates that in the main, LMS have been used more for administrative purposes (Dalsgaard, 2006; Hedberg, 2006; OECD, 2005; Reeves, Herrington & Oliver, 2004) and educators themselves most frequently use LMS as a content management system rather than exploiting the interactive potential of digital media (Boezerooy, 2003; Fiedler et al., 2007). With the official emergence of Web 2.0 in 2004 (O'Reilly, 2005), and the explosion of activity in social networking applications afforded by the technology, it is timely to consider whether the LMS, and the static learning environments they have typically modelled, should at least be complemented by (and perhaps even give way to) more interactive applications.

The original intention of Berners-Lee 'was all about connecting people' (Anderson, 2007). However, the Web was quickly colonised by vendors intent on using it for education purposes as a tradeable global commodity (Cunningham et al., 1998). LMS vendors promised a universal 'Economics 101' subject developed by the best professors in the world, and accessible - at a price - to all (Cunningham et al., 1998). Educators and the instructional designers who developed online materials were paradoxically complicit in this static model, recreating in their online materials the transmission model of pedagogy they inherited as 'the university teaching model' (Laurillard, 2002). Berners-Lee was not alone in his vision for a different technological future. In his book *Mindstorms*, Seymour Papert (1980) developed a compelling case for the potential of technology to mediate thinking in ways that reveal, enrich and expand learning. The prominent educator Paulo Freire (1985) argued that transformative education can only be achieved through a pedagogy that values learning as a process of *asking* questions not just *receiving* answers. The dominance of the administrative functions of e-learning has already been noted, with its preference for *content* over *process* most frequently achieved through one-way (vs. two-way) models of interaction. In these applications the *answer* seems much more important than the *question*. Papert (2000) argued that transformative shifts in the way we use technology will only be possible when educators have time to rethink both the *why* and *how* of its use. Given the widening gap between formal education and Internet culture, and the rise of the millennial learner, it is clear that we can no longer afford not to take time to reconceptualise technology-mediated learning. This will involve the design of a pedagogy that connects and engages learners in activities that value the question as much as the answer. Finding creative ways of using technology to expand and enrich the social base of learning in higher education will become increasingly important to academics and instructional designers alike. However, it is not clear that even the experts in higher education and e-learning can envisage such a pedagogy, with Guess (2007) assessing discussion at the Seattle Educause conference as producing 'more questions than answers' about capitalising on the contemporary enthusiasm for social networking in educational settings.

The project reported in this chapter represents one small step towards testing the applicability of different technologies to higher education contexts. While many of our students are already using various technologies to maintain and develop their social networks, it remains to be seen if these offer viable uses in more scholarly settings.

BACKGROUND

There are a multitude of Web 2.0 services that are readily available to students and educators such as blogs (e.g. Edublogs), wikis (e.g. Wikispaces), collaborative word processors (e.g. Google Docs), syndication and aggregation using RSS (e.g. Bloglines, PageFlakes and iGoogle), social bookmaking (e.g. del.icio.us), shared calendars (e.g. Google Calendar and 30 Boxes) and creative content exchange (e.g. Flickr for images, ccMixter for audio, and YouTube for video). The project reported here arose as a result of intense interest in the use of Web 2.0 technologies in higher education by a group of teacher-scholars. Although some of the group were using several applications successfully in their own teaching, predominantly in the area of media studies, they had little in the way of comprehensive research studies to support their belief that Gen Y students would be more engaged in their learning if formal study programmes incorporated Web 2.0 modalities, with their potential for more interactive construction of knowledge, skills and values.

Since 2002, conventional media and IT consultancy firms have reported exponential uptake of social technologies such as Facebook, YouTube and MySpace, and the near universal use of converged technologies like mobile telephones, at least in the West. Social commentators such as Prensky (2001), and educational technologists and managers such as Diana Oblinger (2004) have argued strongly that 'digital natives', in Prensky's term, demand a new pedagogical approach given their routine use of social technologies in their daily lives. Arguably, this is supported by the growing influence of constructivism as an underpinning tertiary learning theory (Biggs, 1999; Marton & Saljo, 1976), and social constructivism (Renner, 2006), since these theories propose that students mentally 'construct' their own learning, based on a variety of resources, including teachers and peers. Increasingly however, these resources are web-enabled.

Over the past five years in Australian universities, traditional face-to-face delivery has declined as the major mode of university teaching, for several reasons. The first is economic, as funding for teaching activities has decreased (Go8, 2007), and programme hours have been cut in consequence. The second is also economically related: as students' personal costs for tuition have increased, their paid-work commitments have risen to an average of over fifteen hours per week (Universities Australia (UA), 2007). The result has been declining attendances at scheduled lectures (UA, 2007), and demands for more 'flexible' access to learning materials.

As will be discussed further below, the literature presented the research team with contradictory findings. Krause (2006) for example, in her analysis of the decade long studies of the 'First Year Experience' in Australian Universities, argues from her data that students are less comfortable and familiar with new media in their learning environment than has been supposed. Ramsay's early data analysis (2007), supports that view. Berg, Berquam & Christoph (2007) also report some students at the University of Wisconsin-Madison warning off administrators considering muscling in on 'their spaces': 'Don't bother with IM or Facebook – that's **our** way to network. Leave us alone. This is my way to procrastinate. I don't want to feel guilty about it.' Yet Kvavik & Caruso (2005) argued that in their US survey, students were overwhelmingly positive about the attraction of IT in education: it was about 'convenience', easy off-campus access.

The issues underpinning the present project cross the usual boundaries of disciplinary study, making analysis and a standard literature review problematic. Indeed, Cobcroft et al. (2006, p.11) in their 138 page literature review on e-learning, assert that a literature review in this area 'cannot be exhaustive'. This chapter has sought to canvass the more recent and 'typical' of the research, and locate it within industry approaches. A thorough review would take into account not only the more 'academic' studies of technology usage that have methodological rigour, but the 'grey literature' of self-promotional industry reports, mass media reports, and the thousands of opinions available through the affordance of Web 2.0 technology itself, in the form of blogs, wikis etc. It would also situate this literature in the broader context of social and higher education systemic change, such that 'the university experience' no longer encompasses the 'withdrawal' from the world of work of an elite group of the young, to focus on preparation for life and work via study. Clearly such a thorough review is problematic.

Any summary of the literature is also complicated by the nature of inquiry into the phenomenon of social networking: some approaches focus on the technical aspects of social software, others on the sociological implications (the 'generational' or 'digital native/immigrant' line), others still on the philosophical implications of pervasive social technologies, while only a few consider the pedagogical and cognitive dimensions of social networks. Yet another approach is to speculate on the nature of institutional 'disruption' as a result of social and technological networking. This is an immense range of fields to canvass.

There is no doubting the uptake of social applications of technology. The explosion of subscribers to social networking sites is truly astonishing. YouTube, invented only in 2005, reports 70 million viewings per day. It was *Time*'s 'Invention of the Year' in 2006, according to *Time* writer, Lev Grossman, because it promotes 'authenticity'. Australia MySpace claimed on 27 June 2007 that over 48,000 videos had been uploaded in the past three days. It is the most popular social networking site in the country, according to HitWise, an Internet research company based in the UK. 27% of all Internet users regularly use MySpace, and it claims over 160 million subscribers. On that same day in June, Flickr claimed nearly 3000 photos had been uploaded in the last minute ─ at 9.20 am. HitWise reported that Bebo 'surpassed MySpace in weekly market share of UK Internet visits to become the most visited social networking site in the UK for the week ending 5th August 2006', and is the 11th most popular site on the Internet with 22 million users. SecondLife, opened in 2003, claims 7.4 million accounts have been opened, although many are never really 'peopled'. It seems to have over one million active users. The Australian-based Prospect Research (2006) claims that in 2006, 34% of Gen Ys had their own blog, and 13% their own website. Facebook claims 200,000 people sign up each day, and boasted 42 million members in October 2007.

The literature around Gen Y students and social technologies presents a conundrum with much of it falling into five categories:

- **Category 1.** A plethora of 'pop pieces' or 'op ed' pieces in conventional media, typically by amazed later age adults 'discovering' the worlds of Second Life and Facebook, and issuing alarmist warnings about identity theft and potential career damage.
- **Category 2.** The large number of industry reports, typically by IT consultants, and based on limited surveys of Gen Y usage.
- **Category 3.** More considered investigations of the youth demographic and their propensities in regard to technologies and learning approaches.
- **Category 4**. A number of studies, which investigate the pioneering use of new applications in selected universities, although many do not evaluate the efficacy of these applications in learning.
- **Category 5.** A small category canvasses new media usage as the object of academic interest in its own right.

Typical of the Category 1 literature is a piece in the *Weekend Australian Magazine* March 2007, which reflects the amazement of the 'newbie' to the world of social sites. Nussbaum, the writer, reprises the intimate details of one of her featured MySpace users, Kitty, including her sexual experiences and her reaction to the death of her parents at 22. Nussbaum characterises the reaction of the older generation to Gen Y's tendencies to 'self-exposure' in these terms: 'They have no sense of shame. They have no sense of privacy. They are show-offs, fame whores, pornographic little loons who post their diaries, their phone numbers, their stupid poetry ─ for God's sake their dirty photos! ─ online. They have virtual friends instead of real ones. They talk in illiterate instant messages. They are interested only in attention ─ yet they have zero attention span…' (Nussbaum, 2007, p.24).

Alarmist stories about the potential for identity fraud in social networks (www.abc.net.au/news/stories/2007/10/24/2068766.htm?section=justin) deepen concern among many in the general population and older academics regarding Web 2.0.

A common attribute of Category 2 type studies into Web 2.0, which examine its educational implications, is the predominance of IT consultants rather than traditional disciplinary academics among authors. This might be explained by a general lack of knowledge of new technologies among traditional academics, given the aging profile of Australian academics (Hugo, 2005), and their status as 'digital immigrants'. It might also be related to self-interest in promoting new technologies on the part of IT consultants, who also predominated in commentary during the 1990s 'tech boom' in e-learning systems. As then, commentary is usually accompanied by brave predictions on media futures and mobile devices (Franklin & van Harmelen, 2007; Livingstone & Bober, 2005; The Horizon Report, 2007).

Typical of such Category 2 publications is the late 2007 Franklin and van Harmelen study, both authors being IT consultants scanning the practices of five European universities in relation to the impact of Web 2.0 on institutional policy and strategy, and changes in pedagogical practices. The significance of this study is its environmental scan of European institutional approaches and policies around Web 2.0. Like the boosters of the 1990s, Franklin & van Harmelen parlay the 'profound potential' of Web 2.0, including its 'pedagogical efficiency' as well as its promise of 'greater student independence and autonomy' (2007, p.3).

Nevertheless, the Franklin and van Harmelen (2007) study offers cautions:

Because Web 2.0 is a relatively young technology, there are many unresolved issues relating to its use in universities. These include intellectual property rights for material created and modified by university members and external contributors; appropriate pedagogies for use with Web 2.0 (and equally which pedagogic approaches are enhanced by the use of Web 2.0); how to assess material that may be collectively created and that is often open to ongoing change; the choice of types of systems for institutional use; how to roll out Web 2.0 services across a university; whether it is best to host the services within the university or make use of externally hosted services elsewhere; integration with institutional systems; accessibility, visibility and privacy; data ownership; control over content; longevity of data; data preservation; information literacy; and staff and student training. At this stage all that we have to go on are the results of experiments with Web 2.0, rather than a set of solutions that are ready for widespread adoption (p.1).

These are all important issues and need appropriate technical and legal investigation, although the present concern is with pedagogical implications. As one would expect, the report concludes with a recommendation that institutions not 'impose' unnecessary regulations 'in order to avoid constraining experimentation with Web 2.0 technologies and allied pedagogies' (Franklin & van Harmelen, 2007, p.4). As will be seen in our conclusions, we endorse this view.

Franklin & van Harmelen (2007) explore several areas that have bearing on the present study. The first is a finding relayed (Franklin & van Harmelen 2007, p.7) from Arthur (2006) that in Web 2.0, 1% of users create content, 10% comment on that content and therefore add to it, and 89% simply 'consume' it. This, if verified in an educational context, poses difficulties if the learning objective is to *create* content. It is less problematic if the objective is to *disseminate* knowledge.

Franklin & van Harmelen consider that 'much (of the use of Web 2.0 technologies) is still experimental work carried out by enthusiastic lecturers who are willing to devote the time to *make the technologies work for their teaching*' (2007, p. 14; our emphasis). The evidence of this project in terms of the challenges faced at institutional and technical levels would support this observation: enthusiasts 'make' the technologies 'work'; institutional systems are not geared for the systemic incorporation of Web 2.0 in routine teaching practices. Given the case studies presented in the Franklin and van Harmelen report, it would seem that in the European universities surveyed at least, the technologies' most pervasive use has been in social support and building a community ethos, rather than in 'direct' academic work.

This project team supports the notion of using a variety of web applications as providing the most appropriate philosophy and pedagogy for academic users of Web 2.0, consistent with our Manifesto (http://wiki.openacademic.org/index.php/CookBookManifesto), but recognises that this position will be in conflict with many IT systems professionals who try ever harder to manage the unmanageable (Wilson, 2007).

Notwithstanding the many examples of IT consultants as authors of institution-oriented reports, there are a growing number of Media Studies academics conducting small scale research on student use of and attitudes to new technologies in their teaching. Such studies generally focus on particular aspects of technological applications. For example, in the brief report on students' use of Google as a research tool, Head (2007) suggests that the supposed and much deplored reliance on search sites and sources like Google, Yahoo! or Wikipedia has a limited basis in fact, once students have realised the limitations of these tools in providing depth in content. Most students turned first to their subject references as provided by the academic; only 10% used these general sites first in a research assignment. (Head's publication in itself is an indication of the transformation of scholarly publication as a result of the Internet: *First Monday*, its place of publication, is a peer-reviewed online-only journal).

Category 3 studies include those by the highly respected Demos Group: one study reported by the group found that 'one-third of the children surveyed, including one in five 11 year olds, regularly use the Internet for blogging, yet two-thirds of parents do not know what a blog is, and only 1% thought that their child used them' (Demos, 2006, p. 73). Such studies provide valuable background information on the aspirations of Gen Y, and their attitudes to new technologies.

In Category 4 is Anderson's (2007) JISC report from the UK, 'What is Web 2.0? Ideas, Technologies and Implications for Education' - an excellent introduction to various applications and their possibilities and implications. It is particularly useful in that it situates the applications within the wider literature on social, cultural and pedagogical change. EdNA (2007) also lists a number of resources relevant to Web 2.0 in higher education.

Finally, Category 5 is an emerging area where media researchers are closely examining the role of social software in education. Examples include the Rochester Institute of Technology's laboratory for Social Computing (http://social.it.rit.edu), and Seton Hall's virtual worlds projects (http://tltc.shar.edu/virtualworlds).

MAIN FOCUS

The main focus of this chapter is a discussion of the Digital Learning Communities (DLC) project that was funded by the then Carrick Institute for Learning and Teaching in Higher Education. The primary aim of this project was to apply an evidenced-based approach to increasing undergraduate and postgraduate student engagement, especially peer-to-peer interaction and communal learning, through innovative applications of social software in university teaching (http://mashedlc.edu.au/). The context of the three universities involved (University of Canberra, Queensland University of Technology, and RMIT University) was an important consideration: none could be considered 'bleeding edge' in relation to systemic use of sophisticated technologies, although each has a small group of innovative researchers in new media. Two of the universities are large (30,000+ students), with strongly centralised management. The third is small (12,000 students), and its IT services were in flux during the project. An important element of the study for the team as new media researchers was to 'test' the responsiveness of institutional systems to innovative pedagogies.

The general intentions of the DLC project were to:

- enhance student community and peer engagement through socially mediated content creation, classification, aggregation and sharing.
- apply existing free services and applications to maximise accessibility.
- document and disseminate the results in a way that allows immediate and sustainable take-up of these techniques by Australian university teachers.

From the outset of the project it was clear that to gain a better insight into this rapidly changing area we would need to build a multi-faceted evidence and resource base that would help universities understand their student body and offer ways of using social software. To this end we:

- developed a project manifesto that outlined the project team's shared understanding of what constitutes good learning and teaching in higher education.
- conducted a survey to characterise university students' present and emerging use of technology for study, work, and play. In particular we wanted to examine the quantity and quality of the data channels used by students and provide some baseline measures of the uptake of these technologies.
- developed a series of pilot projects to help focus attention on the identification, development and evaluation of how social software can be used to engage learners with emerging social technologies.
- developed a wiki-based resource (called a cookbook) that would help lecturers explore how to use social software in their teaching.

For the purposes of this chapter we will only report some of our preliminary survey results and briefly detail the pilot projects that are currently still in progress.

Social Software Survey

In August 2007 we conducted an anonymous web-based survey of students and staff across three Australian universities. In total we had 853 respondents (41% male and 59% female), 63% undergraduates, 16% postgraduates and 21% university staff. Our preliminary analysis of the data seems to indicate that as a whole, this is a fairly 'connected' group and as such may represent the leading edge of users. Of this group 56% indicated they had their own website, while 39% said they maintained a blog. Further analysis and comparison by discipline grouping will explore this more fully in subsequent reports. Nearly 92% had broadband access with the most common point of access being home (63%), followed by university (22%) and workplace (14%) and 93% had two or more email addresses. The age distribution is shown below.

To get a sense of the ways respondents connected with their peers we asked them to identify the three main ways they choose to communicate (Table 3). Face-to-face meetings and email were most popular, followed by phone and text messaging. The importance of text messaging relative to phone calls perhaps points to potential of texting to deliver a cost effective, reliable messaging platform with minimal disruption for both sender and receiver. Instant messaging (IM), blogs and discussion lists did not figure much at all. One should not read too much into this result, as on many university campuses, blogs and IM are not well supported.

Examining the use of popular social networking applications we asked respondents to characterise their use as either an Internet 'Browser', 'Participator' or 'Contributor'. We suggested that each of these characterisations could be defined in the following way:

- **Browsers:** Tend to mainly read, surf or watch Internet content
- **Participators:** Browse but also make comments, suggestions and critiques of Internet content
- **Contributors:** Browse, participate but also create and upload Internet content

In the three universities we surveyed, most students used social software to browse information (58%). Interestingly for most students, wikis, often held up as the archetypal content creator

Table 3. Choose the three main ways you usually communicate with your colleagues or fellow students

application, were mainly used as an information resource. Given the success of wiki projects such as Wikipedia (http://wikipedia.org/) it is our view that this result may be more a reflection of users' limited understanding of how wikis work rather than a specific flaw of the application. However, specifically designed social networking applications such as Facebook (http://www.facebook.com/) suggest more sophisticated patterns of use with the highest levels of contributors being reported (34%) followed by blogging (27%), photo sharing (21%) and social bookmarking (19%). The questions that arise here are what content is being created and has that content got any educational significance? It is fair to say that at this point we do not know enough about the nature of the content to respond with confidence. Having said that, it is our view that much of the content on, for example Facebook, appears to be directed towards more recreational than educational applications.

In another question, we asked respondents to rate the usefulness of various features of social software on a five-point scale (1- not useful through to 5 -extremely useful). Table 5 shows that the top four features of social software were their search capabilities, opportunities for self publishing, commenting and maintaining friend/buddy lists. All of which suggests students value a role as an author (i.e. able to publish and comment) who can be easily connected with people (i.e. friends) and information (i.e. search) – what

Table 4. Which of the following sites do you: Browse, participate or contribute to?

	Browse	**Participate**	**Contribute**

O'Reilly (2005) and others have referred to as the 'architecture of participation' in which software systems are designed to help users connect with other users.

Pilot Projects

The pilot projects we have established include the use of wikis, blogs and related social networking applications. The underlying pedagogical rationale for the pilot studies was a recognition by each lecturer that the current form of e-learning was too restrictive and that they wanted to explore a different model that might increase student interaction. In one pilot a lecturer explored the use of MyToons (http://www.mytoons.com/), to support the teaching of animation in a New Media course. In a first year Information Systems course, another lecturer is supplementing her WebCT site by using a corporate implementation of the wiki application, Confluence (http://www.atlassian.com/software/confluence/), to build an information systems jobs registry. In a first year Applied Ecology course, another lecturer has given her students a blog through a Drupal-based application (http://community.mashedlc.edu.au) to encourage students to record and share their field notes and laboratory reports. In two similar projects based in two different universities, lecturers are testing a whole-of-programme approach to the use of blogs in New Media courses. Recently, one of these lecturers began using a staff retreat as an opportunity to use a wiki to engage in a curriculum re-design process by getting his teaching staff to work face-to-face undertaking joint curriculum writing activities. The reports from these pilots are still being developed however we can provide some reflection on the Mytoons pilot project.

MyToons (http://www.mytoons.com/) is animation site "…where people who really love animation - from seasoned industry pros to rabid animation fans - can upload and share their creations and animated favorites with the entire world for free". It offers students a wide range of functionality including an online gallery for their work, a personal online portfolio, off-campus access, documentation of personal and group processes, an authentic community of practice, global networks through groups and friend-lists, experience with social protocols and online culture, peer benchmarking, peer critique and technical support.

From the outset of the pilot there were a number of technical problems that prevented students uploading their animations files to the site. While that problem was eventually solved, it did create an initial level of concern amongst the students that they were relying on prototype software to complete their university studies. However by the end of the course students rated themselves as competent users of MyToons and generally believed the site supported their work. While the

pilot group identified themselves as experienced users of social software, their participation in this online community helped further raise their awareness of the risks of internet fraud and spamming and presented the lecturer with an opportunity to talk about ways they could manage their identity through the use of online screen names.

A key recommendation arising from the pilot was that the syllabus should be reoriented from technical mastery of animation tools to also consider the skills students require to effectively engage in an online community. Another outcome of posting their work in such a public space was the heightened awareness of copyright issues. In the lecturer's explanation as their work was now under wider public scrutiny, plagiarism became increasingly socially risky (Barrass & Fitzgerald, 2008). The technical problems early in the unit served to highlight that innovation and experimentation can be risky and that adopting longer implementation time frames would help mitigate some of this risk.

EMERGING ISSUES AND FUTURE TRENDS

While this project continues into 2008 with a second social software survey being conducted in May, we are beginning to see a number of issues emerging that we will briefly detail here.

No One-Size-Fits-All

The rich variety of alternatives and complementary tools available online to support learning and teaching can make the selection of the best tools for a particular purpose difficult. In our experience there is no single application or tool that meets all these needs. What is becoming clear is the potential value of networked repositories and aggregation services that university teachers can subscribe to or track easily. Our project remains founded on the belief that there are a multitude of web services that are readily available to students and educators, and we continue to seek the underlying principles that make these services valuable in learning and teaching rather than building or significantly modifying large information systems. The ALCT is developing an online resource to facilitate sharing and exchange. Referred to as the ALCT Exchange (http://www.alctexchange.edu.au), this project seeks to create an online social networking hub for the exchange of ideas about teaching practice in the Australian and international higher education sector. While this work will be a significant development for higher education, the reality is that it will not be the only space for social networking. We will require a multiplicity of social networks that are designed in interconnecting ways that facilitate communication and exchange across different university networks. Interestingly, students themselves are not seeking ICT solutions as alternatives to traditional teaching. Some recent surveys (Berger, 2007; Ipsos MORI, 2007; Salaway & Caruso, 2007) note that students are wary of too much ICT in teaching and prefer a balance between online and face-to-face instruction. They are also concerned that instructors may not have sufficient expertise to use ICT effectively in teaching: some students feel that they have more expertise than their teachers (Ipsos MORI, 2007).

Institutional ICT Services are not Partners in Innovation

Centralised ICT services departments with their focus on management and standardisation have proved a barrier to the exploration of innovative emerging online technologies and services. There is a pervasive view that external services should not be used for teaching as they represent unacceptable risk. It is not just high profile applications such as Facebook that are frowned upon but often decisions are taken in the interests of simplification and standardisation that effectively limit the choices available to lecturers. In one of our universities, a request to have the Firefox web browser included on the standard computer image was denied by ICT Services because they argued Internet Explorer provided equivalent functionality. Despite concerted efforts both within and outside the university to document the pedagogical strengths of Firefox over Internet Explorer 6 (see http://talo.wikispaces.com/Browsers), only Internet Explorer was retained on student labs. Staff were given the opportunity to use Firefox but only if they were able to develop a business case for their application.

In another example, our need to alert students to our survey highlighted difficulties and gaps in the ways universities communicate electronically with students. Many students do not regularly use their university email accounts due to limited mailbox storage limits and the fact that many university portals cannot be easily configured by students to meet their particular communication needs. The result is that it can be difficult to contact students. There are arguments for standardisation and common approaches for institutional services, but as Franklin and van Harmelen (2007) argue, there is also a need to support innovative and creative activity that explores additional or alternative learning and teaching techniques and environments

Open Source Software and 'Free' Web Services are Vital

Much of what others and we have been able to achieve in the DLC project is the result of the availability of open source software like Drupal and 'free' online services like Google Groups, MediaWiki and MyToons. In institutions where ICT departments can be unresponsive or hostile to requests from academics to use this new software or an online service for research or teaching, access to the Internet's growing range of accessible services provides a more than viable alternative to in-house supplied services. ICT departments are actively discouraging such approaches where they can, for example by denying the easy availability of appropriate browsers on university computers or closing ports on routers used for video collaboration. While there are risks to privacy, questions of accountability, and no guarantees of reliable or continuing services associated with external services, equally there are questions of quality of service, responsiveness and availability of expertise when using institutional services.

Cross-Institutional Innovation is Problematic

Cross-institutional collaboration can be richly rewarding for students and staff. The benefits include raising awareness of best practices, reuse of resources, peer review and economies of scale generally, but there are barriers, not just of time and place. There is a not-invented-here attitude that may have some credibility: individual institutions have their own cultures and timetables that don't necessarily align with others but this should not be a reason to reject outright an approach or resources developed elsewhere. Part of the challenge of working across the sector is that while each institution continues to run its own ICT services, there will be barriers such as authentication issues to impede seamless cross-institutional collaboration. It is time to investigate opportunities to provide ICT systems (like student email, financial management, student management, human resources, student portfolios, alumni services, even a common learning management system) across the higher education sector, not just to facilitate collaboration but also to provide a more efficient and effective service to the community. This is not unprecedented: while the ALCT Exchange may not provide a total solution for collaborative services across the sector, it does provide resources that individual institutions will no longer need to provide for themselves.

Decentralised and Centralised

Our original project was inspired by the loosely connected nature of Web 2.0 services. We have also seen the need to experiment with approaches that offer more stable and managed systems that could integrate with core university systems. In this regard we have been using OpenAcademic (http://openacademic.org/) and their work, to build the Content Management System (CMS) Drupal (http://drupal.org/) as a functional social networking environment. Some of our work and feedback has contributed to the GPL (General Public Licence) release of the Drupaled code base (http://www.drupaled.org/). Drupal has a strong reputation in the field because of its capacity to support both individuals and communities with their web needs from personal web sites or blogs, to community web portals, e-commerce applications or social networking applications. As detailed on the Drupal website (http://drupal.org), the current release of Drupal (Version 6.2) supports a wide variety of uses including:

- Content Management Systems
- Blogs
- Collaborative authoring environments
- Forums
- Peer-to-peer networking
- Newsletters
- Podcasting
- Picture galleries
- File uploads and downloads.

Perhaps the key point in the debate around the use of centralized or decentralized technologies is not really about whether the technology sits inside or outside the institution's firewall but rather how can universities better manage the interconnectivity in a way that is truly student-focussed? As Wilson et al. (2007) explain:

The devolution of technology management from higher education institutions to students is an important step in promoting the transfer of responsibilities, as higher education offers an environment with substantial resources for support, guidance, and community forming. If universities do not make a strategic change to their policy on IT provision, there is considerable risk that education becomes a 'technology ghetto' that offers an increasingly restrictive and un-engaging technology environment that requires constant and expensive care, and feeding by harassed IT staff. (p. 1395)

CONCLUSION

It is clear from the mass popularity of social technologies that a generational shift to working with peers has already occurred in contrast to the individualism that characterised earlier generations, and that we should be capitalising on that social trend in more technologically-mediated ways than we are currently doing. Our approach over the past decade in higher education has been to add a measure of 'group work' to our assessment tasks, but rarely have we deliberately taught the skills of productive groupwork and collaboration to our students: we have simply assumed that groups will 'form, storm and norm' intuitively. However, consider the way MySpace friendship groups develop: the 'intent' is to create the group, not to produce an outcome in the form of an assessment task. We have assumed that students can use their mobile technologies to undertake group work, even if they do not always come to campus to work as a group. But we have not built into our programmes even the simplest of ways to engender a learning group ethos. Nor can we expect our students to make their own connections between formal education and their leisure use of social media. Mass use of such media will always be for diversion, leisure, for 'grazing' and informal interest-driven learning, as Franklin & van Harmelen (2007) have noted. That does not mean we should not make the effort to locate and use the potential of social media for our educational purposes.

Finding creative ways of using technology to expand and enrich the social base of learning in higher education will become increasingly important to lecturers and instructional designers alike. This project represents one small step in testing the applicability of social software to these contexts. While many of our students are already using various technologies to maintain and develop their social networks, it remains to be seen if these offer viable uses in more scholarly settings. Projects such as this, and the Ramsay project mentioned above, provide some baseline data on current students' familiarity with various social technologies, and the efficacy of learning applications of these technologies. Clearly, we are not yet in a position to measure with any validity how Web 2.0 technologies will affect the experience of higher education for our students, but this project, and others, flag ways we might further consider the role of peer learning in universities.

ACKNOWLEDGMENT

The authors thank Dr. Peter Donnan, University of Canberra, for contributing some appropriate references.

KEY TERMS

CMS: Content management system. A general description for a database-driven Web site that allows web-publishing.

Drupal: A popular opensource content management system that allows both individual and community web publishing whose functionality can be extended with an extensive range of add-on modules.

Facebook: A popular social networking site launched in 2004 and originally designed for university and college students.

Firefox: A Web browser developed by the Mozilla Foundation that features numerous add-ons and extensions.

Google Groups: A free groups and mailing list service from Google that includes access a searchable archive of Usenet.

GPL: General public licence. A popular license for free software.

MediaWiki: The opensource software that runs Wikipedia and its related projects.

MySpace: A popular social networking site launched in 2003 and owned by Rupert Murdoch's News Corp.

MyToons: A social networking site designed for animators.

Web 2.0: A term coined by Tim O'Reilly to refer to the shift from static web pages to more interactive web applications controlled by the user.

YouTube: A popular video sharing Website.

Chapter 4.5
Using Social Software for Teaching and Learning in Higher Education

ABSTRACT

This chapter focuses on discussing the use of social software from a social constructivist perspective. In particular, the chapter explains how social constructivist pedagogies such as collaborative learning and communities of practice may be supported by the adoption of social software tools. It begins by briefly discussing the social constructivist perspective considering certain pedagogies such as collaborative learning and communities of practice. Then, it explains how these pedagogies are reflected in actual practice by using a variety of social software tools such as discussion boards, blogs and wikis. Finally, the chapter presents the implications of using social software based on the impact of certain factors such as teachers' understandings of, and beliefs about, teaching in general. The purpose of this chapter is to support higher education practitioners in theory-informed design by distilling and outlining those aspects of social constructivism that addresses the use of social software tools. It is perceived that a gradual introduction of social software to institutional Virtual Learning Environments, with a strong focus on collaborative learning processes and engagement in online learning communities, will highlight the need for discursive tools, adaptability, interactivity and reflection.

DOI: 10.4018/978-1-60566-208-4.ch019

INTRODUCTION

The diversity of perspectives on, and approaches to, the pedagogical use of social software can prove overwhelming to practitioners and researchers alike. In order to make sense of this, this chapter explains how social constructivist theories such as communities of practice and collaborative learning may be assist in the use of social software. This chapter aims to explain the different pedagogical responses to social software tools and social networks regarding specific characteristics of learning, which may inform practitioners in their use of such tools. This is particularly useful in the context of e-learning where higher educators and researchers seek a clear understanding of the affordances of social software and guidance on how to use and integrate these into their educational practice. This may draw practitioners' attention to the relationship between espoused theories and theory in use (Argyris and Schon, 1974) and also for acknowledging curriculum design as a social practice (Conole et al., 2004).

Teaching and learning using social software may require teachers to rethink their beliefs and approaches in order to develop patterns of learning that at least allow and preferably encourage collaboration as a process of planning, criticising and evaluating. This could also allow learners to personalise their learning within a framework where teachers may monitor their progress. In this context, a better articulation and mapping of different pedagogical processes, tools and techniques may provide a pedagogical approach that can be regarded as more consistent and with teachers' theoretical and practical perspectives for teaching and learning using social software. As Downes (2005) argues, educators and practitioners should recognise that social software is not a technical revolution but is about encouraging and enabling collaboration and participation through applications and tools that can support the social constructivist approach to learning. However, adopting teaching and learning activities with the use of social software in a way that promotes interaction and collaborative knowledge building does not mean that it will result in learning per se. These practices require from the teachers an awareness of how students learn and this adds an increased responsibility for teaching and learning. Twigg (1994) argues that many students are concrete-active learners, that is, they learn best from concrete experiences where they engage their senses, and their best learning experiences begin with practice and end with theory.

The purpose of this chapter is to support higher educators for theory-informed design by outlining current issues of social constructivism in a way that assists the use of social software tools but also taking into consideration that creating a network of interactions between the instructor and the students may not lead to effective communication and collaborative knowledge building. For example, the design of a group project may not necessarily lead to the desired learning outcome. At best, it would appear that learning benefits can be achieved under certain circumstances. Students have to contribute to the learning process by posting their thoughts and ideas to an online discussion because learning is an active process in which both the teacher and the students should participate if it is to be successful. Research by Sharpe et al., (2005) provides examples, from a learner scoping study, about the roles of the teacher and the learner for ensuring and enhancing the quality of instructional design and how this relates to effective online learning processes. The scoping study highlighted the holistic nature of students' experiences of learning and proposed that learning design should focus on students' motivations, beliefs and intentions and the meanings they attach to e-learning. For example, as is well known, collaborative learning may not suit everyone (Laurillard, 2002, Mason and Weller, 2001). So a plethora of questions remain about how to design online learning activities whose purpose is understandable by the students. The important issue to note, from research in teaching and learning, is that there may be contradictions between what teachers and students conceive as effective teaching. Highlighting such differences may be helpful in assisting teachers to design learning activities that are adjusted to students' needs. For example, Jones et al., (2004) used semi-structured interviews to compare the student and the teacher perspective of what is good teaching. Students emphasised effective feedback, teacher enthusiasm, encouragement and good organisation and direction for learning. Teachers mentioned these but gave less attention than students to feedback, but added that disciplinary knowledge and technical expertise are important for students' learning. Laurillard (2002) and Thomas et al., (2004) also identified the importance attached by students to feedback, as well as teacher availability and approachability.

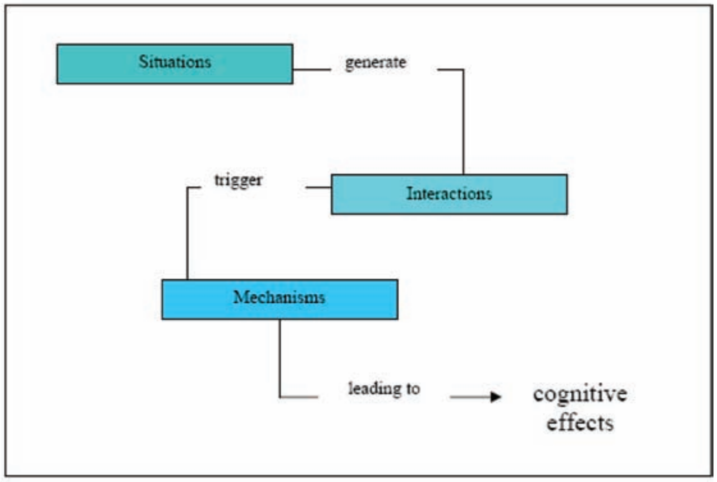
This chapter continues by briefly explaining social constructivist theory. This is important because it allows pedagogies to be described and related to social constructivist theory in terms of the use of specific technological tools and resources. It then discusses pedagogies that could be mapped to a social constructivist perspective such as collaborative learning and the idea of communities of practice. A number of issues related to these pedagogies will be highlighted. Then it explains how these pedagogies may be reflected in practice by using a number of social software tools such as discussion boards, blogs and wikis. Social software could be defined as technologies for the social construction of knowledge that emphasise the design of teaching and learning activities which promote collaborative learning processes and group interactions. Finally, the chapter discusses emerging issues regarding the use of social software in educational contexts. It is perceived that a gradual introduction of social software in the institutional context with a strong focus on collaborative learning and the creation of online learning communities may encourage teachers to design learning tasks which afford the use of these tools while at the same time taking into consideration students' own perceptions of e-learning and how they use technology to learn more effectively.

RETHINKING PEDAGOGY FROM A SOCIAL CONSTRUCTIVIST PERSPECTIVE

The social constructivist perspective views learning as a social activity which is created by the process of conversation, discussion and negotiation (McConnell, 2002, Ernest, 1995). In addition, social constructivists argue that a learner may be able to understand concepts and ideas by teachers or peers who are more experienced. This collaboration between teacher and student may be achieved in learning activities that are situated in real-world contexts. From this perspective, meaning making is the process of sharing perspectives and experiences through collaborative processes and within communities of practice. Therefore, learning can be derived from meaningful discussions with other peers who have similar or different perspectives based on their own experiences.

An important context for thinking about social constructivism is in relation to particular learning processes that are described from two concepts: (1) Vygotsky's 'Zone of Proximal Development (ZPD)' (the term became part of mainstream thinking in pedagogy since the translation of his Mind and Society in 1978), and (2) 'Intersubjectivity' (Jonassen, 1999; Lave and Wenger, 1991). Vygotsky defined the ZPD as the distance between a learner's current conceptual development, as measured by independent problem solving, and the learner's potential capability, as measured by what can be accomplished under the assistance or in collaboration with more capable peers (Vygotsky, 1978). With practice and personal support, learners may increase their learning skills, until they can manage on their own (Cole, 1992). 'Intersubjectivity refers to the mutual understanding that has been achieved between students through effective communication. The social constructivist theme is reflected in the way in which learning occurs through the process of intersubjectivity in the Zone of Proximal Development. That is, learning occurs through negotiation of meaning and com-

Figure 1. Situations, interactions, mechanisms and effects (Excerpted from Dillenbourg, 1999)



munication between students and teachers within a context of real-world activities. Peal and Wilson (2001) summarise the design of web-based tools as ZPDs by adopting the following features:

- Learning activities that are part of real or simulated activity systems, with close attention to the tools and interactions, characteristic of actual situations
- Structured interaction among participants
- Guidance by an expert
- The locus of control passes to the increasingly competent learners

At the same time, there is a wide range of pedagogies that can be mapped to a social constructivist perspective such as collaborative learning (McConnell, 2002) and the accounts of community facilitated by technology with social and situated views of learning. That is, the idea of communities of practice (Lave and Wenger, 1991).

Collaborative Learning as a Process of Interaction

Given the potential of more able peers to help less able ones, researchers have tried to identify the characteristics of collaborative learning. For example, Goodyear (2003) argues that collaboration may be viewed as a mechanism for causing interaction among students which may enable certain processes such as explanation, disagreement and social negotiation of meaning. Dillenbourg (1999) offered an account of collaborative learning processes in terms of developing ways to increase the probability that learning interactions will occur within an educational context (Figure 1).

One way to think about these mechanisms constructively is to consider how these situations can be designed for online learning activities and how these activities can generate interactions between students. At the same time, a key challenge is the question of how to use these mechanisms in order to empower learners to engage actively with the range of tools and resources of the online environment. For example, online discussions may provide learners opportunity for reflection through creating explanations and by posing alternative positions, where negotiation of meaning between peers may occur. In addition, an alternative online activity such as a group-based task within an online learning environment, peers may share learning tasks for ensuring mutual engagement and cognitive load especially when students' skills within group are in advanced level In each case, however, less able peers in particular areas may develop their understandings by observing the more able ones in conducting particular learning activities. An interesting challenge is to think the types of situations that can create collaborative processes within learning communities where learners may give their own interpretations of different views. This might be encouraged by creating and engaging students in communities of practice.

Communities of Practice

The notion of community facilitated by technology have been explored by many researchers with social and situated views of learning and the idea of communities of practice in Computer Supportive Collaborative Learning (CSCL). Accounts of situated learning (e.g. Brown et al., 1989; Lave and Wenger, 1991; Wenger, 1998) have had a particular influence for e-learning. Wenger (1998) argues that issues of education should be addressed primarily in terms of identities and modes of belonging, and secondarily in terms of skills and information. This view regards pedagogy for e-learning not just in terms of procedures and techniques for supporting the construction of knowledge but in terms of their effects on the formation of identities (Mayes and Fowler, 1999). The essence of a community of practice is that, through a joint engagement in a particular activity, learners form identities and develop and share practices (Mayes and de Freitas, 2004). A community of practice has been defined by Wenger (1998) based on three aspects:

- What is about – as a joint enterprise as it is understood and continually renegotiated by its members
- How it functions – as a mutual engagement that binds members together into a social entity.
- What capability it has produced – the shared repertoire of communal resources members have developed over time, e.g. routines, sensibilities, artifacts and vocabulary.

Involvement is central here because it means making conscious commitment to a group. Shaffer and Anundsen (1993) refer to this as 'conscious community' and as described by Wenger (1998) this is a community that emphasises participants' needs for transformation and personal growth, as well as the social aspects of the community. In some instances these learning communities may be more interesting and stimulating because they involve participants with similar objectives and interests. This aspect may be a part of what differentiates community for social networking (e.g. Facebook, YouTube or My Space) and communities that nurture personal growth and development.

The attraction of applying communities of practice in higher education is whether or not students are motivated for conceptualising learning as a process of guided construction of knowledge. This means that teachers need to focus on the student's cognitive activity otherwise there will be no useful learning. For example, Rohde et al., (2007) proposed a design of practice-based courses where students created a community of practice. The online community's purpose was to facilitate the view of knowledge as a construction of students' online interactions within the community and remains within the virtual domain to be accessed, challenged and developed further by other members in the community. At the same time, Goodyear (2003) gives an account of communities of practice as knowledge-sharing by describing a cycle of learning, moving through phases of externalisation (of tacit knowledge) sharing, discussion, refinement and internalisation.

The design of online learning tasks is central here. Goodyear (2003) distinguishes between a task (what gets set by the teacher) and an activity (what follows as the learners' response to the task specified). A number of taxonomies of task types exist, and these can be useful for teachers to decide what specific tasks to set according to the desired software tools to be used. Paulsen (1995) has reviewed a wide range of e-learning and teaching techniques and has produced a taxonomy of online learning tasks. At the same time, in face-to-face mode these learning tasks may be accomplished through the use of simulations, group activities and small-group projects and by encouraging students to pursue topics of their own interest. A sense of community in the classroom may emerge from these activities which may allow students to create physical interactions.

USING SOCIAL SOFTWARE TOOLS FROM A SOCIAL CONSTRUCTIVIST PERSPECTIVE

Successful collaborative processes and the creation of online learning communities emerge and are shaped by their own members. The teacher as a member of that community may influence the structure and the character of the community but not the creation of that community. The teacher, therefore, may set up or modify learning tasks, select and design software tools that may assist to the emergence of the learning community where each student may customise these tools to meet their own needs. The design of these tools may be modified to meet the requirements of a new learning task on which students are working. For example, the teacher has assigned an online collaborative learning task for students to share opinions and ideas. The teacher could initiate that particular task by designing supportive organisational forms and structures necessary for establishing an online social network. These supportive organisational forms may include social software tools for triggering students' action. Social software can be broadly defined as 'software that supports group interaction' (Owen et al., 2006). The most common type is likely to be discussion boards. However, applications like weblogs, and wikis are now widely used for teaching and learning. According to Owen et al., (2006) some of the key attributes of these tools, in relation to higher education, are that they:

- Deliver communication between groups
- Provide gathering and sharing resources
- Deliver collaborative collecting and indexing of information
- Enable communication between many people
- Support conversational interaction between individuals or groups ranging from real-time instant messaging to asynchronous collaborative teamwork spaces
- Support social feedback
- Deliver to many platforms as this is appropriate to the teacher, student and context

Weblogs are updatable personal websites, often used as personal journal, consisting of brief paragraphs of opinions, information and links, called posts (Anderson, 2006). Wiki software allows learners to easily upload content and easily edited by anyone who is allowed access (Owen et al., 2006; Anderson, 2006). One of the well-known examples is the online encyclopedia Wikipedia (http://www.wikipedia.org/). The principle behind the operation of Wikipedia is that a wiki may be regarded as a collaborative tool that may facilitate both the needs of a large group but also may be used as an asynchronous social tool for the particular needs of small groups (Owen et al., 2006). Flexibility, ease of use and open access are some of the many reasons why wikis and blogs are useful for group working.

This section will consider a range of social software tools such as discussion boards, blogs and wikis in relation to the two social constructivist

Table 1. Paulsen's taxonomy of online learning tasks

Techniques	Example methods
One-alone	Online databases; online journals; online applications wikis, blogs, social bookmarking; software libraries; online interest groups, social networking
One-to-one	Learning contracts; Apprenticeships; interviews, collaborative assignments, roleplays, wikis, blogs, social networking
One-to-many	Symposiums; lectures; role plays; interviews, wikis, blogs, social networking
Many-to-many	Discussion groups; simulations; games; debates; case studies; brainstorming; Delphi techniques; Forums; project groups, wikis, blogs, social networking

perspectives: collaborative learning and communities of practice. The particular approaches proposed may provide, to teachers, a starting point for reflection on how collaborative learning and communities of practice may be mapped to teaching and learning using social software. However, there are a number of elements that determine the level of learning that can be achieved by using social software. These limitations may often be apparent to the design of learning activities because students may perceive their engagement, for example, into online learning communities differently often causing lack of engagement, interaction and participation. Social presence becomes a critical element in community building in a way that the instructor should empower students to participate in the community building and exploration of content (e.g. Goodyear, 2001; Ellis et al., 2007). Also, establishing guidelines as a starting point for collaborative processes in a group may serve as a means by which the group defines shared goals and purposes (e.g. Goodyear, 2007; Kanuka, 2007).

Using Social Software for Engaging in Collaborative Learning Processes

Collaborative learning may be instantiated in actual practice by using a number of different tools. For example, discussion boards and blogs may be used to create processes of collaboration and interaction by introducing online discussions through linking and posting information and resources. The interactive nature of online discussions assists in promoting discussion among learners by creating a forum for sharing opinions and ideas. By engaging students in online discussions, teaching and learning may be transformed from a one way instructional approach to a highly interactive approach to learning (Ellis et al., 2006). Additionally, reflection and reflective practice may be seen as one of the most valuable affordances that online discussions can provide. This is particularly useful when face-to-face discussions and online discussions complement each other. For example, the online discussion may be planned not just to be an 'add on' but to be an integral part of the learning environment. Therefore, by integrating blogs or discussion forums for engaging in online discussions into the teaching and learning flow of the classroom, students have the time to foster a habit of reflective practice, critical thinking and articulating online, which can subsequently further develop during in-class discussions.

Research findings show, that online discussions often focus on similar kinds of learning tasks such as the encouragement of participants to put their thoughts into writing in a way that other peers can understand, promoting self reflective dialogue and dialogue with others. That is, effective online discussions through the use of social software tools foster effective collaborative learning (Ellis et al., 2007). However, students may only achieve this deep reflection on the online postings made by other peers, if the purpose of the learning activity is understood by them (Ellis et al., 2004).

For the purpose of developing student's understanding, teachers should view the reflective practice as a part of an active learning structure, for the use of blogs and discussion boards, which facilitate the sharing of different viewpoints and ideas. This is central here, particularly for using blogs where a permanent record of a student's thoughts is provided for later students' reflection and debate, by automatically saving the messages posted in the discussions. This may create a network of interactions, which may form a social network. For example, if blogging activity is combined into two models which can function simultaneously then the particular application can be both user and content focused or a mix of either. The user - focused model may be designed for the purpose of interaction, sharing and formulating social networks. The content –focused model may be used for assigning learning content which can be written from a personal point of view, with students expressing their own range of interests, rather than on an assigned project or a course topic. This provides to students the ability to create their own content by adopting a research-based approach. For example, Britain (2004) argues that the teacher should gradually engage students in collaborative learning by primarily focusing on making explicit students' conceptions of the phenomenon in question which, in turn, they will determine their prior knowledge of that phenomenon. The second stage is to help students to be aware the level of knowledge they already have and this could be accomplished by engaging them in online discussions for exchanging opinions that would assist on experiencing other students' views on the same issue (e.g. McLoughlin and Luca, 2001). Interaction may occur throughout the students' group instead of between students and the teacher within the group setting and therefore, the teacher is acting as a group member who is contributing to the learning process thus, encouraging students to form different communities with different knowledge-building practices. Such communities may be academic or vocational, at a first instance, and ideally students should recognise that both the creation and the application of knowledge within the community are well-understood and have value for the members (Goodyear, 2007).

Creating Communities of Practice With the Use of Social Software

Conceptualising the use of a blog from a content-focused approach, there is the possibility to build learner knowledge networks. That is, the design of a Knowledge Forum, as Scardamalia and Bereiter (2003) addresses it, aiming at supporting learners to pool ideas and reflecting to these by developing supportive arguments. In the form of content, like notes, a multimedia community knowledge space is created through students' different perceptions, models, theories, evidence and reference material in a shared space. Through this space, students may develop a collective responsibility for the solution of knowledge problems, and the teacher is assisting students to grow into that responsibility. The learning activity includes the development of ideas and explanations which then are shared with a group of peers. Then, refinement of these ideas is important as new ideas develop. In this way the use of a blog as a Knowledge Forum has the potential to include an interplay between socially defined knowledge and personal experience which is mediated by a membership of the group. This provides a learning situation that negotiates both an individual's experience, and the knowledge that the individual takes from, or brings to, the community. Consequently, the use of a blog as a Knowledge Forum supports the creation of communities from a focus of carrying tasks and activities to a focus on the continual improvement of ideas and creative problem solving (Scardmalia and Bereiter, 2003).

An important element for social software is linking as it may deepen the conversational nature and also the sense of immediacy (Anderson, 2006). From a user-focused perspective, the process of linking to different communities may lead to 'boundary crossing'. For example, through linking, students can be members of online learning communities that include other cultures, experiences and ages. By this way, students have the opportunity to move beyond their particular social community and enter other communities where new skills are developed with the assistance of more experienced members of the community. In particular, White (2006) argues that teachers may start thinking about strategic approaches to using blogs as a medium for community development. That is, in terms of (1) technology and design: the impact of blogging tools on the community and (2) the social architecture: locus of control, power, identity, interaction processes and the role of subject matter. White (2006) distinguishes blog based communities in three main patterns: The blog centric community, the central connecting topic community and the boundaried community.

The main difference between these kinds of blog based communities is based on locus of control power and identity. In blog centric communities the power is firmly held by the blog owners as they can set the rules and norms of engagement. The topic centric blog community's power and identity is distributed across the community because there is no technological platform and bloggers may select their own tool. In boundaried communities, blogs and blog readers are hosted on a single site or platform. Learners may become members of the community where are offered the opportunity to create a blog. Often boundaried communities have other social software tools such as discussion boards, instant messaging and wikis. Power in boundaried communities is held partly by the owner of the platform, who may impose rules but also is exercised by bloggers in terms of the frequency of posting and interest as measured by how many comments a blogger gets. An example of adopting a boundaried community for teaching and learning would be to design a learning activity where each student would have the chance to log in a Virtual Learning Environment (VLE) where there would be collections of other students' blogs for the students to post their opinions and ideas for the issues discussed. This may lead to faster social connections and community building. However, these blogs are not replacing the forum instead they offer a new community activity because bloggers have more control of the message than in a forum in terms of controlling the pace of the postings and determining their relevance according to their own learning experiences. Therefore, blogs can be regarded as a more personal part of the VLE where the students reflect, criticise and control different posts based on their personal interests.

An interesting point made by White (2006) is that blog communities may take the form of a network since they are not bounded by the technology and may grow beyond the ability of an individual to keep track of the network. With the perspective of social architecture including the roles and forms of interaction within each type of blog communities, teachers may be able to design their blog community while taking into consideration the role of content or subject matter, their role as facilitators and the role of the technology. In essence, the view of online communities provided by White (2006) may form pedagogical approaches for designing and nurturing blog communities by distributing control, power and identity.

A strong element of this socio-cultural view of using blogs and other social software tools is online identity or social presence – what persons become when they are online and how they express that person in virtual space (Palloff and Pratt, 2007). For example, an introverted student, who tends to have more difficulty establishing presence in face-to-face teaching, may become more extroverted by establishing presence and interaction with other peers online. This notion of changing identity when interacting with technology may be caused by the fact that introverted students process information internally and are more comfortable spending time thinking about information before responding to it (Palloff and Pratt, 2007).

Consequently, introverted students may have less difficulty creating a blog for exchanging opinions within a boundaried community where the establishment of a social presence may be easier than in-class. It can be argued, therefore, that the degree of social presence that may be developed within a boundaried community may be attributable to the particular technological tool in use. For example, introverted students may still be introvert when using a synchronous chat because it may be perceived as a "noisier" space where they have to post instantly their thought without having available time for reflection, but when they use a blog they may become more extrovert as they have a sense of control and time to reflect their arguments before posting. However, recent studies that investigated social presence have suggested that the medium does not affect the development of online presence. Instead of the particular tool, the way that the student interacts and behaves with other peers impacts on the development of online presence (Wenger, 1998; Polhemus, Shih, and Swan, 2000; Stein and Wanstreet, 2003).

Learning through an online community may not be accomplished only by designing online learning activities that promote interactions between a learner or learners and an environment that is carried out in response to a task with an intended learning outcome (Beetham, 2004) but by focusing also on the process of learning and on the learning activities that students carry out to develop understanding. Although the teacher is responsible for designing appropriate learning activities that facilitate the process of participation, interaction and expression of different opinions and ideas, students also have to contribute for achieving successful online learning activities. Therefore, in order for the students to be considered 'active' in an online community, they must not only access the online learning environment but they must post a comment of some sort. By posting comments students are considered as active participants and as a result ideas can be collaboratively developed and socially negotiated.

This ability to collaborate and create meaning communally is a clear indicator that students are actively participating in the learning process. For example, an active student who participates and generates knowledge may be the one who gives substantive feedback for other students' ideas but also provides additional resources that other peers may want to review. This development may be considered as a successful learning outcome because the student is able to critically evaluate other students' comments and at the same time being able to gather additional learning resources that go beyond the material assigned, thus developing their skills and their confidence as researchers. At the same time, teachers may offer some guidelines for achieving minimal participation, making it more likely that the students will participate in the learning process. Palloff and Pratt (2007) note that this expectation of participation differs from face-to-face teaching and learning because the discussion can be dominated by more extroverted students giving the impression that the class is engaged.

The opportunity for reflection and the ability to think before responding to a post may help to create a level of participation and engagement that may be greater than a face-to-face discussion. For this reason, the instructor needs to be actively engaged in the process and motivating students to participate by posting interesting topics for accomplishing the desired learning outcome. This may encompass the development of a learning community and not just a social community where knowledge about the learning content can be understood and the ability for collaborative knowledge building can be achieved.

However, research studies reported that students may be uncomfortable to engage in online environments for openly criticizing each others work (MacDonald, 2003), engaging them in peer feedback (Ramsey, 2003) or shifting the power from the tutor to them (Crook, 2002). Sweeney et al., (2004) conducted open-structured interviews with 12 students in a blended course where some sessions were conducted face-to-face and some on discussion boards. Sweeney et al., (2004) concluded that there were students who perceived discussion boards as requiring reflection and hard work whereas others perceived them as offering freedom of speech and deep learning. These variations in students' perceptions may be related to students' understanding of their learning, the role of the learning environment and the activities that are engaged within that. Ellis and Calvo (2006) attempted to investigate these relations by exploring the student experience of learning through discussions in an undergraduate engineering subject. A quantitative approach was used by giving three questionnaires for providing a comprehensive investigation of the qualitative variation in students' experience. They suggested that if students do not understand how discussions could help them reflect on and revise their ideas, they tended not to approach face-to-face or online discussions in ways likely to improve their understanding. They conclude:

"It would also seem necessary to strengthen the relationship between the purpose of the discussions, whether online or face-to-face, in relation to the learning outcomes of the students… Without such strategies, poor approaches to discussions, negative perceptions of workload and a general lack of awareness of the value of discussions for learning will hamper the quality of learning experienced in discursive learning contexts." (p. 67-68)

IMPLICATIONS FOR USING SOCIAL SOFTWARE FOR TEACHING IN HIGHER EDUCATION

Since the use of social software promotes communication, interaction, sharing of resources and social feedback, it is difficult to talk about pedagogically driven practice in terms of using social software without investigating teachers' conceptions, beliefs and intentions of teaching, in order to sketch their main approaches to using social software. However, uptake and implementation does only depend on teachers' beliefs and intentions to using social software but also on students' conceptions of teaching and learning, their conceptions about the learning environment and their conceptions about the subject matter. Part of this section focuses on teachers' conceptions in terms of distilling the main outcomes they imply.

Kember (1997) identified five conceptions of teaching which could be located from a continuum, from a teacher-centered, content oriented conception of teaching to a student-centered and learning conception of teaching as follows:

- Teaching as imparting information
- Teaching as transmitting structured knowledge
- Teaching as an interaction between the teacher and the student
- Teaching as facilitating understanding on the part of the student
- Teaching as bringing conceptual change and intellectual development in the student.

It is apparent that the first two categories have practical implications for using social software. At a first instance these conceptions heavily rely on declarative conceptual knowledge, contemplative forms of analysis and use of textual representations (Barnett, 1997). Therefore, the aim is for the students to absorb predefined knowledge relevant to the discipline's objectives. The main kind of learning outcome associated with these conceptions is the ability to recall prior knowledge and use it for the construction of arguments or for problem solution more generally (Goodyear, 2003). On the contrary, the following three conceptions converge more with the pedagogical assumptions for using social software because the student is supported to handle with confidence concepts, theories and ideas and communicating them with peers and teachers. Also these conceptions encourage informed but critical action by understanding the power and limitations of the field as a resource for action (Barnett, 1997).

These conceptions of teaching may imply that the way social software tools are used depends on the educational beliefs and presumptions of teachers. This also implies that the use of social software is likely to have varied uptake and implementation because of differences in conceiving how these tools may be used between teachers and also between the educational presumptions inherent in these tools. Connected to this observation, teachers may rethink their conceptions, towards a more social constructivist approach for using social software. Teachers that wish to support the use of these tools may plan curriculum design as a social process by:

- Allowing learners to personalise their learning but in a framework that monitors their progress
- Collaborating with experts in a particular domain so students can participate in discussions and become knowledge creators
- Developing learning tasks that encourage collaboration and sharing of ideas
- Supporting the learning experience in terms of designing different learning tasks outside class environment
- Creating organisational structures and deploying appropriate tools for online learning communities to emerge.

These suggestions involve a detailed consideration of the nature of using social software, which may also influence teachers' conceptions of teaching in general. Therefore, for using social software teachers may need to decide what concepts, tasks and methods to introduce based on their conceptions of teaching and the demands of the curriculum. This suggests that particular beliefs and intentions for teaching may bring certain affordances and constrains to the use of social software. This indicates that there is a need for sustained and influential research to understand teachers' conceptions of using social software for teaching and learning.

Another important implication is the integration of social software tools into institutional Virtual Learning Environments (VLEs). Institutions support that these environments reflect the organisational reality. This means that a VLE provides the student with tools such as discussion boards, email, noticeboards, whiteboards, etc and connects the user to university libraries, resources, regulations and specific content such as assessment and modules. The argument is that since VLEs contain all this data, there is the potential to change the particular learning environment (such as the type of learning tasks, learning resources, type of tools, complexity of material, etc) to the student's preferences. However, practitioners now question whether the idea of a VLE can support the integration of social software tools (Anderson, 2006). In response to these concerns, Johnson et al., (2006) investigated the development of a Personalised Learning Environment (PLE) as having a significant effect in managing personal goals in the context of personal development planning and for introducing the integration of social software and e-portfolios.

CONCLUSION

This chapter explained how the social constructivist perspective can inform the use of social software. Certain pedagogies from a social constructivist approach were discussed including collaborative learning and communities of practice. Then, this chapter discussed how these pedagogies may be used for social software. This is particularly useful for mapping the social constructivist approach against specific characteristics of learning, which may enable teachers to design specific learning tasks for social software tools.

This also may allow teachers to make the link between pedagogy and theory more explicit. It is perceived that using social software tools for helping students to engage in online discussions will promote collaborative learning and interactions amongst learners as well as reflective practice. Furthermore, providing the appropriate organisational structures and technological tools enable learners to develop online learning communities where the sharing of learning material and the construction of new ideas, with the help of more experienced peers, may lead to user-generated content. From a user-focused perspective, an important element of social software is linking which gives the opportunity to students to enter other communities, with different cultures and experiences to create new knowledge and skills. This may generate a network of interactions, which can result in the formation of a social network community. Personal identity and social presence are important for establishing internal dialogue for formulating responses which can be potentially different from how students may respond to face-to-face teaching and learning. The discussion and acknowledgement of these issues support the development of control, power and identity in the online community by designing pedagogically informed learning activities. However, we must acknowledge that designing such learning activities may not lead to intended learning outcomes because students' conceptions of teaching and learning and how they intend to engage in the online learning environment may vary.

Teachers' conceptions of teaching seem to be an important consideration for using social software from a social constructivist approach. Teachers may need to decide their teaching strategies (nature of learning tasks, curriculum design, teaching approaches etc), in terms of using social software, based on their particular understandings of the teaching process. This is particularly useful in the context of e-learning, because through teachers' conceptions of teaching, researchers could investigate the impact of factors such as individual perspectives, cultural and discipline differences in terms of using social software.

Further empirical research is needed to understand the role of social software from a pedagogical perspective by investigating how the use of these tools can support students' learning experiences. Social software tools are currently perceived as technologies that imply a different relationship between institutional boundaries and social forms (Jones, 2008) so further investigation is needed to see how current institutional VLEs can afford the opportunity of greater peer-based pedagogy to allowing more radical or diverse learning activities by integrating social software or whether it is preferable to rely on publicly available social software resources which can be used for teaching and learning.

Chapter 4.6
Social Networking Sites and Critical Language Learning

Andy Halvorsen
Nagoya University of Commerce & Business, Japan

ABSTRACT

This chapter looks at the potential use of Social Networking Sites (SNSs) for educators and second language learners. It views SNSs broadly through the lens of Critical Language Learning (CLL) and looks at specific issues of identity formation, student empowerment, learner autonomy, and critical literacy as they relate to the use of SNSs. This chapter also reports the results of an initial project to make use of the MySpace social networking site for Japanese learners of English. It is hoped that this chapter will raise awareness of some of the complex issues surrounding the use of SNSs by language learners and that it will lead to further research and consideration of these issues.

DOI: 10.4018/978-1-60566-190-2.ch013

INTRODUCTION

As technological innovations of all kinds push our society forward at ever increasing speeds, the basic nature of social interaction is being transformed. Social networks are now being formed in ways that no one would have imagined 50 years ago. Currently at the heart of this phenomenon is the massive rise in popularity of Social Networking Sites (SNSs) like MySpace, Mixi, Facebook and others; sites designed specifically for the purpose of developing and sustaining interconnectivity amongst users. Though English may currently be the language favored by the majority of users of SNSs, it certainly does not have a monopoly on this trend. The SNS Mixi, for example, which functions exclusively in Japanese, currently has over 11 million registered users. Indeed, according to recent global trends in blog posting, the Japanese language has actually surpassed English in regards to the number of blog posts per language, with Japanese now generating 37% of the total contribution to the blogosphere (Sertan, 2007; Sifry, 2007). The global ubiquity of SNSs means that second language learners can easily find themselves in contact with native speakers anywhere in the world. Clearly the popularity of the sites, combined with the opportunities for meaningful interaction that they present, potentially make them a powerful platform for second language acquisition, and, in fact, research into how best to take advantage of this opportunity is beginning (Godwin-Jones, 2006; O'Hanlon, 2007; Murray, 2005).

There are complex questions to be considered however; questions that relate specifically to changes in the meaning of identity and the forms of social interaction that occur online. How, for example, can the complexities of second language identity formation be interwoven into one's online identity formation? Or, what new types of literacies are required for decoding and interpreting information in multi-modal, peer to peer environments like SNSs? (Dieu, Campbell, & Ammann, 2006). Could we also consider an analysis from a constructivist perspective? Social constructivism, particularly as it relates to education, places primary importance on the need for mediation and social interaction in the development of meaning (Pasfield-Neofitou, 2007; Vygotsky, 1978). Web 2.0 technologies are, after all, primarily about the construction of meaning through interaction between and amongst users. Some research recently has looked to constructivism and in particular Vygotskian social constructivism as a way to interpret and assess some of the potential benefits of the type of peer editing and collaboration that can take place on wikis and SNSs (Lavin & Claro, 2005). This chapter will attempt to lay a framework for a discussion of these questions and others by looking at SNSs and other associated Web 2.0 technologies from a Critical Language Learning (CLL) perspective and by considering a recent case study looking specifically at the use of the MySpace SNS to facilitate the acquisition of English amongst Japanese university students. Specifically, this case study had three primary objectives:

1. To assess Japanese students' interest level and motivation regarding the use of SNSs to improve their English skills.
2. To consider the use of the MySpace SNS through the framework of the issues of identity formation, learner autonomy, critical literacy, and student empowerment (Pennycook, 1997).
3. To map out potential difficulties and opportunities for further research into the potential use of SNSs for English learners in Japan.

This case study and its associated research relating to CLL and the potential applications for SNSs in the second language classroom is one of the first of its kind, particularly in a specifically Japanese context. It is hoped, however, that this chapter will lead to further discussions and considerations of the relationship between the changing nature of social interaction in the age of the Internet, and the potential opportunities and challenges that these changes present to the second language learner.

SOCIAL NETWORKING SITES AND CALL

Social networking itself is not a new phenomenon. Indeed, our innate need for social interaction has always drawn people together to form real-world social networks where members sought to build and maintain a sense of community through interconnectedness with others. Though CMC (Computer Mediated Communication) has existed in various forms for most of the last 50 years, it is only recently, as the Internet has begun to work its way further into the lives of individuals all around the world, that CMC has become both immediate and global (Lam, 2004). The massive rise in the popularity of SNSs should come as no surprise when we consider two main factors. First, SNSs have become wonderfully efficient at what they propose to do, namely to allow users to share information and interact with one another in a dynamic and multi-modal environment. Secondly the social networking phenomenon fills an essential niche in a modern society that is increasingly finding itself lacking in face-to-face interaction. Some descry this development and the decline in social and interpersonal skills they perceive to be associated with it. However it is equally possible to perceive a future where new technologies empower and enable people to interact with others in meaningful new ways and also allow people to create and shape identities for themselves that would otherwise be impossible.

Whether or not one is optimistic about the future potential of SNSs to transform society, we cannot deny their current popularity. Indeed statistics now show well over 250 million unique visitors to various SNSs around the globe, with interest in certain sites like Facebook up 270% from June of 2006 through to June of 2007 (Comscore, 2007). It should come as no surprise then, that forward thinking teachers and educators across the globe have for several years been involved in considering how to take advantage of both the popularity of SNSs themselves, and the various Web 2.0 applications associated with them (Lantolf, 2000; Murray, 2005; Cummings, 2007). In order to best understand how Web 2.0 technologies may be applied for educational and, specifically, for language education purposes, we should first look at where these technologies fit into the development of Computer Assisted Language Learning (CALL) itself. Some writers (Warschauer, 1999; Warschauer & Healey, 1998; Trotman as cited in Davey, 2005) see CALL as having progressed through three main phases of development: behaviourist, communicative and integrative, with each of them representing higher phases of technical and innovative complexity (Davey, 2005).

CALL itself, in a broad sense, owes much to the growth of the Internet, particularly as a reference tool for both students and educators, but it is specifically in the area of CMC where some of the most significant recent changes are taking place (Hata, 2003; Cummings, 2007). Educators are continuing to look for new opportunities and ways to take advantage of technological innovations associated with CMC. Wikis, blogs, synchronous and asynchronous chat, SNSs, these are just a few examples of potentially beneficial tools for the language learning process that teachers are beginning to turn to in their attempts to blend student interest, technological innovation, and quality pedagogy (Hata, 2003; Lavin & Claro 2005; Murray, 2005). Aside from the technological advances associated with CALL in its present form, we are also seeing a pedagogical shift towards a more socio-cognitive view of how CALL can and should take place (Davey, 2005). Though the technological and pedagogical advances have not necessarily developed simultaneously, it is important to note that they have also not developed in isolation from one-another. In fact, it is not difficult to see that current interactional and social constructivist notions of L2 learning and acquisition may fit nicely with what the Internet can presently offer language learners (El-Hindi, 1999). While the possibilities offered by the Internet to both the teacher and student are only beginning to be explored, it could be argued that the Internet, combined with other multimedia and peer-to-peer technology, has already become a fundamental tool for many in both groups.

WEB 2.0

The concept of Web 2.0, which has become a popular buzzword in the fields of CALL and educational technology since 2004 (O'Reilly, 2005), does not in and of itself represent any significant singular technological innovation. Rather, it has come to be understood in a broad sense to refer to a new series of applications all designed to take advantage of the Internet's potential to allow individuals to participate in new ways in the online experience. According to a recent report by the OECD, the Internet is based on a principle of participation in which collaboration and customization are important factors (OECD, 2007). As an entire new generation is now growing up without questioning the ubiquity of the Internet, individuals are making use of new technologies to share and communicate with one another through user-created content.

The explosive growth in the popularity of blogging is one clear example of the way in which individuals and end-users have sought to take control of the creative process online and generate content of their own. Blogging has, in a very short period of time, become a truly global phenomenon. As noted earlier, recent statistics show that Japanese has now surpassed English in terms of overall blog entries, with other languages like Italian and Farsi showing dramatic increases (Sifry, 2007). Wikis are another area where the users themselves are creating and constantly updating content. Wikipedia, the original online wiki/encyclopedia is among the most visited sites in the world (Comscore, 2007) and its content is almost wholly user-generated and edited. As users across the world are becoming more comfortable and confident with these technologies, either in first or second languages, it is becoming increasingly possible to consider the educational opportunities associated with them.

SOCIAL NETWORKING

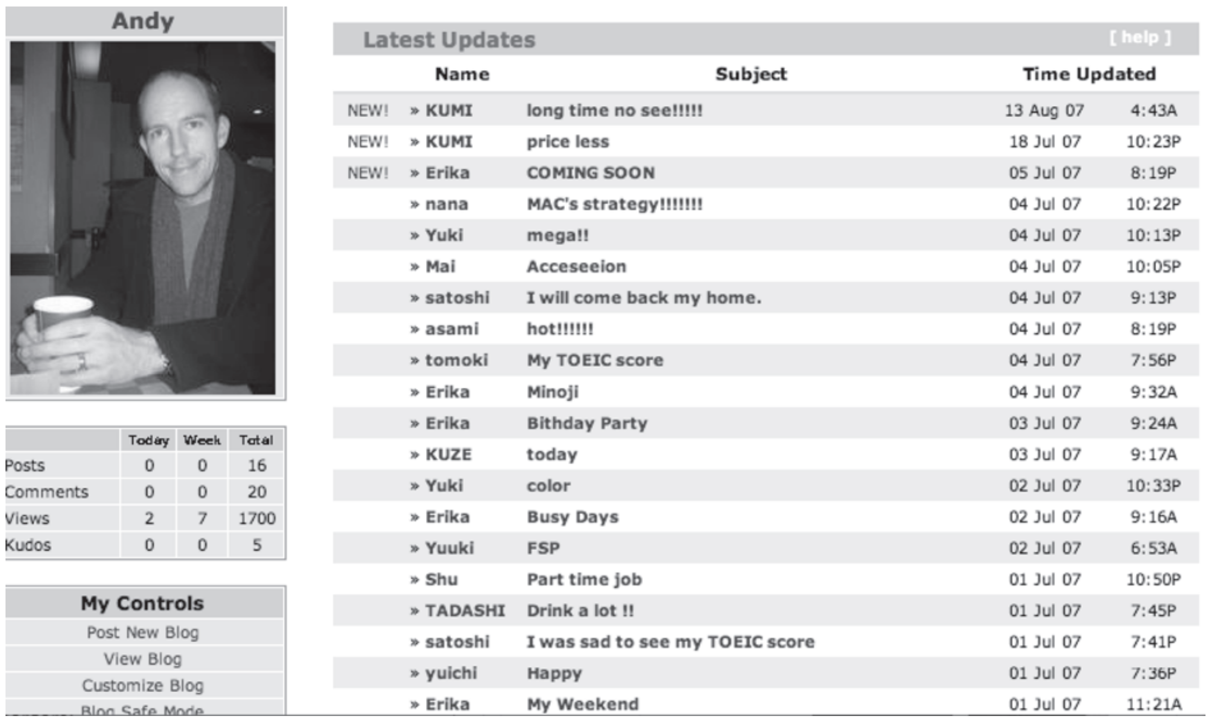
As CMC has gone global, so too has the social networking phenomenon. On sites like MySpace, Facebook and Mixi, millions of users are currently online, sharing photos and information, chatting, blogging, editing friend lists and generally creating and recreating their online identities both through the content they generate and the connections they make with others.

In Japan, the popularity of social networking has tended to center around Mixi. The site, which launched in 2004, has a registered user base of over 10 million people, virtually all of whom are Japanese as their exists no international version. In a review of Mixi, Serkan (2007) wrote that the primary appeal of Mixi seems to be in the simplicity of the interface. Features of the site, including blogging, photo and music sharing, and the establishment and maintenance of friend lists, are essentially equivalent to those of other SNSs like MySpace. Kageyama, however, noted that Mixi has been highly successful in Japan partly because it has a less "me-oriented" focus (Kageyama, 2007) than other SNSs like MySpace. Mixi has successfully found a way to capitalize on Japan's strong emphasis on group relationships, making friend networks the primary focus of the service, whereas MySpace, particularly in the US version, has focused more on making the individual creator of the site the center of attention. This subtle difference in the two sites may go far in determining the future success of the Japanese version of MySpace.

As mentioned, the functionality of both MySpace and Mixi are similar, although MySpace provides a particularly effective blog management tool, allowing users to easily subscribe to the blogs of friends and see instant updates to friends' blogs. Figure 1 shows the blog management interface for MySpace.

Whether it is MySpace, Mixi, or one of the other SNSs being used, they all contain certain similarities. Two key features of SNSs are the ways in which they facilitate user interaction, including, chat, blogging, messaging, file-sharing and other interactive services, and the ways that they allow users to build peer groups based on the recommendations of others.

Figure 1. MySpace blog management screen



It is not difficult to realize why some educators have begun to consider the possibilities and educational implications for wikis, blogs, SNSs and other applications often associated with Web 2.0. From the educational perspective, and particularly with regards to second language learning and acquisition, there are a number of ways in which to frame the potential benefits of these types of technologies:

1. **Learner motivation:** As O'Hanlon (2007) suggests, the high usage patterns of social networking sites by American teenagers indicates their popular appeal. Much research has been done to suggest that learner motivation is a key feature in the process of language acquisition (Gardner & Lambert, 1972) and being able to capitalize on a phenomenon that has already captured the attention of millions of people all across the world has great potential. Though educators must guard against the adoption of technology purely for technology's sake, a further look at the potential possibilities offered by Web 2.0 applications may demonstrate real value for second language learners.
2. **Collaborative learning environments:** Wikis in particular offer a uniquely collaborative online environment where individuals or groups of users can interact with and respond to information generated by others. Even face-to-face collaboration between and amongst language learners, which until just recently was restricted solely to the classroom environment, can now take place in real time with learners spread all across the globe via synchronous video chat.
3. **Social constructivist approaches to education:** Some research recently has looked to constructivism and in particular Vygotskian social constructivism as a way to interpret and assess the potential benefits of the type

of peer editing and collaboration that can take place on wikis and SNSs (Lavin & Claro, 2005). Research along these lines seems promising, as there would appear to be a natural link between Vygotskian social constructivism and collaborative learning online. Vygotsky believed that knowledge was a social construct that individuals uniquely create as they interact with their environment and with others (Pasfield-Neofitou, 2007; Vygotsky, 1978). If we see the Internet itself as our environment, then clearly much of our knowledge of the world can be understood to be mediated through our interaction with that environment and the individuals we encounter within it.

4. **Critical Language Learning (CLL):** CLL is a broad term that can be used to bring together a variety of concepts including, but not limited to, student empowerment, identity formation, learner autonomy and critical literacy. Although some research has begun to look at how CLL can be seen as relating to the current phase of CALL and the various Web 2.0 applications discussed (Godwin-Jones, 2003; Hawisher, 2000; Pasfield-Neofitou, 2007), little consideration has been given to the language learners' use of SNSs from a CLL perspective. Thus, as mentioned earlier, this chapter will attempt to fill this gap by looking in detail at certain elements of CLL and how those elements can be complemented by student use of SNSs. This chapter will also consider in some detail the results of initial research which looked at two groups of Japanese EFL learners and their first foray into the use of SNSs for the purpose of language learning and acquisition. A brief description of the student groups and the tasks they took part in is included below.

PARTICIPANTS

27 students, 14 female and 13 male, from two separate courses spent one academic semester (14 weeks) experimenting with the use of the MySpace SNS both inside and outside of the classroom. These were second and third year Japanese students at a private university in Japan. The groups were of mixed English proficiency, ranging from high beginner (TOEIC score 300) to upper intermediate (TOEIC score 670) and their experience with SNSs, either in English or Japanese was very limited. Just one of the 27 students reported maintaining a regular page prior to beginning the project and 16 students in total reported being aware of SNSs in general, either in English or Japanese.

Aside from overall English proficiency, computer literacy skills were also varied among the two groups. Based on self-assessment data by the students collected prior to beginning the project, only 6 reported being either "good" or "very good" with their computers, whereas 7 students reported their computer skills to be "very poor." This information was supported by continuous observation of the students throughout the process, indicating that as many as one-third of the students struggled significantly with data entry procedures, particularly regarding the filling in of forms online (Appendix A).

RESEARCH OBJECTIVES AND QUESTIONS

As there has been relatively little research to date regarding the use of SNSs in the second language classroom, the objectives of this case study were primarily exploratory. Firstly, it was hoped that this study would show whether or not Japanese university students of English were interested in and motivated by the prospect of using MySpace as a platform for the learning and acquisition of English. It was also hoped that the issues of learner autonomy, identity formation, student empowerment and critical literacy could be viewed discreetly based on data and feedback from the project. Finally, in the interest of laying the groundwork for further research, this project hoped to identify both potential difficulties and opportunities in the use of SNSs in second language contexts. The specific research questions identified for this case study were as follows:

1. Can the MySpace SNS function effectively as a platform for second language learning and acquisition by Japanese university students?
2. How would their use of MySpace throughout the semester impact and relate to the issues of learner autonomy, identity formation, student empowerment and critical literacy in the two groups?
3. What factors seem to impact the students' interest, or lack thereof, in the process of using MySpace for second language learning?

METHOD

The two groups of students were selected based on availability. The students were pre-enrolled, by the university, and the MySpace project was a clearly defined component of their syllabus for the duration of the semester. Prior to beginning the project, data was collected in the form of a questionnaire to assess students' awareness of and interest in SNSs, their level of motivation to use MySpace as a tool for learning English, and their general perception of their own computer proficiency (Appendix A).

During the first two weeks of the project, students were directed, through formal classroom instruction, how to sign up for and log into MySpace. Basic explanations were also provided regarding the nature of SNSs in general and the various SNSs available, both in English and Japanese, and discussions were encouraged relating to how the use of SNSs could potentially improve the English skills of Japanese students. Weeks 3-6 were spent on basic page management skills, including how to customize pages and backgrounds, enter basic personal information in the profile section, and manage and maintain friend lists. Once all students had well established pages on MySpace, the remaining 6-7 weeks of the semester were given over to two particular tasks. First, the blogging feature of MySpace was introduced, and students were taught how to create a blog, update their blog, and comment on the blogs of other students. Second, using Audacity software, students learned how to record their own audio and upload audio files to their MySpace pages. The two groups of students, who had not previously had any interaction with one another, were made to interact through the use of the asynchronous email and blog commenting features of MySpace.

Regular blogging was a course requirement, and the content of the blog entries was both teacher directed and student generated. Students were also required to write regular comments on the blogs of others. The uploading of student created audio files was also a requirement, though the students were allowed to choose the content and topic of the files.

To conclude the project, a final questionnaire was completed by the students during the final week and informal interviews were conducted with the majority of the participants (Appendix B).

In general, initial student interest in the project was high, with 25 of 27 students reporting that they were either "interested" or "very interested" in the prospect of using MySpace for second language learning (Appendix A). During final interviews conducted at the end of the project, student feedback was slightly more mixed though overall responses were still highly positive. 19 of the 27 students reported that they "enjoyed" or "really enjoyed" using the SNS while 5 students reported that they had "not enjoyed" the experience as a whole (Appendix B).

The remainder of this chapter will be given over to a specific look at each of the four components of CLL mentioned earlier, learner autonomy, identity formation, empowerment, and critical and e-literacy, and a discussion of how each of these issues were touched on during the 14 week MySpace project.

CRITICAL LANGUAGE LEARNING

Norton (2004) explains that, "advocates of critical approaches to second language teaching are interested in the relationships between language learning and social change. From this perspective, language is not simply a means of expression or communication; rather it is a practice that constructs and is constructed by, the ways language learners understand themselves, their social surroundings, their histories, and their possibilities for the future" (p. 1). As the above quote makes clear, our use of language impacts more than merely our communicative ability. How we choose to use a language, and the degree of proficiency that we have with it, shapes who we are and who we are able to become in that language. From this perspective, CLL is concerned with learner empowerment and the degree to which limited proficiency users of a language will be able to shape, control and define their futures. CLL also considers a learner's identity in a second language and how that identity is able to develop, grow and change. Autonomy, and the degree of autonomy available to limited proficiency users of a language is also an important concern. Ultimately, CLL can be seen as a lens through which to examine issues of power, control, and autonomy in language learning.

There would seem to exist a somewhat natural link between the CLL perspective and some of the types of Web 2.0 technologies mentioned earlier in this chapter. A blog, for example, can give a second language student a clear form of autonomy from the traditional classroom writing environment, freeing them to choose topics of their own interest and write in a less structured and controlled environment. This could be said of journal/diary type writing also, something that second language writing teachers have advocated for many years, however, blogs have the added advantage of being relatively public and open to the suggestions and comments of peers. And what about the use of student generated content in wikis? Clearly empowering students to create content of their own promotes autonomy by de-emphasizing the role of the teacher in the language acquisition process. So it would seem that a connection is not hard to make between CLL and Web 2.0 concepts like user-generated content and the participatory and interactive nature of some of these new applications.

IDENTITY FORMATION

Web 2.0 technologies are changing the way individuals create themselves online and the way they are perceived by others. SNSs allow users a platform on which they can create, shape, and re-create their own identities. Through photos, blog entries, videos, musical selections, and friend lists, users are able to share their personalities and interests in an almost immediate fashion. Cummings (2007) sees this new type of identity formation as a dramatic change in people's willingness to share personal information; he writes, "we are starting to construct our identities, both anonymous and real, within the realms of Web 2.0 environments … at no other time in democracy have we chosen to expose ourselves to people we have never met, and will never meet" (p. 2). Some find this willingness to share unsettling, others may consider it a revolution.

For second language users, the issues of identity formation and the presentation of self online can be complex but sometimes liberating. Warschauer (2000) found, in a project looking at the use of the Hawaiian language, that online interaction freed students up to not only make more use of the Hawaiian language, but also to explore and further develop their Hawaiian identities. In a review of the Warschauer study and several others, Murray (2005) points out that second language users involved with CMC often develop both global and local identities to deal with the differing social and linguistic environments with which they are confronted.

A fair amount of research has been done in the field of SLA regarding the relationship between identity formation and language learning. In particular, researchers have considered how language use and proficiency in second language can contribute to, enhance, or hinder the development of a sense of self and unique identity in the new language (Belz, 2003; Hawisher, 2000; Norton, 2000). Belz notes also that some recent research has begun to consider the role of language play in second language learning, and she reports a study in which students studying German were "able to occupy third spaces from which they could both play with and reflect on multiple linguistic identities" (2002, p. 28).

It is not difficult to view the use of SNSs as a form of language play and indeed the enormous popularity of sites like Facebook, MySpace and Mixi demonstrates clearly that many millions of people around the world are already involved. Pasfield-Neofitou (2007) argued that, "online identity is largely constructed through one's textual behaviours, so it is important for learners to manipulate the language effectively" (p. 148), however, it would seem that, within the multimodal, peer-to-peer environments of current SNSs, this focus on text may be becoming less and less necessary. Users determine how they are perceived by others not merely through text and chat alone, but through their photos, music, videos, and shared friend lists.

For Japanese students in particular, it has been noted that second language identity formation may facilitate the development of a sense of ownership of the target language, something that has been a struggle for English language education in Japan. For example, Ha (2005) pointed out that English education in Japan has, up until now, had less to do with mastery of the language and the understanding of English as a tool for global communication than with the Japanization of English.

One significant aspect of the MySpace project was the possibility to witness and visually record the students' personalities taking shape on their pages. Because, as noted earlier, MySpace pages are almost infinitely customizable, all manner of characteristics can be displayed. Aside from color schemes, backgrounds and photos that quickly overwhelmed the pages, students also discovered the use of "theme music" that would begin to play as soon their pages were opened. Blog topics formed another component of the sense of self that came through in the students' pages, with topics demonstrating not just student interests, but also their day-to-day routines, political tendencies, and all manner of other things. In the post-project questionnaire students were asked to consider what aspect of the project they most enjoyed and it would seem clear that the ability to decorate, modify, or otherwise customize pages was one of the primary elements that students enjoyed about the project.

Other student feedback also seemed to indicate that the multi-modal nature of SNSs was significant in relationship to the mixed ability levels of the students. Those students with a greater proficiency in English were more able to manipulate the primarily text-based aspects of the project, including the blog entries and personal profiles, whereas students with less proficiency were not left out as they were able to express themselves through the photos, audio and video files, and backgrounds that they chose. In a follow-up blog posting, one student wrote that she "*liked to see the other peoples' pages. It helped me know them more*." The use of MySpace seemed to allow mixed ability groups to gain insights into the characters and personalities of other students in a way that

Figure 2. What part of the MySpace project did you enjoy the most?

Response	Number of students	Percentage
A. Writing my own blog	6	22%
D. Commenting on other blogs	3	11%
B. Putting pictures on my page	8	29%
E. Putting music on my page	5	19%
C. Recording audio	0	0%
F. Looking at other MySpace pages	5	19%

would not otherwise happen in a traditional classroom environment.

COLLABORATION AND STUDENT EMPOWERMENT

SNSs tend to be, by their very nature, collaborative and collaboration between and amongst language learners is of central significance in both constructivist and critical approaches to language acquisition and learning. When assessing the value of wikis from a social constructivist viewpoint, Lavin and Claro (2005) note that, "whereas in a discussion forum, it is easy to talk about something but not manipulate it directly, a wiki is suited to actually construct something (e.g. a knowledge base) collaboratively" (p. 10). Here again we see a distinction between earlier forms of CMC, that were primarily text based, and more current forms, like wikis and SNSs, that allow for a multiple modes of expression. Lavin and Claro were speaking of wikis and their usefulness as a platform for students to collaborate to create something. SNSs on the other hand focus more clearly on the identities of the users themselves and on collaboration between them as opposed to the collaborative creation of some kind of final product, as in the case of wikis.

Allowing for and encouraging student collaboration helps to empower students in two primary ways. First it de-emphasizes the role of the teacher and helps make clear to the students that learning can take place in a variety of contexts (Lam, 2004). Second, collaborative activities build a sense of community and purpose for students. SNSs for example allow users to easily identify and share common interests with other users. Groups of second language learners who are united through common difficulties with the language are empowered when they collaborate with others and realize that they are not alone in their frustrations. Regarding the participatory and collaborative nature of blogging, Godwin-Jones (2003) points out that, "blog entries are normally followed by a comment button, allowing readers to write a reaction, which is then logged and linked, along with all other comments, into the original text. While most blogs are created and managed by individuals, group blogs are also possible. Blogs

Figure 3. What part of students' English improved the most during the project?

Response	Number of students	Percentage
Reading	7	26%
Writing	10	37%
Speaking	5	19%
Listening	3	8%
None	2	7%

Figure 4. Comments regarding the use of MySpace for international communication

1. *It is my first time to use blog. It can communicate with people of all over the world.*
2. *We can make a lot of friends all over the world and our life will be much fun so I liked using My Space and I want use it from now on.*
3. *And using my space communicate with other countries people, and people who are learning English tell me how to write good English. Native English help me when I contact with foreign friends. Especially sending Email...*
4. *I liked using Myspace this semester because it can contact with many countries people, so I can enjoy it!! I can understand everyone's hobbies, and favorite music, so I thought we could know more each other.*

are easily linked and cross-linked, to create larger on-line communities" (p. 13). Group blogging, or topically themed blogging targeted towards groups (e.g. communities of students) has great potential for second language learners and SNSs offer a functional platform for this type of work as all major SNSs sites allow for personal blogging, linking and sharing of blogs, and commenting on the blogs of others.

During the MySpace project the clearest example of the benefits of collaboration came through in the level of peer support that developed both face-to-face in the classroom itself and on the MySpace pages. Differing levels of computer literacy were a major factor here, meaning that certain tasks were relatively easy for some students and much more difficult for others. Peer support was the obvious solution to this issue, and it developed spontaneously in both class groups. This type of collaboration was significant in that it allowed students themselves to temporarily take on the role of educator, thus de-emphasizing the role of the formal classroom instructor and at the same time encouraging and empowering the students. It is also significant that the face-to-face interaction and learner support that took place in the classroom seemed to naturally occur in the target language of English. This form of peer-to-peer support may partially explain the fact that 5 of the 27 students surveyed felt that their spoken English improved more significantly during the project than either their reading, writing or listening.

The shared sense of community was strong in both classes, the idea that they were involved in a project together, and that they were faced with similar difficulties along the way helped bind them together. In an interesting twist, difficulties that students faced with the project, for example how to properly upload their audio files, often led to social networking opportunities, with students sometimes using their MySpace pages to interact with one another to work through difficulties.

Relating to collaboration in general, one underdeveloped component of the project was the lack of involvement of a fixed group or groups of native speakers of English with whom the students could interact. The primary purpose of the project was simply the exposure of students to the concept of social networking and an introduction to page management, blogging, and the uploading and importing of content to pages. Although throughout the course of the semester many students did interact with native speakers of English, this was a by-product of the social networking project, not an expressed goal. Looking through student comments and feedback however, it is clear that one of the components of the project that generated significant interest was the potential that SNSs offered to bring them into contact with native speakers of English. A summary of several students' explicit comments regarding this aspect of the project is included in Figure 4.

From data like this, it was possible to define what a potential next step in a project of this nature could be. Namely, the introduction of a system whereby students are encouraged in some manner to interact with native speakers of English through the tools available on MySpace. The simplest way to do this would be to partner with another group of language learners (in this case native speakers of English learning Japanese) and set up a series of collaborative and interactive assignments. The drawback to this approach however would be the reduction in learner autonomy that would result from instructors directing and controlling the social networking process in this way.

LEARNER AUTONOMY

Learner autonomy, though linked in various ways to learner empowerment, is a slightly different issue. Raising learner awareness of their own role in the complex processes of language learning and acquisition is of central importance in the development of learner autonomy. Autonomy is also an integral part of what Web 2.0 technologies are coming to represent. That is, autonomy from the top-down, media and corporate driven content that dominates so much of 21st century culture. Web 2.0 is partly about allowing individuals the freedom to create and express themselves online, to author their own content, and to share that content with others in efficient and meaningful ways.

For language learners, authoring and sharing content of their own can be an exercise in the building of autonomy and independence. It can also be motivating. Hata (2003) points out that greater learner autonomy leads to both increased motivation and greater achievement. Davey (2005) also notes that "these tools [blogs] and facilities that allow the learners to become creators rather than passive recipients of material, again demonstrate the task-based nature of the Internet, which can easily be adapted to provide student-centered and communicative style tasks" (p. 212). The movement from recipient to creator can then be seen as an essential step in the development of learner autonomy and SNSs allow for this movement in a number of ways. The degree to which pages can be customized by users allows autonomy with regards to the page creation. Individuals are also free to create content designed specifically for their page (user profiles for example) and to import content from other sources. The degree of autonomy is so great in fact that the end result is most often a wholly unique and original expression of self online. When making use of SNSs for second language learners, the role of the classroom instructor may also be redefined and importantly, the learners' perception of the teacher's role may be reformulated also. Learner autonomy is related to the degree of independence that learners perceive that they have from the traditional classroom centered and teacher centered models. With SNSs, where learners are connected to one another through shared friend lists, the teacher may become simply another face on the list. This promotes a natural redistribution of the power relationship and puts the student and their page at the center of the learning equation.

Autonomy in computer mediated learning contexts is not without some difficulties however, and the primary concern is the degree of teacher support that is required to help students through the process. Murray (2005) points out that teachers often need to direct students through the websites and applications that they use in order to mediate level appropriacy and this type of teacher mediation contradicts the goal of learner autonomy – in conclusion he argues that teaching using technology needs to be carefully scaffolded. That is, not initially autonomous but building towards autonomy. In the case of SNSs for example, teachers may need to assist students in the process of setting up the pages and learning how to use the various features. This does not necessarily detract from the ultimate goal of learner autonomy however,

Figure 5. Comments regarding blogging and the use of audio files

1. *I liked using My Space because I could practice writing English. I made own my blog for the first time so I was very excited. I also could read English because most of people used in English so I was so happy to read them.* 2. *I like using MySpace this semester. Because I could know how to write blogs.* 3. *I liked using MySpace this semester because ... First it was fun to write to blog, make sounds file and put it on my website.* 4. *... it was fun to write about the topics and add comment to other persons.* 5. *And then, we can debate some topic by my space that we can communicate with another tutorial people, another person and my Tutorial member. It means that people checked my topic and me idea. It leads to growth of the knowledge by changing an opinion.*

because this type of teaching enables students to move towards a larger goal of beginning to author content of their own.

During the MySpace project, Murray's (2005) criticism of the potential for learner autonomy in a computer mediated learning environment proved accurate. Since students were, at each step in the process, essentially dealing with issues that were entirely foreign to them, a high level of teacher involvement and direction was to be expected. This, combined with the language difficulties inherent in such an undertaking in a second language, meant that the instructor's level of control over the project had to be relatively high, particularly in the beginning. Students were not completely free for example, to set up pages as they liked because their ability to do so was mediated by the need for instruction in how to go about this.

This is not to say that autonomy was a failure in the project. In fact, particularly in regards to the authoring and sharing of personal content, many students seemed to enjoy the semi-autonomous nature of the work. Figure 5 provides a brief review of some students' comments on blogging, and the uploading and sharing of audio files.

Some of these reflective comments demonstrate a strong learner awareness of the processes of language learning and acquisition. Evidence of this type of thinking is significant in that it is indicative of both a level of individual autonomy in the learner, and a type of critical awareness of their own role in the learning process.

CRITICAL READING, LITERACY, AND CRITICAL E-LITERACY

Many terms have been used to attempt to describe the new skill set required to make efficient use of all of the materials, tools, and resources available online. Digital literacy, web literacy, silicon literacy, information literacy – these are just a few of the terms in common use (Murray, 2005). One of the simplest and most effective of these may be electronic literacy, but even here, definitions are difficult. Godwin-Jones (2006) sees complexity in defining the term due to the increasingly rapid pace of technological change in society. He writes, "electronic literacy today is a moving target. How and why we read and write online are evolving at the fast pace of Internet time" (p. 8). There is also the question of critical literacy to consider, one's ability to sort through and effectively analyze information is mediated not only by decoding abilities within the language, but also by the ability to critically reflect on the content: "Web browsing and reading must be supplemented by abilities in sorting, navigation, and critical thinking. Integration of other media into texts complicates further the notion of literacy" (Godwin-Jones, p. 8).

A good deal of research over the previous 15 years has looked at how both computer mediated language instruction and general Internet use can enhance and develop critical literacy skills (Warschaeur, 1997; Davey, 2005). Critical literacy must be carefully considered in reference to Web 2.0 technologies in general, and the use of SNSs in particular because literacy itself has an inherent socio-cultural component (Murray, 2005). Belz, in a study of tellecollaboration between American students of German and German students of English noted in her recommendations that the study could have been enhanced had the students participated in "guided cultural sensitization on social patterns of communication" (Belz, 2002, p. 76). She went on to suggest that "more time could have been spent on critical comparisons of the two partner institutions as represented by their official websites. Students [could have been] guided in the development of their critical cultural awareness of both self and other" (p. 76). Her comments suggest that relatively less difficulty was encountered with literacy as it pertains to the decoding of text itself, whereas greater difficulties arose relating to critical awareness and the social nature of literacy.

As mentioned earlier, several of the students involved in the MySpace project demonstrated a level of critical reflection in their interviews and comments at the end of the project, mostly relating to a meta-awareness of the type of positive impact that SNSs could potentially have on their own language learning. Comments, for example, like, "*I liked using my space in this semester, because I think my space helped my writing skills and communication skills*, or, *it leads to growth of the knowledge by changing an opinion*," show that some participants were able to critically reflect on the learning opportunities that the use of MySpace presented to them.

Another factor to look at is that of electronic literacy in general and the impact it had on the project. With specific respect to the issues faced in this project, it may be helpful to look at both computer literacy (the ability to use the computer efficiently, cutting and pasting of information for example, or saving, storing and managing data) and online literacy (related to the ability to source information online and to sort relevant and irrelevant material).

Within both groups it quickly became evident that computer literacy skills varied widely between students. This was less of a problem that might have be imagined however, and, as noted earlier, it led to quality peer-to-peer teaching opportunities for more computer savvy students. It was an issue that was not lost on students however, and several student comments were related to it.

1. *I liked using my space in this semester because when I using my computer I think the class is faster than other class. I think using computer in class is enjoyable for students. So I think using my space in this semester is good thing for students.*
2. *We used PC that we can understand that how to use this site and PC, and we can know some good PC system and site for me.*

The second comment in particular speaks to the issue of the development of computer literacy skills and how this can benefit students.

Online literacy was another issue and here the difficulties were often language specific. As Godwin-Jones (2005) noted, web-surfing skills are critical in nature in that they require individuals to sort data based on relevance and to quickly skim through and analyze that data. Most participants in this project took a great deal of time when they were asked to source information (through Google search for example) and they were very often unable to discern relevant and irrelevant content. This fact led to an increased need for teacher-directed activities and, therefore, a decrease in learner autonomy. Though it is true that intermediate level users of a language can be taught certain techniques to enhance their efficiency online, the overwhelming amount of linguistic input makes this a problematic issue.

CONCLUSION AND FUTURE RESEARCH

Little research has as yet been done relating the use of SNSs to second language learning and acquisition, particularly in the context of the Japanese classroom (Dias, 2000). Hopefully this preliminary study has been able to lay the groundwork for future research in this area. Overall, MySpace appears to be a functional tool for use by English language learners in Japan. Japanese users of SNSs seem to prefer Mixi, either for ease of use issues or socio-cultural appropriateness, however, as there exists no English language version of this site, MySpace, with its multilingual interface and global appeal, is a viable alternative. Regarding the aspects of CLL mentioned in this chapter, particularly as they relate to Japanese learners and their use of SNSs, there would seem to be many interesting research opportunities available. It is clear for example, that a strong element of learner collaboration and support developed during this project. The work was empowering for the students in that they were freed up somewhat to express themselves in new and different ways. Further research in these areas could prove meaningful.

As this was a primarily exploratory study, it was limited in a number of ways. Firstly, the study made no attempt to measure student progress or change relating to their own sense of autonomy, empowerment or identity. Future research could look specifically, for example, at how students perceived their own degree of autonomy in the language learning process before and after a project of this type. Secondly, this study simply explored students' use of the MySpace SNS. It did not provide a comparison or control group, something that could help determine the effectiveness of the project. Also, this work with MySpace only very briefly touched on the possibility of the use of mobile phones for blogging and posting information to MySpace pages. Young people in Japan are often more comfortable interacting with a mobile phone than a personal computer, indeed entire novels are often composed solely on mobile phones in Japan. An analysis of the possibility of mobile phone use for MySpace would also be interesting and meaningful in the Japanese context. Lastly, as mentioned earlier, many of the participants in this project were excited by the prospect of interacting with native speakers of English. The addition of a fixed group of students to a project of this nature, possibly native speakers of English studying Japanese, would greatly enhance student interest and the potential for more meaningful language interaction.

Finally before concluding this chapter, I would like to look to the future, or more accurately, to the present, to consider briefly some current trends in CALL research, their potential relationship with CLL, and possible research opportunities they may present. One interesting area of development is coming from online gaming. Some recent research has begun to look at online gaming, and in particular the use of MMORPGs (Massively Multiplayer Online Role-Playing Games) in relationship to second language acquisition. This is interesting in how well it fits with the current focus on activities that are learner-centered, communicative, and collaborative. Bryant (2006) explains that MMORPGs are, "online role-playing games where players move, act and communicate with other players in an Internet-based virtual three-dimensional environment … players group together online to achieve certain goals and thereby progress through the game. Communication plays a central role in the game. Audio and video are embedded throughout the environment, and it is also necessary to communicate with other players in the game through audio messengers or text chat programs" (p. 1). Clearly this type of learning environment could be potentially motivating to language students (Toyoda & Harrison, 2002). It also demonstrates numerous similarities to the use of SNSs for language learning and has a strong connection to CLL. In particular it would seem that issues of learner autonomy and identity formation in the MMORPG context would be interesting to explore.

Another relatively new concept is the development of SNSs specifically for language learners. According to a recent *Japan Times* article, this is exactly what is being developed by Yang Yang Xi at Kyoto University. This project, currently called Lang-8, is designed to facilitate interaction between native speakers and language learners in a variety of languages. The article reports that the site, "allows people to write daily diaries on whatever topics they choose and in any language they want. These diaries are then edited by their friends on Lang-8, who are native in the particular language in which the diary is written" (Manlove, 2007, para 3).

This project is particularly interesting in that it addresses what was one of the key areas of student interest regarding the use of SNSs for language learning; the ability to interact with native speakers of the target language. It will be interesting to see how this project progresses and if it proves a success with language learners.

Finally a brief mention of the relatively recent phenomenon of "tagging" or "social tagging" online. In his 2006 discussion of emerging technologies, Godwin-Jones talks about the growth of tagging online and its potential to help users sift though the enormous amount of information available to them online. Tagging, or shared tagging, is essentially a bookmarking process that allows individuals to personally assign key words or phrases to information they find on the web. This allows for easy retrieval later on, as they are stored much as bookmarks are stored in your browser, and they are social in that tags that are ascribed to webpages or pieces of information can be accessed and referenced by others when made public. As Godwin-Jones points out, it is not possible to tag a website without the ability to critically analyze its contents.

This tagging concept is potentially of interest to second language learners online because, as many students involved in this project discovered, accessing and assessing information found online can be a great challenge. This idea also relates specifically to at least two of the aspects of CLL mentioned earlier. It is empowering in its reliance on social collaboration and peer support, and the act of creating tags requires critical and reflective reading skills. Clearly, interesting research is yet to be done in this area of social tagging by and for second language learners.

In conclusion, it would seem that viewing the use of SNSs for second language learners in Japan through the lens of CLL offers some interesting insights into various aspects of computer mediated language learning. Critical literacy, learner autonomy, student empowerment and identity formation are important components of the language learning and acquisition process and an analysis of the use of SNSs for language learning would only be partially complete without considering the relevance of these issues.

KEY TERMS

Autonomy: For second language learners, autonomy has to do with the degree of independence that learners have from traditional teacher fronted classroom approaches and their ability to advance and progress as independent learners.

Critical Language Learning (CLL): CLL is a broad term for an approach that focuses on the social implications of second language learning. This approach is characterized by an interest in issues like student empowerment, identity formation, critical literacy and learner autonomy.

E-Literacy: E-literacy has been defined in a variety of ways but it generally relates to the skill set required to make efficient use of all of the materials, tools, and resources that are available online.

Empowerment: Within the context of critical language learning, student empowerment is concerned with providing students with access to the tools that they need to become independent and autonomous learners.

Identity Formation: In the second language learning context, identity formation refers to the development of one's unique identity in the target language. Identity formation can also relate to the development of on-line identity through social networking sites like MySpace.

MySpace: MySpace is one of many social networking sites currently in popular use. In June of 2007, MySpace was the most visited social networking site in the world with over 114 million users.

TOEIC: The Test of English for International Communication (TOEIC) is a highly regarded English language testing system that is especially prominent in Asia and taken by almost 5 million people throughout the world each year. The test consists of a listening and reading component, to which a speaking element has recently been added.

APPENDIX A

Questionnaire A

This semester we are going to use the MySpace social networking site to improve English skills. Please answer these questions before we begin. Circle the best answer for each question.

1. Are you familiar with social networking sites like MySpace, Mixi, or Facebook?

Yes No

2. Have you ever used a social networking site (MySpace, Mixi, Facebook, etc.) in English?

Yes No

3. Have you ever used a social networking site (MySpace, Mixi, Facebook) in Japanese?

Yes No

4. Do you have your own profile on a social networking site?

Yes No

5. Do you think using social networking sites in English could help you improve your English?

Yes No

6. What do you think about your skill in using a computer?

Very good Good Not so good Poor Very poor

7. What do you think about your typing on a computer in English?

Very fast Fast OK Slow Very slow

8. How interested are you in using social networking sites to help you improve your English?

Very interested Interested A little interested Not interested

APPENDIX B

Questionnaire B

The semester of using MySpace has finished and I would like to know how you felt about the project. Please answer the following questions honestly. Circle the best answer for each question.

1. How did you feel about using MySpace this semester?

Really enjoyed Enjoyed OK Did not enjoy

2. Do you think you will continue to use MySpace in English in the future?

Definitely Maybe Probably not No

3. Do you think your English improved through using MySpace?

Yes No Not sure

4. What part of your English improved the most?

Reading Writing Speaking Listening None

5. Would you recommend MySpace to your friends as a way to learn English?

Yes No Not sure

6. What part of the project did you enjoy the most?

A. Writing my own blog B. Commenting on other blogs

C. Putting pictures on my page D. Putting music on my page

E. Recording audio F. Looking at other MySpace pages

7. What part of the project did you enjoy the least?

A. Writing my own blog B. Commenting on other blogs

C. Putting pictures on my page C. Putting music on my page

E. Recording audio F. Looking at other MySpace pages

APPENDIX C

Comments taken from students' MySpace blogs in response to the question, "Did you like or not like using MySpace this semester? Please explain."

1. I liked using My Space because I could practice writing English. I made own my blog for the first time so I was very excited. I also could read English because most of people used in English so I was so happy to read them. I think My Space was a good place to practice writing and reading English so the students should use My Space. People can get opportunity very easily and we need only PC. If you want to practice English, you should register now. We can make a lot of friends all over the world and our life will be much fun so I liked using My Space and I want use it from now on.

2. I liked using my space in this semester because when I using my computer I think the class is faster than other class. I think using computer in class is enjoyable for students. So I think using my space in this semester is good thing for students.

3. I'm sorry. I don't like using my space because I don't like writing blogs. I think writing blog is not fun. I want to spend time to debate. Debate is very difficult, but it's enjoyable and helpful. And also, I need time to write graduation essay in class. other tutorial class students write essay in class.

4. I like using MySpace this semester because it made me enjoyed. It is my first time to use blog. It can communicate with people of all over the world. I want to use blog from now.

5. I liked using Myspace this semester because it can contact with many countries people, so I can enjoy it!! I can understand everyone's hobbies, and favorite music, so I thought we could know more each other. Another point is we can get ability of writing skills. For example, "Tobacco is illegal or legal" is title, and we should think and write own ideas quickly. Therefore it was very important for me to think about many things quickly. To use Myspace is very useful.

6. I didn't like using Myspace this semester because it was hard to use it. I couldn't understand how to use it. Therefore, this way takes extra time to me. In addition, we cannot do this without PC, so we had to bring PC every week. PC is very heavy so it was very hard. Sssss

7. I like using MySpace this semester. Because I could know how to write blogs. And this is little interesting for me. But I fell regret that I can't use all tools.

8. I think that I liked using my space in this semester, because I think my space helped my writing skills and communication skills. And using my space communicate with other countries people, and people who are learning English tell me how to write good English. Native English help me when I contact with foreign friends. Especially sending Email or letter. In addition, using my space give me chance to write English diary, so I'd like to keep writhing English using my space.

9. I like using My Space this semester because I am enjoyed this semester. We used PC that we can understand that how to use this site and PC, and we can know some good PC system and site for me. And then, we can debate some topic by my space that we can communicate with another Tutorial people, another person and my Tutorial member. It means that people checked my topic and me idea. It leads to growth of the knowledge by changing an opinion. So, it is very good, using my space for us.

10. I liked using MySpace this semester because…First it was fun to write to blog, make sounds file and put it on my website. Second it was interesting to talking about topics in each groups and represent it. And also it was fun to write about the topics and add comment to other persons.

Chapter 4.7
Creative Waves:
Exploring Emerging Online Cultures, Social Networking and Creative Collaboration through e-Learning to Offer Visual Campaigns for Local Kenyan Health Needs

Andy Polaine
The University of New South Wales, Australia

Rick Bennett
The University of New South Wales, Australia

ABSTRACT

The past few years have seen the promise of online collaboration vastly augmented by developments in online technologies and emerging creative practices. Through our work with the Omnium Research Group, the authors argue that design should never be a solitary activity and benefits from many levels of collaboration - never more so than when dealing with complex issues facing today's world. The highly connected global society in which many of us now live frequently uses web-technologies to enhance nearly every facet of day-to-day life. The authors strongly believe that design education should not isolate itself from such communal and collaborative potential. This chapter explores what happens when online creative collaboration is applied to a real-world design project tackling critical health issues affecting local communities in Africa. It offers an account of the most recent, fully-online Creative Waves project - Visualising Issues in Pharmacy (VIP) that saw over 100 graphic designers join forces with a similar number of pharmacists from over 40 countries worldwide to produce graphic proposals for public awareness campaigns about six health issues seriously affecting the people of a village community in Kenya. The three-month VIP project is explained in relation to its aims, objectives and graphic outcomes, as well as the online environment in which it took place. Creative Waves is a concept created in 2005 by the Omnium Research Group, based at The University of New South Wales in Australia, to form online communities of design students from many institutions around the globe. Consisting an array of enthusiastic students, teaching staff, professional practitioners and luminaries invited as special guests, these online creative communities have proved that amazing results can

DOI: 10.4018/978-1-60566-727-0.ch003

be produced through careful facilitation between distanced individuals who will most likely never meet. The Creative Waves concept has to date been offered twice in collaboration with Icograda and the Icograda Education Network.

INTRODUCTION: EMERGING ONLINE CULTURES AND SOCIAL CHANGE

Before we examine the role of online communities and global creative collaboration within the most recent *Creative Waves '07* project, offered by the *Omnium Research Group* (Australia) in collaboration with Icograda and its education network (IEN), it is important to take account of vast social and cultural changes emerging online over the last few years. As we will see, the philosophy of online creativity and collaboration from which Omnium was borne a decade ago has since become part of the fabric of many online cultures. Such change poses great impact in academic settings because students today are some of the most 'savvy' users of ever-evolving digital and web-based technologies. For the current generation these technologies, that have been the subject of so much academic research and speculation, are now so everyday that we need to take account of new ways of working, socialising and collaborating that have subsequently emerged. As we have argued elsewhere (Bennett, Chan, & Polaine, 2004), we are beyond asking "should we use these technologies within education?" and now have much to learn from a generation that have already been using them for most of their lifetime.

Quite apart from their use in educational settings, the impact of the kinds of collaborative processes we will outline below are affecting the world of professional practice and wider society in extraordinary ways. The Internet has clearly changed the nature of communications and communities in the last decade and this has led to new ways of living and working (Castells, 2000; Johnson, 2001; Rheingold, 2003; Leadbeater, 2008; Weinberger, 2007).

Blogs and blogging are possibly the most well known explosion in this area. Blogging has grown so fast that statistics are continually out of date (and thus hard to measure), but at in late 2007 the blog tracking service, Technorati, was tracking over 72 Million blogs and the 'blogosphere' was over 100 times bigger than it was just three years before (Sifry, 2007). YouTube, another famous online success story, was already serving 100 million videos per day and received over 65,000 video uploads daily back in 2006 (YouTube, 2006). These successes are not just digital – the Jubilee Debt campaign started with one person in a shed in London and gathered enough momentum and 24 million signatures which helped force Western governments to cancel US$36 billion of debt owed by Third World countries and developing nations (Leadbeater & Miller, 2004, p. 54).

There are three emerging and overlapping areas to examine in the context of the *Creative Waves* projects:

- Social networks and communities
- Collaboration, open-source and the rise of the pro-ams
- Organisational change

Social Networks and Communities

In recent years the rise of portable or time-shifted media (such as podcasts, the iTunes Music Store and the video equivalents), blogs and social networks have created enormous shifts in traditional relationships to everything from media, to education, to consumer and political behaviour. Collectively, web applications such as YouTube, Flickr, GoogleMaps, Digg, Facebook, MySpace, Last.FM and WIkipedia are known (and hyped) as Web 2.0 applications (O'Reilly, 2005); a term that describes some of the technical approaches to their creation, but generally describes the idea that users and their audience create the content and form communities around this content, sometimes known as the 'read/write' or 'living' web.

The very first Omnium project in 1999 (Bennett, 2000) was developed through an awareness that the landscape of design *practice* was changing and that design *education* was failing to keep in step with these changes. It is essential to explore these emerging trends in order to better understand the role of online creative collaboration within educational settings because our younger students are the age group that are at the forefront of this change (Lenhart, Madden, & Hitlin, 2005; McMillan & Morrison, 2006; Green & Hannon, 2007; Holden, 2007). How this demographic of young people experience the world will have an enormous effect on the way we all teach, learn and work. In fact, the *way* in which our students learn is possibly becoming far more important than *what* they learn.

The strength of social networks and online communities is that they provide both a way through the enormous amount of information on the web as well as creating social bonds and capital. The collaborative filtering evident in contexts like Amazon.com and iTunes ("people who bought X also bought Y") or recommendations from social networks like Last.FM are very different from the paradigm of searching, which is currently the process generally taught in information literacy courses in universities and colleges. When you *search* you know what you are looking for, you just need to find it. When you click through recommendations via *collaborative filtering* you don't know what you are looking for but find things of value to your tastes by following the connections that other people have made, often without realising it. *You find what you never knew you were looking for*. This is a very powerful process indeed, as anyone who has spent a fortune on Amazon.com in one sitting can confirm.

This process can either happen by accident (e.g., we don't pay that much attention to what we buy, but Amazon's tracking database does) or more deliberately by tagging content and adding our own connections to the group pool. People can also add to your tags and content and here we see the rich abilities of re-mix culture come into play, something that is central to the *Creative Waves* projects.

In terms of education, the value here is that we make connections between areas that appeared to be unrelated at first glance, and this encourages inter-disciplinarity. It also solves the oft-asked student question, "How do I know what to do when I don't know what I can do?" All the while strengthening the bonds between people with shared interests and creating communities of practice.

A final aspect to this is that people who are used to working in socially networked communities often harbour a set of values that are worth encouraging. Yahoo!'s Tom Coates (Coates, 2006) sums up the three main requirements for any social software application thus:

- An individual should get value from their contribution
- These contributions should provide value to their peers as well
- The organisation that hosts the service should derive aggregate value and be able to expose this back to the users (Coates, 2006)

This is an excellent blueprint for any endeavour, yet the ability of most existing educational structures to change in this direction is questionable. Indeed, providing advice and value to peers would often result in accusations of plagiarism, yet these are powerful *social values* in which the value of your own interests also creates value for those around you and the environment you are working in, much like open-source projects.

Collaboration, Open-Source and the Rise of the Pro-Ams

As Charles Leadbeater and Paul Miller argue in *The Pro-Am Revolution* (Leadbeater & Miller, 2004), a combination of technical and social changes have led to the rise of 'professional amateurs' or Pro-Ams. These groups generate a great deal of social, as well as financial capital and, according to Leadbeater and Miller, are "the new R&D labs of the digital economy" (2004, p. 67).

From astronomy to activism to software design and saving lives, the Pro-Ams are a powerful force and one in which collaboration, often via the Internet, is key:

Traditional innovation policies subsidise R&D and accelerate the transmission of ideas down the pipeline and into the market. Pro-Ams are helping to turn this closed model on its head... ideas are flowing back up the pipeline from avid users to the technology producers. (Leadbeater & Miller, 2004, p. 64)

Open-source software projects, in which many hundreds and thousands of people voluntarily contribute to the greater good, are the clearest example of this. Software projects are so complex it is virtually impossible for a single entity (even a company as large as Microsoft) to manage the process. By creating an open environment in which anyone can contribute changes thousands of workers and testers are brought into play and they can apply multiple minds to the complexity of the problem.

All these people contribute their time for free, on the understanding that the more they contribute the more they receive in the end (because the software is improved) and there is also a social kudos to this. Again, this is a valuable ideal for educational situations in which groups are collaborating, but it is also a powerful *social charter* that ripples upwards into the professional world as much as the corporate landscape is starting to change from above. Put simply, many hands make light work.

Organisational Change

Working Progress, also by Demos (it is interesting in itself that this research has not come from an academic institution, but an independent one who's motto is 'building everyday democracy' – they work outside of, but often advise the UK government), examines the nature of organisational change and the 'disconnect' between young people and employers (Gillingson & O'Leary, 2006). The authors reveal that organisations are finding it difficult to recruit graduates with the right skills even though they acknowledge that graduates are more highly qualified than ever: Graduates used to working in the peer-to-peer environment of the university find it hard to shift to organisational hierarchies and difficult to relate to their bosses (*Ibid.* p. 14).

At the same time, these organisations themselves are changing and the hope is that these two changing patterns, from what has traditionally been seen perhaps as the 'top' and the 'bottom', have a chance of meeting in the middle. They argue that hierarchical companies are slowly shifting and being replaced by the networked, organisational structures that we have already seen online.

Gillingson and O'Leary (2006, p.38) surveyed Human Resources directors from FTSE200 companies and the top four employee qualities the directors rated most highly were:

- Communications/communicating ideas
- Problem-solving
- Team-working
- Creativity and Innovation

These are several of the qualities we have researched and engendered in our past Omnium projects to date. For example, anyone can learn how to use Photoshop or Illustrator - they are tools just like a pencil - however design, creativity and collaboration *is* about process more than skilful practice (though it requires that too). The Creative Waves VIP project, detailed further in part two of this paper, was a collaboration between pharmacy students, lecturers and professionals as well as the same within design disciplines. It became clear during the duration of the project that many of problems relating to six health issues faced by the village of Winam in Kenya were not through a lack of medical knowledge or research, but a lack of communication of that knowledge effectively. Once again, we see that it is not the *specific knowledge of information* that it is important, for that is easy to come by these days, but *how to create new knowledge, make new connections and how to communicate* that are the fundamental qualities required of the 21st Century graduate and the rest of us:

If innovation flourishes within and across teams, then we need to be able to work within them. If the formalities of hierarchy are being overlaid with social networks inside organisations, then we need to negotiate our way through them. (Gillingson & O'Leary, 2006, p. 40)

The Omnium Project and Online Collaborative Creativity (OCC)

Initially founded as an individual research project in 1998, The Omnium Project has grown considerably through its ongoing online initiatives and creative activities to become a well-established research group based at the College of Fine Arts (COFA), the University of New South Wales in Sydney.

Omnium's continuing research focuses on exploring the notion of online collaborative creativity (OCC) and how the Internet can be best used to help geographically distanced individuals interact and work together creatively from any location worldwide. For nearly a decade, Omnium has offered a range of fully-online creative communities, facilitated a series of global and fully-online collaborative creative projects, as well as designed and written some ground breaking e-learning courses and programs. In addition, by designing and producing the unique Omnium® Software, specifically for online creative collaboration, and offering it as either a serviced package or an open-source option to other institutions around the world, Omnium has to date linked over 10,000 creative students, educators, professional practitioners, theorists and writers from over 50 countries worldwide.

Omnium has always maintained two underlying aims through all its online creative and e-learning projects and courses: to design, produce, test and evaluate:

- a revised online creative process through exploration into the generation of creative ideas and concepts, collaboratively, digitally, and across distance by individuals in collaboration via the Internet.
- a unique technical platform that enables the application of such a revised online creative process within a technical interface that uses 'virtual' space for its classrooms and studios.

In summary, Omnium bases its research investigations upon two significant and rapidly changing paradigms:

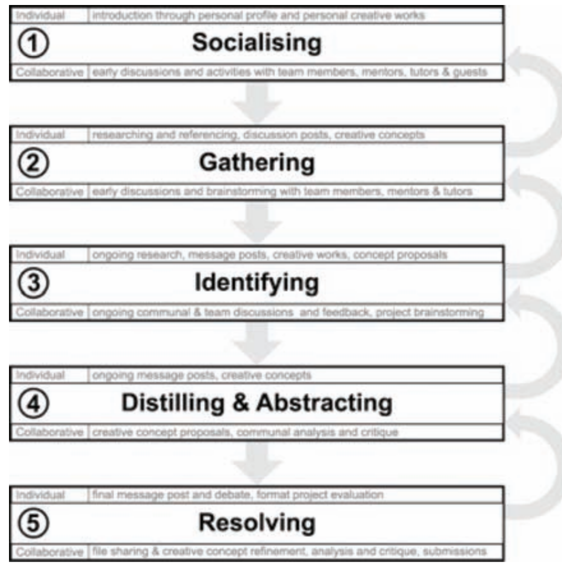
- **Education:** Observing and contributing to the changing face of education through the availability and affect of web technologies and how these are challenging many well established principles upon which many education institutions have traditionally been founded.
- **Creativity:** From predominantly individual production through to increasingly collaborative and collective approaches that have emerged increasingly over the last decade within many creative industries, studios and agencies.

Omnium's Five-Stage Process for Online Collaborative Creativity (OCC)

Although originally constructed by recollecting our own collective educational experiences throughout art and design colleges, and later our experiences in professional settings as designers and educators, we have continued to adapt and modify a five-stage online collaborative & creative (OCC) process by aligning our own perceptions to achieve an effective, analytical and intelligent working, teaching and learning methodology (Figure 1):

- **Socialising:** The first stage of Omnium's online collaborative creativity process aims to encourage initial individual involvement by all participants to not only introduce their own work, but introduce themselves through early discussions and autobiographies. Through construction orientation tasks requested by project facilitators participants are also subtly introduced to the technicalities of the user-interface without tedious formalities of a technical 'how-to-use' guide.
- **Gathering:** The second stage of the process aims to encourage initial individual contribution from all participants, while simultaneously producing process work that provides the project with a rich and varied mixture of cultural and personal backgrounds. It is a chance for each participant to feel they have contributed to the project and grow in confidence as a rich resource of visual research material, ongoing discussions and suggested links to other online resources grows. This stage is also the beginning of an array of feedback to the students in their working teams from the range of free-roaming mentors and invited special guests.
- **Identifying:** Following the more individual 'gathering' stage of the process, a project will subtlety evolve into a more collaborative community at this stage where emphasis is placed on each creative team recognising, via discussions and dialogue, points of contact, commonality, difference and overlapping interests arising from process works being produced as a result of the initial activities. It is also a stage within the process to begin identifying what a creative team may aim achieve as a result of the project and delegating roles for each member to take responsibility for.
- **Distilling & Abstracting:** During the *distilling and abstracting* stage each working team continues to discuss their intended creative direction and establish their collaborative working process. This stage breaks down ideas from the works produced from the preceding *gathering* and *identifying* stages and places an increasing demand on the participants' abilities to critically assess their combined creative outcomes through discussion and feedback. Working collaboratively as small teams, this stage is most interesting in regard to the collective decisions made to keep and/or discard ideas previously offered and challenges the notion of individual possession of ideas and promotes issues of collective ownership.
- **Resolving:** The final *resolving* stage ultimately leads to the production of collaborative final submissions. The execution of final works provides opportunities for participants to then reflect upon the entirety of their creative process: from the individual beginnings of a project to the collaborative and collectively examined outcomes. In a project such as Creative Waves 07, there is arguably a further stage of *implementation* where the outcomes are manufactured or produced and implemented to the communities that a project is aiming to assist.

Figure 1. The Omnium Five-Stage Online Collaborative & Creative (OCC) Process



The Omnium five-stage OCC process, described above, is not intended to be totally linear in progression, and would often be applied in different depths depending upon time available for a project. It would be recommended that participants using this process always reflect both individually and collaboratively on each stage and use a reiterative process en route. Each stage is designed to include both individual and collaborative components; contributions which steadily progress each student from a valued individual contributor with elements of collaborative discussion (stage 1), through to a fully interactive collaborative contributor who is still required to make individual contributions in terms of messaging, debate reflection and critique (stage 5).

On reflection, Omnium five-stage online collaborative creativity process shares many ideologies with previously identified characteristics of more traditionally defined creativity and creative interaction. Graham Wallas (1926) describes a four-phase process for creative thinking*: preparation, incubation, illumination, and verification.* This too was derived from his own introspection and observations, rather than systematic empirical observations, although has since become widely accepted by theorists of creativity. Catherine Patrick (1937) proceeded to confirm Wallas' process through a more systematic and psychological research study. Analysing her findings, she confirmed Wallas' four-phases although added revision to accompany the final *verification* stage.

The way in which Omnium's own five-stage OCC process is applied through a learning context also closely mirrors established models for learning within online environments. Perhaps the most notable of these is the Five Stage Model offered by Prof. Gilly Salmon (2000) in which a suggested progression for online learning is illustrated and described from both a facilitators and learners perspective. Salmon's Five Stage Model, describing processes of *access and motivation*, *online socialisation, information exchange, knowledge construction, and development,* also views the online learning process from both an e-moderating and technically supported perspective.

Throughout the entirety of the Omnium's OCC process, a project and its participants are supported by a series of specifically written lectures or readings, online activities to support those lectures and constant feedback from fellow students, project coordinators, roaming mentors and the invited special guests. It is the incredible amount of interactivity between participants in both social and working discussions that make Omnium's online studios consistently reported as highly social communities and free of the scourge of isolation reported by many e-learning or distance education offerings.

CREATIVE WAVES: AN OMNIUM INITIATIVE IN COLLABORATION WITH ICOGRADA

Having created and run several global online creative collaboration projects since 1998, in 2005

Omnium began an exciting collaboration with the International Council of Graphic Design Associations (Icograda) by conceiving a series of free and voluntary online design projects for students and their teachers around the globe under the banner of *Creative Waves*. Three significant projects have taken place under this banner to date (Creative Waves '05, Creative Waves '07 and Collabor8) that collectively have involved approximately 500 individuals from over 50 countries worldwide. Notably, the second Creative Waves project, that took place over three months in 2007 called *Visualising Issues in Pharmacy [VIP]*, progressed the *Creative Waves* direction to align with Omnium's more recent research activities that encourage online collaboration on more socially-aware design projects to aid people in less fortunate locations around the world.

The initial *Creative Waves* project, titled *03>04>05* and held over a seven-week period during March and April in 2005 saw a cross-disciplinary e-learning project between graphic design and photo-media students. The Creative Waves '05 project linked over 100 art and design students and their teachers from member institutions of the worldwide Icograda Education Network (IEN) and was structured to examine new ways of working collaboratively online and the prospects these open up for communicating visually with people around the world who would most likely never ever meet. By doing so, it continued Omnium's existing research that challenges traditional paradigms of individual creative processes and their championing of exclusiveness, isolation and sole-ownership of creative outcomes.

Throughout the project, the volunteer participants formed strong creative and social bonds with partners in distant parts of the world, receiving regular feedback and support from not only the variety of teachers who volunteered to take part, but also established creative professionals using the Internet as their sole communication tool. An added complexity of the project was the introduction of official mentors housed within each of the small creative working teams and the inclusion of invited special guests to add expertise and excitement to the proceedings.

In hindsight, the first *Creative Waves* project received a significant amount of acclaim, however, the real success of the project was not so much the creative work that took place, or that resulted, but the interaction and socialisation between so many distanced people that occurred. One of the main aims we intended for the project was in fact to open up discussion about the process of designing and in particular the critique of visual communication processes – to this end the project was a great success. Too often perhaps, especially in areas of graphic design, visual end-results are left to be viewed in isolation and to explain themselves, whereas this project aimed to address the prospect of discussion about works in progress and to be able to view the entire process of so many young designers around the globe and not just be presented with their end results.

Following conclusion of the *Creative Waves '05* project, the processes involved and the outcomes produced by the many participants were, as mentioned earlier, presented at numerous design and education conferences in many countries; including the 2005 Ascilite (Australasian Society of Computers in Learning in Tertiary Education) Conference in Brisbane, Australia. During this conference Omnium was awarded the 2005 Ascilite President's Award for the inaugural Creative Waves initiative as well as for the Omnium® Software used to host the entire event. Additionally though, the conference was to have a more important part to play in the next few years for Omnium's research. Following the presentation of the *Creative Waves '05* project at the conference, Omnium was approached by staff from the University of Auckland's School of Pharmacy who were interested in discussing some sort of collaboration to progress teaching and learning strategies for their undergraduate pharmacists. Like many other disciplines outside of the visual arts and design, pharmacy curricula

Figure 2. The visual progression of one team's work process from the first Creative Waves project

increasingly are able to include more and more visual and digital materials available to students and teachers.

Many of the more traditional scientific diagrams and tables used in previous texts are now being produced in highly graphic formats including movie files and 3D animations. In addition, students have a vastly increased resource of materials through the many avenues offered by the web. It was a suggested collaboration that seemed highly appropriate and an opportunity for Omnium to try to improve the opportunities for a completely 'new' discipline, in the same way that it had been doing for the visual arts for nearly a decade.

Around the same time, Omnium and Icograda were already in discussions again for a follow-up to the initial *Creative Waves '05* project; one that again could be offered to students and teachers globally. Omnium's intentions with a subsequent *Creative Waves* project was to include its new direction of offering a project that had more of a purpose and real brief; one that would align itself with the aims to help less fortunate people in remote parts of the world by connecting like-minded creative folk who could offer their own time to help such a cause.

Creative Waves '07: Visualising Issues in Pharmacy [VIP]

Following nearly twelve months of planning and preparation, which included the design, programming and introduction of a brand new version (v4.0) of the Omnium® Software, the *Creative Waves '07* project, titled *Visualising Issues in Pharmacy [VIP],* was ready to be launched. The new VIP project ultimately aimed to produce a series of visual campaigns to raise public awareness of six health issues that were chronically affecting small rural communities in Kenya, Africa. Through a combination of over one hundred pharmacy participants around the world, together with a similar number from design disciplines, the VIP project would attempt to produce campaigns to cover issues relating to:

- Malaria
- Tuberculosis
- Adherence (regarding the correct usage of medicines)
- Sexually Transmitted Infections (notably HIV/Aids)
- Chronic Disease
- Immunisation

As a result of a short promotional campaign, using a simple information website about the project built by the Omnium team, as well as announcements through both the Icograda and Icograda Education Network newsletters, hundreds of people had applied to take part in the *Creative Waves '07* project from over 35 countries worldwide. The combined project participants were split into four user-types: students; teachers acting as free-roaming mentors; invited special guests; and the six pharmacy and four design coordinators with the overall project was convened by the Omnium Research Group. In addition, the entire project was formally endorsed by, and offered as a collaboration between the worldwide professional governing bodies of Icograda (representing the graphic design side of the project) and the Federation Internationale Pharmaceutical - FIP (representing the pharmacy/health sciences side of the project).

When facilitating online projects on such a global scale, with clearly structured e-learning intentions, Omnium has for many years established and strongly recommended the need for two very inter-dependent foundations: a clear and well documented working process; and a highly user-friendly and technically proficient software platform. In regard to the technical platform (software), despite it being a crucial aspect to offering such projects and an aspect that has demanded huge amounts of time, expense and consideration over the last ten years, it is not the main focus of Omnium's projects or research, albeit a necessity. For the purposes of this paper, we will describe some of the software's features used as we detail the progression of the work but mainly concentrate on how the VIP project was facilitated and structured around Omnium's five-stage creative process for online creative creativity. We should also explain that the VIP project was separated into two overlapping seven-week phases (pharmacy and design) which both applied the five-stage process equally efficiently, although again for the purposes of this paper, we will concentrate on the latter design phase.

Creative Waves '07: Design Phase

Following an initial seven week start to the VIP project that saw over one hundred students, teachers and special guests from various areas of the health sciences and pharmacy collaborate together to ultimately form six detailed research reports on each of the recognised health issues (identified above) that affect the specific rural community of Winam in Kenya, an equal number of design participants took over the project for a further seven weeks - interacting with the pharmacy participants who in many ways acted as the clients and advisors.

Of critical importance to the designers, who resided in numerous countries worldwide, was to have a base of advisors located in Kenya itself, who could relay information about the culture, traditions, behaviours, living conditions and even folklore of the people whom the project was intended to assist and help. Such an important resource to a project of this nature included students, teachers, health workers, renowned professionals in the field and non-profit organizations who were familiar with or directly located in the targeted area. Two of the most influential contributors to the project were George Onyango and Salim Opere from the Help Heal Organisation, located in the village of Winam, Kenya and directly assisting the villagers facing the daily difficulties caused by the six identified health concerns. A highly evocative, frank and influential lecture written by George Onyango, could be argued as the catalyst to the entire project and a series of accompanying photographs, made available through the Omnium® Software galleries pages, gave participants the instant reality of the problems being faced.

Of the many discussions that occurred throughout the three-month Creative Waves VIP project, two discussion threads in particular generation an enormous amount of interaction and direct information from the location itself. The two threads, facilitated by George and Salim, along with many other Kenyan participants, together generated over 20,000 words of text in a series of questions and answers from participants to those able to advise from the location.

Following a highly structured format of progression through Omnium's five-stage working process, including daily news announcements, weekly lectures written by project coordinators and invited guests, live online chat sessions with luminaries in the field of design and health sciences, and progressive design briefs to facilitate the process of designing public awareness campaigns about eh six identified health issues, the project began to hone down a wide variety of suggested creative approaches until several focused studies were formed. It was interesting, as well as somewhat frustrating to observe, that the designers in their smaller design teams were arguably selecting specific ideas to work on too early in the process without fully investigating the scope of ideas that could be potentially created.

During the third *identify* stage of the project, the design convenors introduced the notion of "*worldstorming"* where each of the 100 design participants were asked to come up with ten quick ideas for campaigns that could promote awareness of the six health issues. Within a very short time, over six-hundred ideas were suggested which were in turn sent to the Help Heal workers in Kenya for their opinion and feedback. As a result it was decided that three sets of suggestions would be taken through stages four and five of Omnium's OCC working process – a game for school children to play with their teachers, peers and families; a series of stickers that conveyed simple messages about prevention and adherence; and designs for s set of soccer uniforms to be worn by both formal teams of young local footballers as well as the average kid in the street who would be wearing the outfits as simply trendy street wear as opposed to formal uniforms.

Figure 3. One of the outcomes of the Creative Waves VIP Project was a set of soccer kits with slogans about the dangers of HIV to engage the young men of Winam who play soccer a great deal. Here are the packages of the shirts being sent off to Kenya.

The designs for each set of campaigns were themselves taken through the five-stage process by students and mentors who had been arranged into new working teams until final solutions were presented at the end of the seven week design phase. Each of the final designs were versatile enough to be able to be adjusted and amended to deal with any one of the health issues and to date Omnium is in a stage where it is seeking sponsorship and/or assistance to have the design realised. On completion of the final designs being produced, each of the public awareness campaigns is to be sent to the village of Winam to be facilitated to the community by the volunteers in location.

All of the process work from both the pharmacy and design phases of the project can be viewed at the archive of the Creative Waves project interface – creativewaves.omnium.net.au – within the Galleries area, along with every other facet of the project including lectures, discussions, team work, transcripts of the live chat sessions and profiles of every participant who took part.

The third in the series of Creative Waves projects, titled *Collabor8* – creativewaves.omnium.

net.au/c8 – was recently run in 2008 and saw students from art & design colleges in Australia and China link together online to examine specific cultural, visual and language differences that affect creative work taking place between the two countries. For details of all the projects and to view the archives since 1998, visit the Omnium website: www.omnium.net.au

Chapter 4.8

Using Social Networking to Enhance Sense of Community in E-Learning Courses

Steve Chi-Yin Yuen
The University of Southern Mississippi, USA

Harrison Hao Yang
State University of New York at Oswego, USA

ABSTRACT

This chapter provides an overview and development of sense of community and social networking; discusses the potential uses of social networking in education; and presents a case study that integrates social networking into two graduate courses for the purpose of building a sense of community, improving communications and interactions, and promoting student-centered collaboration. The construction of class social networking sites, the implementation of these networks, and their effects on the students' learning experience are examined. In addition, an analysis of feedback from students on the value of social networking in learning is included.

INTRODUCTION

The rapid technological change and proliferation of information resources are lineaments of our contemporary society. Online information and communication are changing the way instructors and learners interact within the teaching/learning process. Online teaching and learning represents a new educational paradigm. The "anytime, anywhere" accessibility of e-learning courses provide students and teachers the opportunities to work at their own pace and at locations they are able to control (Berge, 1995; Edelson, 1998; Spiceland & Hawkins, 2002). Furthermore, as Richardson and Swan (2003) indicated, "[e-learning] allows students to reflect upon the materials and their responses before responding, unlike traditional classrooms" (p. 69). Currently, there are two main types of e-learning applications within higher education courses: (a) fully online applications in which teaching and learning activities take place entirely at an online computer-mediated communication (CMC) setting; (b) hybrid applications in which both traditional classroom instruction and online CMC are blended. In either online or hybrid applications,

DOI: 10.4018/978-1-60566-729-4.ch016

online learning content is typically provided by courseware authors/instructors, structured into courses by a learning management system (LMS), and consumed by students. This approach is often driven by the needs of the institution/corporation rather than the individual learner.

While online and hybrid courses are expanding and the numbers of participants are increasing, questions are being raised on conventional LMS based e-learning. For example, researchers are asking how best to foster community among learners and their instructors who are physically separated from each other, as well as separated in time (Palloff & Pratt, 1999; Rovai, 2002a, 2002b). Such separation may increase social insecurities, communication anxieties, and feelings of disconnectedness (Jonassen, 2000; Kerka, 1996). As a result of such separations, Sherry (1996) stated that "the student becomes autonomous and isolated, procrastinates, and eventually drops out" (¶ 27). Previous studies suggest that a sense of community, which is related to connectedness and learning, is essential for an e-learning course to occur (Yang & Liu, 2008).

With the emerging Web 2.0 technologies, more opportunities and possibilities to enhance existing e-learning courses are provided. For instance, social networks are collections of Web 2.0 technologies combined in a way that help build online communities. Social networking sites are on the rise globally and are developing rapidly as technology changes with new mobile dimensions and features. These sites are changing the ways people use and engage each other utilizing the Internet (Childnet International, 2008). Today's technology enhanced students have shown growing interest in social networking sites because of the community, the content, and the activities in which they can engage in the sites. Students can share their profile information, find out what their peers think about topics of interest, share music and playlists, and exchange messages with friends. Students use social networking sites to connect daily or even hourly for social as well as educational activities. They get to know their classmates through Facebook and share their lives with others on MySpace. Students use other social networking sites like RateMyProfessors and PickAProfessor to learn about their professors and choose their classes. In addition, they share their photos on Flickr and their videos on YouTube (The New Media Consortium, 2008).

Social networking sites are changing the social fabric of colleges and universities. In its fifth study of undergraduate students and information technology, the EDUCAUSE Center for Applied Research (ECAR) investigated the use of technology by undergraduate students in American colleges and universities. The *ECAR Study of Undergraduate Students and Information Technology, 2008* analyzed the Web-based survey responses of over 27,000 freshmen and seniors at 90 four-year institutions and eight two-year institutions, as well as findings from focus group discussions. The key findings of the Social Networking Sites section of the study included:

- Over 85 percent of respondents reported using social networking sites. The striking change over the last two years was in how many respondents now use social networking sites on a daily basis, from 32.8 percent in 2006 to 58.8 percent in 2008.
- Facebook was the most commonly used social networking site (SNS) (89.3% of SNS users), with MySpace as the second choice (48.3% of SNS users). Traditional college-age respondents (18 to 24 years old) used Facebook more than MySpace. However, older respondents used MySpace more than Facebook.
- Over 55 percent of SNS users spent 5 hours or less per week on SNSs, and about 27 percent spent 6 to 10 hours per week. Younger respondents reported spending more time than older respondents.

- Half of SNS users used social networking sites to communicate with classmates about course-related topics, but only less than 6 percent of them used social networking sites to communicate with instructors about course-related topics (Educause Center for Applied Research, 2008).

Social networking is already second nature to many students. Social networking sites not only attract students but also hold their attention, impel them to contribute, and bring them back time and again. Because of students' tremendous interest in social networking, many educational institutions are now evaluating existing social networking tools and even developing new ones, experimenting with social networking tools to support learning, and examining the effects of social networking in education (Educause Center for Applied Research, 2008; The New Media Consortium, 2008). Consequently, educators are beginning to recognize the popularity of social networking, to understand the importance and appeal of social networking among young people, and to explore the possibility of using social networking to enhance the sense of community in e-learning courses. This chapter provides an overview and development of sense of community and social networking. It then discusses the potential uses of social networking in education, and presents a case study that integrated social networking into two graduate courses for the purpose of building a sense of community, improving communications and interactions, and promoting student-centered collaboration. The construction of class social networks, the implementation of these networks, and their effects on the students' learning experience are examined. Also, an analysis of feedback from students on the value of social networking in learning is included.

DEVELOPMENT OF SENSE OF COMMUNITY AND SOCIAL NETWORKING

Sense of Community

The early research concerning community can be traced back over 30 years (Sarason, 1974). Sarason (1974) defined psychological sense of community as "the perception of similarity to others, an acknowledged interdependence with others, a willingness to maintain this interdependence by giving to or doing for others what one expects from them, and the feeling that one is part of a larger dependable and stable structure" (p. 157). Since then there have been various studies that attempt to describe and measure the sense of community (Buckner, 1988; Chavis, Hogge, McMillan, & Wandersman, 1986; Davidson & Cotter, 1986; Doolittle & MacDonald, 1978; Glynn, 1981; McMillan & Chavis, 1986; Pretty, 1990). The most influential and frequently quoted study is probably McMillan and Chavis (1986), who defined the concept as "a feeling that members have of belonging, a feeling that members matter to one another and to the group, and a shared faith that members' needs will be met through their commitment to be together" (p. 9). They proposed that a sense of community was composed of four elements: (a) membership; (b) influence; (c) integration and fulfillment of needs; and (d) shared emotional connection. The dynamics among these four elements were demonstrated by McMillan and Chavis in the following example:

Someone puts an announcement on the dormitory bulletin board about the formation of an intramural dormitory basketball team. People attend the organizational meeting as strangers out of their individual needs (integration and fulfillment of needs). The team is bound by place of residence (membership boundaries are set) and spends time together in practice (the contact hypothesis). They play a game and *win (successful shared valued event). While playing, members exert energy on behalf of the team (personal investment in the group). As the team continues to win, team members become recognized and congratulated (gaining honor and status for being members). Someone suggests that they all buy matching shirts and shoes (common symbols) and they do so (influence). (McMillan and Chavis, 1986, p. 16)*

McMillan and Chavis's view of sense of community has been well supported and documented. Previous research studies indicated that spirit, trust, sense of belonging, interactivity, common goals, shared values and beliefs, and common expectations were the most essential elements of community (McMillan, 1996; Rovai, 2002a; Royal & Rossi, 1997; Shaffer & Anundsen, 1993; Strike, 2004). Rheingold (1991) and Hill (1996) suggested that the sense of community differed from setting to setting. Rovai (2002a) noted, "one such setting is the classroom where learning is the goal" (p. 201). Tebben (1995) found that student satisfaction and success were mainly attributed to the caring attitude of the instructor and the supportive environment created by classmates. McKinney, McKinney, Franiuk, and Schweitzer (2006) investigated the sense of community in a college classroom and found that six variables could significantly predict students' classroom attitudes, perception of learning, and actual performance on course exams: connection, participation, safety, support, belonging, and empowerment.

Wighting (2006) found that using computers in the classroom positively affected students' senses of learning in a community, and that students believed the connectedness with their peers was the most important variable in developing a sense of community. Bellah, Madsen, Sullivan, Swidler, and Tipton (1985), Rheingold (1991), and Wellman (1999) pointed out that the communities most important to people might not be defined within a geographical sense but instead consisted of groups of people who had common interests and may never physically meet each other. Accordingly, as Rovai (2001) noted, "community can be examined in virtual learning environments used by distance education programs" (p. 34). Studies on online environments have indicated that the sense of community could be created and supported through various interactive electronic media (Baym, 1995; Dede, 1996; Reid, 1995; Rheingold, 1993). Rovai (2001) explored the community of students in an asynchronous learning network course and found that the sense of classroom community grew significantly during the course in terms of spirit, trust, interaction, and learning. Rovai (2002a) refined the Classroom Community Scale focusing on: (a) connectedness, which represented the feelings of students regarding their cohesion, community spirit, trust, and interdependence; and (b) learning, which represented the feelings of community members regarding the degree to which they shared educational goals and experienced educational benefits by interacting with other members of the course.

Using the Classroom Community Scale, Rovai and Jordan (2004) examined the relationship of sense of community among traditional classroom, blended/hybrid, and fully online higher education learning environments, and found that blended courses produced a stronger sense of community among students than in either traditional or fully online courses. However, a large body of literature was somewhat limited in that it only assessed and reported the sense of community in CMC environments. Wilson (2001) pointed out that this type of research could be a useful component in tracking and assessing group cohesiveness, "while a reported sense of community does not itself establish effective community" (¶ 15). Rovai (2002a) argued:

Proper attention must be given to community building in distance education programs because it is a "sense of community" that attracts and retains learners. Educators who perceive the value of community must conceptualize how sense of *community can be nurtured in distant learning environments. (p. 199)*

Accordingly, there are a growing number of research studies on the sense of community through a complex interplay of social, instructional, and technological variables. Yang and Liu (2008) found that sense of community could be enhanced among students in e-learning courses through pedagogical, social, managerial, and technical functions.

Social Networks

Social networks are a social structure of nodes (individuals or organizations) and the relationships between the members. Social networks are usually built based on the strength of relationships and trust between the members (Liccardi, Ounnas, Pau, Massey, Kinnumen, Lewthwaite, Midy, and Sakar, 2007). Boyd and Ellison (2007) define social network sites as Web-based services that allow individuals to: (a) construct a public or semi-public profile within a bounded system, (b) articulate other users with whom they share a connection, and (c) view and traverse their list of connections and those made by others within the system. Social networking is when individuals or organizations are tied together through a similar objective or interest. There are many ways to participate in a social network. The most common is through the Web-based social network services that provide a variety of ways for users to interact, such as chat, messaging, email, video, voice chat, file sharing, blogging, discussion groups, and so on. Social networking sites focus on building online communities of people who share interests and activities, or who are interested in exploring the interests and activities of others (Wikipedia, 2008). Social networking sites allow users to create, develop, and manage their online presence.

Social networking sites have created powerful new ways to communicate and share information. Social networking sites are being used regularly by millions of people; and they keep people connected through a fast, free, simple, and an accessible way. Social networking sites play a role in social life, business, health care, and charity. People from all walks of life participate in social networking. Social networking sites are used not only for people to communicate on a local and global scale, but also to advertise their products and services, to network other business and industry professionals (e.g., Linkedln), to highlight individual physicians and institutions in the medical field, to connect with other patients dealing with similar issues and research patient data related to their condition (e.g., PatientsLikeMe), to locate pedophiles by many police investigations/trials using MySpace and Facebook pages as evidence, and to locate college students participating in illegal activities. Businesses and entrepreneurs have joined the young adults who connect through social networking sites. Also, companies use the sites to communicate with customers, promote themselves, recruit employees and conduct market research. (Wikipedia, 2008).

Childnet International (2008) reviewed the current range of social networking services available and grouped the social networking services into two main formats: sites that are primarily organized around users' profiles, and those that are organized around collections of content. In addition, social networking sites are classified into 6 categories: (a) Profile-based services (e.g., Bebo, Facebook, MySpace); (b) Content-focused services (e.g., Flickr, YouTube); (c) White-label networks (e.g., PeopleAggregator, Ning); (d) Multi-User Virtual Environments (e.g., Second Life, World of Warcraft); (e) Mobile services (e.g., Twitter); and (f) Microblogging/Presence update services (e.g., Jaiku, Twitter). Young people use social networking sites for various activities: (a) communicate with their contacts and develop friendships, (b) create and develop an online presence, (c) search information, (d) create and customize personal profiles to show their online identities, (e) create and upload their own digital media content, (f) add and share third-party content on their pages, (g) post public and private messages through message boards or internal email, and (h) collaborate with other users (Childnet International, 2008).

In the United Kingdom (U.K.), Ofcom's *International Communications Market 2007* report indicated that more adults use social networking sites than in any other of the European countries included in the survey (Childnet International, 2008). Also, a report published by ComScore (2007) revealed the European social networking community stood at 127.3 million unique visitors in August 2007 – reaching 56 percent of the European online population. The usage of social networking sites in the U.K. were heavier than the European average in terms of hours spent, pages viewed, and the number of visits per month. The average visitor to social networking sites in the U.K. spent 5.8 hours per month on those sites and made 23.3 visits. Ofcom reported that 39% of all U.K. Internet users use social networking sites, while the ComScore figures show 24.9 million individual social networking site visitors in August 2007 (Childnet International, 2008; ComScore, 2007). The most popular dedicated social networking sites in the U.K. and Europe are Bebo, Facebook Hi5, MySpace, Tagged, and Xing (Childnet International, 2008; Wikipedia, 2008). MySpace and Facebook are the most widely used in North America; Friendster, Orkut, Xiaonei and Cyword in Asia while Orkut and Hi5 in South America and Central America (Wikipedia, 2008).

Social networking sites such as Bebo, Facebook and MySpace facilitate informal communications and information sharing across the Internet. Many social networking sites target teenagers and young adults. Most of the social networking sites have a minimum membership age of 13 or 14, and may explicitly state that they are designed for individual 18 years or older. Services aimed at younger children typically have stricter privacy settings, greater levels of moderation and more limited user interactions. Some even require parental permissions for signing up and setting communication preferences (Childnet International, 2008). A research study by the Pew Internet and American Life Project (2007) indicates that 55% of teens between the ages of 12-17 use social networking sites. According to the study, older female teens use sites, such as Facebook and MySpace, primarily to reinforce pre-existing friendships, while male teens use them to flirt and create new friendships.

SOCIAL NETWORKING IN E-LEARNING

Digital Natives and Social Networking

According to Wolfe (2008), the worldwide generation Y population is nearly 2 billion strong and outnumbers the baby boomers, the previously largest generation. Generation Y is also known as boomlets, echo boomers, millennials, or net generation. Generation Y is born after 1980 and some of the older millennials already graduated and entered the workforce. Prensky (2001a) described the generation Y as digital natives and their predecessors as digital immigrants. Digital natives have been reared with technology, and most have had the Internet at their disposal during their younger years. So, this generation of digital natives is unique in that it is the first to grow up with digital and Web technologies and have had online and digital media access all their lives. They have made websites like YouTube and Facebook a massive phenomenon. Social networking sites like Facebook and MySpace are the backbone of their relationships with friends and family. Digital natives are comfortable with technology and the idea of sharing information via the Internet. By age 21, digital natives will have spent 10,000 hours on a cell phone, 10,000 hours playing video games, sent 200,000 emails, watched 20,000 hours of television, watched over 500,000 TV commercials, but spent less than 5,000 hours reading (Prensky, 2001b). Computer games, email, cell phones, mp3, flickr, Facebook, YouTube, and the Internet are integral parts of their lives.

As digital natives raised in an age of media saturation and convenient access to digital technologies, they have distinctive ways of thinking, communicating, and learning. Digital natives are highly connected, increasing mobile, interactive, and electronically social. They are visually-oriented, technologically savvy, and they see technology as an essential part of their lives. In addition, digital natives rely heavily on communications technologies to access information and to carry out social and professional interactions. They prefer multi-tasking and quick, non-linear access to information. Although they value education highly, digital natives learn differently from their predecessors. Digital natives prefer active learning rather than passive learning and have a low tolerance for lectures (Prensky 2001a, 2001b; Oblinger, 2003).

Social networking is deeply embedded in the lifestyles of digital natives. One of the popular technology tools the digital natives use to interact with others outside of school is the social networking sites such as Facebook and MySpace. Results of a 2007 national study conducted by the Pew Internet and American Life Project show that 55% all online American youths between the ages of 12 and 17 use social networking sites for communication. Forty eight percent of teens visit social networking sites daily or more often. Furthermore, 91% of all social networking teens say they use the sites to stay in touch with friends they see frequently, while 82% use the sites to stay in touch with friends they rarely see in person (Pew Internet & American Life Project, 2007).

The Office of Communications (2008) report, *Social networking: A quantitative and qualitative research report into attitudes, behaviours and us,* draws on numerous qualitative and quantitative research studies conducted in U.K. in 2007. The key findings of the report include:

- Social networking sites are most popular with teenagers and young adults.
- The average adult social networking users have profiles on 1.6 sites, and most users check their profile at least every other day.
- Two-thirds of parents claim to set rules about their child's use of social networking sites, although only 53% of children said that their parents set such rules.
- Social networking users fall into five distinct groups based on their behaviors and attitudes: a) Alpha socialisers, b) Attention seekers, c) Followers, d) Faithfuls, and e) Functionals.
- Non-users of social networking sites fall into three distinct groups: a) Concerned about safety, b) Technically inexperienced, and c) Intellectual rejecters.
- Only a few users highlighted negative aspects of social networking.
- Seventeen percent of adults used their profile to communicate with people they do not know. This increases among younger adults. Thirty-five percent of adults spoke to people who were 'friends of friends'.
- Facebook is the most popular site with adults followed by MySpace and then Bebo. For children aged between 8 and 17, Bebo was the most used social networking site.
- Some teenagers and adults in their early twenties reported feeling 'addicted' to social networking sites and were aware that their use was squeezing their study time.

Another study, *Creating and connecting: Research and guidelines on online social- and educational-networking,* conducted by the National School Boards Association (NSBA) indicates that American children are spending almost as much time using social networking sites as they spend watching television – around nine hours online, compared with 10 hours of TV. The report is based on online surveys of approximately

1,300 American children from 9 to 17 years old and over 1,000 parents. Additionally, telephone interviews were conducted with more than 250 school district officials. The findings of the study indicate that 96% of students with Internet access engage in social networking. Almost 60% of students said they use the social networking tools to discuss classes, learning outside school, and planning for college. Students also reported using chatting, text messaging, blogging, and online communities such as Facebook and MySpace for educational activities, including collaboration on school projects (National School Boards Association, 2007).

Digital native students are the most avid users of social networking sites, but older students are joining the social networking users ranks as well. Students typically join one or two social networking sites and do not change their profile often. They use social networking sites to keep in touch with their friends – most of whom they have already met in person – and to communicate with their classmates. These digital natives are not very concerned about privacy and security issues (Educause Center for Applied Research, 2008).

Social Networking for Teaching and Learning

Social networking has great potentials in education and will likely impact the teaching and learning process. The *2007 Horizon Report* described six areas of emerging technologies that will have significant impact on college and university campuses within three adoption horizons over the next one to five years. These areas are presented in priority order: (a) user-created content, (b) social networking, (c) mobile phones, (d) virtual worlds, (e) the new scholarship and emerging forms of publication, and (f) massively multiplayer educational gaming. The report further suggested that user-created content and social networking are the nearest adoption horizon. Social networking is already a fact of life on campuses across the world and examples are readily available. Social networking may be an important way to increase student access to and participation in educational activities (The New Media Consortium, 2007). Also, social operating systems are identified as one of six emerging technologies as likely being of increasing relevance to educators in the *2008 Horizon Report.* The time-to-adoption horizon of social operating systems is four to five years (The New Media Consortium, 2007). According to the *2008 Horizon Report*,

> *The essential ingredient of next generation social networking, social operating systems, is that they will base the organization of the network around people, rather than around content. This simple conceptual shift promises profound implications for the academy and for the ways in which we think about knowledge and learning. Social operating systems will support whole new categories of applications that weave through the implicit connections and clues we leave everywhere as we go about our lives, and use them to organize our work and our thinking around the people we know. (The New Media Consortium, 2008, p. 4)*

Many of today's learners use technology primarily for social networking, and they are quite familiar with using social networking sites (JISC, 2007). Social networking sites have the capability to deliver a platform for learning where the student is potentially at the center of activities. (Oradini & Saunders, 2008). Students are far more ready and comfortable using social networking sites than their teachers. Cengage Leaning (2007) conducted a survey of 677 professors teaching at two- and four-year colleges to examine faculty views on social networking sites and new media tools. The survey results revealed that 65% of the respondents are not familiar with social networking sites and those who used social networking sites used them for both personal and work purposes. Nearly 50 percent of faculty respondents who are familiar with social networking sites felt such sites have or will change the way students learn. Furthermore, nearly 90% of respondents who are familiar with social networking sites said they know about sites that allow students to grade or rate professors, and 67% have checked if they have been rated.

In recent years, social networking sites have received significant attention in higher education as increasing numbers of digital native students have made use of public systems such as Facebook and MySpace. Such sites, along with other Web 2.0 tools (e.g. social bookmarking and syndication technologies), help students find information, create work, and share knowledge (Oradini & Saunders, 2008). Many educators and researchers are now developing their own social networking system and exploring the uses of social networking in teaching and learning (e.g., Marsh & Panckhurst, 2007; Oradini & Saunders, 2008). According to Oradini and Saunders (2008), several universities in the U.K. have recently experimented with the provision of institutionally owned social networking (e.g. the University of Brighton's Community System, University of Westminister) or blogging systems (e.g. the University of Leeds). Marsh & Panckhurst (2007) conducted a pilot study to explore the opportunities for a more flexible learner-centered approach through the provision of an online social network. They set up a private community eLEN (eLearning Exchange Network) using Ning (www.ning.com) to provide virtual space with a social network environment. Two groups of graduate students from France and the U.K. were invited into the eLEN. Their study showed that collaborative learning could take place in a social network. Their social network (eLEN) gave the students a sense of belonging, a sense of freedom, and a sense of pedagogical innovation. Also, the social network provided a learning community for knowledge sharing.

Childnet International (2008) offers many ideas for school administrators to explore the use of social networking sites in education. Educators may use social networking sites for delivering staff development and digital literacy; providing information about a school, college, or organization; supporting e-learning; and developing ICT provision planning and personal learning environment planning. Also, there are many potential educational benefits to students using social networking sites: (a) allowing learners as social participants and active citizens to discuss issues and causes that affect and interest them; (b) developing a voice and building trust in a community; (c) allowing students to become content creators, managers, and distributors of their work; (d) supporting students to work, think, and act together as collaborators and team players; (e) encouraging discovery learning and helping students develop their interests and find other people who share their interests; (f) becoming independent and building resilience; and (g) developing key and real-world skills (Childnet International, 2008).

Social networking offers many potential uses in education. Social networking can be used in education for: (a) providing a casual place of learning; (b) developing literacy and communication skills; (c) providing effective communication and collaboration; (d) enhancing students' learning experiences; (e) building an online learning community; (f) offering immersion in a foreign language environment; (g) developing e-portfolios; (h) learning about data protection and copyright issues; (i) learning about self-representation and presentation; (j) learning about e-safety issues; (k) producing public showcases for work, events, or organizations; (l) forming communities of practice; (m) organizing and scheduling educational timetables; and (n) being where learners are (Childnet International, 2008).

While social networking shows great potentials for e-learning in general, little is yet known about how to integrate social networking focusing on building a sense of community, particularly in e-learning courses. As Wilson (2001) suggested, "[w]e need continuing development and publishing of specific teaching models and frameworks that can be studied and shared through research—the profession thus emulates the community behaviors we are talking about" (¶ 14).

CASE STUDY: INTEGRATING SOCIAL NETWORKING IN E-LEARNING COURSES

To obtain specific information about the process of the social network instructional approach and participants' perceptions on the use of social networking on the sense of community in e-learning, two courses in a blended learning or hybrid format were selected for this study. It should be noted that the participants were selected by the way of convenience sampling since one of the researchers for this study was the instructor of both courses. Furthermore, the sample size was relatively small. Therefore, instead of any strict inferential attempts, a descriptive research design was utilized in the study. The following questions guided this study:

- How could the researchers design and implement a social networking site for teaching an online or hybrid course?
- How did students feel regarding the use of a social networking site in learning?
- What were the effects of using a social networking site in a course on the sense of community among learners?
- Were there differences in the use of a social networking site and the sense of community among different learners (age and gender)?

Design of Social Networking Sites

A social networking site was created for each course using Ning (www.ning.com). The unique feature of Ning is that anyone can create their own customized social network for a particular topic or need, catering to specific audiences. Also, minimum technical skills are required to set up a social network, and there are no limits to the number of networks a user can join. Ning has a very good user-friendly interface that allows even novice Web users to create his/her own highly customized social network free of charge. Also, Ning has excellent functionality similar to that of more well-known social networking sites, such as Facebook and MySpace. Various features allow Ning users to read news or learn about related events, join groups, read and comment on blog entries, view photos and videos, and participate in forum activities. Other social network sites such as Facebook, MySpace, etc. were not chosen to use in the study despite the popularity of these social networking sites. Facebook and MySpace tend to be used by many students for personal or social extra-curricula networking tools. It was the belief of the researchers that a personal social networking site created with Ning seemed more appropriate and provided an exclusive and personalized learning environment for the students.

Each site allowed students to create their own profiles; upload photos, audio, podcasts, and videos; create and join discussion groups; send messages; and publish blogs and presentations. Each social networking site was designed for private use. Only class members in each course were invited to join the class social network. No guest or outsider was allowed to join or participate in the social network. Figures 1 to 5 show the main features of a class social network.

Participants

The participants were 30 students enrolled in educational technology classes from two universities during the spring semester in 2008. Specifically, the participants were enrolled in the course *Seminar in Instructional Technology* (Course A) at a state university in the southern region of the United States and the course *IT Management in School* (Course B) at a public university in Hong Kong. Both of these courses

Figure 1. The Social Network Main Page for Course A

Figure 2. A Personal Page on a Social Network

Figure 3. The Forum Page

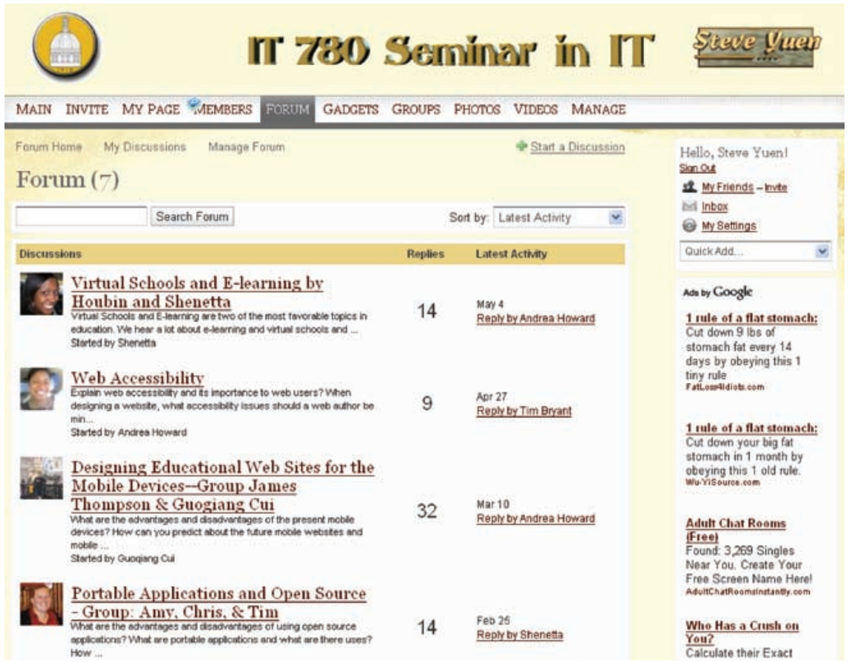

Figure 4. The Videos Page

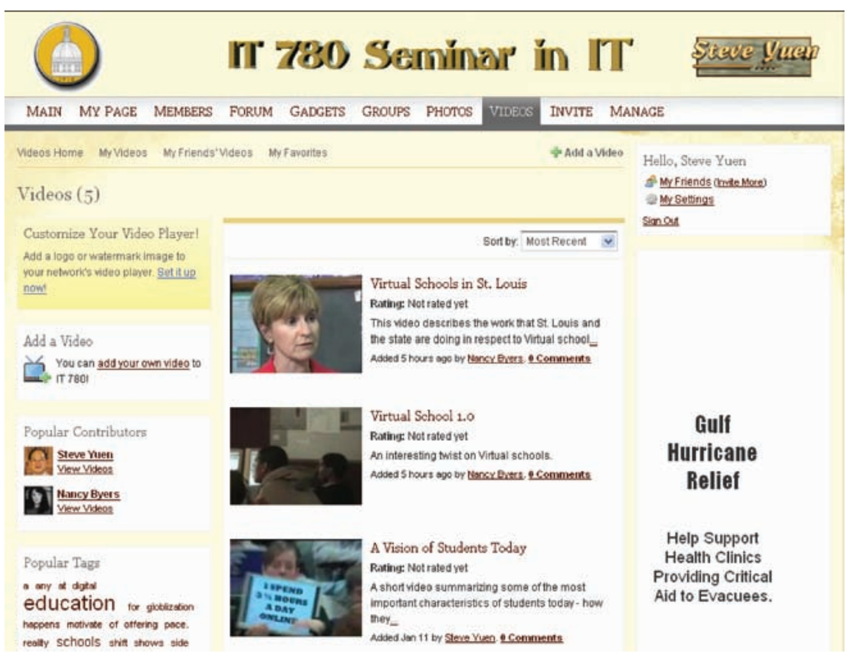

Figure 5. The Social Network Main Page for Course B

were graduate level courses in educational technology and were offered in blended learning or hybrid format, where approximately one-half of the course learning activities was scheduled in an online environment. Furthermore, the course *Seminar in Instructional Technology* was offered in a regular 15-week semester while the course *IT Management in School* was taught in an intensive 4 weeks format. The majority of participants in both courses were part-time in-service teachers who were pursuing a master's degree or a graduate minor in educational technology. In addition, one of the researchers of this study served as the instructor for both courses.

Implementation

Two social networking sites were designed and tested prior to the beginning of class with each having a similar layout and identical features and components. Both courses were taught by the same instructor/researcher in spring 2008. In the beginning of the semester, social networking concepts and the social networking sites were introduced in the courses. Also, the instructor/researcher gave a hands-on demonstration on using the social network site and explained how the social network could be used in the course.

Students in each course were invited to join the respective social network. No outside-of-class students nor the general public were allowed to join the class' social network. Each student was required to create a personal profile that included a personal introduction, current status, e-mail address, city of residence, personal Web site, instant messaging accounts, and interests. Also, each student was encouraged to post personal media (digital photos, music, and videos) as well as personal blog, podcasts, and videos related to the course content to the social networking site. Class information such as the course syllabus, schedule, assignments, instructor's blog, the links to the lecture notes and resource materials were provided by the instructor on the social networking site. Bi-weekly class discussions were facilitated by the forum on the social networking site. Each student was required to participate in the class discussions and shared their opinions on the current class topic. In addition, students were encouraged to form groups and initiate and moderate a forum for other personal or class activities. At the end of semester, students in both courses were requested to complete a survey designed by the researchers.

Data Collection and Instrumentation

A questionnaire was developed to evaluate the use of social networking in teaching and learning and assess its effectiveness on the sense of community among learners. The questionnaire consisted of three major parts. Part A consisted of 8 items to collect background information such as age, sex, types of Internet connections, Internet access locations, years of using computers, social network memberships, frequency of access to a social network, and numbers of friends in a social network. Part B consisted of 18 items which were designed to obtain students' feedback regarding the use of a social networking site in teaching and learning. A five-point Likert scale was used for the 18 items, with 4 representing a strong agreement and 0 representing a strong disagreement. In addition, two categorical types of questions regarding the access and profile and one open-end question were included. Part C consisted of a 20 item Classroom Community Scale (CCS) developed by Rovai (2002a). CCS was adopted to measure the sense of community for students on two factors: connectedness and learning. A five-point Likert scale was used for items 1, 2, 3, 6, 7, 11, 13, 15, 16, and 19, with 4 representing strong agreement and 0 representing strong disagreement. A five-point Likert scale was also used for items 4, 5, 8, 9, 10, 12, 14, 17, 18, and 20; but for these items, 0 represented strong agreement and 4 represented strong disagreement. The scores of odd items (1, 3, 5, 7, 9, 11, 13, 15, 17, and 19) were added together for the connectedness subscale score. The scores of the even items (2, 4, 6, 8, 10, 12, 14, 16, 18, and 20) were added for the learning subscale score. Scores on each subscale ranged from 0 to 40, with higher scores reflecting a stronger sense of classroom community (Rovai & Jordan, 2004).

To ensure the reliability and content validity of the instrument, the questionnaire was sent to a jury of experts to determine the appropriateness and content validity of the Part A and Part B of the questionnaire. Their comments and feedback were used to refine Part A and Part B of the questionnaire. Also, a reliability test was conducted for the 18 items of Part B, and a Cronbach's coefficient α was 0.93 indicating excellent reliability. According to Rovai (2002a), Cronbach's coefficient α for the full Classroom Community Scale was .93 and the equal-length split-half coefficient was .91, indicating excellent reliability. Cronbach's coefficient α and the equal-length split-half coefficient for the connectedness subscale were .92 each, and for the learning subscale were .87 and .80, respectively.

All students from both courses were requested to complete the questionnaire at the end of the spring semester. Thirteen out of 13 students' responses (100%) from Course A, and 17 out of 18 students' responses (94.4%) from Course B were completed and usable.

Findings

This section reports on an analysis of the use of social networking site by participants in two graduate courses at two different universities. Quantitative data was collected via questionnaires in the spring semester of 2008. Table 1 shows the demographic profile of the participants. Seventy-seven percent of participants were between the ages of 25 to 39. Sixty percent of them were female. Ninety-four percent accessed the Internet

Table 1. Frequency Distributions of Demographic Variables

Variable	Category	N	Percentage
Age	Under 20	0	0.0
	20-24	1	3.3
	25-30	10	33.3
	31-34	6	20.0
	35-39	7	23.3
	40 and above	6	20.0
Gender	Female	12	40.0
	Male	18	60.0
Internet Connection	High speed (Cable, DSL)	20	66.7
	T1/LAN/WAN	8	26.7
	Other	2	6.6
Internet Access Location	Campus	8	29.6
	Home	9	33.3
	Workplace	10	37.0
Computing Experience	<2 years	1	3.4
	5-7 years	2	6.9
	7+ years	26	89.7
Social Network Member	Bebo	1	3.3
	Classmate	6	20.0
	Facebook	17	56.7
	Friendster	3	10.0
	Linkedin	3	10.0
	Myspace	10	33.3
	Tagged	1	3.3
	Xanga	7	23.3
	Ning	7	23.3
	No social network	5	16.7
Access Social Network	Everyday	8	26.7
	Every week	9	30.0
	Every 2 weeks	4	13.3
	Every month	3	10.0
	Less Frequently	6	20.0
Number of Friends on Social Network	<10	11	36.7
	11-20	3	10.0
	21-30	3	10.0
	31-40	2	6.7
	50+	11	36.7

with high speed connections (cable, DSL, T1 and etc). Almost 90% of the participants had over 7 years of computing experience. The majority of them (57%) had a Facebook account while only 33% used MySpace and 23% had a Xang or Ning account.

Students' Perceptions of the Use of a Social Network

Most students indicated positive and favorable feelings of using a social networking site in both courses. Among the respondents on the Part B of the survey, 100% of them agreed/strongly agreed on items 2, 3, 4, 5, 6, 7, 8, 10, 13, 14, 15, 17, 18, and 19. Ninety-seven percent of the students agreed/strongly agreed on items 9, 11, 12, and 16: "My class social networking site allows me to communicate with classmates about course-related topics;" "My class social networking site provides collaborative learning opportunities;" "My class social networking site gives me a sense of belonging, and "Social networking can be used for professional development." Ninety percent of the students agreed/strongly agreed on item 1 "I feel comfortable using the class social networking site." In comparison of the two courses, as indicated in Table 2, the mean score on each item in Course A was higher than that in Course B. Furthermore, t-test analysis showed nine significant differences were found between respondents in Course A and Course B on items 2, 3, 3, 7, 8, 10, 13, 18, and 19 (p<.005). This indicated the students in Course A felt much stronger about the use of social networking in learning than students from Course B.

In addition to the 19 survey items, participants indicated they accessed the class social networking site every day (13.3%), every week (73.3%), or less frequently (13.3%). They changed their profile in the class social networking site daily (3.3%), several times per week (13.3%), monthly (23.3%), or once a semester (60%). Also, all participants (100%) in both courses indicated that their overall experience using the class social networking site were positive or very positive. Furthermore, participants were also encouraged to provide their personal feedback and comments on the survey. Here are their written comments regarding their class social network:

[Student 1 in Course A]

The more I used the class social network – the better I became at it. And we did share information. I enjoyed everything.

[Student 2 in Course A]

It is really a great experience. I like this experience to be communicating with others and this gives me more knowledge about the social networking, so I can set up my own social network.

[Student 3 in Course A]

I enjoyed using the social networking. There was almost never a moment of uncertainty. I could be in touch with anyone from class. Very good! Might very well be the BEST class I've taken! Very helpful and I honestly learned a lot!

[Student 4 in Course A]

This was the first course that incorporated a social network with the activities. The social network encouraged a laid back atmosphere that one could personalize and share with other classmates. It was different from the normal learning environment and I felt more apt to access the site than I would with your typical online course site (WebCT).

[Student 5 in Course A]

The class social networking site was very fun and meaningful. I enjoyed using Ning and creating anything I want. This was truly a remarkable project. I will use Ning continuously.

Table 2. Means and Standard Deviations of the Class Social Network Items

Item			Course A
			(n=13)
		M	SD
1.	I feel comfortable using the class social networking site.	3.08	0.76
2.	My class social networking site allows me to interact and build a learning community.	3.46	0.51
3.	My class social networking site allows me to personalize pages to express individuality and creativity.	3.62	0.51
4.	My class social networking site allows me to pose questions to the community.	3.54	0.52
5.	My class social networking site allows me to share photos, music, and videos.	3.62	0.51
6.	My class social networking site allows me to hold forums to discuss topics of interest.	3.62	0.51
7.	My class social networking site allows me to find and share educational resources.	3.62	0.51
8.	My class social networking site allows me to create study groups.	3.62	0.51
9.	My class social networking site allows me to communicate with classmates about course-related topics.	3.62	0.51
10.	My class social networking site encourages learner-centered activities.	3.46	0.52
11.	My class social networking site provides collaborative learning opportunities.	3.38	0.51
12,	My class social networking site gives me a sense of belonging.	3.08	0.76
13.	My class social networking site promotes knowledge sharing.	3.38	0.51
14.	My class social networking site is user-friendly.	3.54	0.52
15.	Social networking is a great tool for class communications.	3.69	0.48
16.	Social networking can be used for professional development.	3.62	0.51
17.	I will become more actively involved in courses that use social networking.	3.77	0.44
18.	I would like to see more social networking class sites used in other classes.		3.65
	Overall	3.51	0.35

[Student 6 in Course A]

I had a great experience using the social network and the site is easy to navigate through and user friendly. I enjoyed reading other people's view on different technology issues from reading and writing on different topics under the site. I have gained much knowledge on new technology.

[Student 7 in Course A]

I enjoyed using the site, working with peers using the forum was the most valuable. I wish the social networking site allowed a little more "personality." I would have liked to have a Wordpress plug-in for Ning.

[Student 8 in Course A]

Using a social networking site has helped me stay in touch with friends and classmates. The ability to share ideas with people worldwide is one of the best benefits I have experienced. I believe social networking sites have great potentials for teaching students in K-12 and college and for connecting teachers with each other in professional development.

[Student 1 in Course B]

It is useful to share experiences with classmates and get information from others.

[Student 2 in Course B]

The feeling of the site is rather formal making it less attractive compared with famous sites, like Facebook.

[Student 3 in Course B]

I started my class social networking recently and already loved it because it provides a good platform for students and colleagues to share their experience and post topics for discussion.

[Student 4 in Course B]

I liked using the class social networking site. I thought it was a great way to discuss topics and I could have used even more.

Connectedness

Most of the students indicated positive and favorable feelings of their cohesion, community spirit, trust, and interdependence from both courses. Among the respondents on the connectedness subscale of the CCS, eighty-seven percent of them agreed/strongly agreed on item 3 "I feel connected to others in this course;" approximately 83% of the students agreed/strongly agreed on item 1 and 11: " I feel that students in this course care about

Table 3. Means and Standard Deviations of Connectedness Subscale by Courses Learning

	Overall	3.13	0.65	2.60	0.29	2.83	0.54

each other;" "I trust others in this course;" about 83% disagreed/strongly disagreed on item 9 "I feel isolated in this course;" about 80% agreed/strongly agreed on item 7 " I feel that this course is like a family;" about 77% disagreed/strongly disagreed on item 5 "I do not feel a spirit of community;" about 73% agreed/strongly agreed on item 19 "I feel confident that others will support me, " about 70% agreed/strongly agreed on item 13 "I feel that I rely others in this course;" about 53% disagreed/strongly disagreed on item 17 "I feel uncertain about others in this course." In the comparison of the two courses, as indicated in Table 3, the mean scores on all items in Course A are higher than those items in Course B. The students in Course A felt much stronger in connecting with their classmates than students from Course B.

Most students indicated positive and favorable feelings of community members regarding the degree to which they shared their learning experiences by interacting with other members in both courses. Among the respondents on the learning subscale of the CCS, eighty-seven percent of them agreed/strongly agreed on items 2 "I feel that I am encouraged to ask questions;" approximately 80% of the students disagreed/strongly disagreed on item 20 "I feel that this course does not promote a desire to learn;" approximately 77% disagreed/strongly disagreed on item 14 "I feel that other students do not help me learn" approximately 73% disagreed/strongly disagreed on item 4 "I feel that it is hard to get help when I have a question;" approximately 73% agreed/strongly agreed on item 6 "I feel that I receive timely feedback;" approximately 70% disagreed/strongly disagreed on item 18 "I feel that my educational needs are not being met;" about 63% agreed/strongly agreed on item 16 "I feel that I am given ample opportunity to learn;" and approximately 53% disagreed/strongly disagreed on item 10 "I feel reluctant to speak openly." As indicated in Table 4, the mean scores on all items in Course A are also higher than those items in Course B. The students in Course

A felt much stronger about sharing their learning experiences by interacting with other members than students from Course B.

Age and Gender Differences on Social Networking and the Sense of Community

A one-factor analysis of variance was used to investigate the differences in students' age and gender on their social networking experiences as well as their sense of community. The results showed that no significant differences were found in students' age and gender on their social networking experiences as well as their sense of community in terms of connectedness and learning.

DISCUSSION AND CONCLUSION

With the recent advances of Web 2.0 technologies, the role of social software has become increasingly popular in recent years. Social network applications have great potential in education because of their open nature, ease of use, and support for effective collaboration and communication. Today, social networking is very popular and digital natives already found social networking tools integral to daily life. Social networks could be used in education to enhance students' learning experiences. This chapter yields findings of previous research related to sense of community and social networking in the e-learning environment and indicates the social networking approach should be considered, designed and implemented for e-learning courses.

The findings of the case study indicated that the approach of designing and integrating a class social networking site into two courses were fun, worthwhile, and positive. Students in both courses welcomed the opportunity to experience and explore the use of a social network in teaching and learning. They had positive experiences using a social networking site in learning. They found the class social networking site was user-friendly and gave them a sense of belonging. All participants in both courses felt comfortable using the class social networking site, and they felt more actively involved in the courses that use social networking. Participants in both courses felt that social networking is a great tool for class communications and can be used for professional development. They used their class social networking site to pose questions to the community, share digital media, hold forums to discuss topics of interest, share educational resources, create study groups, and communicate with classmates. Furthermore, they indicated the class social networking site can encourage learner-center activities, provide collaborative learning opportunities, and promote knowledge sharing.

The study revealed that using a social networking site in a class could build a sense of community among learners. All items in CCS received moderate high means except item 15 “I feel that I can rely on others in this course.” Perhaps, students who rely more on self-regulation have stronger sense of community. It was interesting to note that participants in Course A had more positive and favorable feelings about the use of a social networking site in learning than participants in Course B. Also, participants in Course A had a stronger sense of community in both connectedness and learning than participants in Course B. Although both courses were taught by the same instructor and used a very similar social networking site with identical features, design and layout, Course A and Course B were offered in different countries and in different formats (regular 15 weeks for Course A versus intensive 4 weeks for Course B).

It appeared that the length of time using a social networking site in a class could be an important factor. As compared to participants in Course B, participants in Course A had a much longer time to explore, learn, communicate in a social network and develop a stronger sense of community. Also, it is possible that culture plays a role in social networking since Course A was taught in the United States while Course B was taught in Hong Kong. It appeared that students in the United States in general are more open and more acceptable for online culture and socializing. It is recommended that culture issues be investigated for further research.

Chapter 4.9
Publishing with Friends:
Exploring Social Networks to Support Photo Publishing Practices

Paula Roush
London South Bank University, UK

Ruth Brown
London South Bank University, UK

ABSTRACT

Publishing with friends is the account of an action research cycle in which a print-on-demand Web site, Lulu.com, became a classroom for second and third year digital photography students to publish their photobooks. Building on the earlier use of a blogging platform as a personal learning environment, this narrative explores the pedagogical prospects of the read/write Web, and illustrates the way in which students use social networks for creative produsage (Bruns, 2008). Students were positive about the pedagogical approach, and the opportunities to gain valuable hands-on experience in their chosen field of study.

INTRODUCTION

The web is coming of age. Predicted almost 20 years ago, users with relatively unsophisticated information technology skills are now able to use the internet as a medium to communicate and publish in what we have chosen to describe as the read/write web. (Also known as Web 2.0 technology, the "read/write web" seems to us a more descriptive appellation.) The increasingly ubiquitous nature of the web, and its unquestioned affordances, now challenge the academy to embrace technology in appropriate curricula and, in the process, to investigate the move from an industrial production model to the pragmatics of the web-led produsage, or user-led production, approach. Bruns (2008) focuses on the fluidity of the produsage process as a main characteristic – it is in the evaluation, the flexible leadership, its iterative nature and the attribution of social capital, rather than an end product, that the concept is defined.

Produsage in the higher education setting is the underlying theme of the chapter which maps this particular instance of produsage onto Bruns' model. In the process, it describes the pedagogical underpinnings of the inquiry through the account of

DOI: 10.4018/978-1-60566-826-0.ch013

the use of the read/write web as an environment to teach students of digital photography; discusses the design of learning tasks and the engagement of students in the design of an assessment and feedback rubric; and explores the findings from the students' evaluation of the research intervention. Lastly, the implications of the research for future iterations of the digital photography units are set out.

BACKGROUND

The roots of the read/write web were described by Berners-Lee and Cailliau (1990); they explained hypertext and foresaw two phases in its development: firstly the use of existing browsers to access information (the read web) and also ease of publication on the web (the write web) with "the creation of new links and new material by readers. At this stage, authorship becomes universal." The authors predicted that "this phase [would] allow collaborative authorship" facilitated by the annotation of existing data, linking and adding documents.

Almost two decades later, their vision has become a reality. Online participatory culture is ubiquitous, and evidenced by the popularity of social network and media-sharing sites, multi-player games and other applications generally know as social software.

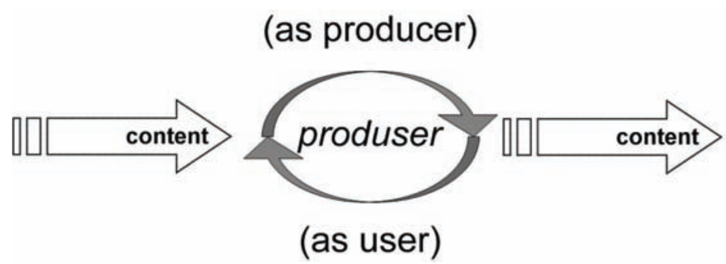
The academy is slowly entering this stage of "collaborative authorship". The term "classroom of the read/write web," coined by Richardson (2006), uses a familiar metaphor to translate this into a teaching and learning construct. Educators can assemble their own toolbox of freely available applications using the self-publishing technologies now abundant on the Internet; these may include weblogs, wikis, aggregators, social bookmarking, photo-sharing, rubric-making tools and many others. In his model, Richardson provides a pedagogical framework for the integration of these technologies in teaching and learning, in the context of the publishing affordances of the read/write web, and emphasizes the four core literacies – reading, publishing, collaborating and information management – that can be developed in the online environment.

In practice, the read/write web classroom demands major shifts in the ways we think about content and curriculum. Richardson (2006) identifies these as follows: the web is viewed as an open classroom; learning takes place 24/7 in interaction between online peers and experts; collaboration leads to the social construction of meaningful knowledge; teaching is democratized, a conversation rather than a lecture; knowing where to find information takes precedence over the acquisition (and regurgitation) of facts; students aspire to edit information critically, to develop active reading and writing skills; web applications are used as digital notebooks to store and share information found online; writing is lent richness by augmentation with photography, audio and video; mastery of skills is demonstrated and assessed in the product (e.g. digital content creation) and marked tests are dispensed with; and, finally, course materials and coursework are a contribution to a larger body of knowledge (the web), can be reused by others, and are not completed and discarded at the end of the semester.

This model of the open classroom is a major challenge for the academy. Many artists and designers already use the read/write web in their everyday life, but universities seem reluctant to make the transition from an industrial age concept of knowledge (production) to one more in tune with the information age model of user-led education (produsage). Bruns (2008) coined the word produsage to describe the process of user-led production in the setting of networked practices.

Engagement in the read/write web or, more specifically in this instance, in the contemporary online self-publishing environment, allows academe to explore novel opportunities for teaching and learning. These are underpinned by the four key principles of produsage: the implicit evalua-

Figure 1. The produser. (© 2008, Axel Bruns. Used with permission.)



tion by the community of users of artifacts prodused by individuals; the flexible leadership of projects which is grounded in personal strengths; the recognition of the iterative and inherently "unfinished" nature of the produsage process which is constantly revised by interested parts of the community; and the recognition of excellent individual contributions to the community by attributing social capital.

The model of the creative as an online produser (Bruns, 2008) is useful as it expresses the authentic practice of artist-teachers and artist-students. The term encapsulates the reality of artistic creative environments such as photograph- and video-sharing blogs, and social network sites like Flickr, YouTube, MySpace and Facebook and 3-D multi-user spaces like Second Life.

The focus is often on the personal content that circulates in these sites. While life caching (uploading of personal content for friends and family) may be one application of these platforms, specific groups of users have emerged which engage in the proper produsage of creative content:

… within such produser groups, content is exchanged not merely for its inherent personal or communicative value, but overtly as creative work to be showcased to and exchanged with other members of the community. Participants both comment on and critique one another's works; they collaborate on creative projects both by pooling together their individual collaborations to form a composite whole, and by directly editing, rearranging and remixing the material already provided by others; and in the process they in effect collaboratively curate an ever-expanding, constantly changing exhibition of the community's creative works. From such practices also emerge heterarchical structures of recognition and merit within the community. (Bruns, 2008, p229)

Specific studies on the impact of Flickr in photographic creative practices have revealed the personal and learning implications of the photo-sharing site. From her study, Van House (2007) reveals four social uses of personal photography: firstly, it is a memory device to build narratives of the self; it also serves as a form of self-representation or self-portrait; it may be a way of creating a relational sense of togetherness, an expression of sociability; and it can also have the purpose of displaying one's artistic and creative work, a kind of sociable exhibition. In the academic context, the use of Flickr in blended teaching for a first year photography unit articulates with the students' daily use of social networking sites for their photo practices (Robbie & Zeeng, 2008). Flickr's tools for commenting on and notating each other's images facilitates analytical critical reflection and feedback between students. It also situates their work in the nexus between students' studies and their professional practice; allows conversations to develop beyond the classroom, which addresses the balance between work and study; and is an affordable way of exhibiting images publically.

Studies of print-on-demand, and its relationship with photography and design communities, are also available. Lulu.com, in particular, is referenced in studies of the relationship between self-publishing and emerging online economies. Anderson (2006) explores Lulu as a prime example of the existence of long-tail markets, which are possible because of the unlimited shelf space provided by online digital databases. The reputation economy is a description of the self-promotion value attached to publishing; it explains the added attraction of publishing online, a motivational factor that outweighs the small sales volumes that characterise these niche markets. Specifically, the adoption of print-on-demand to self-publish photobooks allows emerging photographers to bypass the lengthy process involved in traditional publishing, with total financial independence – there is no need to fundraise – and full editorial control (Forrester, 2007).

Against this background, the possibility of teaching units on photobook publishing in an authentic produsage environment was a motivating factor in engaging in this qualitative pedagogical project. Other higher education projects using Lulu.com for graphic design are available (Philippin, 2008; Hochschule Darmstadt, 2008) but none comments on the pedagogical process involved in using the platform, choosing instead to present the students' work as an enquiry into the digital printing output achievable at Lulu. Our study explores the features of lulu.com that can be used as part of a "classroom of the read/write web" and discusses the results with reference to the self-publishing capacities involved in reaching the learning outcomes.

CASE STUDY: PHOTOBOOK PROJECT FOR PHOTOGRAPHY STUDENTS

There is an expanding field of inquiry into what constitutes artists' publications. Critical features of this interest are the combination of artistic approaches with networked practices, and the investigation of the latest technologies that many artists and publishing groups have started to explore as an alternative to traditional press. An artist's book, in this genre, is not an illustrated book characterized by high production values and a conventional separation text-image; nor is it a photo album containing the family's best moment's snapshots. Instead, it means working within a "zone of activity" (Drucker, 2004) at the intersect of conceptual art and photography, independent publishing, activism, fine art practice, sculpture, installation, book arts, performance, self-publishing fairs, and online produsage environments and social networks. The terms of reference for artists' publications may still be vague, but there is general agreement amongst practitioners and scholars that the final criteria rest upon the engagement of the work with the specific features of a book; this is the expression of the work's 'bookness'.

The emphasis of the photo publishing unit of this study is the genre of the photobook, "a book – with or without text – where the work's primary message is carried by photographs … an event in itself … a concise world where the collective meaning is more important than images" (Parr & Badger, 2006). This implies that the students come to think of the photograph in relational terms, develop skills as curators or editors, and learn to use current available digital technologies to publish and distribute independently. The genre has been developing since the conception of photography, but as printing technologies have gravitated towards a networked model, photographers have adapted their practices to take advantage offered by print-on-demand (POD) publishing models.

Teaching photographers to develop photobooks also means going beyond focusing on the 'best photo' to consider photographs as groups or collections. Free from the conventional photo-to-print relationship, the learner starts thinking in terms of the book's visual structure (Smith, 2005). The unit of meaning – the graphic layout as double page spread or as subchapter – conceptualises the narrative or meta-narrative aspects implied in grouping, serializing and sequencing the photos. Experimenting with the conventions of the book page becomes a key pedagogic strategy. The process allows deliberate disruption of conventional book flow – the distribution of text and image to create movement from page to page – to raise awareness of the relationship between page and image.

The book-making process starts with the creation of book dummies, 3-D mock-ups of the book that provide an excellent tool to play with the images and develop understanding of visual structures. Teaching the fundamentals of photobook publishing also implicitly equips students with in-depth knowledge of prepress, the steps necessary to prepare the work for a commercial printer. In the adoption of the desktop environment for publication design, creating a book means assuming responsibility for a series of processes: layout, typography and text formatting, preparation of images in Photoshop (color space and resolution), preflight and the creation of a robust .pdf file that the commercial printer will translate into a professional-looking photobook. Understanding and anticipating the printer's output environment is thus an important part of the learning program.

Why Teach Book Arts in a Produsage Environment?

While opportunities for self-publishing of photography online abound, few students take full advantage of the possibilities offered by the online photobook companies, like Lulu or Blurb. While students already use Flickr, deviantART and other photo-sharing sites for their photos, research shows that many photographers are exploring the professional photobook companies' sites for publishing their book works (Forrester, 2007). For our students, engaging in the professional environment represents the next step in their development; having completed a photographic brief, their focus changes to considering the editing of their work with a view to publication. Whilst other university assignments are produced for the teacher and the classroom, studying this unit unlocks the many possibilities of the classroom of the web.

With the availability of these technologies and the widespread opportunities for online publication, creating a photobook implies thinking beyond the screen and positioning the photographic work in the wider publishing context. Taking into account the current interest in e-books and readers, it is still a challenge in this unit to combine the best of digital technologies and paper-based media. Facilitating a semester unit on book-making for digital photographers means considering the book in the age of the digital press; the enterprise of the online print-on-demand photobook companies offering the latest developments in "digital/paper hybrid product" (Sarvas, Mäntylä & Turpeinen, 2007); and the paper-digital technologies that allow for both printed and online book publishing outputs.

An additional opportunity in such produsage environments is the uploading and sharing of images, mainly an individual activity, or the creation of personal sets of photos. The art of produsage, however, also offers other possibilities, such as the sourcing of images from pools, or creating groups on particular themes; this activity exemplifies a shift from the photographer-author to the photographer-editor, involved in the curation of collections. Such collective (or networked) projects are exemplified by photographers editing found photography (Brittain, 2006) or the management of photos uploaded by participants into paper-based publications, as in JPG magazine (Bruns, 2008). Thus, the opportunity of teaching students to work as editors of someone else's material is indispensable to publishing practice and in this instance the involvement in social networks is an essential way of sourcing images.

The unit aims were to:

- identify and analyze the context of self-publishing practices, as evidenced by participation in rubric-led assessment and feedback, and the participation on e-tivities at Lulu.com;
- demonstrate a critical understanding of the genre of photo publishing, as evidenced by the output of two photo publications (a photobook and a photo magazine);
- develop skills in visual communication, as evidenced by their work with the structure of the visual book including creating a book dummy, using InDesign to layout photo and text; and
- use the print-on-demand publishing model, as evidenced by the use of Lulu publishing and networking platform.

Research Methodology

This study is shaped by an action research methodology. A qualitative research paradigm, the aim of an action research cycle in an educational setting is to identify an area of practice that might benefit from improvement, to design an intervention and implement it and then to observe the effect on the learning experience (Arhar, Holly, Kasten, 2001). This case study describes a single iteration of this "reflect, act and observe" cycle with relation to the two cohorts of students that participated in the research; it builds, however, on an earlier intervention described below and anticipates a further cycle in the final reflection.

The Choice of a Produsage Environment

The project built on an earlier photo publishing unit, from the first semester of the 2006/07 academic year. In this earlier (level 3) unit, the digital photography students used WordPress blogging platform, to publish their coursework and Lulu.com to publish the finished photobook. As they were entering the final year of their studies, it was important to address the acquisition and consolidation of a series of digital literacies and capacities that allowed them to engage critically with these online environments, whilst simultaneously creating quality professional work in them. This included the publication of their critical writing as well as their photographic portfolios and, in particular, introduced the use of the digital press for the publication of paper-based photo books.

We noticed, however, that not all students participated at the same level of engagement. Whilst some engaged with the produsage environments, finding and analyzing pertinent information and contributing to the conversation via posts and comments, others needed extra support to actively engage with the produsage tools. We also found evidence of what Bruns describes as a new form of digital divide, "between those already tuned in to the produsage process and those not yet motivated to participate, as well as between those who already have the skills and capacities to contribute ...and those for whom participation in such environments remains an apparently insurmountable challenge." (2008, p.338)

The development of a blended learning pedagogical approach with the selection of Lulu.com as the main produsage environment – both as a digital notebook and publishing platform – and the inclusion of e-tivities and rubrics to encourage peer feedback aims at improving on the earlier pedagogical framework.

According to a recent study (Forrester, 2007), there are more than 55 online photobook companies all offering similar print-on-demand services. In each, the user downloads the company's software (or the software is browser-based), inserts the photos and text in pre-designed templates, chooses a binding and cover format, and places an order which is printed and delivered, typically, in 10 days.

Lulu, however, has special produsage features that make it a preferred choice for teaching: it

Figure 2. An example of a student's book page from Lulu.com

may be viewed as a two-sided produce-sell (or dashboard-storefront) platform. The dashboard is a private node (accessible only when the user is logged in), which accesses 'my projects' (a catalog of all the user's books), as well as the user's storefront, blog, groups, message box and friends. Additional account management features such as account preferences and access to the files associated with the user's publishing activity are also available from the dashboard.

On finding a (prod)user's name in Lulu (often through a search box), one is directed to their storefront – a public-facing interface which can be fully customized by the seller, and which provides a variety of information about their associated activities: a profile, list of lulu friends, group memberships, lulu interests, published books, blogs and other feeds (del.icio.us bookmarks, for example).

An important storefront feature is the book page, which offers information about the book: a preview, publisher and licensing information, a description of the book content, and the book specifications (number of pages, use of color or black-and-white, format and binding). The page also states the prices for printing and downloading (which may be different), the book's tags, categories, reviews, and sales information such as the lulu sales ranking and other books bought by the customers who bought the book. A link to the shopping basket allows the viewer to place an order, pay and enter a (virtual or actual) shipping address. If the book download is free, clicking on the 'download now' button initiates its download. Opening the tags or categories reveals a catalog of other publications with similar tags and categories, and the licensing link accesses the licensing deed: either copyright or a chosen variation of creative commons.

The Lulu community supports forums, groups, a newsletter and the Lulu blog. The forums, in a variety of subjects related to self-publishing such as cover art, or storefront, are maintained by Lulu experts and archived in a variety of self-publishing related threads, easily accessible via search menus. International forums provide support in a wide number of languages, and users can also start their own group for more focused interests such as book promotion or teen literature.

Of all the online photobook companies, Lulu is the one that offers the platform with the most interesting blend of features with which to teach digital photobook publishing. In the first place, the dashboard is the most project-oriented of all the photobook companies; it allows students to design their books using InDesign, the desktop publishing software used in class, and to upload the resulting PDF file, while other companies require the use of their own software. Further, unlike other companies that keep the design document in-house for printing-on-demand purposes only, Lulu allows the design document to be accessed and shared digitally.

The online store also offers two methods of making the content available: the print version delivers a paperback that can be purchased using the online ordering process (shopping basket; online payment and delivery to the shipping address); and the download version, either as a paid or free PDF download. Whilst other companies may offer an online store, they do not offer access to the digital files. The dual options of the Lulu online store integrate well with the principle of common gains/individual rewards of the produsage environments.

Blogs, another of Lulu's tools, create opportunities to publish works-in-progress and to receive feedback from peers; the comments feature encourages analytical reflection and an extension of the online conversation beyond the classroom. The groups and friends' lists (social networking features) promote working as a group and extending classroom support into the online space.

Lastly, the forums in which users and experts exchange information on topics related to many aspects of digital online publishing offer a pool of extra teachers, available 24/7, that are supplemented by live help from Lulu, a feature that makes possible to obtain support from a company representative via a chat board.

The Design of Learning Tasks

The embedding of the teaching in this produsage environment was achieved by using a blended pedagogical framework, which consisted of twelve weekly face-to-face meetings in the media lab interspersed with eleven weekly e-tivities.

A particular intention in the design was a balance between individual expression and group work. The first project, an individual photobook, called for the selection of photos from students' own archives, the development of a visual structure for the book, the preparation of a book dummy, and the final production of the photobook. This project carried 25% of the marks for the unit. The second assignment was a collaborative one: working as editorial team, each group created a collective photo magazine using photos selected from a social network situation. They were required to prepare and submit a magazine dummy showing the visual structure, and to publish the photo magazine in Lulu.com. This, too, accounted for 25% of the marks for the unit.

The balance of the assessment was by way of weekly structured e-tivities (Salmon, 2004), posted to Lulu.com. The e-tivities supported the process in which students were required to analyze the production process and to reflect on online research and peer feedback. Each week's e-tivity was designed to further embed the online publishing environment in the students' experience, and dovetailed with the face-to-face activity for the week. In week one, for instance, the e-tivity was designed to help students become familiar with Lulu's tools. Subsequent e-tivities explored the definition of photobook, the structure of a visual book, how to create book and photo magazine proposals and dummies, participation in group forums, customizing the storefront for a book, bookmarking using del.icio.us, and book reviews. The last e-tivity required the students to reflect on their Lulu experience.

In addition to those available in Lulu.com, students used a variety of other digital tools for this project, including proprietary software and a free online platform. Adobe CS3 software was used for photo publishing. This package has been developed for desktop publishing and includes InDesign (for publication design), Photoshop (for color space management and photo optimization) and Bridge (for photo management). All the pre-press was handled in InDesign.

To operate in the Lulu.com environment, students created personal profiles and learned to use the various features related to managing publishing projects; they customized their blogs and storefronts, and developed a social network with their peers and the lulu community. In order to participate in the weekly e-tivities, they learnt how to blog (using the Lulu.com blogging tool), how to create links and post images, and how to reply to each other's messages. To collaborate during the design phase, they subscribed to the group's forum and participated by posting their questions and replies. To share their research on photo publishing with each other, they learned how to create a del.icio.us account and to use the features of social bookmarking.

Creating a Framework for Feeding Back and Assessing the Process and the Product

A fundamental philosophy underlying the development of this unit was Biggs' constructive alignment (2002). In this approach, it is the articulation between the stated learning outcomes, the teaching (and learning) activity and assessment that results in a meaningful learning experience. The approach to assessment that was used in this unit is commonly referred to as "criterion-referenced". Biggs (1999) states that there is "no *educational* justification for grading on a curve" (emphasis in original), a reference to the relatively common practice of measuring students' performance against that of the rest of the group. We believe that assessing against criteria measures more objectively the extent to which students have achieved learning outcomes, and that, for this reason, it is a more student-centred approach.

It is apparent from the statement of the learning outcomes and the description of the learning activities that there is a causal connection between the two. This is no quirk of fate; the relationship was built into the design of the unit by adopting a constructive alignment approach. Similarly, attention was paid to the crafting of the assessment criteria. They were developed by the students in a joint activity with the teacher; in the process, the students not only gained insight into the purpose of assessment but were also empowered by the process of identifying the most important criteria against which to evaluate their work.

Using the learning outcomes as a point of reference, the learners were required to develop assessment criteria that would be used in rubric form to mark their projects. They were provided with a list of questions to guide their discussion, and were asked to engage with the following tasks: firstly, they had to develop six assessment criteria that articulated with the learning outcomes; then they were asked to rank these criteria, from most to least important; and finally, each group presented their two top criteria to the whole class.

During this report back process, all the groups' top criteria were written up on the board, and the whole class agreed on the four criteria that articulated most closely with the learning outcomes for the unit; these criteria then formed the basis of the assessment. This engagement in formulating the criteria against which their work would be measured empowers students with a sense of ownership, and a real interest in their own learning process (Stix, 1997). Andrade and Du (2005) point out the added value of using rubrics "to clarify the standards for quality performance, and to guide ongoing feedback about progress toward those standards." The incorporation of rubrics into learning design helps the students to visualize what it means to successfully address the learning outcome and to adjudge the quality of their own and others' work; in this sense, rubrics can also be said to be an instructional tool.

Once the assessment criteria were agreed upon, the class created an "irubric"which was developed using RubricStudio software from FacultyCentral.com. We define an irubric as a carefully crafted matrix that lists the assessment criteria and qualitatively describes different levels of excellence in achieving each criterion. This matrix constitutes the marking grid used by the teacher and students. The assessment criteria were listed down the left side of the rubric and the excellence descriptors for each criterion were entered in columns headed 0-5 (the potential marks for each criterion). The irubrics were used in two distinct ways: firstly, they provided a frame of reference within which to generate peer and tutor feedback. They were also used by the students and the tutor, as well as the second marker, as the statements against which the students were graded.

Different Approaches to Feedback

Rubrics are often used for assessment, but our review of literature on rubric-referenced assessment revealed that they can be a good tool for both assessment and feedback. Mertler (2001) points out that the analytic nature of the rubrics offers added advantage: the degree of feedback offered to students – and to teachers – is significant, and students receive specific feedback on their performance with respect to each of the individual scoring criteria – something that is unlikely to occur when using other forms of feedback.

In addition to this use of what we term "rubric-referenced feedback", students were required to provide feedback on the development of their peers' projects in the e-tivities. In that this second kind of feedback takes place in the distributed learning environment of the students, we have chosen to call it "distributed feedback".

It is clear that working online guarantees neither student participation nor feedback. E-tivities (Salmon, 2004) are, however, a useful approach to increase online peer-feedback and their potential was explored throughout the 12 week teaching semester. In addition to the articulation between learning tasks and the e-tivities, outlined above, the e-tivities were used to enhance the feedback activity in various ways. Firstly, students were required to give feedback each week on each others' posts (the e-tivity defined the task to be completed and the requirement to respond to peers' work). Then Salmon's weaving technique was used to integrate the themes of the students' posts and to create a weekly summary that was posted to the blog. In two e-tivities, learners were asked to contribute to group discussions on photo publishing, and in another, they were asked to swap reviews of each others' books and post them to each others' storefronts. The last e-tivity required that learners reflect on the Lulu.com experience: their work, their peer's feedback about the course and the technology used. Figure 3, below, sets out the last e-tivity:

THE FINDINGS: STUDENTS' PERCEPTIONS OF THEIR ENGAGEMENT IN THE READ/WRITE WEB ENVIRONMENT

We have described, this far, the rationale for (and the design and implementation of) the interventions that engaged the digital photography students in the produsage environment of the read/write web. In this section, we will report the students' own perceptions of the experience.

While students were free to write about any of the issues suggested in e-tivity 11, four emerged as particularly important to them: digital pedagogy; communities of practice; the value of publishing as a group; and the comparison of the Lulu.com environment with other social networking sites.

Figure 3. E-tivity 11: My Lulu experience (after Salmon's e-tivity model, 2004)

E-tivity 11: My Lulu experience

Purpose: Now that you are an expert in photo publishing, Lulu and print-on-demand, it's time to review all that happened, and share what you've learnt. This can help you put your experience in perspective and also help other people who are still on the look out for a way to publish their photobook. The best thing you can do to help others is to share your experience with them!

Task: Write about your experience in photo publishing with Lulu. Your reflection should include at least one of the following issues:

- Digital pedagogy: what are the differences between learning digital media in online and in offline environments?
- Communities of practice: what does it means to learn in a community that extends the classroom into the publishing market?.
- Vernacular versus academic culture: what are the implications of circulating the work in the field of popular culture side by side with non academic, 'amateur", production?
- A challenge to the hierarchical nature of the institution; what is the personal and social impact of starting publishing while you are still a student?
- The meaning of self-publishing: what does it mean to publish independently of a selection by committee (editors/ curators)?
- The value of publishing as a group, relying on the support of your peers' network.
- The advantages/constraints imposed by the POD templates on the format of the photobook.
- The lulu environment compared to other (publishing) social network sites.

Digital Pedagogy

The Lulu.com environment forced a steep learning curve for both teacher and students. While really good for publishing, Lulu is not particularly appropriate for communication and group work; searches for information are painful, the menus badly organized, and the navigation system awful! Nonetheless, students identified positive benefits from the experience. The novelty of the method was deemed appropriate by students: *"Learning mostly online through practical demonstrations and experimentation on various related websites with self-publishing and online collaborative rubrics to assess our projects provided a new experience, for me at least",* and *"Personally I believe anything that challenges the norm and gets you thinking in different ways is a good thing. This module is not presented to us in a traditional, stuffy, listen and take notes old school university style. We are studying a new art form and our lecture methods should reflect the move away from tradition."*

Another student remarked on the benefit of the hands-on approach: *"It is easier in my opinion to learn digital media practices on the Internet as opposed to the classroom or lecture hall – personally I am a more practical individual and feel the need to actively do something to learn effectively"*, which underscores the need to recognize different students' different learning styles. There was also a link made between the day-to-day online activities of students and the shift towards the Internet as a teaching medium: *"I welcome online learning as an idea very warmly. As most of my generation is connected to the Internet one way or another anyway, it's only a matter of when digital pedagogy becomes a standard."*

A caveat against seeing online learning as a silver bullet came from two students who showed their appreciation of more traditional approaches. *"Learning about digital media in an online environment as opposed to a more traditional format (i.e. a classroom) has been slightly chaotic at times. It's an unfortunate fact that sometimes you simply need a person on hand to help with problems, and online learning cannot always provide this."* and

"The printed handouts on prepress fundamentals for InDesign were very useful too, as most of the class had not used this software previously."

Communities of Practice

Students explored the concept of community of practice in a very practical way in these units. This student seems to doubt the personal value, but clearly recognizes the benefits to classmates: *"Learning by way of a community has been great for this unit, though I have not myself benefited from being part of a community it has clearly been a help to some members of the class who find websites and concepts such as those we have been studying more difficult than the theoretical issues in photography."* Another student came face to face with the diversity to be found in such a group: *"Become* [sic] *an online community was an interesting look at the class and how each person expressed themselves. There was such an array of difference in style of each person's e-tivities and how they coped with doing them."*

A particularly interesting comment was from a student who clearly found the online community too large for their liking but who had come to recognize that there were certain benefits. *"Like many others in our class, I found publishing our work online and making it available for anyone in the world to buy a very exciting aspect of the unit, and probably one which we would be keen to explore in the future. Publishing on Lulu however does put our work in with thousands of similar pieces, some interesting pieces and some rather less well put together. It would be good to find a more specialist online publishing site for our photobooks & photomags, however this would mean losing the huge numbers of visitors to Lulu. It's a trade-off I guess."*

The Value of Publishing as a Group

The principle value related to working as a group that was identified by the students was that help was immediately available: *"The support of the group was very helpful, especially the ability to post questions to the online forums and answer other's queries very quickly."*

Another student valued the collaboration in the community, too: *"There was a lot of help being given through blogs, forums and in person between all classmates during this period. Considering so many seemed unfamiliar with Indesign only a few weeks ago we all managed to create and upload an interesting mix of books into the Lulu store."*

It is interesting that none of the students identified any of Johnson and Johnson's five pillars of group work (n.d.): positive interdependence; group interaction; individual and group accountability; interpersonal skills; and group processing as valuable in the course of this unit. Their focus appears to be at a micro- rather than a macro-level.

A Comparison of Lulu with Other (Publishing) Social Networking Sites

There were varying opinions about the usability of Lulu.com relative to other social networking sites. One student commented that, *"Other social networking sites feature the same kind of real time features that Lulu does but many offer better usability and are far more effective."* Another clearly felt that the social side of the site was a positive: *"Lulu.com has much more of a social side to it than most other self-publishing websites"* but agreed with the critique on its usability: *"Whilst the design of the site is at the very least questionable, it does for the most part work well if you have the time and patience to figure it out!"*

This student pointed out that the cost effectiveness of Lulu was possibly outweighed by its design. *"To be able to publish your work cheaply and easily is a great asset afforded to us as a group, but Lulu seems to be experiencing problems with the way it functions. It is tricky to use and everything seems to take a long time to do. Unlike other sites that involve social-networking, Lulu suffers from a lack of user friendly features."*

In addition, she offered some useful comments on the overall impact of using a better managed site: *"Overall, I see Lulu's merits and potential and also value certain aspects of the site but I think that with a better technical support and development the site should be more accessible and thus would have more of an impact and not come across as amateurish as it does now. Would the site be more interactive like Facebook with constant technical updates which facilitate the use it would be more popular and more people would use it, thus creating a bigger market for self-publishing."*

Possibly the view of the majority is summed up in this student's comment: *"Unfortunately, Lulu.com is not exactly a user-friendly environment and it isn't welcoming enough for constant digital activities like blogging, commenting and change of information. There are other, far more sophisticated environments for that (e.g. Facebook), which make users want to spend as much time as possible online."*

It is apparent from some of these remarks that the students lost sight of the requirement to compare Lulu.com with other publishing social networks. Nonetheless, their comments clearly indicate that they were at times frustrated by the Lulu experience.

Other Themes that Emerged from the Students' Writings

Some additional themes surface in the reading of the students' reflections. Firstly there is a concern about the ownership of their work: *"Another issue that was voiced by a large amount of our group was the fact that, while publishing as students, we do not control the simple intellectual copyright to our work. This is instead handed to the University who could, in theory (I hope not practice), profit from our work and charge us royalties for what is essentially our own personal art."* They also expressed a lack of experience and a lack of confidence with the medium: *"Having set tasks within Lulu really made me play around and explore the system, something I have previously not done before. I do tend still to be scared of computers and really have no idea what they are capable of doing for me. Throughout this term I have had to face this fear and play around, do a lot of problem solving on my own and learn that these systems actually have everything explained for you if you use their 'help' and 'search' options."* Another student said: *"This has been a great struggle for me as I rarely use the Internet for social networking, I barely knew what a blog was. This unit was not something I enjoyed but I feel it helped me to get an understanding of how modern photographic practice operates on the Internet. I have learned how to produce my own book, which will be useful in the future I'm sure"*, which is a confident note upon which to wind up this discussion!

OVERVIEW OF OTHER FINDINGS FROM THE STUDY

From this study about the use of social networks for self-publishing, and engaging the students in the design of assessment criteria and the provision of feedback, we can confidently say that in a self-regulated learning environment, students can become a valuable source of feedback for their peers. It is also apparent that, with the right technology, feedback can be a tool for students to monitor their learning and guide them to achieve their learning outcomes.

In the Lulu.com domain, students viewed feedback through their familiarity with other social networking sites (SNSs). Throughout the semester, there was incidental collection of data which, when viewed holistically, points to cohorts of students who were generally comfortable in the online environment; who wanted a critique of their work in the form of feedback from the tutor, peers and the wider digital publishing community; and who would like to retain the benefits of face-to-face interaction in the classroom.

From a survey on their experience of SNSs, it was plain that the majority of the students (more than 90%) were competent in their use; almost 60% actively participated in more than one such site. While some of the students use SNSs to post pictures and stay in touch with friends – with some showing a preference for one SNS over another – their primary interest was to get feedback on their creative practice. One student explained, *"I use Flickr as a means of receiving feedback on my photographs and as an online portfolio - I prefer its emphasis on the work I produce and not on social aspects prevalent in many other sites with similar intentions"*, while another said, *"I use deviantART - a large artistic network which supports other artists and generally gives lots of feedback."* A third said, *"I use deviantart.com - to showcase my photography and receive detailed critiques based upon them. Also used to socialise with people who have similar interests. Research tool."*

This desire for feedback carried over into the Lulu environment. While Facebook, MySpace, Flickr and deviantART are used to post images and communicate with friends, they are also perceived as a way to get feedback about their creative practice from a like-minded community of artists. In the same way, students expected similar opportunities for feedback in a pedagogical project that is situated on a SNS; some saw this as a major advantage of delivering the course on Lulu as opposed to the classroom: *"The support of the group was very helpful, especially the ability to post questions to the online forums and answer other's queries very quickly."*

But others expected more! *"I do not see any advantages from publishing my book in a group (apart from getting one review) as only a few people downloaded it (which I cannot change and it's okay) and even less left comments in my development blog, which was incredibly disappointing as I put a lot of work into it and hoped to get some good feedback and constructive criticism. However, this is not lulu's fault but more the group motivation so I think next time there is a unit with such a heavy reliance on online media there should be more emphasis on the importance of this online activity and networking."*

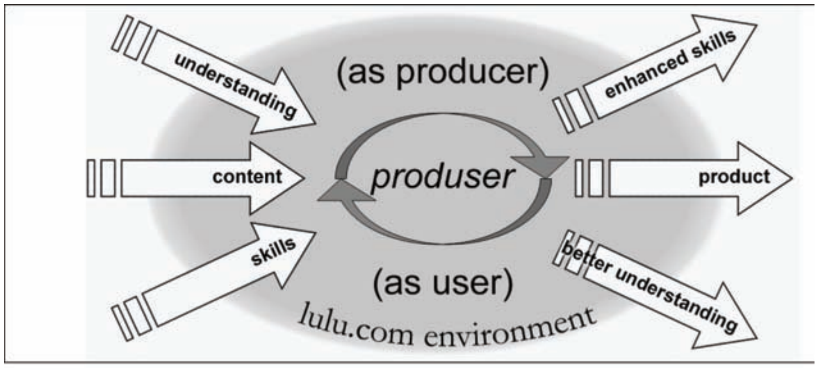
DISCUSSION

This study explored the features of read/write web to teach digital photobook publishing in a higher education context. The choice of Lulu.com as a software environment was partly a response to the hybrid digital-paper nature of the print-on-demand photobook project. The variety of tools available on the Lulu.com platform allowed us to view in context the core capacities of the digital art worker, the 5Cs of creative, collaborative, critical, combinatory and communicative work that characterize the art of produsage (Bruns, 2008). Figure 4 depicts the Bruns' produsage model in the context of this study.

Using the software to explore the meaning of **co-creativity**, and developing new work in dialogue with other creators was successful; meaningful learning was achieved in the group process, from establishing the cohort's online community to engaging in authentic group work by publishing the collective magazines. As has been noted, however, the technologies that support this interdependency are still in their infancy and in need of further development. Lulu.com is no exception. Studies have shown that people use social networking sites and media-sharing platforms to find people they already know with whom to work. If the interfaces make it difficult to find such friends and classmates, this can be a major barrier (Boyd & Ellison, 2007). The social browsing, for example, that is such a great feature of Flickr and Facebook, is still very limited in Lulu; enhancing this tool to the level of other SNSs would be a great asset. There is, in general, a need for better interfaces to facilitate produsage (Lerman & Jones, 2006).

As social networks grow, it will be impossible for users to keep track of their contacts through

Figure 4. The produser in the Lulu.com environment. Adapted from The produser (Figure 1 above.)



the kinds of simple interfaces now offered. Better interfaces, for instance ones that create personal Explore pages by finding 'interesting' images from among those produced by the user's contacts, are a feasible solution to information overload. (p8)

The **collaborative** aspects associated with sharing one's work on the Internet require an understanding of appropriate legal frameworks, and this is greatly encouraged by Lulu's support of varied licensing deeds. The software's embedded licensing menus – with scope for creative commons licensing – provide a good opportunity to discuss the licensing of creative work, whether this is available as a free download, or as a profitable POD. The legal framework for this project – the Creative Commons Attribution Non Commercial Share Alike 2.0 negotiated with the University's copyright lawyer – offers a context within which to discuss issues of intellectual property in the academic environment. For the students, the principle of sharing their photographic work as a free downloadable PDF can be a watershed; this may be the first occasion in their time at university that their work is placed online, and made available for others to use.

The **critical** tools embedded in the software – the use of blogs for commentary and feedback, and the potential for peer review in the book pages – generated possibilities for giving and receiving constructive feedback as part of the ongoing collaborative process. The traditional domain of the "crit" session in art and design studio practice was partially moved into an online environment: this is a way of addressing the changing patterns of student learning and the students' push for independent learning (Percy, 2004).

In the read/write environment, students can explore each other's work in their own domain and engage at their own pace; the opportunity appears greatly appreciated as time pressures arise as a result of the new work/study balance (Robbie & Zeeng, 2008). There are also issues raised that relate to an understanding of the students' needs and expectations in relation to online critical engagement. When used in the context of book reviews, the peer review in Lulu.com can be as effective as that on fanficton sites where beta-readers working in the same genre can help emerging authors develop genre-specific skills (Black, 2005). On the other hand, using the software to facilitate feedback can be disappointing, for instance when students invest a lot of effort in customizing their blogs and there is a lack of comments or, specifically, substantive ones (Stern, 2008).

The process of breaking down the complex assignments of photo publishing into a granular sequence of simpler tasks (from photo editing to online publishing) engaged the students in a series of mix and remix **combinatory** processes, and encouraged them to harness individual chunks of information. This is associated with engagement with multiple literacies; additional online tasks such as customizing profiles and storefronts, creating links, and uploading images side by side with text all encourage the development of all-round skills, and create a measure of granularity that is reinforced by drawing on the software's ability to aggregate feeds. This multimodality hallmarks young people's creative online practices (Thomas, 2007) and is connected with the aesthetic of remixing. It is a sign of new networked material, intelligences and tools (Perkel, 2008) that characterizes the photobook and photo magazine assignments through the remixing of one's own work and the work of others for the photo magazine.

The **communicative** aspects of the software, used by the students to publish their book analysis, pitch for their proposals, post questions and get technical help, were central to eliciting mutual constructive criticism between the participants; overall, the publishing of the work process as a digital sketchbook serves as "tangible evidence of participation" (Soules, 2001). This archive of works in progress and the development of ideas is still available online at http://stores.lulu.com/photocultures, and can be accessed by others.

Lastly, the platform provided an opportunity for the students to publish a photobook and a photo magazine in 12 weeks, a work flow that is only possible using an online photobook company. They did this with no financial burden and with total editorial control, a real achievement considering the limited opportunities available and the restrictive editorial policies of most established publishing houses. Whilst the field of artists' publications has always been strategically associated with independent publishing initiatives, self-publishing is still considered a stigma for some (Forrester, 2007). With the increasing availability of print-on-demand it may be the best opportunity for emerging and established photographers alike to embrace it.

FUTURE IMPROVEMENTS AND RECOMMENDATIONS FOR PRACTICE

Feedback received from students and colleagues has been used to develop the latest version of the course, which is currently running with 34 level 2 digital photography students. For example, we removed the magazine brief and concentrated instead in the photobook, so that students can focus on developing critical thinking in the process of creating a single photo publication.

This is complemented by a move to reduce the number of e-tivities. Developed by Professor Gilly Salmon of Beyond Distance Research Alliance at the University of Leicester, *Carpe Diem* is quick prototyping methology to repurpose existing material for online delivery. Feedback from a *Carpe Diem* workshop that focused on this unit helped us to identify and retain the most successful e-tivities and discard the rest. The four e-tivities that remain address two particular areas: two encourage students to write about their own photobook and publishing practice, and the other two involve writing about their peers' photobooks and publishing practices. This allows for both self-reflection and collaboration, and students are supported by particular readings that coincide with the start of the e-tivities and help them to develop reflexive and critical skills in the analysis of photobooks, a zone of critical activity.

Finally, in response to the critique of the social aspects of Lulu as a networking environment, we decided to diversify. In addition to Lulu.com as the publishing site, in the latest action research cycle we use Facebook as the main social networking site for group communication and Blackboard, the University's virtual learning environment, as the repository/archive for all course documents.

Chapter 4.10
Technosocial Space:
Connecting People and Places

Anne Sofie Laegran
Norwegian University of Science and Technology, Norway & Research Centre for Social Sciences, Edinburgh, UK

ABSTRACT

The chapter is based on a study of Internet cafés in Norway, and interrogates the way space and place is produced in interconnections between people and technology in the Internet café. Drawing on actor-network theory and practice-oriented theories of place and space, the Internet café is understood as technosocial spaces producing connections between people and places at different levels. Firstly, the Internet café can be understood as a hybrid, a site where users and technologies as well as space are coconstructed in entwined processes where gender, as well as other identity markers, are central in the way the technology, as well as the cafés, develop and are understood. The next level looks at the production of Internet cafés as technosocial spaces. Despite being perceived as an "urban" and "global" phenomenon, Internet cafés are configured based on local circumstances, in urban as well as rural communities. Differing images of what the cafés want to achieve, as well as material constrains, are at play in this process. Finally, the chapter shows how Internet cafés are places of connections, producing space beyond the walls of the café, linking the local into a translocal sphere.

INTRODUCTION

In recent years, we have seen several studies exploring the intersection of space and new information technology. Much of the early generation writings about the Internet suggested a placeless character in which electronic media implied a loss of sense of place (e.g., Meyrowitz, 1985), where the online experience gave a feeling of being "nowhere" or "everywhere," independent of the place you are located physically (Negroponte, 1995), and where you could live a "life on the screen" separated from "real life" (Turkle, 1995). Manuel Castells (1996) argued for an emergence of a network society structured around a bipolar opposition between the "Net" and the "Self," and in which "spaces of flows" will replace "spaces of place." These studies may serve as examples of what Daniel Miller and Don Slater (2000) call the "early generation" studies of the Internet, which talked of cyberspace and virtuality and how the Internet was built up by spatial metaphors. However, there was as Stephen Graham noted in 1998 (p167): "little conscious thought put [in]to thinking conceptually about how new information technologies actually relate to the spaces and places bound up with human territorial life."

Although recognizing that virtual communities may exist based on shared interests and feeling of community independent of geographical location, this chapter will argue against the placeless character of electronic communication. To understand the uptake and use of new technologies, it is important to study the variety of places and social circumstances in which it is used. Most studies on the use of ICTs in particular places have focused on computers in the home or office or among young people in schools. Few studies have gone out of the home and work spheres and looked at how computers and the Internet are integrated in public leisure places. This chapter takes us to the Internet café, a contemporary meeting place resembling any other café, where at the same time new forms of socialities develop in the intersection of the technology present and the clientele. The study is based on ethnographic studies of four Internet cafés in Norway conducted from 1999 to 2002.

In line with other recent research on the Internet (e.g., Miller & Slater, 2000: Valentine & Holloway, 2002; Woolgar, 2002), I will show how the Internet, as well as Internet cafés, are integrated in practices taking place in the spaces of everyday life and thus must be understood according to local context. This is, however, not just a study about technology "in space." Following Henri Lefebvre (1991), I shift the focus from *things in space* to the *production of space,* where the Internet café is seen as a mediator in different ways within the local community, as well as reaching out of the local community through the Internet. To understand this process, a concept is required that sensitises us to the need to integrate space, social relations, and the materiality of technology, when studying phenomena like the Internet café. The point is to emphasise that technical or material, social, and spatial aspects need to be analysed, not as causal relationships, but as intersecting and transgressing moments. This will be developed in the following, drawing on theories from cultural and social geography and science and technology studies (STS), in particular, actor-network theory (Latour, 1987; 1999; Law & Hassard, 1999).

STS is founded on the idea that the social and the technical/material must be seen as part of the same entity rather than as opposites in a causal relationship to each other. Social and cultural geography, on the other hand, challenges common conceptualisations of space as frame in which social practice occurs, but sees the social and spatial as integrated in practice. I take my point of departure from an understanding that merges all these elements together; technology, the social and the spatial are entwined or interwoven in a "seamless web." From an STS point of view, this implies a greater awareness of the spatial aspect in the study of socio-technical relations, an awareness of how place and space matters in the design and use of technology, but also how design and use of technology do not just occur in space. In fact, technological artefacts and agents are forces or mobile actants that produce space. From the view of social and cultural geography, on the other hand, this approach implies a greater awareness of the role of technology in the production of space, not as a more or less determining structure, but as actants that, through relations to other human as well as nonhuman entities, are actively involved in the production of space.

PRODUCING SPACE IN THE INTERSECTION OF THE SOCIAL AND MATERIAL

From the 1990s, there has been an increased focus on space in social theory. This is partly related to the increased focus on globalisation, but also prevalent in studies focusing on situatedness and the body. However, as Kirsten Simonsen (1996) noted in the mid-1990s, there is maybe less consciousness as to how space is conceptualised; what do we mean by the concept? This question is still highly relevant, in particular, when discussing space and spatiality in interdisciplinary contexts.

Among works that do problematise space and place, Simonsen (1996) identifies three main conceptualisations that, put together, form a triangle implying they are all somewhat interrelated despite their difference. The probably most common understanding is to see space as *material environment*, the natural or culturally produced surroundings we all live in. This conceptualisation is common within architecture and traditional regional and landscape geography, but is also prevalent in some sociological studies, particularly those of urban space. It claims, to a greater or lesser degree, that physical surroundings have causal or conditional power on social phenomena. Space as *difference* is the second category that Simonsen identifies in postmodernist and poststructuralist thinking as well as in economic regional geography based on critical realism. This conceptualisation focuses on how places and localities are different in material as well as immaterial sense and thus, provide different conditions for social practice and processes. The problem, however, is that little is said about how these differences are produced. Space thus still becomes a background or a container in which social action takes place.

Simonsen's point is that although both these categories of space address important issues, within social theory, it is only by taking the starting point in social, or more specifically human, practice that the relation to material environment, as well as spatial differences, can be understood and explained (*ibid*.). She continues to say that in social theory, materiality has to be studied, as mediated through and subordinated to social practice. This can be done in three modes; as study of the production, the use of, or the ascription of meaning to the material environment. The differences that space makes are also created through social practice. This brings us to the third, and for Simonsen, the preferred conceptualisation of space; *space as social spatiality.* This is in line with much writing within human, particularly cultural and social geography in the last couple of decades, where practice or doing is seen as constitutive for, as well as constituting space (see for example Massey, Allen, & Sarre, 1999; Thrift, 1996). I take the point of departure in practice when I develop the concept technosocial space. However, in line with the thoughts of, amongst others, Nigel Thrift (1996), Nick Bingham (1996), and Sarah Whatmore (2002), I do not follow Simonsen's ideas in the way she treats the material. To me the concept of practice does not only include interaction between human beings. Material objects are also included, not as frame or structure, and not as entities with causal power in themselves, but as *actants* that, through relations with other nonhuman as well as human entities, may have agency in the production of space.

Technosocial Space: The Material and the Social

In recent years, a few studies have merged insights from science and technology studies (STS), particularly actor-network theory, into social and cultural geography (e.g., Bingham, 1996; Graham, 1998; Kirch, 1995; Laurier & Philo, 2003; Murdoch, 1997; Thrift, 1996; Whatmore 2002). Common to these authors is an attempt to integrate material objects and other nonhuman entities into social theory, not as a determining structure, but as actants that, through the way they relate to humans as well nonhuman entites, are active in the production of space. This builds on a relational understanding of agency as an effect distributed through a heterogenous arrangement of materials rather than as the intentional activity of human beings (Law & Hethrington, 2000). The main inspirations for this thinking are actor-network theory (Callon, 1987; Latour, 1987; 1999; Law & Hassard, 1999) and the cyborg metaphor as developed by Haraway (1991; 1997).

Actor-network theory takes a rather pragmatic approach in its concern to describe how things occur; in particular how things are moving and are moved; how actants move each other. Imbued in this is a call for symmetry in the analytical treatment of nonhumans, including material technical objects, and humans; arguing that there is no a priori difference between the two when analysing socio-technical relations. The point is to identify properties borrowed from the social world to socialise nonhumans and likewise, properties from the nonhuman world in order to naturalise and expand the social realm (Latour, 1999). One of the main points is to deconstruct the dichotomies of the subject and object and the human and nonhuman, thus defining social in a very different way from the way it is traditionally perceived (*ibid*.). Nonhumans are, as Latour says, the "missing masses," knocking on the door to be counted into the fabric of social theory (Latour, 1992). They participate in building heterogeneous networks that bring together actants of all types and sizes, and neither simple technological determinism nor social constructivism are sufficient to describe these networks (Akrich, 1992).

Agency in this context is not defined as intentionality. The material-semiotic approach argues that entities like material objects take their form and acquire their meaning in relation to other entities (Law, 1999). Thus, entities have no inherently essential qualities. Following from this, agency is produced in the relation between actants, it is not a property imbued in the actants (Thrift, 1996). Agency is understood as mediations where nonhumans and humans are interlinked in such a way that we can talk of transformations; as opposed to understanding the relation between human and nonhumans as intermediaries where the action can be identified by its input and output (Latour, 1999). As Callon (1987) says, this goes against mainstream sociology (and social science in general), where practices or intentions of human beings have priority in the analyses, and humans are the only ones to be counted as actors.

The concept technosocial[1] space helps to highlight the role of technology in the production of space without falling into technological or social determinist traps. Following from this, technosocial space is produced through technosocial practices involving humans as well as technological artifacts. Technosocial practice means that technology, as well as its users, are part of the mediation or transformation that practice implies. These practices are in themselves spatial, at the same time as they produce space. Technosocial practice embraces the material "doing," the concrete movements of humans and nonhumans in space. In this "doing," we make use of symbols as well as discourses related to technology as well as other aspects of society; symbols and discourses that simultaneously are produced through technosocial practice. In the Internet café, as we shall see, the artefacts of the computers, the Internet connection, as well as the décor and design of the café space, are of importance for the technosocial practises that develop.

Internet Cafés as Technosocial Spaces

Internet café or cyber café is a label used to describe many different settings providing Internet access in public space, and have in the last decade become a ubiquitous feature of urban and, to a lesser degree, also rural space all over the world. While some Internet cafés are analogous to provisions to make other technologies accessible in public, such as telephone booths, or laundrettes, where there may be some social interaction between the users as well, others put a lot of effort into developing a good ambience where the sociality around Internet usage, as much as access in itself is the attraction. While there were several attempts to provide telecommunications in public contexts from the 1980s, the opening of Cyberia in London in 1994 launched the wave of Internet or cyber cafés as we know them now. Cafés have always found new ways of being centres for communication, as newspapers as well as financial institutions have developed closely knitted to cafés (see e.g., Sennett, 1977). Thus, computers put together with nice coffee in a trendy café ambience was a novelty in terms of public access to the new technology, but part of a history with long roots.

In the UK, although not providing financial support, the government saw commercial cyber cafés as one of many significant places for the distribution of access to the Internet (House of Lords Select Committee on Science and Technology 1996 cited in Liff, Steward, & Watts, 2002). The view of the UK government was that such cyber cafés would provide a supportive environment for new users, crossing boundaries between education and leisure through the café environment. They did, however, consider this as a transitory phenomenon and a means to achieve home access (*ibid*). Internet cafés have played a minor role in Norwegian policies on access to the Internet, and were not mentioned in the first significant policy report on Norway and the information society, published after the widespread utilisation of the Internet (Ministry of Transport and Communications, 1996). It seems that rather than developing new institutions, the idea has been to use existing infrastructure like work places, schools, and libraries in the strategies to include people to the Internet. Local governments have been involved in setting up Internet cafés in some places. Interestingly, however, this has not been linked to ICT policies, but to youth and rural development.

In 1998 and 1999, there was a heated debate on the future of the countryside in Norwegian newspapers, after statistics had shown the migration stream still going from rural to urban areas. A headline in Dagbladet suggested a simple prescription: "More Internet and cappuccino to the countryside," following up in the same article by quoting one of the youth interviewed saying "An Internet café would have been fine. [2]" This was before Internet cafés with cappuccino really had established themselves in the bigger cities, yet it was interpreted as an urban trend diffusing to the countryside. The Internet café, in this context, was not interpreted just as a place with Internet access, but with cappuccino and possibly other trendy features attached. Quite a few Internet cafés of this sort were opened in small towns and rural areas in Norway, and increasingly commercial Internet cafés have opened in the cities, some with cappuccino, some not.

Most of the socially oriented commercial Internet cafés in Norway are based around gaming, and may be seen as an extension of another phenomenon linking computers to sociality: "computer parties." These are noncommercial gatherings where youth meet in big sports halls and the like, bring their own computers, and link them together to socialize, play, and compete with programming and computer games (see Nordli, 2003). Internet cafés provide use of a local area network (LAN) as well as access to the Internet, and may thus work as a permanent mini-computer party. Some of the cafés also arrange organized events in LAN. The gaming community, in particular the enthusiastic players of a "first person shooter" game called Counter Strike, are, to a large extent, organized and identified through a network of game-oriented Internet cafés. Programming enthusiasts, however, would find the machines in an Internet café insufficient for their use. Many of these cafés put less effort into coffee and the like than the "trendy" version of the net café, and may be characterised as computer game centres or a modern version of pin-ball halls, as much as cafés. In this study, only one of the cafés is run as a commercial business, and this is the one that is most strongly linked to the game culture, being open around the clock and providing space for enthusiasts playing several days in row.

UK statistics from October 2001 showed that out of the 53% of the adult population that had accessed the Internet that month, 10% had done so from an Internet café or shop, the same figure as for libraries (Bowman, 2002 in Liff & Laegran, 2003). This shows that Internet cafés were significant as a point of accessing the technology. In Norway, monthly statistics on Internet access and use ask where access was reached, but the figure for other places than school, home, and work are too small to be presented in the statistics.[3] Based on the numerous interviews and conversations I had with the users of the Internet cafés, I can say that most, if not all, the users in this study have access to the Internet in other places as well. When they go to the Internet café it is not because it is a "last resort access" (Liff & Lægran, 2003). Rather, it is a positive choice because the Internet café has other attractions, such as faster lines, games, and a gaming community (particularly for online based gaming), and because they provide a venue to meet friends. The Internet café thus complements or enhances the experience of Internet access they could have elsewhere (*ibid*.)

CASE STUDIES: FOUR INTERNET CAFÉS

The chapter is based on a larger study of young people and technologies in and around four Internet cafés in rural and urban spaces in Norway. The empirical fieldwork consisted of interviews and group interviews among users of the cafés, including people working there, in addition to participant observation during several visits from 1999 to 2002. Before analysing the different levels at which space is produced, I give a presentation of the cafés.

The first case is a trendy café located in Fjordvik[4], a beautiful village situated by the fiord, with a particular cultural profile comprising a fine art gallery, a jazz orchestra, and other features not necessarily mainstream in rural villages. The café was started by a group of students at the secondary school with support from enthusiastic adults. The local government, as well as local enterprises, provided financial support. The design of the Internet café was in line with the artistic orientation, using the trendy interior including fine art from local artists, as well as cappuccino, in promoting the café. Together with the Internet, this contributed to the café being seen as a new and cosmopolitan invention in the countryside. The target group was defined as "youth between 0 and 100," and included pensioners who came to play bingo during daytime once a week. Quite a few adults would also drop by for a coffee, for instance, after a visit to the art gallery. Anyway, the main target group among the youth were those aged 16 to 20, mostly students at the upper secondary school. The Internet provided a new activity, but maybe more than that, it had significant symbolic meaning:

It's really cool that we have Internet at the café. Internet is in a way something that goes along with this kind of café – like those in the cities. But I go there just to meet friends – to do nothing with somebody (Boy, 18).

The Internet is important in constructing an "urban" atmosphere, but as this boy says, a lot of the clientele came to the café to have a meeting place to "do nothing" with mates. It soon became clear that there was a divide in interest among the clientele. Whereas young boys came to use the computers, most of the students (boys and girls) and adults (mainly women) came for the café atmosphere; the nice cappuccino and carrot cake. This actually created two different places within the café; the café, characterized by low-voiced talking and discussions over coffee, and the computer corner, characterized by a noisier and more frantic way of showing enthusiasm and eagerness. Occasionally, the café guests would go to the computer corner and check their e-mail, but they would often find that part of the café less inviting. After a period with some tension between the two groups, a wall was actually built between the computer corner and the café itself to prevent the noise from the computer corner disturbing the other guests. The trendy café and the somewhat nerdy image of computing did not go together as an integrated entirety. The wall, however, made the two coexist in the same space although in different places. The use of the computers behind the walls consisted mainly of game play in networks for the younger boys, and surfing of the Internet for information, discussion groups, and keeping in touch with friends elsewhere for the older youth.

The guidelines suggested the café provide a meeting place for all, possibly breaking down barriers between various groups of youth. However, the café seemed to communicate to few, in particular students at the branch for music dance and drama at the secondary school, whereas other groups felt excluded. This accounted in particular for a group of car enthusiastic young men who hung out with their cars at the petrol station. This group were sceptical to the cultural profile of the village as a whole, and saw the new café as yet another sign of artistic-interested youth "getting everything" whereas they themselves "got nothing." In this way, the Internet café, though meant to be a measure for young people as a whole, became an actant in a power struggle between youth groups and cultural profiles in the village (see Laegran, 2003a).

The Internet café in Fjordvik got a lot of positive attention in the media, and soon delegations from other villages in the region came to have a look and get inspiration. One group of young people and representatives from the municipality came from Fjelldal, a village in a mountainous valley in the same region. Inspired by what they saw, they went home and made plans to start a café after similar guidelines. The local government was more involved in Fjelldal. From the start, the idea was that this would be a café for everyone, not a youth centre, although young people as a target group were strongly manifested in the guidelines. Being located 45 minutes from the nearest town, the café would be a long-desired urban spot in the rural community. However, despite being initially built on the same idea, the Internet cafés in Fjordvik and Fjelldal evolved to be quite different from one another, as the implementation process and integration of the cafés took place within the respective local contexts. The trendy interior, including a fancy Italian coffee machine required to make urban cappuccino, turned out to be too challenging to accommodate for the local government. Arguably, it was hard to find money within tight budgets, but it also seemed like bureaucrats and politicians were quite ignorant or indifferent to the importance of design and trendy features, illustrated by this quote from one of the managers in the administration: "We already have enough cafeterias." Thus, the café atmosphere vanished before it was established, and the place became an indoor shelter for young people who had little to do in the evenings than hanging out in the centre of the village. Some of them came for the computers, whereas others came to hang out with friends and saw little point in the Internet. Unlike in Fjordvik, the Internet did not have a symbolic meaning as being cool and linking the local to an outside world; it was seen merely as a toy or game along with other activities.

The next café is in Landby, a town that constitutes the administrative centre for this mainly rural-based region. This café was also government funded and worked as an information centre for youth, with several government-funded youth projects having offices within the premises. The initiative takers knew that young people in this town, with their particular tastes, required more than a shelter, and thus insisted on funding for proper redecoration. The café section had a modern design, comprising cappuccino and the like, with four computers with Internet access. The café was open to everybody, but contrary to the previous two, it was never an aim to attract a cross generational clientele. Being located in a town where there were already other, also "trendy," alternatives for an older age group, what was needed was a place for the youth. Being run by two male youth workers and a number of conscious objectors, by definition men, the place got a certain masculine dominance. A few girls would drop in to check the Internet, but the community created at the café comprised mainly of boys and young men. Some of the boys were game enthusiasts, playing "first person shot" games such as Counter Strike. Most of the regulars, however, did not really use the computer, but came to meet friends to chat, and listen to the music played rather loudly from the sound system at the café. Interestingly, the few girls who came spent most of their time on the computers, playing quiz-games, chatting, and using e-mail. At the time I did the fieldwork, a separate room was about to be built for a Linux-programming club in the basement of the café. Programming requires better machines than the Internet café can provide, the room was, therefore, facilitated so the programmers could bring their own computers, but be together in a social environment.

The last case is the "City Internet café," which provided 30 computers spread over two floors and a limited kiosk service including filtered coffee. It is a franchise of a chain that was started by students and graduates who wanted to create their own business based on their interest in computers. Whereas the other cafés featured in this study have varied functions in the local community in addition to computer services, this was a more specialized café where the computers, in particular gaming, were in focus. It was open from 10 AM to 4 AM, and 24 hours on weekends. During the day, a varied clientele came to check e-mail and search the net, while the game enthusiasts dominated the place during afternoon and evening hours. They played online games such as Counter Strike and Ever Quest; linking up with other players around the world. The online links to the rest of the world are common to all the Internet cafés, but the City café is, to larger extent than the others, integrated in a national as well as global network of game-based cafés. Being, in fact, pretty much a game centre, the label Internet café attracted a more varied crowd during the days. However, some of the nongame customers did not really approve of the activities at this café:

It is an OK place to be during the day and in the afternoon, but in the night the "coke bottoms"[5] *take over and the place changes (Girl, 20).*

Rather than having different rooms, the technosocial practices at this place changed during the day; a business-oriented Internet-based sociality with little interaction between the clientele during the day, and a boy's room gaming community during the night. As we shall see later, however, the gaming community also produced different technosocial spaces.

In the following, we are going to look further into the coproduction of sociality, technology, and space in the Internet cafés.

Hybrids: CoConstruction of Users, Technology, and Spaces

Technosocial practice builds on the conception of the user and technology as part of a seamless web, where the user and the technology are mutually constituted or coconstructed. As space is integrated in, and produced through, these technosocial practices, space also becomes entwined in this coconstruction process. This implies that use of the Internet, despite the rhetoric of its "placeless" character, is influenced by the kind of place in which the activity occurs. This applies to space on various geographical scales: from the Internet café as a site in everyday life in contrast to home and school, to various local communities in urban and rural spaces. The very idea of putting computers in a public place illustrates that the café setting adds value to the experience of computing, be it using the Internet or playing games. The installation of a room, where people can bring their own computers in Landby, illustrates this further; it is not just the access in itself, but the technosociality of the Internet café that attracts a lot of people to these places. Playing with the computer is simply different according to where it takes place. One of the gamers illustrated it this way:

It is like playing football on the fields with friends or playing "keepie uppie" by yourself at home. It is more fun to play with friends in a café. (Boy, 19)

The particular technosociality that develops plays back on the space, as we see in the next section.

The Internet as technology was coconstructed with the users of the Internet cafés, and something to identify with or against, accordingly. This was particularly true in Fjordvik, where the position of the Internet café in a power struggle between different youth groups, in fact, made resisters of the Internet café also reticent, if not totally opposed to the idea of using the Internet (Laegran, 2003a; forthcoming). The technology was coconstructed with its perceived users and their culture, and rejected on that basis. Similarly, various constructions of "same" and "others" occurred in the other cafés, in Fjelldal, between the users and nonusers of the Internet within the café; in Landby between the gamers and the Linux programmers; and in the City café between those who dropped in to use the Internet during the day and the gamers at night. A further distinction was developed here between the calm Ever Quest players who could be in their online dream world several days in a row, and the more frantic and excited Counter Strike players. According to the players, which game you preferred reflected your personality, and continuing playing would reinforce certain aspects at the cost of others. The difference of the technosocial practices are illustrated by this quote from two Ever Quest enthusiasts:

Boy 19: *The CS people are different – they shout – oh my god.*

Boy 20: *Yeah, they are really troublesome – like if somebody has luck, they jump around in a corner and shout – you hear them screaming. Splints in the table – and the neighbours… If you play EQ you just sit still and write in a chatbox, whereas a CS player beats the table so that you leap into the air!*

Although playing with the same artefact, the computer, we see that the identification with the respective games is significant for how not just the game, but also the gamers are perceived. In this quote, the spatial and material aspects of the difference are striking. Although the game is online, the differences in game socialities have offline implications; Counter Strike players use the materiality of the place in a more explicit way than the Ever Quest players, as we shall look further into in the next section.

Technologies and spaces are also gendered through this coconstruction. In studies of young people and use of computers, the boy's room metaphor has been used to describe the particular competence boys gain through their play with computers in the bedroom (Gansmo, Lagesen, & Sørensen, 2003). Is the café, as a public place often with feminine connotations, an alternative to the boy's room, where also girls may take part in this competence building? In Fjordvik, the café had what we could say was a feminine-connoted design and was used by a majority of girls and women, but the computers were still largely the domain of the boys. The same tendency was seen in the other cafés as well, where girls were in minority also among users of the space as a whole. This is true in particular for games and extended use. This does not, however, imply that the Internet cafés live up to stereotypical notions of "nerdy" places; rather than one dominant form of masculinity, the computers, as well as the places, provide space for performing and negotiating a large variety of different masculine identities related to the café community as well as the technologies (Laegran, 2003b).

Connected Spaces of Connections: The Production of Internet Cafés

Despite being perceived as an "urban" and "global" phenomenon, the findings showed that Internet cafés are configured based on local circumstances, in urban as well as rural communities. Concepts and ideas that, at the start, were quite similar got different manifestations in different local contexts. The "trendy," "nerdy," and "healthy" are three images that the cafés consciously and unconsciously use in their configurations, both in their strategies to attract the desired clientele, setting up the computers, and with regard to the interior design of the place (Laegran & Stewart, 2003). Through the way different actors play with these dimensions, different places with different technosocial practices are developed, yet with some recognizable features.

Although the idea of the Internet and coffee represents something new and possibly trendy, the actual use of the computers consisted of largely mundane activities resembling reading a paper or playing a table game. Just like sending e-mails from an Internet café, writing cards or letters has always been a common activity to do from a café. The difference is, of course, that in the case of the Internet café, the communication may occur synchronically with people located at different places. The computer and the Internet represent interactivity both related to the machine directly, and to the machine as mediator between people behind their respective screens. This makes the technosocial practice in an Internet café different from in any other café or similar locality.

The computers, as well as other material objects, are significant in the way the spaces are produced. In particular, in the trendy café in Fjordvik, a lot of emphasis was put on configuring the interior, the computers, as well as the clientele, into creating a specific form of technosociality, although the trendy idea of computers and coffee, as integrated, failed.

The way the computers are set up influences the character of the place; computers without the most popular first person shoot games, like in Fjordvik, created a different atmosphere in the café than those with these games. From the City café, we saw, in the previous section, the two dominant games also created different technosocialities. Whereas Ever Quest players preferred sitting calmly with coffee and a smoke in front of the screen several hours if not days in row, Counter Strike players got excited by the game, shouting around and beating the table. There was a tendency to spatial differentiation between the group as the consists of two floor levels. The Ever Quest players kept mostly to the second level, where they could look down at the Counter Strike players on the first floor. There were two simple material reasons for this: The machines on the first floor were faster and thus better for Counter Strike play. Furthermore, the second floor was a smoking area, so Ever Quest players could have their smoke whilst sitting down calmly with their coffee, playing the game.

The City café, and the one in Landby were the only ones with broadband, and in particular, the City café was dependent on stable high-speed connections to facilitate their gaming community. This was a constant issue, a slight panic occurred several times when the connection broke down. The café in Landby actually saw the limitations of what a publicly funded place could offer in terms of computers and facilitated space where Linux enthusiasts could bring their own machines for their programming.

However, not only the Internet, the defining technology of the Internet café, is of importance. As the development of the café in Fjelldal showed, the coffee machine, or the absence of one, was seen as significant for why the café failed to gain a clientele beyond that of a youth centre. However, although coffee makers are seen as something that belongs to the Internet café, it seems to be hard to integrate the café culture with cappuccino, and the like, with the actual practice of using computers. It seems more typical that two separate spaces are developed; one café and one computer-oriented space. In Fjordvik we saw that a wall was installed to divide the two spaces. The interior and wall decorations are also important in the production of the Internet cafés as technosocial spaces. In Fjelldal the budget did not allow for decoration other than posters of pop and rock-stars brought by the regulars. The interior of the City Café, on the other hand, was strictly neutral and streamlined in order not to put off nonregular customers.

Three of the cafés were part of a strategy for rural development or youth policy, developed by the initiative takers with support from municipalities. In these cases, the Internet café is used as an agent to modernise the countryside, building on the idea that an informal meeting place with a touch of something modern may do something to and for the community. However, it seems that the presence of an Internet café maintains or reinforces the already dominant trend rather than creates something new. In Fjordvik, the Internet café was welcomed among people who already knew the concept; it fitted well with the art gallery and other features not necessarily associated with the rural. In this way, the coconstruction of the Internet café and the community reinforces a modern or "urban–like" feature of the community, but maintains the divide between those who subscribe to this perception of what the place should be like and those who stand for possibly more "traditional" practices, like car enthusiastic boys at the petrol station (Laegran, 2002; 2003a; forthcoming). In Fjelldal the Internet café, rather than being an agent of change, as intended by the original initiative takers, became domesticated and appropriated into the local community so that it became a popular place to hang out for some of the young people, but it did not really represent anything new or alternative culturally.

Connecting Places: The Production of Space from the Internet Cafés

Internet cafés are places with blurred boundaries; the Internet transgresses boundaries both locally and globally. The Internet café community consists not only of those who are there at the time, but also of the more or less identified persons behind the machines that are linked up through the Internet. While many of these identify themselves and take active part as social persons, others are anonymous game or chat partners whereby the computer, more than the person on the "other side," is the actual opponent in the game or the chat. Thus, the Internet café is a space where the clientele interact not just with each other, but also with the machines. The technical artefacts take part as actants in the production of space inside the café as well as linked outwards through the Internet. In addition to being a node in a local technosocial space, the Internet café thus provides a road to the "information superhighway," connecting to translocal communities in a "virtual" world. However, the technology is used to transgress spatial barriers in different ways.

In Valentine and Holloway's (2001) study of young people's use of the Internet in the countryside, parents were concerned that what they perceived as positive aspects of growing up in the countryside may actually encourage the kids to be too inward looking when they grow up. The Internet, they perceived, could compensate for this by providing access to a new world that could increase the kids' cultural competence and make them more prepared for the world outside the village. I did not make formal interviews with parents, but talked to several who expressed similar views. However, there was also a concern about what this may lead to in terms of the future of the rural, as this father expressed:

When I look at how my daughter uses the Internet, she seems to become more global and urban.

And if this continues, then this region will be no alternative for her.

However, Valentine and Holloway (ibid.) found that there was a gap between the parent's ambitions and the actual practices of Internet use. Rather than useful activities linked to future prospects, they were looking up Web pages of pop and film stars, and having rather casual chats with peers online. In my findings, with slightly older youth, I found that the Internet was used both for "useful" and more entertaining purposes. Linking this to spatial aspects, however, the question of usefulness or entertainment is not really interesting. Studying the practices in the Internet cafés, it was clear that the Internet expands the radius of activity and the range of experiences. Those who used the Internet experienced it as a medium without borders, where it was possible to get impulses as well as contacts and friends from all over the world. The gamers in the City café, for instance, expressed that the sociality with people around the world were maybe as attractive as the games themselves. Several of the informants had made close friends, even boyfriends and girlfriends with people in other countries, and a former member of the Ever Quest community had found love in Australia through the game and moved there. She still kept in touch with the EQ community in the café though, through her character in the game as well as in real person through the chat room.

I also found that the youth were keen on expanding their space locally through the net. The Internet café, as well as the Internet, was important in maintaining links between peers and friends, but it was also used to get new friends locally. Like this girl from Fjelldal says:

Girl, 17: Yes – this friend of mine, she had met this guy on the net – he is from the neighbour village. And they became friends, and she gave me his mobile number so I just texted him – and now we text several times a day. And I sometimes talk to him on the net.

Interviewer: *Have you met him in real life?*

Girl, 17: *No – not yet. But I know who he is. I have seen him in town and all that.*

These boys show a similar example in a discussion about the excitement of a local chatroom,just for the village Fjelldal:

Boy, 19: *We may meet just occasionally, so it is fun to meet on the IRC too.*

Boy, 17: *And you do sometimes talk to people there, who you may not talk to generally.*

Boy 19: *Yeah, I actually talk to a lot of people on the IRC-channel Fjelldal who I do not talk to at all. We know about them, but there are like groupings and so even at this small place. So you do not talk to them in reality.*

Interviewer: *So what about when you meet after you have met on the Net?*

Boy, 19: *I have experienced that a couple of times. But the feeling was not so mutual from my side. (…) You have another identity on the IRC. It is not really like the real world. (…) You are hidden. So you can be anyone. It is easier to say things. (…) But I never cheat; say I am somebody who I am not.*

Interviewer: *So you are just yourself, but still different?*

Boy, 19: *I won't say different. Just that I dare to say things I won't normally say. And take contact with people who I won't have talked to elsewhere.*

These are examples of how the community increases in local rural areas where the number of youth in the same age may be limited. As we see, part of the excitement is that it is a non-face-to-face contact, even though they know who the other person is. In this way, technology provides a new form for sociality, where the technology actually plays an important part not only in mediating contact, but in defining the character of the practice and sociality in itself.

The importance of the Internet and the café as arena for expanded sociality was particularly important for people with what may be seen as special interests within the community. One of the regulars at the café in Landby identified herself as a "gother." With the black hair, white skin, heavy makeup, and jewelry, she was definitely "different" in the community, and it was hard sometimes, she said. By going to the Internet café and being on the net, however, she met a lot of people from the same subculture with which to identify. Having that contact increased confidence that made it easier to be confident enough to be different in the rural community as well.

Technology connects people and places through the Internet café, and we see the production of space extends beyond the walls of the café and the borders of the village. It also has the potential to transgress less tangible borders that are to do with cultural and social aspects of being youth, including the constructions of self and other in communities, as people who would most likely not meet face-to-face can do so through technology.

CONCLUSION

Castells (1996) argues that while media have become globally interconnected, "we are not living in a global village, but in customised cottages that are globally produced and locally distributed" (p341). Following this thought, Internet cafés would be a good example of global cottages distributed locally. However, as we have seen in this chapter, the Internet café, as any other place, is not global, nor is it local. The Internet café is a place produced in the intersection of the activities within the four walls, the village or city where it is located, national and transnational discourses and structures, as well as through the way the Internet connection links it with the "other side" of the computer screens.

The understanding of Internet cafés as hybrids emphasises the entwined coconstruction of users and technologies, as well as space, where gender, as well as other identity markers, are central in the way the technology, as well as the cafés, develop and are understood. The next level focused on the production of Internet cafés as technosocial spaces, where materiality, including technological artefacts as well as images, are used in the local configuration of the Internet café as space. Finally, we saw how Internet cafés can be understood as places of connections, where technologies are actants in the production of space as well as new technosocialities, linking the local to the global, as well as expanding the range and radius of activities within the local.

By using the Internet café as an example, I hope to have shown how the Internet, in particular, but also other technologies and materialities, are integrated in technosocial practices producing spaces in the local, as well as reaching into the translocal. While the Internet may be seen merely as a mediator connecting people, it is important to stress that the presence of the technology taking part in the practice makes a difference. The Internet café, however, is just used as an example. When it comes to connecting people, the mobile phone is probably the most significant technology, a technology that has changed technosocial practices and the way people interact in many different ways in recent years. In order to understand this phenomenon, it is important to look at technology, as well as the social, as integrated in the production of technosocial spaces.

ENDNOTES

1. Twenty years ago, Bijker, Hughes, and Pinch (1987) presented several approaches highlighting the seamless web of the social and technical, coining the term sociotechnical. These approaches had a starting point in studying large (socio)technological systems (*ibid*.). In this study, the starting point is not technological systems, but social practice, where findings show how integrated technology is in the actual practice. Hence, technosocial seems like a more precise concept. It also highlights the transformation of socialities that new technologies may imbue, which is indicated by the fact that the previous use of the term technosocial has been linked to new technologies like ICTs (Bingham, 1999; Escobar, 1996) and biotechnology (Oudshoorn, 2003).

ABSTRACT

This chapter presents some recent studies of the social and human dimension of Semantic Web services in the era of virtual organizations, focusing on the challenges, effects, and implications. The issues and results presented refer to the virtual organization known as the Virtual Research Laboratory for a Knowledge Community in Production (VRL-KCiP), Network of Excellence (NoE). In this chapter the authors analyze the risks arising from the modern communication process in this new form of organization, focusing in particular on the knowledge sharing process. Furthermore, they discuss the cultural aspects of managing a virtual organization that determine the efficiency of the knowledge management processes. The aim is to consider the challenges and the associated effect on developing Web services from the social/human perspective and to examine the impact on an organization's cultural dimensions.

DOI: 10.4018/978-1-60566-650-1.ch018

INTRODUCTION

Semantic technologies are "meaning-centered." They include tools for auto-recognition of topics and concepts, information and meaning extraction, and categorization. Semantic technology software encodes meanings separately from data and content files, and separately from application code. The objective is to enable machines and people to share understanding and reason while programs are being executed. Semantic technologies then provide an abstraction layer above existing information technologies in order to bridge and interconnect data, content, and processes. Using semantic technologies, the process of adding, changing and implementing new relationships or interconnecting programs is relatively straightforward. From the portal perspective, semantic technologies can be thought of as a new level of depth that provides an improved, intelligent, relevant, and responsive interaction compared to that available with “classical” information technologies alone.

Hence, these technologies seem to hold the promise for improving communication and collaboration among dispersed organizations worldwide. This chapter discusses how such technologies functioned in a virtual organization involving numerous partners.

After describing the operations of the VRL-KCiP Network of Excellence (NoE) over the past three years, we briefly review the promising challenges of Web services. We then describe the Web services implemented and provided to VRL members. We show that even if these services are necessary for common and distributed work among the various partners, they alone cannot solve communication problems arising from misunderstandings. Based on the results of a previous study, we describe these misunderstandings and then examine cultural aspects of communication within the NoE which were determined to be critical factors in misunderstandings. These cultural dimensions cannot be handled technically but must be taken into account for Web services to be efficient.

THE CASE OF VRL-KCIP NOE

The Virtual Research Laboratory for a Knowledge Community in Production (VRL-KCiP) is a Network of Excellence (NoE) established in 2004 as part of the EC Sixth Framework Programme (Contract no. FP6-507487). The 27 member teams from 16 different countries (see Table 1) sought to create a new delocalized research structure at the European level, in which they would share research strategies, knowledge and resources, responsibilities, rights, and duties, as well as industrial contacts and contracts.

The idea behind the network (virtual organization) was to overcome fragmentation by applying the network principle to research. The NoE applied a multicultural approach both to the integration of modeling and simulation of knowledge-based production processes and to the relations among the joint partners. The objective of the VRL-KCiP was to support dynamic organizations, inter-enterprise operability, and necessary standardization. The network was driven by advances in virtual production, supply chain and life-cycle management, interactive decision-aid systems, development and rapid manufacturing. Incorporating these factors necessitated bi-directional relationships with industry. The virtual organization also aimed to benefit from the different approaches of the multicultural teams in treating common manufacturing problems and in promoting successful technology transfer. This would be achieved by incorporating emerging technologies driving new production paradigms in all phases of the complete/extended value-chain (design, production, distribution, use and end-of-life phases, including recycling) to allow development of new knowledge-based, added value and quality products and services in traditional sectors (Tichkiewitch, 2005).

The network attained industrial involvement and commitment by incorporating selected European industries to play a key role in providing industrial viewpoints on research relevance, research directions and awareness of integration activities and research topics related to production. Moreover, the joint research outcomes were publicized to attract and recruit new members.

Obviously, such a network is not primarily hierarchical in nature, and co-operation cannot be dictated from above. The research topics are

extremely diverse and evolve significantly, which may appear to some extent uncontrolled. Thus we can assume that networks of excellence are adaptive and flexible but hard to manage and co-ordinate (Shpitalni, Guttman, Bossin, 2005).

The main activities of research in the VRL-KCiP NoE were as follows:

1. **Integrating activities:** The goal of these activities was to create the integrated infrastructure (processes, tools, and procedures) required to establish a sustainable, integrated, European level virtual research laboratory.
2. **Joint research activities:** These research activities were designed to evaluate the joint research capability of the network, improving constantly as the infrastructure developed as part of the *"integrating activities"* evolved. These research topics were determined both by the ongoing research in the different labs and by the research directions determined together with large EU industrial members. The research teams were determined by taking into account actual member competencies, in order to reduce research fragmentation in Europe and

to create the best complementary activities between the actors.

3. **Spreading excellence activities:** These activities were directed at extending the scientific benefits of the network to academia and industry and, disseminating new knowledge by means of training sessions, scientific journals, web sites, and conferences.

The large number of network participants together with the network's multicultural, multidisciplinary, multilingual inherent characteristics require advanced knowledge and information sharing services, which may be facilitated by implementing Semantic Web services. The following overview discusses the promising challenges of available Web services, and describes those implemented in the VRL.

THE PROMISING CHALLENGES OF WEB SERVICES

A Web service is a set of related application functions that can be invoked over the Internet as an integrated part of any program code. Businesses can dynamically mix and match Web services to perform complex transactions with minimal programming. Web services allow buyers and sellers worldwide to discover each other, connect dynamically, execute transactions, and share information (data, knowledge) in real time with minimal human interaction.

Web services are self-contained, self-describing modular applications that can be published, located, and invoked across the Web:

- **Web services are self-contained:** On the client side, no additional software is required. A programming language with XML and HTTP client support is sufficient to get started. On the server side, a Web server and servlet engine are required. The client and server can be implemented in different environments. It is possible to turn an existing application into a Web service without writing a single line of code.
- **Web services are self-descriptive:** The client and server need to recognize only the format and content of request and response messages. The definition of the message format travels with the message; no external metadata repositories or code generation tools are required.
- **Web services are modular:** Simple Web services can be aggregated to form more complex Web services either by using workflow techniques or by calling lower layer Web services from a Web service implementation.
- **Web services are platform independent:** Web services are based on a concise set of open, XML-based standards designed to promote interoperability between a Web service and clients across a variety of computing platforms and programming languages.

Examples of Web services may include applications used for theatre reviews, weather reports, credit checks, stock quotations, travel advisories, or airline travel reservation processes. Each of these self-contained business services is an application that can easily integrate with other services, from the same or different companies, to create a complete business process. This interoperability allows human activities, interactions and/or collaboration to dynamically publish, discover, and bind a range of Web services through the Internet. Table 2 presents the main categories of Web services.

Web services make up a connection technology, providing ways to connect services together into a service-oriented architecture. A network component in Web services architecture can play one or more fundamental roles: service provider, service broker, and service client.

Table 2. Categories of Web services (Source: www.service-architecture.com/web-services/index.html)

No.	Category	Description
1	**Business information**	A business shares information with consumers or other businesses. In this case, the business is using Web services to expand its scope. Examples of business informational Web services are news streams, weather reports, or stock quotations
2	**Business integration**	A business provides transactional, "for fee" services to its customers. In this case, the business becomes part of a global network of value-added suppliers that can be used to conduct commerce. Examples of business integration Web services include bid and auction e-marketplaces, reservation systems, and credit checking
3	**Business process externalization**	A business differentiates itself from its competition through the creation of a global value chain. In this case, the business uses Web services to dynamically integrate its processes. An example of business process externalization Web services is the associations between different companies to combine manufacturing, assembly, wholesale distribution, and retail sales of a particular product.

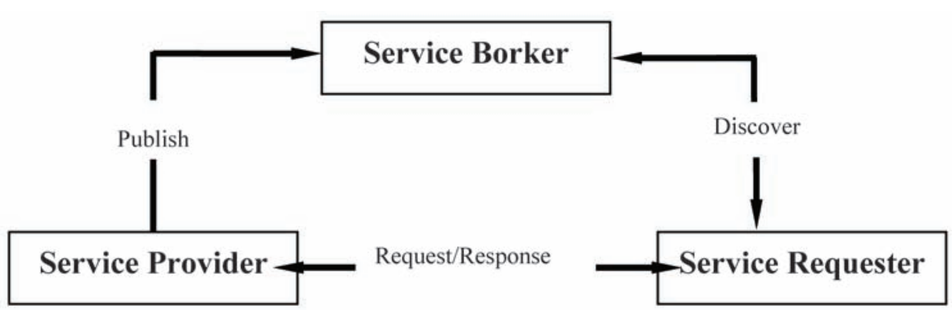
Services providers create and deploy their Web services and can publish the availability of their WSDL-described services (Web Services Definition Language) through a service registry, such as a Universal Description, Discovery, and Integration (UDDI) Business Registry.

Services brokers register and categorize published services and provide search services. For example, UDDI acts as a service broker for WSDL-described Web services.

Services clients use broker services such as the UDDI Business Registry to discover a needed WSDL-described service and then to bind to and call the service provider. Binding involves establishing all environmental prerequisites necessary to successfully complete the services. Examples of environmental prerequisites include security, transaction monitoring, and HTTP availability. The relationships between these roles are described in Figure 1.

In this chapter, the term Web services refers to technologies that allow connections via the web. A service is the endpoint of a connection. Moreover, a service has some type of underlying computer system that supports the connection offered. The combination of services—internal and external to an organization—makes up a Service-Oriented Architecture (SOA), which is essentially a collection of services that communicate with each other. This communication can involve either simple data transfer or two or more services coordinating some activity. Some means of connecting services to each other are needed (www.service-architecture.com).

Figure 1. Service roles and interactions



WEB SERVICES FACILITIES IN THE VRL-KCIP NOE

The following Web service facilities were used for internal and external communication between the partners of the Virtual Research Laboratory for a Knowledge Community in Production (VRL-KCiP) Network of Excellence (NoE). The main achievements to support internal communication included:

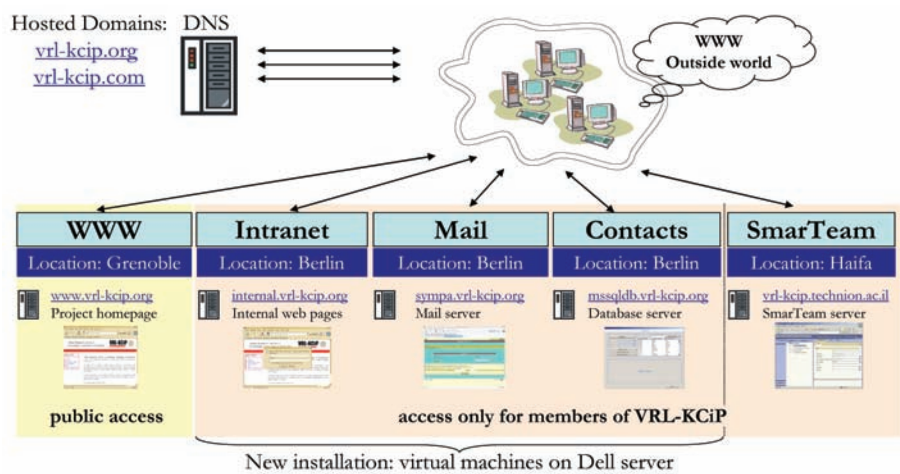
1. Registration and administration of the VRL-KCiP Internet domain, and installation of a DNS server for the domains vrl-kcip.org and vrl-kcip.com;
2. Implementation of an internal website for NoE members with access control;
3. Provision of the project partners' contact data, CV, areas of research, collaborations, and publications;
4. Specification and development of a tool for central administration of contact data and task allocation (the VRL Shepherd);
5. Installation and maintenance of a central contacts database;
6. Development of a communication handbook (*The Hitchhiker´s Guide to VRL-KCiP*);
7. Installation and administration of a mail server for mailing lists (Sympa);
8. Issuance of document templates for all kinds of documents needed within the project (e. g. for presentations, poster, reports) to ensure a unified appearance and facilitate management and assignment of documents to different operations;
9. Implementation of knowledge management capabilities and file sharing among members of the NoE using the SmarTeam tool.
10. Implementation of a common calendar for publishing important events.
11. Implementation of a common topic based forum capability.
12. Implementation of an expertise mapping capability

After communication and groupware services were initially installed on numerous PCs at the beginning of the project, it became evident that a more stable server platform was needed to deliver stable and reliable services to network members. To this end, in early 2005 Fraunhofer IPK began planning an adequate IT infrastructure. After analysis, it was decided to implement the new infrastructure using only two servers and a client PC for administration, made possible by utilizing virtual machine technology with multiple virtual PCs / servers running on a single computer (Figure 2). The implemented environment is described below in further detail.

Experience from past project coordination showed delivering reliable Web services requires that the corresponding server applications run on separate server machines. Moreover, some of the utilized services require different operating systems. An analysis of the required services for the IT infrastructure of VRL-KCiP internal and external communication indicated that a reliable implementation would need a total of eight machines. During a test phase these services were installed on eight physical test machines. This infrastructure had suitable performance but maintenance of the hardware turned out to be rather difficult. Also, running eight physical machines seemed to be unreliable since the malfunction of one machine could paralyze all services. Therefore, after an analysis of how to improve the infrastructure, a server was specified to run virtual machines, each hosting a separate PC, and a backup server was specified as well.

The IT infrastructure for VRL-KCiP internal communication is now based on two Dell servers and a virtual environment containing eight virtual machines, replacing eight physical PCs (Figure 3). This virtualization technology has enabled the organization management to reduce cost and optimize redundancy for the whole

Figure 2. Web service facilities: Intranet services



infrastructure. A Dell workstation is used in addition for administration and development tasks. The hardware specifications are presented in Table 3.

The virtualization of the information technology infrastructure for VRL-KCiP internal communication is based on VMware Server Software. VMware provides a virtual layer residing on a Windows 2000 Server local host system. The virtual server farm is divided into two virtual segments:

- A live segment hosting all live virtual servers with their services;

Figure 3. VRL-KCiP virtual segments

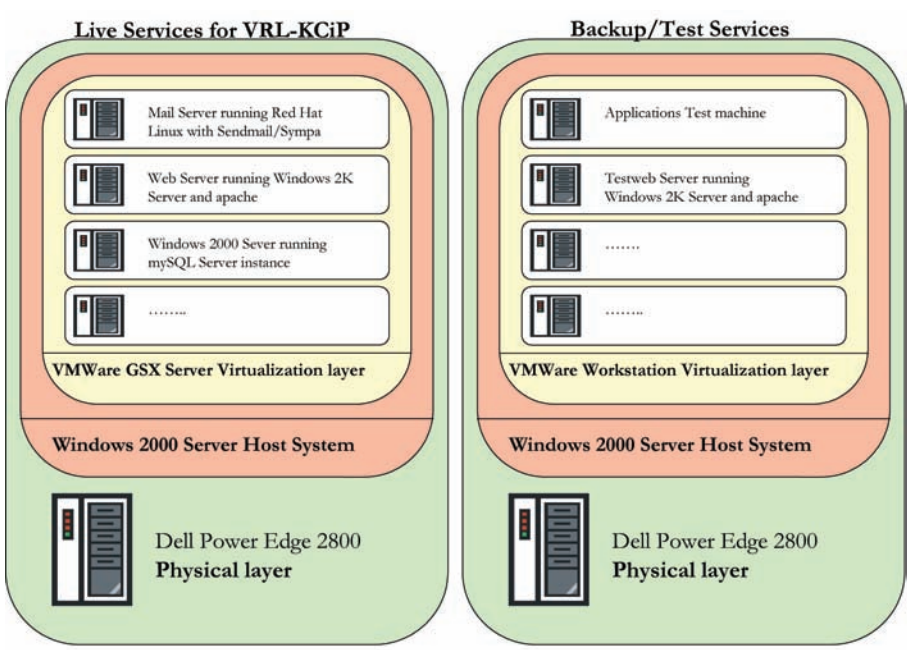


Table 3. Hardware specifications

Hardware	Parameters / Specifications
Server 1	Dell Server Power Edge 2800: Dual P4 Xeon 3,0 GHZ; 3 GB Ram; Hard drives: 450 GB Raid 5, 73 GB Raid 1
Server 2	Dell Server Power Edge 2800: single P4 Xeon 3,0 GHZ; 1 GB Ram; Hard drives: 73 GB Raid 1
Workstation	Single P4 3,0 GHZ; 1 GB Ram; Hard drives: 80 GB Raid 1

- A backup/test segment hosting all tests, daily backups for the live-Segment.

Based on the described virtual platform, servers have been set up to provide all VRL-KCiP partner services, as follows:

- **Mail Server:** running Red Hat Linux with sendmail and Sympa;
- **Web Server:** running MS Windows 2000 server with Apache as web server software;
- **Database Server:** running Windows 2000 server and a mySQL server instance holding all the data for the VRL-Shepherd client;
- **Database Server:** running Windows 2000 server and a mySQL server instance. This server will provide a centralized login data for web and forum services;
- **Backup Server:** running Windows 2000 for disc-to-disc backup of all live virtual servers from segment 1 to segment 2;
- **Web Server:** a mirror of the web server mentioned above acting as a test platform for all releases before going live;
- **Application Server:** a standard client machine for testing purposes of the VRL Shepherd client;
- **Forum Server:** running windows 2000 server with apache and forum software.

For effective communication and project management a number of groupware services needed to be implemented and deployed. These "VRL-KCiP member services" include Web-based Intranet as a hub for information distribution, management of contact data information, document management and e-mail exchange. All of these VRL-KCiP member services have been set up and are widely used by network members. Access to the services is available via the network's public web site (www.vrl-kcip.org) or via a direct URL at http://internal.vrl-kcip.org/. Access to member services requires a login with username and password on the VRL-KCiP Intranet section of the virtual organization's Web page (Table 4).

The Web service facilities define the "**VRL world**". These facilities supported the development of human relations among the laboratories and universities involved in the partnership. They served as the foundation of building the knowledge community in the field of manufacturing, the project's main objective. Despite communication problems and cultural differences, the members met the challenges of working together. They succeeded in creating a unified integrated world that can be easily navigated and that presents the network's members, research areas, publications and collaborations all in context over the web.

SOCIAL / HUMAN CHALLENGES AND IMPACT ASSOCIATED WITH WEB SERVICES IN THE VRL-KCIP NETWORK OF EXCELLENCE

The Web service facilities in the VRL-KCiP have some unique features:

- The service providers and service clients are members of the same knowledge

Table 4. The VRL-KCiP Intranet: Web services for the virtual organization members

Network organization	
Hitchhiker's Guide	Hitchhiker's Guide is the project management handbook for VRL-KCiP. It provides information about who's who in the network and about the different internal communication facilities
Who's who	Who´s Who in VRL-KCiP: 1. Organigram; 2. Contact data of all members of the network; 3. Registration process.
Mailing	All mailing lists are displayed and can be downloaded as .xls file.
Templates	Templates for all documents which are needed within the network, e. g. posters, presentations, deliverables.
Deliverables	All Deliverables for VRL-KCiP can be downloaded from the Intranet.
Registration process	New members of the project have to be registered by the main representative of the laboratory they belong. This will ensure consistency and avoid non-project partners attaining project internal information. The new member has to give information about personal data and membership to organizational units (categories) within the NoE to the main contact.
Logos	The logos of all organizations within the VRL-KCiP network and the VRL-KCiP logo can be downloaded in different files formats.
VRL shepherd reader	VRLshepherd. It can be used to view partner and organization data.
VRL Web shepherd reader	Test version of the new web based VRL Web Shepherd.
Member Services	
SmarTeam	The SmarTeam Knowledge Management System is used for asynchronous data exchange
CDC tool	Tool for financial management of the NoE is located at CDC, Paris
Discussion Forum	Forum for discussion of relevant network themes
Calendar	All project internal dates, meetings, deadlines etc.
Video conferencing support	Instructions for use of VRL-KCiP video conferencing system
News section	Actual news concerning VRL-KCiP are presented for members only
Software Demonstration and Exchange Platform	The platform gives an overview on software tools developed by NoE partners
Key Performance Indicators	Input platform for indicators to evaluate VRL-KCiP performance

community. They work together to enrich the knowledge base system;

- The management team (which acts as broker) supports both the service providers and the clients, piloting the virtual organization's activities with respect to European Commission "rules" and performance indicators for the 6th Framework Program.

The VRL Web service facilities must support the *virtual knowledge work* of different researchers working in distributed laboratories in different countries (see Table 2). The heterogeneous backgrounds of the participating professionals, the diverse professional interactions (among the team members and with industries), and the challenges to be met can generate various kinds of misunderstandings, leading to errors and conflicts. Our experience with the VRL NoE showed that despite innovative Web services, the problem of misunderstandings still remains. These misunderstandings can interrupt activities and lead to decisions that are later regretted. In other words, the NoE, assumed to provide a creative forum in which researchers and companies can interact and share knowledge, often must face major complexities due to accumulated misunderstandings. Experience has shown that to manage the risks linked to such misunderstandings, we must focus on communication errors. In this context, we propose general guidelines for cross-cultural communications and discuss the potential role of IT-based tools in solving misunderstandings in virtual engineering teams.

Misunderstandings in the VRL-KCiP Communication Process

According to the Free Dictionary (http://www.thefreedictionary.com/misunderstandings), the term "misunderstanding" can be explained in two ways:

1. Putting the wrong interpretation on;
2. An understanding of something that is not correct;

Another related word in this context of explanations is misconception, which is an incorrect conception.

These definitions underline the causes and effects of misunderstanding. The consequences of misunderstandings must be avoided.

According to international standard ISO/IEC 11179-4, misunderstanding in information technology must be avoided: "Precise and unambiguous data element definitions are one of the most critical aspects of ensuring data shareability. When two or more parties exchange data, it is essential that all are in explicit agreement on the meaning of that data. One of the primary vehicles for carrying the data's meaning is the data element definition. Therefore, it is mandatory that every data element have a well-formed definition; one that is clearly understood by every user. Poorly formulated data element definitions foster *misunderstandings and ambiguities* and often inhibit successful communication".

All these definitions and contextual explanations of misunderstandings are linked with communication and human perception of concrete terms, concepts, information or knowledge.

Communication is not only a necessary process for solving technical problems. It is also a very important tool to manage a team, both to motivate people and also facilitate knowledge transfer between team members. Misunderstandings and errors can occur during the communication process, as outlined below (Paek & Horvitz, 2000):

- Channel failure, overhearing (Paek & Horvitz, 2000);
- "Non-understanding" (Hirst et. al., 1994); "Problematic reference" (Schegloff, 1987); "Communication breakdown" by cochlear-implant user (Tye-Murray & Witt, 1996); Jargon (Ahlsen, 1993);
- Misunderstanding by abduction (McRoy & Hirst, 1995), by coherence (Ardissono et. al., 1998); "Negotiated misunderstanding" (Blum-Kulka & Weizman, 1998); Conventional breakdown in cross-cultural interaction (Ulichny, 1997); Input failure (Ringle & Bruce, 1981); Underspecification (Deemter & Peters, 1996);
- Misconception (McCoy, 1989); Breakdown by unshared conventions (Gumperz, 1995); Co-membership differences (Schegloff, 1987); Problematic sequential implicativeness (Schegloff, 1987); Pracmatic infelicities (Marcu & Hirst, 1996); Model failure (Rigle & Bruce, 1981);
- Contribution (Clark, 1996).

This interdisciplinary taxonomy of communication errors is not meant to be a complete or exhaustive review of the research literature. Rather, it serves as a preliminary attempt to correlate different types of communication errors. All the definitions of misunderstandings, groundings, and mentioned causes can be integrated in the six semiotic layers mentioned by Stamper (1973 & 1996).

The most relevant sources of communication errors in the VRL-KCiP virtual organization are explained below (Lewkowicz, Wijnhoven & Draghici, 2008):

- **Video conference:** Video conferences are marked by a time lag between when a question is asked and when the other party perceives the question. For example, three seconds can elapse between the time you ask a question and the time your question is perceived at the other end. That's a long silence to tolerate. Many conferences fell apart because someone repeated a question while the person on the other end was trying to answer, resulting in a waste of time. Functional errors of the video conference system that can induce misunderstandings are as follows:
  - Delays between a speaker's explanations and presentation image reconstruction;
  - Echoes causing voice distortions and missing information;
  - People who do not take system delays into consideration and therefore speak too quickly. Misunderstanding is generated because slow voice refreshing can affect the duration of the meeting.
- **Language:** Misunderstandings are often generated because English words and phrases are mispronounced and/or used incorrectly by people whose native language is not English (i.e., Romanian, Hebrew, French, Greek, Hungarian, Spanish, Swedish etc.). While people seem to have accepted each other's pronunciation styles, sometimes English-speaking partners speak too quickly and are misunderstood. Such misunderstandings can be avoided by e-mail communication.
- **Cultural gap (communication gap):** Due to differing perceptions (or prejudice) about the work process and possible work solutions (cultural influences, education in national systems, experiences in national companies), misunderstanding in cooperation can occur. Most of the researchers, task and work package leaders believed in the importance of the following:
  - Face-to-face meetings and early involvement of all key players;
  - Common objectives, commitment, clear roles and responsibilities, rules and practices Team research and goal setting theory has demonstrated the importance of establishing a common purpose among team members and then working towards this purpose to increase team effectiveness (Hacker & Lang, 2000).;
  - Ongoing follow-up video conference meetings and
  - Well established standard tools and good systems that are compatible in terms of software, hardware, electronic communication / data transfer.
- **Cultural differences, cross-culture communication:** Cultural issues and poor leadership lead to misunderstandings and conflict that are not easily resolved. Cultural differences must be acknowledged and carefully handled. Communication feedback (even in the case of e-mail communication) is necessary to avoid misunderstandings.
- **Knowledge Management Systems:** The main drivers for implementing KM initiatives are as follows: dissemination of best practice to a key set of employees; retention of the tacit knowledge of key employees; promoting continuous improvement; responding to customers more quickly; and reducing rework. The VRL-KCiP Knowledge Management System (KMS) was developed using the SmarTeam application. The most frequent misunderstandings with the KMS were generated by difficulties connecting with the server, which did not allow data saving and forced people to input the information again. Moreover, access to specific items in the KMS was very difficult for most people in the

beginning because of problems using the SmarTeam interface. These problems have been partially solved by enabling external data input possibilities, and by publishing the knowledge from within the SmarTeam system on regular web pages.

- **Annual evaluation / motivation / recognition:** The VRL management team agreed that these practices definitely helped motivate the network members. However, it was mentioned by some that this could be further amplified by developing a complementary incentive program celebrating the achievement of key project goals. Such measures quantify network achievements and the contribution of each separate team in achieving network goals. The idea was to develop common goals and agreed upon measurements that were known to all teams in order to reduce misunderstandings of the aims and the means required to achieve them.
- **Experience:** As project managers gain experience in global virtual team projects, they learn how to overcome the challenges and drastically improve project performance metrics, among them engineering cost, construction cost, engineering time, overall project delivery time, engineering quality, and construction quality. Figure 4 shows the semiotic layers of misunderstanding together with human guidelines for improving cross-cultural communication skills. Improving knowledge sharing and communication in virtual engineering teams could be an important management tool (Lewkowicz, Wijnhoven & Draghici, 2008). This improvement can, for example, help detect and diagnose non-functioning design teams, advance understanding of how design teams acquire and maintain their collective identity, and help serve as a means for understanding the evolution of information needs in design teams.

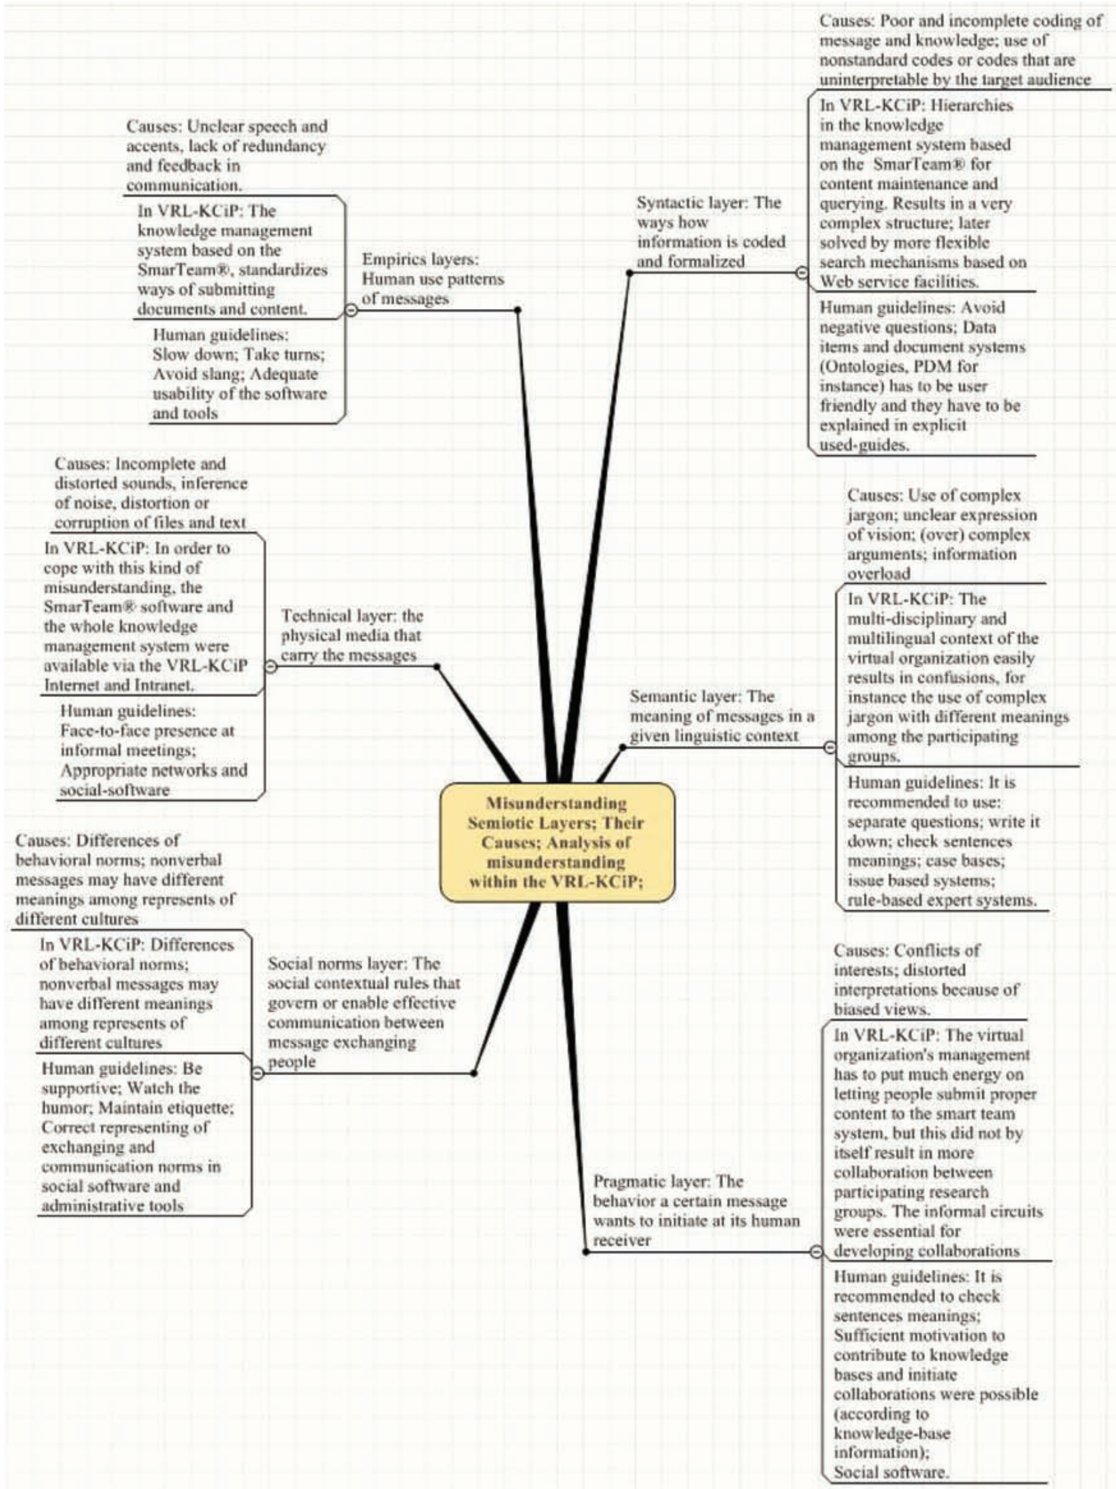
Currently, no well developed tool exists for identifying level of understanding, and especially for detecting potential misunderstandings in a global virtual engineering team. As indicated above, such a tool is urgently needed. It can be built by means of further literature research, survey studies (to learn the business magnitude of this problem more precisely), possible tests of such tools, and making these tools part of common project management practices for virtual teams. Some initial attempts at such research have already been made in the field of off-shore information technology development (Kernkamp, 2007), and the field of manufacturing and product engineering must soon follow.

The above review of the literature combined with our experience in the VRL-KCiP NoE has led to the synthesized presentation in Figure 4. The figure shows the misunderstanding semiotic layers together with their causes, an analysis of the communication errors in the VRL-KCiP organization and some human guidelines (Lewkowicz, Wijnhoven & Draghici, 2008). Even though the word *virtual* is found in global virtual engineering teams, some element of face-to-face interaction is critical and cannot be avoided. One of the most crucial failure factors was a lack of understanding of local work practices, cultural differences, and language issues.

Organizational Culture Assessment and Study

Another aspect of social/human impact associated with Web service creation and use in the VRL-KCiP is multi-cultural synergy. This synergy had an impact upon organization management, approaches to knowledge management and, in particular, knowledge sharing. The debate started from the potential advantages of virtual communities, which can create culturally synergistic solutions, enhance creativity and cohesiveness among team members, promote greater acceptance of new ideas and provide a competitive advan-

Figure 4. Synthetic presentation of the misunderstanding semiotic layers



tage for the whole organization. Yet, culture is not a sure or stand-alone remedy for improving organizational performance, which is complex, multileveled and deeply rooted. Culture must be observed and analyzed at every level before it can be fully understood or successfully changed and managed.

In this context, a study of organizational culture research was carried out within the VRL-KCiP NoE. The questionnaire was inspired by the survey presented by Anawati and Craig (2006). The main ideas in building the questionnaire were:

1. **General overview** of the virtual team: awareness of cultural differences; accepting cultural differences; allowing team socializing/informal chat; rewarding good behavior in culturally appropriate manner.
2. **Spoken and written** characteristics for communication and inter-relation development. The general overview takes the following into consideration: avoid slang, colloquialisms, jargon, acronyms; use simple language; avoid metaphors; avoid humor; keep to the point; confirm understanding by asking open-ended questions; reiterate key points; use follow-up emails for feedback; formulate criticism/ praise carefully. In addition, **spoken language** is linked with verbal dialogue, so the following aspects are relevant: speak slowly/clearly; acknowledge/invite each individual to speak; allow for "think time" between responses; alter tone of voice (do not be too abrupt); supplement discussions with written text or visual. Some important aspects regarding **written** communication are: write from the receiver's point of view; be more descriptive; use lists/points; vary between formal and informal writing.
3. **Religious belief** is important for scheduling meetings and deadlines (religious holidays or celebrations must be considered).
4. **Time zone** is linked with time organization: allow extra time for time zone differences; attempt to schedule meetings during work hours; rotate meeting times to share the burden of after-hours work.
5. **Face-to-face** meetings are the most relevant way to build trust in the organization and should be encouraged: initiate team face-to-face meeting if possible; initiate team video conferences; put team member photographs on a website; rotate face-to-face meetings in different locations.

This research underlines that cultural aspects have had an important influence on the VRL-KCiP network. The organizational culture emphasizes the individual teams'/partners' culture, and this culture is in a state of transition. In the following, the research results are examined by analyzing the answers given by each thematic group to each question (122 respondents). The nationalities of the participants involved in the research were: Spanish, Hungarian, German, Colombian, Japanese, Slovene, South Korean, British, Romanian, Dutch, Greek, Israeli, Italian, French and Swedish. For analysis purposes, the participants were divided into four groups: Northern Europe (British, Dutch and Swedish), Central Europe (Hungarian, German, Slovene and Romanian), Southern Europe (Spanish, Greek, Israeli, Italian and French) and East Asia (Japanese and South Korean). The participants' average age was 37.07 years. This low average isan advantage for the VRL-KCiP organization, as the population of Europe, and particularly the research community, tends to be older. The youngest participant was 24 years old, while the oldest was 62; 24% of the participants were female, and 76% were male. Table 5 presents the most relevant research results.

In our study, we focused on discovering and describing the impact of multi-culturally in virtual teams, and in particular in the VRL-KCiP Network of Excellence. The potential advantages of global virtual teams are that they can create culturally synergistic solutions, enhance creativity and cohesiveness among team members, promote

Table 5. Relevant research results

Question	Comments
1. Inter-relationship development inside the organization	
How do you rate the importance of socializing (e.g. informal chat, subjects out of work, jokes)?	The participants mainly rated the importance of socializing as very high or high; no one rated it as rather or completely unimportant.
Do you tolerate the religious beliefs of others (e.g. prayer time, religious holidays)?	The results do not show a significant tendency. While most of the participants pay attention to this topic, others consider it less important. Possible causes for this could be either that religion is not of great importance for them, or they think that religion is a private matter that should be kept out of work.
Should the other team members be aware of your culture?	According to Anawati and Craig (2006) this should be the case. For 31% of the participants it is very important that others are aware of their culture, and for 45% this is sometimes the case; 24% of the participants think that culture should not be of importance.
2. General differences	
Have other team members sometimes behaved in a way that bothered you?	To obtain the answers to this question, comparable answers were assigned with a value (3/often, 1/sometimes, 0/never) and then scaled relative to the number of each group's participants. The following hypotheses were assumed, based on culture (discussed in the answers to the next question): **Hypothesis 1:** *The environment of Northern Europe is informal;* **Hypothesis 2:** *The environment of Central Europe is hierarchical;* **Hypothesis 3:** *The environment of Southern Europe is informal;* **Hypothesis 4:** *The environment of East Asia is hierarchical.*
Is your environment rather hierarchical or informal? Is this due to your culture, workplace, religion or others (please specify)?	In general, the participants consider their environment as rather informal. The research results validated hypothesis 1 and 3; hypothesis 2 could not be validated because of the distribution of the answers, and hypothesis 4 was not admissible. For 76% of the participants, workplace relations were the decisive factor in this estimation; 31% mentioned culture, while religion did not play a decisive role in human relations. In this context, it must be considered that workplace relations will, in most cases, be influenced by the culture of the surrounding environment.

a greater acceptance of new ideas and, hence, provide a competitive advantage for multinational corporations.

We were interested in describing and characterizing the human/social aspects and relational dynamics generated by modern information and communication technology methods and tools implemented in a virtual organization (and/or the impact of creating Web service facilities), in particular for the VRL-KCiP NoE.

We have presented the results of the research conducted within the setting of VRL-KCiP and based on the topics presented by Anawati and Craig (2006). The results show that it is very difficult to formalize cultural issues, as every individual ultimately acts differently. But when the virtual team members behave in a tolerant and endeavoring way they can overcome culture-related difficulties. If the commitment to the common task is granted to the required extent, the task will be accomplished successfully.

Desktop conferencing/collaboration tools can provide very good support for intercultural collaboration as they offer many possibilities to express and explain even complex matters and can be therefore recommended as useful investments. Finally, even if today's technology provides possibilities for cross-cultural virtual teams, the classic face-to-face meeting remains indispensable as a decisive part of effective team building.

The research, statements and observations regarding the VRL-KCiP organizational culture point out two largely shared perspectives: (1) the culture emphasizes the individual teams' (partners) culture, and (2) the culture is in a state of transition. It seems that organizational culture and Web service facilities are connected in their evolution.

FUTURE RESEARCH AND TRENDS

Our research approach will be repeated in the future because the VRL-KCiP has been extended to become EMIRAcle – European Manufacturing and Innovation Research Association, a cluster leading experience, whose aim is to valorize the results of VRL-KCiP as a legal entity in the form of an international non-profit association according to Belgium Law (AISBL). Until the end of June 2008, the NoE and the association co-existed in order to guarantee a seamless transition between the two organizations. EMIRAcle is an important element of the common marketing and dissemination strategy created by VRL-KCiP members.

The present and future trends of real organizations are focused on encouraging the development and implementation of virtual teamwork. As organizations worry about their bottom lines and reduce travel, they will begin to more strongly support virtual teams. They will also begin to focus on increasing the productivity of those teams. In the new millennium, the competence of most organizations will depend on innovative deployment of new technologies for effectively managing knowledge networks for organizational performance (Tapscott & Williams, 2006). Many such "virtual" organizations using information and knowledge as their fundamental bases are redefining the "reality" of their traditional environment. In the process, they are also posing challenges and opportunities by redefining traditional thinking about industries, organizations, competition, products, services, technologies, people and economy (Draghici & Draghici, 2006).

CONCLUSION

This chapter has presented some of the human dimensions of a virtual organization (in particular the VRL-KCiP NoE). In our approach, the Web services term/concept refers to the technologies that allow connections, and a service is the end-point of a connection. For effective communication and project management, a number of groupware services were implemented and deployed in the "virtual space" of the NoE. These "VRL-KCiP member services" include: Web-based Intranet as a hub for information distribution; management of contact data information; document management; e-mail exchange. All of these VRL-KCiP member services have been set-up and are widely used by network members. Access to the services is available on the network's public web site (www.vrl-kcip.org) or via a direct URL at http://internal.vrl-kcip.org/. Despite all of these services, misunderstandings still remain. We then focused on discussing the challenges and impact associated with web services development, from the social/human perspective and its impact on the organizational culture dimensions of VRL-KCiP NoE.

The potential advantages of virtual teams are that they can create culturally synergistic solutions, enhance creativity and cohesiveness among team members, promote greater acceptance of new ideas and provide a competitive advantage for the whole organization. Yet, culture is not a sure or stand-alone remedy for improved organizational performance. Culture is complex, multileveled and deeply rooted, and must be observed and analyzed at every level before it can be fully understood or successfully changed and managed.

The theoretical aspects are verified through the results of organizational culture research within the VRL-KCiP. The questionnaire used in the research was inspired by the survey presented by Anawati and Craig (2006). These researchers proposed a framework of behavioral adaptations in order to give an orientation for cross-cultural virtual team members by considering the following items: general overview of the virtual team; spoken and written characteristics for communication; religious belief importance for scheduling meetings and deadlines; time zone linked with the time organization; face-to-face meetings, which are the most relevant ways for building trust in the organization. The research underlines that cultural aspects have had an important impact on the VRL-KCiP network. The organization's culture emphasizes the individual teams'/partners culture, and this culture is in a state of transition.

Future studies will be developed in the context of VRL dynamics and its transformation into the EMIRAcle association.

KEY WORDS AND DEFINITIONS

Ad-Hoc or Virtual Team: Is a recombinant structure for work that pulls people and resources together quickly to solve a particular problem or client issue (Koulopoulos & Frappaolo, 1999).

Core Competency: Represents the overriding value statement of an organization. Core competency need not be narrow (Kotler, 2000). Hindle (2000) identifies three essential elements of a core competency: (1) provide potential access to a wide variety of markets; (2) make a significant contribution to the perceived customer benefits of the end product; and (3) be difficult for competitors to imitate.

Expertise: Is the property of a person (that is, expert) or of a system that delivers a desired result, such as pertinent information or skills.

Expertise generally implies providing useful and large amounts of knowledge and action quickly (fluency). In general, expertise has several synonyms, among them know-how, skill, knowledge, competence, or excellence.

Knowledge Community: Is a community of people, groups or teams that share competencies, information and knowledge (in a specific field of activity) based on a specific knowledge management system defined in the context of a knowledge sharing culture with a proper ICT system. Web services support knowledge communities.

Misunderstanding: Can be explained in two ways: putting the wrong interpretation on; b. an understanding of something that is not correct. Another related word in this context of explanations is misconception, which is an incorrect conception (according to the Free Dictionary http://www.thefreedictionary.com/misunderstandings). In information technology must be avoided: "Precise and unambiguous data element definitions are one of the most critical aspects of ensuring data shareability. When two or more parties exchange data, it is essential that all are in explicit agreement on the meaning of that data. One of the primary vehicles for carrying the data's meaning is the data element definition. Therefore, it is mandatory that every data element have a well-formed definition; one that is clearly understood by every user. Poorly formulated data element definitions foster *misunderstandings and ambiguities* and often inhibit successful communication" (according to international standard ISO/IEC 11179-4)

Organizational Culture: Is a concept in the field of Organizational studies and management which describes the attitudes, experiences, beliefs and values of an organization. It has been defined as "the specific collection of values and norms that are shared by people and groups in an organization and that control the way they interact with each other and with stakeholders outside the organization." (Charles & Gareth, 2001).

Semantic Technologies: provide an abstraction layer above existing information technologies in order to bridge and interconnect data, content, and processes. Using semantic technologies, the process of adding, changing and implementing new relationships or interconnecting programs is relatively straightforward. From the portal perspective, semantic technologies can be thought of as a new level of depth that provides an improved, intelligent, relevant, and responsive interaction compared to that available with "classical" information technologies alone.

Virtual Research Laboratory for a Knowledge Community in Production: (acronym VRL-KCiP) Is a virtual Network of Excellence (NoE) established in June 2004, consisting of 27 partners (more than 200 researchers) from 16 different countries that decided to work together and build a knowledge community in the field of design and manufacturing research (www.vrl-kcip.org). VRL-KCiP is financed by the European Commission in the 6th Framework Programme.

Web Service: Is a set of related application functions that can be invoked over the Internet as an integrated part of any program code. Businesses can dynamically mix and match Web services to perform complex transactions with minimal programming. Web services allow buyers and sellers worldwide to discover each other, connect dynamically, execute transactions, and share information (data, knowledge) in real time with minimal human interaction.

This work was previously published in Handbook of Research on Social Dimensions of Semantic Technologies and Web Services, edited by M. M. Cruz-Cunha; E. F. Oliveira; A. J. Tavares & L. G. Ferreira, pp. 357-378, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 4.12
Social Software Use in Public Libraries

June Abbas
University of Oklahoma, USA

ABSTRACT

With the emergence of Web 2.0, libraries have started employing social software applications (such as blogs, tagging, social networking, and wikis) to engage readers, encourage user-contributed content, and connect with user populations in novel ways. However, little research has been conducted on the applications of Web 2.0 technologies within public libraries. This chapter focuses on the applicability of social software in a library setting and examines the use of such innovative techniques as live tagging, social cataloging, and social bookmarking. The chapter evaluates the potential of social software tools for facilitating collaboration between librarians and library patrons; it addresses the concerns expressed by the library and information science community related to the issues of trust, authority, accuracy, responsibility, and ethics in the context of the Library 2.0.

DOI: 10.4018/978-1-60566-368-5.ch040

INTRODUCTION AND BACKGROUND

User-centered philosophies are at the heart of libraries' service and have been in practice long before the emergence of Web 2.0. However, with the advent of the social-interaction technologies, such as blogs, wikis, and social bookmarking, libraries have seen a radical shift as they are now faced with web-users' expectations. These expectations may not be met with less interactive computer technologies, such as library online public access catalogs (OPACs). Libraries have recognized the value that technologies of Web 2.0 can provide to their users and are implementing social software in innovative ways. This chapter provides an overview of social software use in public libraries and evaluates its potential for facilitating collaboration between librarians and library patrons. The author focuses on the applicability of Web 2.0-type technologies in a library setting and presents an overview of social software use in public libraries. Additionally, the chapter addresses concerns expressed by library and information science professionals related to the issues of trust, authority, accuracy, responsibility, reliability, and ethics in the context of Web 2.0, as well as outlines the directions for future research.

Web 2.0

At the base of all social software use is the concept of Web 2.0. The term itself was coined in 2004 by Tim O'Reilly and John Battelle, at a conference on web technologies (O'Reilly, 2005; Anderson, 2007). O'Reilly (2005) defines *Web 2.0* as:

"the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually-updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an architecture of participation".

Abram (2005) expands the philosophy further to include more human aspects of interactivity, such as conversations, interpersonal networking, personalization, and individualism. He explains *Web 2.0* as:

"fundamentally about a transition of the Web site and email-centric world from one that is mostly about information to one where the content is combined with functionality and targeted applications….It's primarily about a much higher level of interactivity and deeper user experiences….characterized by open communication, decentralization of authority, freedom to share and reuse, and the market as a conversation." (emphasis added)

Stephens and Collins (2007) view *Web 2.0* as "the next incarnation of the World Wide Web, where digital tools allow users to create, change, and publish dynamic content of all kinds… to make connections, carry on conversations, and collaborate" (p. 253). They distill Web 2.0 principles to:

- **Conversations:** User participation, discussion and feedback are welcomed and encouraged
- **Community:** Open conversations can lead to a sense of community and belonging
- **Participation:** New information is created via collaboration between users
- **Experience:** Engagement with other users and the community is rewarding and provides some type of fulfillment
- **Sharing:** Users can contribute as much or as little as they like (p. 253)

O'Reilly (2005), Anderson (2007), and McDermott (2007) develop a conceptual framework for the examination of Web 2.0 philosophies and technologies in the context of libraries. For instance, Anderson (2007) emphasizes a need for more serious discussion on Web 2.0 and expands on O'Reilly's "Six Big Ideas" of individual production and user-generated content, harnessing the power of the crowd, data on an epic scale, architecture of participation, network effects, and openness (2005). Anderson suggests a) focusing on both mature social software applications, e.g., blogs and wikis, and new applications, e.g., data mash-ups, which build on earlier applications; and b) investigating web technologies and standards that enable the software applications of Web 2.0, including XML and AJAX (p. 196). McDermott (2007) presents a breakdown of the specific functions of each application as a means to evaluate Web 2.0's potential and uses.

The most commonly used technologies in libraries include:

- Blogs (for example, "What's New" pages; blogs designed for specific user audiences or community outreach programs)
- Wikis (mainly used *within* libraries by library staff)
- Social bookmarking sites such as Del.icio.us, LibraryThing, and photo sharing sites where users can describe books or photos (used to provide book reviews, reader's advisory lists, user contributed subject terms or "tags")
- Open source software (used to develop or enhance library OPACs to allow user comments, reviews, and tagging)
- Social networking tools such as Facebook or MySpace (to notify specific user groups about programs or new resources in the library)
- Podcasting or videocasting (to teach library/information literacy skills; to let users know about new programs and resources; or for guest lectures)

Library 2.0 Timeline

Applications of Web 2.0 philosophies within the library context have been conceptualized as *Library 2.0,* or *L2* for short. The term *Library 2.0* is attributed to a post by Michael Casey in 2005 on his blog "LibraryCrunch." Casey and Savastinuk (2006) emphasize the need for user-centered change, encouraging participation by users in the creation of both physical and virtual library services, and the breaking down of barriers between libraries and users. However, in libraries, as in any other organizational or cultural context, radical trust is required to embrace change. According to Fichter (2006), "radical trust" implies trust within the community, allowing and encouraging users to participate in developing library services. In libraries, one area where the issues surrounding radical trust are seen most is through libraries' use of social software by allowing users to contribute to library OPACs. Librarians are concerned with the loss of authority and accuracy when users contribute content, such as tags, reviews, or comments to library catalog records. However, Abbas and Graham (2006) see this user participation as a means to bridge the chasm between users and library resources. Learning more about user-generated, collaborative content can also inform library and information professionals of new ways to augment past practices and develop new systems and services (Abbas, 2007; Graham & Abbas, 2007; Spiteri, 2007).

Below is a brief timeline demonstrating milestones of social software adoption in libraries. This timeline, however, is not inclusive of all forms of social software, as little documentation is available about the initial use of blogs, wikis, or podcasts in libraries.

Prior to 2003 – 2004: One of the first websites that allowed users to contribute links and sites to newstories was Slashdot, which was developed in 1997. Further sites such as Del.icio.us (developed by Joshua Schachter in 2003-2004), Furl (in 2004), and a host of others (Simpy, Spurl, Raw Sugar) were developed during 2003-2004. The year 2004 also saw the first use of the term *Web 2.0* by O'Reilly and Battele.

2005: *Library 2.0* was coined by Michael Casey and LibraryThing, Flickr, and other social sharing sites were made available on the web in 2005. Users were encouraged to organize and tag their own collections of books, photos, and bookmarks, and to tag and comment on other user's collections as well. The Steve.museum.org tagging project began to explore user-generated tags in museum's online collections. This project illustrates one of the first large scale research efforts to learn more about the feasibility of employing user-contributed tags to index images on the museums' websites.

2006: The PennTags project at the University of Pennsylvania began. The University of Pennsylvania community is invited to tag or comment on library resources within the library's OPAC using a homegrown system developed by the University of Pennsylvania. Library integrated system vendors also begin to integrate tagging, faceted and visual search and classification into library OPACs.

2007: Libraries begin implementing user-contribution features into their library OPACs. For example, in Jan. 2007 SOPAC was developed by the Ann Arbor District Library, which incorporated tagging, commenting, and reviews into the library's OPAC. In May 2007 LibraryThing for Libraries was launched. Libraries could connect their OPACs to LibraryThing using specialized software, that allowed users to provide tags for library resources. Danbury Library, in Connecticut, was the first library to have gone live with LibraryThing for Libraries. As of February 2008, the LibraryThing for Libraries site notes 40 member libraries.[1]

USE OF SOCIAL SOFTWARE IN LIBRARIES

To date, little research has been conducted into the extent, uses, and implications of social interactive technologies in libraries. Abbas, Chen, and Lomax (2007) and Bejune (2007) focused on the use of social software in public libraries. A landmark study conducted by the OCLC Online Computer Library Center (2007), a nonprofit service and research library consortium, presented attitudinal responses from the general public and library directors about the role that libraries should play within social networking. The study also measured the general public and library directors' use of social networking and social media sites, as well as other online habits (e.g., use of commercial sites, search engines, etc.). The results related to the use of social software in libraries are presented below.

Contemporary research on Web 2.0 technologies in libraries appears to be concentrated on the phenomena of "tagging" within social bookmarking and photo sharing sites like Del.icio.us, Furl, LibraryThing, and Flickr. One such study that is tangentially related to libraries' use of social software was conducted by Spiteri (2007), who explored how tags in Furl, Del.icio.us, and Technorati reflect current standards for developing controlled vocabularies (thesauri and subject heading lists).

It is important to note that research on the use of "user-generated content" in libraries began much earlier than the emergence of the concept of Library 2.0. Image retrieval researchers concerned with achieving better access to rich collections of images in contexts such as libraries, archives, art history departments, and newspapers have been exploring the use of user-generated descriptors (user-contributed content) since the mid 1990's to present. Examples include:

- Hastings (1995) had users apply their own descriptions to a collection of Caribbean paintings, and O'Connor, O'Connor, and Abbas (1999) explored the gathering and application of user-defined/supplied descriptors for personal photographs;
- Ornager (1997) and Neal (2006) examined how newspaper journalists requested and searched for images by using captions in newspaper databases;
- Greenberg (2001) examined user-supplied descriptors for business and medical applications;
- Abbas (2001, 2005) explored the vocabulary problem in digital libraries and systems designed for youth, and proposed utilizing most frequently used search terms as user-defined descriptors to build controlled vocabularies;
- Reuter and Druin (2004) used descriptors provided by children for digital picture books in the International Children's Digital Library.

Most of the related literature focuses on defining Library 2.0, as well as presenting the best practices and ideas for using the different technologies in one's own library. The literature demonstrates how libraries can implement proprietary applications that augment existing systems, use open source software, develop their own in-house applications, and integrate currently available social interaction technologies.

Additionally, the literature conveys a number of concerns that members of the profession hold, including acting too abruptly to embrace new technologies before they are fully matured; or, as is the case in many libraries, before their basic web presence has developed. Breeding (2007) sees the current implementation of Web 2.0 technologies as creating "silos of information" or "small containers of isolated information" on a library website (pp. 24-25). As a result, patrons may experience difficulty navigating through library websites to locate the silos that may be present on blogs and wikis pages. Breeding is concerned with the issues of interoperability between systems, as well as the need for the development of common information architecture for library systems. Interoperability issues still remain in the current library automation environment, and Web 2.0 tools have done little to resolve them.

Bejune (2007) presents the first study on the use of wikis in libraries. The study uses the framework of CSCW (Computer Supported Cooperative Work) to examine how libraries and librarians are using wikis to collaborate with each other and with users. Bethune used a sample of 33 wikis identified from a review of library and information science literature, the Library Success wiki,[2] and messages from three professional listservs (LIBREF-L, Web4lib, and DIG_REF). Bethune developed four categories of collaborations using CSCW as a framework. Results of his study (p. 32) demonstrated that the majority of library wikis (77.1%) were used for collaboration among libraries and among library staff within a library (categories I and II). Collaborations between library staff and patrons or between patrons themselves (categories III and IV) were less frequent (22.9%). The results are summarized below.

- Collaboration among libraries (extra-organizational) 45.7 percent
- Collaboration among library staff (intra-organizational) 31.4 percent
- Collaboration among library staff and patrons 14.3 percent
- Collaboration among patrons 8.6 percent

Further examination of library wikis reveals that the majority of the wiki sites analyzed by Bejune were hosted by academic libraries (19 out of 33), including 1 public library, 1 school library media center, 3 professional library associations, 2 wikis related to professional conferences, and 3 associated with either national or state-wide digital library projects. While Bejune's study is by no means exhaustive, it does provide a useful framework to study the application of wiki technologies within the library community. Bejune also presents some ideas on why wikis are used more in categories I and II rather than in III and IV. For example, librarians are accustomed to collaborating with each other within their organization or between libraries. Reasons for low use in categories III and IV include: (1) libraries are perceived by users as repositories of resources, not places for collaborative work; (2) there may be concerns within the library community about authority, responsibility, and liability; (3) wikis may be better suited for activities in categories I and II; and (4) wikis are still new technologies. Librarians may be experimenting within "safer contexts" before trying more public projects (p. 32-34).[3]

OCLC Study of Attitudes toward Social Software Use in Libraries

To learn more about online habits, social software, and social media site use by the general public and library directors, OCLC (Online Computer Library Center) conducted an online survey of 6,163 members from the general public of Canada, France, Germany, Japan, the U.K., and the U.S.

Researchers also surveyed 382 U.S. library directors. The findings illustrated the use of social interactive technologies in libraries worldwide. The survey also uncovered many telling features related to the attitudinal views of the general public and library directors related to social software use in libraries. The study did not measure the actual use or implementation of social software within libraries, since few libraries were actually using social software at the time. The key attitudinal points were identified as follows:

- The general public does not currently see a role for libraries in the social networked world
- 6% of the general public answered that they were very likely/extremely likely to describe their collection on a library social site
- 5% of the general public would share videos/photos on a library social site
- 13% of the general public would like notifications when new items were added to the library
- 8% of the general public would share ideas with library staff about services
- 6% of the general public would participate in online discussion groups or use library social sites to meet others with similar interests
- 14% of U.S. library directors considered building social networking sites for their communities (OCLC, 2007, pp. 5-1 – 5-5).

In an effort to ascertain the implementations and use of social software within libraries and museums, Abbas and colleagues have been conducting a census of social software use and tagging in libraries and museums. Preliminary findings of this research were presented at the 2007 annual meeting of the American Society for Information Science & Technology (ASIST) during a panel session on tagging activities in libraries, newspapers, and education (Abbas, Chen, & Lomax, 2007). The sampling frame, method, and preliminary findings of this ongoing study are presented below. The study is currently examining the extent of use of all types of social software within libraries.

Sampling Frame and Research Method

To gather a sample of libraries (public, academic, school, and special), a directory of library web sites and catalogs (lib-web-cats) was utilized. [4] The lib-web-cats directory is a searchable database of over 32,000 libraries worldwide developed by Marshall Breeding, the Jean and Alexander Heard Library's director for innovative technologies and research at Vanderbilt University in Nashville, Tennessee. The directory contains links to each library's website and online catalog, information about the library type, geographic location, address, current and previous library automation systems used, size of the collection, and also presents the most exhaustive source of information on libraries. At the time of the study, the site included information on 16,887 public libraries in the U.S. In addition, research literature on libraries and tagging was reviewed and all websites listed there were visited.

Libraries were selected by state from within the U.S from the lib-web-cats database. To provide a random sample, every tenth library site was accessed. Data was gathered on types of social software being used by the library, whether or not the library allowed users to tag or create content on their website, any specific uses noted, audiences/users targeted by the technology, type of library, location, as well as issues with accessing or locating the social software within the library's website. The data were gathered in a Microsoft Access database and notes about access issues and other relevant information about each site were recorded in a spreadsheet.

Preliminary Findings

As mentioned above, since this is an ongoing study, the findings presented reflect the study as reported in 2007 and only focus on use of social software and tagging within libraries.

A total of 70 sites were reviewed for this analysis. Of that sample, it was found:

- 70% of the total sample of libraries and museums (49 out of the total sample reviewed) included some mechanism for tagging on their website
- 81% of the public library sites reviewed (30 out of 37 total public library sites) included some mechanism that allowed users to contribute tags to their library
- 76% of the academic library sites reviewed (13 out of 17 total academic library sites) provided user tagging, and
- 37.5% of the museum sites reviewed (6 out of 16 total museum sites) included user tagging.

Tagging in libraries was found to employ different methods of social cataloging, live tagging, and social bookmarking, described in detail below.

Live Tagging and Social Cataloging

Some libraries allowed users to contribute their own subject terms or tags directly to online public access catalogs (OPAC):

- Tags appear on records in the library's OPAC catalogs
- Users can choose from a tag cloud, e.g., "500 Most Popular Tags," "Top 10 Tags" or "10 Most Recent Tags"
- Users have access to customer reviews
- Users are offered cooperative bookmarks such as "Customers who checked out this item also checked out…"

Only the Ann Arbor District Library, SOPAC, and two academic libraries, the University of Pennsylvania, and Midlands Technical College in South Carolina were employing live tagging at the time of the study.

Libraries can utilize LibraryThing services as follows: (a) they can link directly to their LibraryThing account where users can view a tag cloud of tags used by the library; (b) with LibraryThing for Libraries, the library's OPAC is integrated with LibraryThing.

- Users can search by tags through a special "Tag Browser"
- Tags are imported from LibraryThing
- Users of the OPAC catalog cannot directly add their own tags.

At the time of the study, the Danbury Public Library, in Connecticut, was the only public library employing LibraryThing for Libraries, and no academic libraries were using LibraryThing.[5]

Social Bookmarking

Libraries use social bookmarking sites to organize online resources for their patrons. Typically, there is a link to the Del.icio.us page from the library's website, though few libraries in the sample linked back to the library's website from their Delic.io.us site. Delic.io.us was also used by libraries to set up online reading lists for their users. This social bookmarking site was the most popular technology in use–80% of all public libraries in the sample that provided mechanisms for tagging used Delic.io.us. Academic libraries also used Del.icio.us, but preferred more academic-centric social bookmarking sites, e.g., Connotea and CiteULike.

FUTURE TRENDS

As mentioned above, there is little research focused on the adoption and applications of Web 2.0 technologies within public libraries. The research by Bejune and Abbas provides a useful framework to study this issue in greater depth. The OCLC study offers valuable insights into the attitudinal views of both the general public and library administrators on the role of libraries in the social networked world. For now, these views do not overly support the adoption of social interactive technologies, although the findings encourage libraries to do so. More research into the extent of use, motivations for use, and feasibility of using each novel technology is needed.

The social and organizational aspects of implementing and utilizing Web 2.0 technologies in libraries should also be addressed. The literature illustrates the concern that library and information professionals express about issues of trust, authority, accuracy, responsibility, reliability, and ethics related to employing Web 2.0 tools. These discussions also raise the question of whether or not library and information professionals believe the critical tenants of librarianship are being challenged when libraries encourage collaboration and contribution by their users in this novel, ever-changing environment. Overall, several areas of interest within the library and information science (LIS) community relating to future research of social software have been identified (Graham & Abbas, 2007): (a) the long-term success of social software and tagging in practical and scholarly use, (b) specific use in scholarly environments, (c) effect on LIS practices of annotation, cataloging, and indexing and abstracting, (d) effect on LIS education, (e) scalability within systems, and (f) continued support and participation by users.

CONCLUSION

Social software deployment in libraries is an important phenomenon that requires further study. As more libraries begin to use social interaction technologies, more research into practical, social, organizational, and professional issues encountered by the library and information science community is needed so that libraries can make informed decisions about whether or not to use social software. While it is beneficial to hear success stories to garner ideas for augmenting library services, there are still technological and ethical issues needing exploration. Web 2.0-based applications can offer much to libraries, and while the philosophies of Web 2.0 and Library 2.0 may refresh and advance the thinking of the profession, their adoption should be looked at with an eye for outcomes and usefulness, and not on the threat of being outmoded.

KEY TERMS AND DEFINITIONS

Blog: Short form of the word *weblog*. Blogs are online interactive journals or newsletters. Readers are encouraged to post comments and to engage with the author and other readers. Blogs can include other Web 2.0 technologies, such as RSS feeds, podcasts, videos, and tagging.

Library 2.0: The application of the Web 2.0 technologies and philosophies within the library context to improve or provide new services to user communities.

OPAC: A library's online public access catalog that provides access to the services and collections of a library.

Social Bookmarking: Web environments that provide users with the means to organize, describe, and share their resources (web bookmarks, books, and photographs) with others. Sites such as Del.icio.us, LibraryThing, and Flickr are examples.

Social Networking: A Web 2.0 service that provides users with a platform to set up personal spaces online to share information, music, software applications, etc.

Social Software: Web 2.0 technologies used to communicate, share, organize, collaborate, and extend functionality of other web applications. Blogs, wikis, social bookmarking, and social networking technologies are examples.

Tagging: Providing terms to describe resources in a social bookmarking environment. Tags can be used to sort, retrieve, and find the resources by the tagger or others that use the site. Tagging is also referred to as *user-generated descriptors* or *user-contributed content*.

Web 2.0: Using the World Wide Web as a service-oriented platform to connect devices, protocols, standards, and applications. The Web 2.0 philosophies include: rethinking how software is developed and distributed, and enabling more human connections through conversations, collaboration, participation, and exchange of ideas and technologies.

Wiki: A collaborative website that provides a platform for users to contribute, edit, or remove content.

Chapter 4.13
Social Computing:
Implications for E-Government

Rhoda C. Joseph
The Pennsylvania State University Harrisburg, USA

Jose Esteves
Instituto de Empresa Business School, Spain

ABSTRACT

This article examines the area of social computing and its implications for electronic government (e-government). Social computing is a broad term that refers to different products and services that supports human interaction in a computer mediated environment. Terms such as online communities, peer networking, and social software have overlapping meanings with social computing (Parameswaran and Whinston, 2007). E-government refers to the delivery of government services via information and communications technology to citizens, businesses, employees, government agencies and special interest groups. In this article we present a theoretical model for the application of social computing in the area of e-government and we use an analysis of state websites to assess the extent of social computing development in the e-government domain. Our findings indicate that social computing is in its infancy in e-government applications. We make recommendations and analyze the potential value and challenges of social computing in e-government.

IINTRODUCTION

Social computing refers to a variety of web-based products that allow individuals to interact with each other in both synchronous and asynchronous environments. Social computing is demonstrated through means such as online communities, virtual games, newsgroups, and online chats. In May 2006, approximately 74% of United Stated internet users visited a social networking site (comScore, 2006).

The prominence and popularity of government websites is minuscule when compared to social computing environments. In the global arena, many countries have undertaken ambitious e-government projects to interact with their constituents. The four main constituents interacting with governments are citizens, employees, businesses, and other governments. Globally, e-government has advanced at different rates and varies depending on the level – local, country, or region. The global e-government leaders, identified by the United Nations (UN) e-government readiness index are ranked as 1.Sweden, 2.Denmark, 3.Norway, 4.United States, and 5. Netherlands (UN E-government survey, 2008). The e-government readiness index is a composite value that includes components for the country's telecommunications infrastructure, the stage of e-government development, and the human capital index (adult literacy and gross enrollment ration) (UN E-government survey, 2008).

Social computing provides an avenue to take e-government to the next level of development. In this article we explore the value of incorporating social computing capabilities into e-government initiatives. As e-government advances, interactive components can enhance user involvement. This study presents a theoretical framework for inclusion of social computing in e-government projects. We then use state websites to examine the current level of adoption of social computing in e-government, and present recommendations for future research projects. The aim of this study is to fill the gap in the existing literature with respect to the application of social computing in the domain of e-government.

SOCIAL COMPUTING

Social computing is a broad term that refers to different products that support human interaction in a computer mediated environment. Terms such as online communities, peer networking, and social software have overlapping meanings with social computing (Parameswaran and Whinston, 2007). Social computing incorporates tools such as threaded messages, blogs, and wikis for individuals to share information (Neumann, Hogan, and MacDonaill, 2005). Additionally, virtual worlds, social networks, multi-player games, and newsgroups are also examples of social computing. Social computing is different from traditional face-face social environments because it is: "mostly decentralized, highly dynamic, highly transient, fluid boundaries, rich content, highly mobile, very highly scalable (Parameswaran and Whinston, 2007 pp.338)." Globally, six of the ten most popular websites are social computing environments (Alexa, 2008), for the list of top ten most visited websites see Table 1.

The term "blog" derived from the term weblog, is typically a website where an individual makes periodic entries. A blog is defined as a website with dated entries – or "posts" – in reverse chronological order, written by a single author or a group of authors, often accompanied by links to other blogs that the site's editor visits on a regular basis, in order to allow for further exploration of the sources. In many cases, those frequently visited pages are grouped in a list of favorites or "blogroll". Each post usually allows for comments, and can also provide an instrument to "track back" or back link posts in other blogs that refer to the original one. With these instruments, visitors can not only follow a specific blog, but also expand their sources to other blogs that link to or are linked from the first one, forming a web of related blogs.

Early blogs were started by web enthusiasts who would post links to "cool stuff" that they found on the Internet. They added commentary and began posting daily. They read and linked to each other's blogs. In this sense, Kumar et al. (2004) affirm that blogs tend to be quirky, highly personal, typically read by repeat visitors, and provide an inside into a very active community. Vogelstein (2005) identifies blogging technology as among the top "10 tech trends to watch in 2005" by Fortune magazine. Ashley (2002) mentions

Table 1. Global top 10 websites

Website	Description
1. Yahoo (www.yahoo.com)	Personalized content and search options. Chatrooms, free e-mail, clubs, and pager.
2. YouTube (www.youtube.com)	YouTube is a way to share videos.
3. WindowsLive (www.live.com)	Search engine from Microsoft.
4. Google (www.google.com)	Search engine.
5. MySpace (www.myspace.com)	Social networking site.
6. Facebook (www.facebook.com)	Social networking site.
7. Microsoft Network (www.msn.com)	Content provider
8. Hi5 (www.hi5.com)	Social networking site.
9. Wikipedia (www.wikipedia.org)	An online collaborative encyclopedia.
10. Orkut (www.orkut.com)	Social networking and discussion site operated by Google.

that blogs and their model of content production and platform interoperability are proving to be increasingly useful and powerful, inspiring innovative developments and uses for the web. The power of blogs is their ability to immediately put form to thought, and in seconds, share it with the world.

From a historical perspective the earliest social computing initiatives were USENET newsgroups of the late 1970s (Reid and Gray, 2007). Online newsgroups provide an asynchronous environment for users to share information via posted messages. Online newsgroups allow users to create threads for new messages, and also respond to comments posted by other users. Recently, the increase of synchronous methods for online interaction such as chat, has resulted in a steady decrease in the use of online newsgroups (Zaphiris and Sarwar, 2006).

Wikis are open content material that are editable by all members of the community (Neumann et al., 2005). Wikipedia is the best know wiki with over six million articles in over two hundred and fifty different languages (Orr, 2007). Due to the open nature of Wikipedia the accuracy of its content is sometimes questioned, however a recent study by *Nature* journal indicated that for any article, Wikipedia's content had approximately four errors while Encyclopedia Britannica had three errors (Giles, 2005). A controversy naturally ensued as Britannica vehemently disputed the study's results (EncyclopaediaBritannica, 2006). In a business context wikis provide an opportunity for collaborations, but they also increases vulnerability to web site vandalism and destruction of intellectual property (Wagner and Majchrzak, 2006-2007).

Virtual worlds such as Second Life represent another dimension of social computing. Second Life users create a digital persona and engage in activities akin to those of the real world. Second Life members engage in activities ranging from financial transactions to networking with other members. Businesses and institutions such as IBM, Dell, Cisco, Nissan, National Public Radio, Harvard Law School, and Emory University all have created a virtual presence in Second Life (Bray and Konsynski, 2007). Virtual worlds represent a "resort economy" where people use real money to consume virtual products and everyone is "having a good time" (Noam, 2007). Unfortunately, social, legal, ethical, and political ills of the real-world can also encroach into virtual worlds.

A social network is broadly defined as a group of individuals connected by a set of relations

(Downes, 2005).Online social networks, such as Myspace, Facebook, Friendster, and HiFive provide a platform for users with common interests to share information with each other. In 2005 there were over 300 known social networking sites online (Reid and Gray, 2007). The popularity of social networking sites has ignited research interest in the current academic literature (Charnigo and Barnett-Ellis, 2007; Neumann et al., 2005; Reid and Gray, 2007). Online social networks serve as a complement or extension of the user's real-world life since many users in online social networks interact in an off-line environment (Charnigo and Barnett-Ellis, 2007).

Massive Multiplayer Online Role Playing Games (MMORPGs) such as Everquest (www.everquest.com) and World of Warcraft (www.worldofwarcraft.com) represent another dimension of social computing. The main difference between MMORPGs and other social computing environments is that there is usually an explicit plot for users in the former, while the later does not (Bray and Konsynski, 2007). MMORPGs are designed for entertainment purposes, but they also represent a world where users can become immersed into the life of their virtual persona. It is estimated that Korea has over half a million online game addicts, and the government is trying to combat the problem by conducting annual surveys and providing counseling services (Ihlwan and Jacobs, 2006).

Web 2.0

Web 2.0 services, facilitate interactivity and fluid boundaries between users and developers (O'Reilly, 2005). O'Reilly, the originator of web 2.0 also identifies companies such as Flickr and Napster and items such as blogs, wikis, cost per click, and search engine optimization, as examples of what characterizes web 2.0 and differentiates it from web 1.0. Open source applications are also driving the development of web 2.0 applications (Gupta, 2007).

Web 2.0 encompasses a wide range of products, services, and applications and is not constrained by a single static definition. Businesses recognize the value of web 2.0 applications and are harnessing available opportunities. RSS (real simple syndication) is another web feature associated with web 2.0. RSS allows users to subscribe to their favorite sites and receive information every time the site is updated. The international investment bank Dresdner KLeinwort Wasserstein has successful implemented wikis which replaced intranet pages, and are used for project development and information sharing by approximately 2,500 employees (Orr, 2007). Web 2.0 applications can also have negative social implications for the business world. Recently, companies like Delta, Google, and Microsoft have terminated employees that published disparaging comments about the company on blogs (De Piante, 2007).

E-GOVERNMENT

E-government refers to the use of information and communications technologies (ICTs) by governments to interact with citizens, employees, businesses, and other government agencies. E-government is generally classified into different groups based on the primary stakeholder (citizens, employees, businesses, governments) that is interacting with government. The main e-government categories are government-to-citizen (G2C), government-to-employee (G2E), government-to-business (G2B), and government-to-government (G2G); with G2C as the most dominant area of interest to both developers and researchers.

The goals of e-government projects range from providing increased services to citizens to reengineering internal business processes. The e-government platform introduces an alternative medium for citizens to interact with government. Successful e-government projects can improve strategic planning, reduce costs, and also improve relationships between management and employees (Ruël, Bondarouk, and Looise, 2004). E-government projects can be implemented at different levels including country level, federal level, state level, and local level.

Several different researchers (Andersen and Henriksen, 2006; Layne and Lee, 2001; Murphy and Shleifer, 2004; Siau and Long, 2005) have defined models to explain the growth of e-government. Layne and Lee's 2001 model describe four stages of e-government development: cataloguing, transaction, vertical integration, and horizontal integration. A second model (Ke and Wei, 2004), identifies three sequential phases for the development of e-government projects: initiation, infusion, and customization. Andersen and Henriksen (2006) identify four stages: cultivation, extension, maturity, and revolution. Siau and Long (2005) used a meta-synthesis of other e-government models to create a newly synthesized model with four stages: web presence, interactions, transaction, and transformation. The common theme across the e-government development models show e-government as an evolutionary process, typically with early stages of static web-pages that leads to more advanced stages with interactivity and political participation.

E-Participation

As governments move online, a major objective is for citizens to access the services that are available. E-participation serves as an umbrella term for user involvement in online activities. In terms of e-government, e-participation can involve activities such as using government services, online polling, online voting, and attending online meetings. *E-political participation* addresses online participation in political activities ranging from information searches to political activism. Further, users that participate in online social and economic activities have an increased likelihood of participating in e-political activities (Shelley, Thrane, and Shulman, 2006). Demographic factors such as higher education and youth (Shelley et al., 2006) are also positively correlated with e-political participation. Although teenagers and senior citizens select divergent topics in online social groups, politics is the one theme that is captured across both demographic groups (Zaphiris and Sarwar, 2006). Interestingly, e-political participation does not necessarily translate into actual off-line political participation in activities such as voting.

In 1999 over 100,000 supporters used blogs and the social networking site Meetup as part of the presidential campaign for Howard Dean (Reid and Gray, 2007). In 2008 presidential candidates Hillary Clinton, John McCain, Barack Obama, and Ron Paul (listed alphabetically) all used social networking sites to generate support for their campaigns. The number of Facebook supporters listed for each candidate was: Clinton-143,529; McCain-106,410; Obama-341,270; Paul-84,365 (Facebook, 2008).

THEORETICAL FRAMEWORK

Social computing provides a new area for development and expansion of e-government initiatives. Each area of e-government: G2C, G2E, G2B and G2G, can be impacted by social computing. Social computing can be used instead of paper forms to manage feedback from citizens to government agencies (Bevarly and Ulma, 2007/2008). Online communities have traditionally been anonymous (Parameswaran and Whinston, 2007), but today many users see anonymity as optional. Whether anonymous or not, social computing provides a platform for stakeholder involvement with e-government. We propose that social computing will impact e-government in two main areas: communication type and interaction level. Communication type refers to whether social computing is occurring in a synchronous or asynchronous mode. Interaction level refers to whether e-government facilitates interaction with stakeholders through their participation or through the implementation of government regulation. Participation refers to actions initiated by the user, such as chatting or posting a message. Regulation refers to actions initiated by government such as tickets, and fines. Figure 1 represents the theoretical framework for this study.

An e-government project can provide the platform for virtual meetings with citizens, employees, and businesses. The town of Cary, North Carolina has used the web to post detailed staff reports and also interactive components such as online surveys and discussion boards (Bevarly and Ulma, 2007/2008). As e-government services expand, fully operational virtual meetings can add another dimension of interactivity to involve different stakeholders in democratic processes. Employees at different levels can also benefit from the introduction of virtual meetings. As an e-government project matures, horizontal integration - linking different functional agencies, and vertical integration – linking different levels of government (Layne and Lee, 2001) can utilize virtual meetings to support a geographically dispersed workforce.

From an e-government context, virtual communities can also be used to foster community spirit and encourage participation in community activities. The focus of virtual communities has shifted from technology developments to usage, with individuality vs. community membership as an emerging theme (Jakala and Pekkola, 2007). At the local government level, virtual communities can provide an additional environment for individuals that already know each other to foster stronger community ties. However, one concern is that negative real-world influences can also be incorporated into virtual communities.

Online virtual worlds present a unique opportunity for government interaction through e-government. Virtual communities such as Second Life use real money for virtual transactions (Noam, 2007). The implications of such transactions indicate that there are real taxes that can be generated from virtual communities and the possibility of entities using virtual worlds as tax shelters (Bray and Konsynski, 2007). As the e-government platform matures federal, state and local governments can integrate functions into virtual worlds to collect taxes. Government regulation in the real-world involves financial penalties for traffic violations, property violations, misdemeanors, felonies, and other illegal activities. Since many real-world businesses have already assimilated into virtual environments, government involvement can be the next frontier.

Figure 1. Theoretical framework – social computing in e-government

INTERACTION LEVEL / COMMUNICATION TYPE	***Participatory***	***Regulatory***
Synchronous	-Chat -Virtual Community Eg: community meeting	-Chat -Eg: Issue citation
Asynchronous	- Message Board - Blogs Eg: community forum	-Forum Eg: post codes of conduct

METHODOLOGY

This study examines the websites of the fifty states in the United States (U.S.) for evidence of social computing. This is an exploratory study and we use only the state governments' website to examine for the social computing constructs. We used a bimodal variable where yes=1 and no=0 for the presence of each item found. Each website was examined until it led to an external site. An external site is considered to be any site outside of the main e-government page. Examples of external sites include universities, businesses, non-profit organizations, and any other entities that are accessed from the government page. The primary page that was accessed was the United States government page (www.usa.gov/Agencies/State_and_Territories.shtml) that then provided links to the official state web pages. Each state website was examined for the following eight components: chat, message boards, virtual communities, forums, blogs, wikis, RSS, and other (representing any *other* or novel approach to social computing)

To conduct a search for the above listed items we accessed the states' websites. While on the page we traversed each section for evidence of the above listed items. We also used the pages' internal search engine and submitted each of the above options as part of a key word search. The list of the fifty sites visited is available in Table 2. All data was collected over a two-week period in the spring of 2008.

RESULTS AND IMPLICATIONS

The websites of all fifty states in the United States (U.S.) were examined for the presence of social computing components. This section presents the results of the data analysis and discusses its implications. Of the fifty sites examined 34% contained a chat feature. In all instances the chat feature was used to provide live help to visitors of the website. Interestingly, the live help chat feature was usually provided as a service on the website, but affiliated with the public library system. Only one site provided a feature that looked like a message board. The site allowed people that lived in the state to comment on personal experiences while living there. A note on the site indicated that all comments will be reviewed by an administrator before being posted on the site.

Only two sites provided the opportunity to participate in a virtual community. The two sites allowed users to link to external sites and participate in a virtual community. One state allowed its residence access to a Facebook group where they can communicate about the state. The second site allowed users to participate in a social group to quit smoking. Neither of the two virtual communities identified were sponsored by the official government site. They however, are relevant to this study since they were both accessed from the state's primary e-government page.

Blogs were identified on 18% of the state pages examined. The contents of the blogs identified were associated with the following: 1.activities of the state's governor, 2.travel and tourism experiences, and 3.small business initiatives of the state council. The blogs were accessible for all visitors of the website. Lastly, the most common component identified on these sites was RSS. Of the 50 websites, 56% allowed visitors to subscribe for an RSS feed. RSS is a proxy for web 2.0 services that are available on the website.

As outlined in the earlier sections of this article, there are many potential benefits of incorporating social computing into e-government projects. However, as with any emerging technology there are opportunities for abuse. There can be unintended adverse effects associated with the use of social computing in e-government. Anonymous leaks can be used to disseminate confidential information and make unauthorized disclosures of government information (Swartz, 2007). However, in the sites examined, there was very limited use of social computing components. The few sites that

have adopted social computing initiatives as part of their e-government platform seem to be very cautious and conservative in their approach.

LIMITATIONS AND FUTURE DIRECTIONS

This study is exploratory in nature and provides a template for the examination of social computing in the emerging area of e-government. The study provides a theoretical framework for the inclusion of social computing into the e-government landscape, and uses state e-government websites for analysis. However, the main limitation of this study is the small sample size. Examining only fifty websites makes it challenging to generalize the findings to a generic e-government environment. A further study will require analysis of a much broader sample including local e-government sites such as cities, counties, and municipalities.

E-government website administrators and developers can also be interviewed to determine if social computing is part of the future agenda on the e-government site. As part of a future study, we can further examine how sites intent to use social computing, and what factors are supporting or hindering the use of such initiatives. One concern however, is that once social computing is incorporated into e-government, politicians can exploit the existing networks by influencing the community through establishing ties with the network's leadership (Murphy and Shleifer, 2004). This type of behavior is already prevalent in real-world settings so transference to social computing will not be entirely shocking. An empirical investigation of political influence through social computing is another area for further examination.

CONCLUSION

This study contributes to the growing literature examining social computing. The specific context examined is the emerging area of e-government. We use the fifty U.S. state e-government websites to examine the presence of social computing. The results of this study indicate that social computing is very new in the area of e-government. As e-government develops, social computing can be incorporated to support participation of citizens in government activities.

Globally, e-government is an emerging phenomenon and is in different developmental stages. The primary manifestation of e-government projects is through an official government website typically represented with a ".gov" extension. Social computing tools can be a valuable addition to e-government sites to increase both usage and visibility. However, some inherent challenges associated with site management and accountability can occur. Important questions pertaining to who will monitor and edit the content on e-government social computing sites also need to be addressed as developments occur. As with any emerging technology, initial capital expenditure by the government entity may also prove to be a limiting factor.

Social computing combined with e-government represents an exciting new frontier for exploration by both developers and researchers. E-government administrators can use the social computing platform to attract users to their sites. From the research perspectives, this area represents fertile soil for research projects ranging from usability studies, adoption facilitators and inhibitors, firm level impact, and individual behavioral components.

Chapter 4.14
Designing for Disaster:
Social Software Use in Times of Crisis

Liza Potts
Old Dominion University, USA

ABSTRACT

Using the London Bombings of 7 July 2005 as a case study, this paper illustrates the need for sociotechnical interventions in systems design. By employing Actor Network Theory the author makes visible the active participants and technologies within the ecosystems of social software. Such visiblity provides insight to the designer seeking to optimize communication systems in the wake of disaster. Guidelines for improving systems and user interfaces based on disaster scenarios are described.

BRIDGING THE SOCIAL AND TECHNICAL WITH ACTOR NETWORK THEORY

The rapid development of people-powered communication tools—cell phones, digital cameras, blackberries, laptops and their accompanying software, wikis, Facebook, My Space, and blogs have created a dynamic, constantly evolving space where ordinary people can communicate almost instantly. Moreover, the ability to easily place links and send data means that these dynamic sites weave themselves into an endlessly shifting web of interconnected references and allusions.

These Information and Communication Technology (ICT) systems have evolved amidst a tumultuous period of crises and disasters affecting millions. The urgency of upheavals—be they natural disasters or terrorist events—has spurred on the rapid creation and transformation of communication tools. Online social software, in particular, has a participatory culture that has responded to events in ways that add to and even circumvent traditional media channels. Our methods as designers of ICTs have not kept pace with the rapidly evolving technologies and the communities they support. In this paper, I propose a sociotechnical approach that can optimize these systems based partially on a previously published conference proceeding (Potts, 2008b) and my unpublished dissertation (Potts, 2007).

The acid test of sociotechnological design might just be the minutes, hours, and days after a natural or manmade disaster. Researching how people find and exchange information, share links, and offer support during these events can yield a more complete, detailed, and accurate understanding of how individuals communicate in response to terrorism, hurricanes, tsunamis and other crisis situations. Extending the sociotechnical discipline further by encouraging designers to become active participants within the activities they are trying to design for will lead to more robust systems that can mediate communication between participants. However, you cannot optimize that which you cannot recognize, and that is why finding a means to map situations and players is the essential starting point for improving design.

Actor Network Theory (ANT) offers an excellent method by which designers can begin to make visible and respond to social software ecosystems. ANT's creator, Bruno Latour, noted that his method should be used when "boundaries are . . . terribly fuzzy," since other social theories do not work so well when "things are changing fast," and this certainly describes the post-bombing activity on the internet (Latour, 2005). The major tenet of ANT is that all participants, whether they are human or non-human, have equal agency to affect any given situation. These participants are referred to as "actors," and they can be people or technologies. Actors come together to form a network, creating assemblages of relations, which are often temporary and specific to an individual action or a broader event.

Understanding this concept allows designers to see a landscape of participants—human or technological—who cooperate to create, validate, and share information. Illustrating these scenarios as well as finding the pathways taken by the participants of these social software systems will help designers rethink their current strategies for design and contextual use. Researchers have used ANT to reconsider the design of Common Information Spaces (CIS) with regard to Computer Supported Collaborative Work (CSCW) (Rolland, Hepsø, & Monteiro, 2006) to bring to light social issues within technology design (Berg, 1998), to understand emergence and diffusion of technology (Bruun & Hukkinen, 2003), to explore sociopolitical frameworks for user-centered design (Spinuzzi), and to support application development (Mackay, Carne, Beynon-Davies, & Tudhope, 2000; Tatnall & Gilding, 1999).

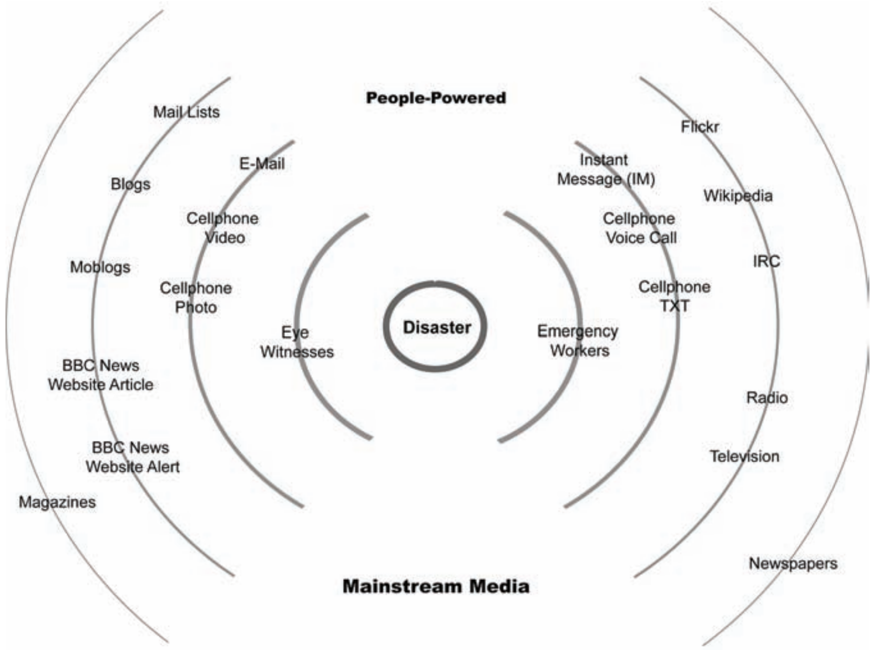
While I am not suggesting ANT as an "answer" or an end point for better social software design, I am claiming that it will provide designers with a methodology for leveraging their own participation, to gain insight into technology and its cultural use. In other words, it enables designers to see the social and the technical elements of systems including ephemeral, shifting, and expanding systems for which they are designing.

EMERGENT SOCIAL SOFTWARE ECOLOGIES

Over the last few years, social software such as blogs, wikis, and media-sharing sites have provided an outlet for people to share and distribute information. Some of these tools are already deployed, others are modified as disasters unfold, and a few are created as a result of the disaster.

The diagram in Figure 1 captures the sociotechnical context of an event. While this diagram

Figure 1. Sociotechnical ecosystem that must be made visible to design optimized systems



approximates disaster response generally, it draws on the specific ecosystem around the London Bombings of 7 July 2005. I cannot capture all of the ecosystems' participants, let alone represent Michael Callon's "mass of silent others," (Callon, 1987) the lurkers; nonetheless, this diagram offers a fairly comprehensive representation of the post-bombing communication activities (Law & Mol, 2003). This diagram illustrates emerging social software and traditional media systems as they extend outward from the center of a disaster. This figure deploys three principles Callon identified as crucial for regarding humans and technologies equally: agnosticism, symmetry, and free association (Callon, 1986). Agnosticism refers to examining human and non-human actors equally, with priority given to neither the technology nor the social issues surrounding them. Thus, technology and people are regarded as equal agents of action, and symmetry enforces the use of the same language to describe the actions of either humans or technology. Free association requires that such distinctions between humans and technology cease. This concept confronts both technological determinism and social constructionism. Two researchers who examined ANT as a methodology for examining information systems states that "we think in binaries which often leads us to designate an entity as either technological or social, and then we attribute specific properties to that entity in order to explain its behavior, thereby, adopting an essentialist position" (Tatnall & Gilding, 1999, p. 957). ANT seeks to avoid those binaries by equally granting agency and using similar language to describe the actions of these actors.

Adhering to these principles helps ensure that we use the same language to discuss how these actors are employed during an event and that we consider them on equal footing such that we can create a sociotechnical system optimized for exchanging information during a disaster. Closest to the center are humans who are direct participants in the event. Reverberating outward are the multitude of person-to-person (P2P) technologies typically used by those affected in the immediate area of the event or by those who have a stake in the outcome of the disaster. Farther out, the next layer includes social software and traditional media channels that distribute information to different community members. The outer layer includes the least effective tools for immediate communication, such as traditional newspapers and magazines with longer to-market schedules. The nearer to the center an actor is, the more effective and immediate communication to and from this actor will be during and immediately following a disaster.

The remainder of this paper will uncover and trace through the lens of ANT how those active participants are able to coordinate information (Callon, 1986). This can be quite complex. For example, take the case of an actor posting an image to Flickr in the wake of a disaster. Another actor sees the image, recognizes it as her son, and posts her recognition on Flickr. According to ANT, this single communication act contains at the minimum six actors: Flickr, the poster of the image, the mother who posts a comment, the son in the image, the camera that took the image, and the terrorists who caused the disaster in the first place. Once these communication exchanges are made visible, completely new associations can be seen and traced further. ANT reveals these traces, allowing the actors to instruct the designer on what these connections might mean. Such involvement makes the designer aware of and socially engaged in how everyday people are employing these communication tools. These insights will aid designers in creating future communication tools based on real-world participant activities.

CASE STUDY: LONDON BOMBINGS OF 7 JULY 2005

Designers can neither create new systems nor optimize current tools if they do not recognize how people are currently using these systems. When we understand the sociotechnical context and visualize it, we can begin to optimize these systems and design for flexibility to support cultural change and technological improvements.

On 7 July 2005, London's public transport system was attacked by a series of suicide bombings that killed 52 and injured over 770 people. The attack occurred during the morning rush hour, and many of the victims were commuters toting communication devices, such as cell phones, blackberries, and laptops—the newly indispensable tools of their trade. As the crisis unfolded, these victims and bystanders were poised and ready to exchange information with unprecedented detail and speed. Directly after the bombings, participation on social software websites spiked as commuters snapped photos with cell phones, posted to their mobile blogs ("moblogs"), and swapped questions, news items and links to more relevant information.

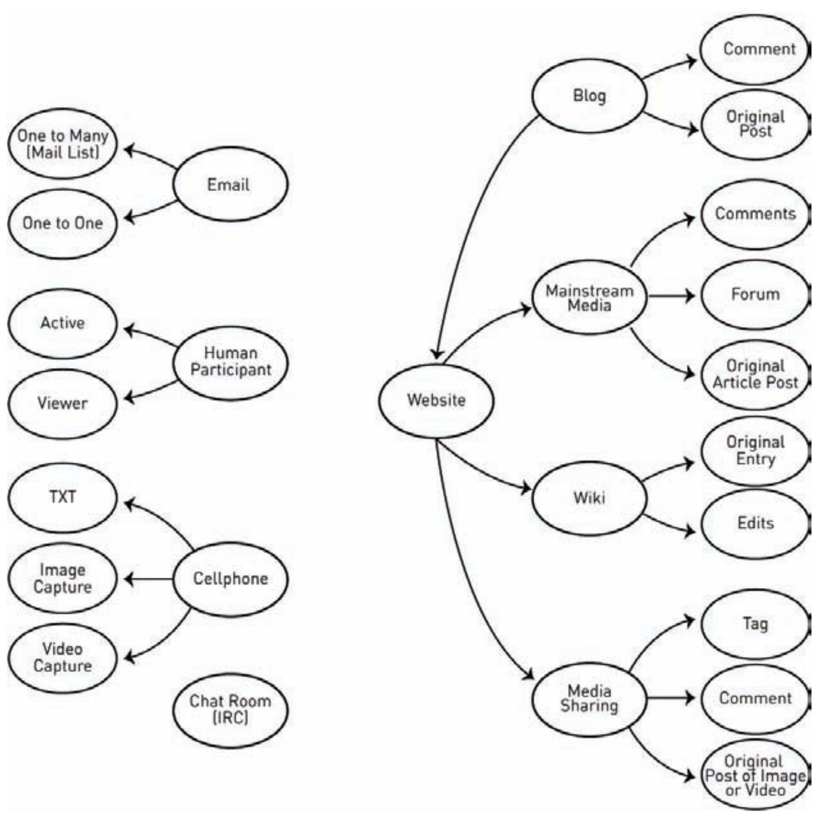
Unlike earlier, static websites, social software is a participatory medium; people are able to create and shape experiences using available tools such as "tagging" and distributing images on Flickr, a photo sharing site; or linking content from one site such as the BBC home page, to another, such as a Facebook page. These instances of swapping or linking across different software systems and sites are the use cases that are in need of a sociotechnical-inspired response. The online situations I observed after the London bombings were in constant flux, and multiple participants usually originated them across multiple sites rather than by a single author on a single site. By making these moments of sharing and linking visible, the designer can understand these use cases as holistic experiences that are no longer limited to one activity on one website. They are revealed instead as part of a greater ecosystem of social software tools and participants. I purposely use the word ecosystem, because I want to describe these tools as living, organic sites of active knowledge sharing, information gathering, and data validation.

Amidst the chaos of exchanging information and discussing the 7 July bombings, victims and bystanders posted to blogs, added text to wiki pages, chatted on IRC channels, posted images, and exchanged text messages using their cellphones. The use of hyperlinks proved an effective means of guiding people to information points. Links allowed information to travel throughout these networks, providing a sense of consistency and validation when multiple actors would refer to the same links to exchange information.

In terms of ANT then, actors in this amalgam of post-disaster scenarios include cellphones, human eyewitnesses, digital cameras, mainstream media websites, social software websites, friends or relatives of participants, friend-of-a-friend (FOAF) participants, and outlier participants who may not be local to the area but nonetheless are active in locating and sharing information. In this and similar situations, a key component of maintaining and encouraging this communication is the presence of a moderator and other human aggregators to help with data collection, with linking of information and with posting original content, as well as having technological infrastructures in place such as websites and text messaging systems.

Figure 2 illustrates the ecosystems in which participants of the London Bombings of 7 July 2005 communicated. This is an abbreviated look at the numerous actors involved, listing sites of major interest because of their comparatively widespread use during times of crisis when information coordination is taking place. The

Figure 2. Social software actors employed in the wake of the London bombing disaster



scenario reveals how being able to trace these actors allows us to find tangible evidence of these networks. These details can inform the designers about these communities so they make visible the often-unknown ecosystems that surround users of social software. These ecosystems are unknown to those who are not active participants within these communities. Making these ecosystems visible by diagramming them provides designers a tangible representation of the multitudes of available social software systems employed by a particular community. Such visibility can prompt designers to move beyond creating systems that are walled gardens—social software systems that constrain activities to a single system such as Flickr, Blogger, and MySpace. By opening these walled gardens and creating open systems, designers can enable participants to share content across multiple social software systems. Participants are already climbing these walled gardens because their social context is not bound to a single system or community, as evidenced by their posting of links and creating workarounds to share information from one walled garden to another. We, as designers, need to recognize these activities and create systems that can facilitate such participation and knowledge sharing.

It is by embedding themselves within these scenarios that designers can understand what it is to be participants, negotiating often broken systems and manipulating tools in order to communicate as effectively as possible. By embedding, I mean for designers to become a part of these communities, observing how people use these systems by participating rather than silently observing. By adding tags to images, tracking down the missing online, commenting on blogs, and witnessing how participants stretch social software tools in ways that the authors of these systems never intended, designers can gain an understanding that simple observation would never provide them because participation demands that designers use these systems. Such insights lead to designing the kinds of solutions that will allow for quicker adoption of these tools when they are needed most – the moments after a disaster occur.

The mapping I suggest reveals how data is aggregated and exchanged and locates the numerous minor actors who provide meaningful information to help in the creation of these assemblages. The context and communication of this text is a tangible, material expression of these actor networks. They are not constrained to any localized spatiality (Law & Mol, 2003), so much as they are a series of transactions that can be traced when these communicative functions surface on various social software systems.

Many initial reports about the London Bombings surfaced on blogs, especially on group blogs. Communicating information between blogs and their participants occurred regardless of international boundaries; Americans, Britons, and other nationals were able to exchange information, regardless of time zone and location. They listed links, posted chat histories, and coordinated information.

An example of this phenomenon of how effective comments can be for allowing people to share information and build assemblages within their visible networks is Alfie's Moblog. This blog was used extensively on the day of the bombing because of blog owner Alfie Dennen's posting of Adam Stacey's photograph (Dennen, 2005) of people evacuating a damaged carriage in the London Underground (Figure 3).

This image would be broadcast later across the world and posted to numerous social software sites including Flickr (Applegate, 2005), as seen in Figure 4. The flow of the image of Stacey throughout the social software ecosystem speaks to how information can remain a stable assemblage as it moves throughout a communication system. The information is made fluid by these movements and encourages communication from other actors as the data propels through the network, creating an assemblage of information (Law & Mol, 2003) as seen in Figure 5.

Figure 3. Image of Adam Stacey evacuating the London Underground (Dennen, 2005)

Figure 4. Adam Stacey's image as posted to Flickr (Applegate, 2005)

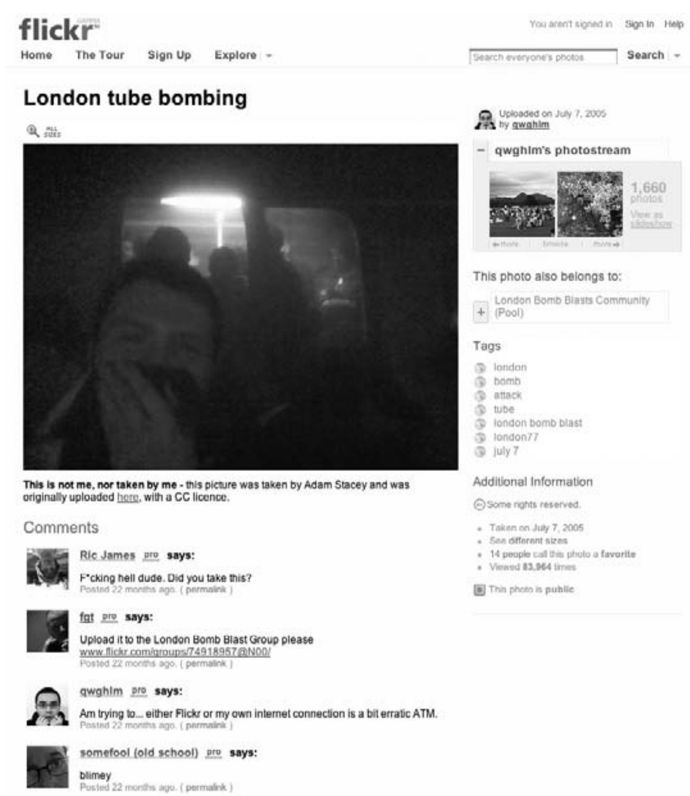


Figure 5. Actor network created by the reverberations of Alfie Dennen's post featuring the image taken by Adam Stacey during Stacey's escape from the London Underground (Potts, 2008a)

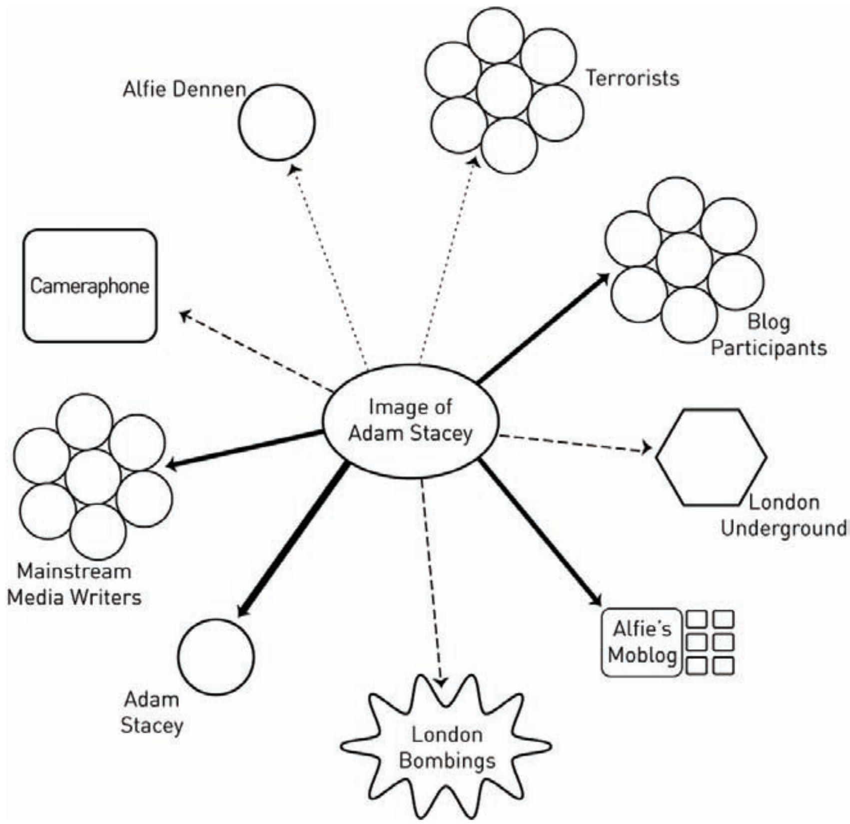

An overview of the actor network invoked by this post is shown in the actor network diagram I created in Figure 5 (Potts, 2008a). There were multiple actors participating in this information coordination: cellphones, computers, news outlets, Adam Stacey, Alfie Dennen, Flickr, the BBC News website, and the numerous participants who helped distribute the photo and inquire as to Stacey's well being. Participants who posted comments were able to relay information about the safety of the photographer of this image as well as discuss other victims of the attacks. Participants from Wikinews asked where and when the photo was taken, trying to add information to the event's entry on the cooperative news site. Through linking to other sites and allowing audience participation, these blogs were able to create an assemblage both of the bombing event and for tracking down the author of the photograph within this ecosystem. By making visible these connections through such diagramming, designers can begin to understand the pathways and traces of these images and communities as they flow across multiple ecosystems. Understanding how this information flows is indispensable for creating social software systems that allow for such communication. Such systems must be flexible enough to provide tools to participants that can be modified on-the-fly, aggregate information that the community deems important, and allow for validation of this information by other community members, moderators, and technologies.

By using ANT, we can see what users need and want within these current sociotechnical settings.

It behooves us as designers to design with them and for them, rather than over and around them. The issue is not what went right or wrong with the communication systems on 7 July. Rather, the issue is how we can best use our expertise as both systems designers and participants to make confronting the next disaster less painful.

DESIGNING FOR DISASTER

In this section, I will briefly discuss several proposed design guidelines as well as solutions based on my research of the use of social software during times of disaster. When disaster occurs, people attempt to reunite the missing, share eyewitness accounts, and coordinate information. As a participant, an observer, and a designer, I have witnessed these use cases first hand. Unfortunately, none of these sites are actually talking to each other, which means that the participant is burdened with 1) finding all of these disparate sites, 2) leaving their information on these sites, 3) remembering where they left the information, and then 4) scouring the sites to see if any replies to their inquires were made. Individuals use these different systems to learn, share, and build content without any central repository or authoritative confirmation of data. A solution must be found to unite content to confirm, validate, and redistribute this information back to these various web sites and web services. Such a solution would need to address the issue of openness across systems as well as the more specific example issues below.

In considering the design of sociotechnical systems, it is critical that special attention be paid to language and culture. For example, in labeling information, tags can be incredibly helpful as they provide data points on which other users can pivot to find similar content. However, quite often Flickr participants do not tag their photos, or they do so inconsistently. For example, across Goodman's pool of ten photos mentioned earlier, sometimes he tags photos with "train" and sometimes with "trains." On different photos, he uses the tag "bomb," "bombs," and "bombing" to describe the event. Morville explains how tags "serve as threads that weave a disparate collection of objects together" (2005, p. 138). If one participant cannot consistently tag his content from a single event posted all on the same day, how can we hope to have any consistency of labeling across an entire community during any given disaster. And yet, such consistency is necessary in order to have any hope of locating this sort of first person information in time to coordinate information, locate the missing, and create a sense of community during disaster. Looking across the Flickr community, there were easily 25 different tags used to describe the event, including "terrorism," "bomb," "killings," "blasts," and "londonattack."

An immediate solution for this issue on Flickr would be to create an autocomplete feature much like the one currently employed on social bookmarking tool del.icio.us (2007). When bookmarking a page using the del.icio.us tool, users can label the bookmark. As seen in Figure 6.1, the del.icio.us tool suggests relevant tags from three sources: recent tags used by the participant, tags used by the participants' community, and tags used across del.icio.us community. Such tagging suggestions allow for articulations to take place, uniting content and normalizing language for a community to support information coordination. This is a participant-centric solution, empowering the human participant while allowing actor tags to support knowledge management and information distribution through the network, all of which pushes the "thinking" to the side, so participants can interact with the tools that they build — whether these are folksonomies or more elaborate systems such as searching for content on Flickr and uniting that content with other participatory systems. While people clearly make do with cumbersome implementations, creating frameworks to support information coordination would help propel black boxes of information through the network, allowing participants to find the information they need when they need it.

By looking across multiple systems, designers can implement affordances that work well, such as the del.icio.us implementation for consistent tagging. This relatively simple design adjustment can help support communication as frantic and frenetic as disaster communication. When typing in a new tag, del.icio.us also provides users with an autocomplete function that provides visual cues to the user about prior tags they have used. For example, for adding a new bookmark, when the user types "f," del.icio.us would suggest "food" and any other word that begins with the word "f" in that participant's list of tags. This is where metadata emerges for the user, allowing the participant to connect the tags with each other to produce relevancy about the item they are tagging. This metadata allows for ease of searching by other participants who share an understanding of the folksonomy created with this tag. Such functionality could be added to Flickr as a quick fix solution for gaining consistency across an individual participant's tags. Another solution that would take a step further would be to pull up all tags posted that day across any community to which the participant belongs or across the entire Flickr community. A further solution would be to look at the tags the participant created for a given image, and then make suggestions to add further tags to these images. For example, all photos tagged "bomb" on 7 July 2005, could also be tagged with these keywords: bombing, blast, london. This solution would also help with creating more advanced aggregators, a further design innovation that I consider a next logical step in this sociotechnical design solution. All of these solutions take into consideration the social needs of the participants, treating each item within the network as an empowered actor. Such a framework aids in building a design that allows exposing the kinds of information people need to locate, validate, and push through the network.

An effective development of the tagging feature will have to include a way to identify and reroute inappropriate and mislabeled entries that can waste time or needlessly muddy the exchange of information. On the day of the bombings, a false alarm occurred in Brighton. One user tagged his images of this police response to this incident with "brighton" and also "londonbombing," even though the images posted clearly were not images of the London Bombing. These are not eyewitness images of the London Bombings, although they meet the requirements of being in the same country and during the same time span. The same occurred with images of the Swindon Railway station evacuation that occurred on the same day. They are much too far away from the actual bomb sites, and Flickr participants were quick to post their annoyance at these images being added to the London Bomb Blasts Community photo pool. One user, known as Drift Words, commented "Swindon!! That's hours away!" Clearly, some intervention on the part of the moderator was necessary in order for such restrictions of temporal space and location to be met to keep a sense of relevancy within the London Bomb Blasts Community. Being made aware of these actor networks is essential for a machine aggregator to be able to assist in the parsing of this information.

If moderators could help make these networks visible by describing the type of event and data they need to locate and collect, we could work towards developing systems that could aggregate this information for us using artificial intelligence (AI) based on people-powered constraints for each individual event. This will help us move past generalist search engines and towards finding relevant content as specific needs arise. By embedding ourselves in these communities of practice, we will also know what sort of cues to look for – examining the temporary connections between participants, the keywords created during times of disaster, and the networks that propagate outwards from the postings of information. Designing by collecting and examining the whole picture of actors and connections can help lay out the entire mediascape, allowing a holistic picture to form of interactions, communications, and aggregations.

The deeper technical implications of leveraging sites such as Flickr and determining what can be extracted through these systems could be crippling for designers and participants. Most web sites are closed systems that do not allow for the exchange of content outside their system. This creates daunting conditions in which to try verifying and exchanging information during a disaster or when attempting to research these events from a historical perspective. There are multiple owners of disaster content, from the news corporation to bloggers; there are also multiple maintainers of this content, including BBC News producers, chat participants, and Flickr pool moderators. Sources of this content can be wide in scope, from the Wikinews site to the Have Your Say section of the BBC News, to more obscure web sites or the moblogs that were used during the London Bombings. Locating these web sites, verifying data points, and exchanging information between them is a formidable crisis for online communication.

Today, many systems provide RSS feeds for participants to access content. Flickr also allows for RSS feeds to be published by user participants. Unfortunately, Flickr does not expose enough information through their web service and does not retain enough information in their database about images, participants, postings, and interactions for this social software site to be as effective a tool as it could be during times of disaster. The available Application Programming Interfaces (APIs) that can access information provided by the Flickr web services are maintained and created by community members. Written in different versions relating to various programming languages such as Java and PHP, each has its own limitations. This versioning could very well force a researcher to need to use multiple APIs to try to extract the most data. We must encourage unifying these APIs with a set of best practices. The APIs, however, while a huge problem for developers and researchers, represent a relatively minor obstacle compared to the limits Flickr imposes upon the amount and kind of data it is currently logging.

Flickr is currently incapable of cataloging many important details about the data it contains. I shall now briefly highlight a number of issues regarding how Flickr catalogs information, in preparation for the discussion below about areas for improvement in social software more generally. In fact, many of the problems found in Flickr are problems with social software in general. Put simply, Flickr does not catalogue detailed information about the data it is holding, and by doing so, it does not enable the level of participation necessary to support the complex communication needs of people affected by disaster.

When a tag is added to an image on Flickr, there is no corresponding date information associated with it — it is simply saved into Flickr's system. Therefore, determining when a tag was added to an image is not possible, given the standard Flickr API and web service. To illustrate this shortcoming, I have the following example. A developer conducts a search using the Flickr web service for the tag "bomb" posted to any Flickr image between 6 July 2005 and 8 July 2005. When this search was conducted on 1 January 2007, 2489 images were found. When this search was conducted a month later on 25 February 2007, there were 2492 images found. During that intervening time, an indeterminate number of photos that fell within that criteria were deleted, modified, and/or added, resulting in a positive gain of three extra results in the later search. Of course, hundreds of photos could have been added or removed, but the current state of Flickr's data holdings does not allow us to ever know the exact number or find any important data we may have lost forever. Missing data is a huge problem for those studying these events after the fact.

There are at least two possible solutions to this issue. The best method would be to convince Flickr to record and expose the tag creation date. The other way would be to monitor and record changes on the Flickr system and record the information along with enhanced data into a separate repository that can handle the additional information. This way is not optimal because it requires an extremely reliable system on both ends of the web services and requires the creation and long-term maintenance of both hardware and software to gather this data. Regardless, this still hides information from everyday participants. Exposure of these networks is necessary to further the creation of more articulations that will allow for the free flow of information through these fire spaces.

A similar problem occurs with Flickr groups. An image can belong to one pool, many pools, or no pool at all (aside from the user's personal photostream). Quite often, a picture will be added to a group at a much later date and sometimes at the request of another user. However, using the currently exposed web service, one cannot pinpoint when this addition was made. We might know that a person asked the owner to add a photo to a particular group, but it is impossible to find out when, if ever, that image owner complied. Knowing if and when a poster responded to a query would not only leave us a more complete history of the posting, but also help us understand moderator influence. Without this data, I needed to walk through each photo to find moderator comments and see if the response was positive. This is not an effective solution for long-term tracking of a moderator's sphere of influence and ability to affect community during times of disaster, for those who are studying these efforts and for those trying to design improved communication systems, and for those victims and volunteers trying to find validated information.

The same issue occurs for the comments posted to these images. When they are first posted, comments list the time and date that they were posted. Over time, the comments lose these date and timestamps, reverting to more general descriptions of "Posted 7 months ago." This is too vague to enable community members to trace usage, and it is utterly useless for those tracking historical data. Timestamp data must be kept, for Flickr or any other social software system, to be an effective and reliable communication tool. To omit this vital data when it could so easily remain present and intact is a great disservice to the community and to those attempting to document historical usage to create more effective systems. Timing — both literal and figurative — is of the essence for coordinating disaster information.

All of the issues and solutions discussed in this section were made visible by the use of Actor Network Theory. This theory provides ways of understanding each participant – whether it is a technology or a human being – as an integral part of any communicative act. By examining these situations through such a lens, designers can be active participants at the center of these interactions rather than developing interfaces and systems from the sidelines.

CONCLUSION

The various actors—images, systems, participants, cellphones, websites, etc.—have the potential to provide relevant data that could be better coordinated if a system were in place to gather this information and distribute it to those in need, either of emergency services, or connecting the missing with the found. By leveraging the actors and ecosystems that already exist, designers can foster the free flow of information through these systems, and this could reduce the anxiety and chaos that inevitably follow a disaster.

As geopolitical instability and climate change promise to make crises even more frequent, a method for aggregating visual and textual narratives so that they are easier to locate in times of emergency is becoming increasingly critical. Arranging this information so that it is readily available and locatable will ensure that it is also easier to coordinate and leverage to answer the many questions that indeed go unanswered or simply arrive too late to be effective.

In order to create such systems, we need tools such as ANT so that we can recognize the systems we must optimize. A major strength of ANT is that this theory allows designers to document all of the relevant actors—people, tools, and resources—that allow information to flow through these networks. ANT encourages designers to overlook nothing and, rather than imposing hierarchies and taxonomies on these communities, allows actors to suggest connections between people and technologies. By extending this theory to allow for the prioritization of these human needs, we can use ANT to improve the design of these mediated systems. Finally, by understanding these experiences through participating within these systems, designers will be empowered to create systems that are far more inclusive, operate across numerous networks, and enable everyday people to communicate during times of disaster.

Chapter 4.15
Student Use of Social Media:
University Policy and Response

Tamara L. Wandel
University of Evansville, USA

ABSTRACT

This chapter presents information on the usages and intent of social media by college students and administrators. Primary and secondary quantitative data is provided, as well as qualitative information obtained from interviews of multiple constituents. Researchers and postsecondary employees can more effectively examine technological trends in regard to online social networking for non-academic purposes after considering this data. Theories of self-esteem, interpersonal communication, decision making, and innovation diffusion are integrated throughout the chapter.

INTRODUCTION

Millions of American high school and college students have one thing in common: they log in daily to Web sites to view recently uploaded photographs, check out opinions on blogs, and see if friends have made any changes to their onscreen profiles. Individuals born between 1981 and 2000, coined *Millenials*, are growing up in a world in which participation in online social networking is considered conventional behavior. Timothy Hawkes, the headmaster of The King's School in Sydney, Australia, perhaps summarized it best. As quoted in *The Sydney Morning Herald* (Goodman, 2007), Hawkes said, "…technology isn't part of students' lives these days. It is their lives."

Social networks refer to a collection of individuals linked together by a set of relations (Downes, 2005). Associated research tends to focus on social network analysis, a framework intended to enhance the sharing and interaction among groups and communities (Cho, Stefanone, & Gay, 2002). Online social networks possess a parallel purpose, with Web sites intended to assist users in meeting new people or staying connected with friends or associates. The Web sites allow for searches based on a multitude of factors including affiliations such as a college or high school. Some sites like Shelfari are designed around a common interest, in this case targeting book aficionados. Other online social networks are centered on a professional component, a quasi modern-day version of the now more traditional

DOI: 10.4018/978-1-60566-104-9.ch010

networking after-hours event. Two such examples include LinkedIn and MyRagan, designed for all professionals and professional communicators, respectively.

Online social networks are also termed virtual communities or profile sites, and the relationship-building capacity of these sites present more than simplistic social consequences. Network participants are exposed to groups centered on the advantages and/or disadvantages of specific colleges, clubs and professors. Higher education institutions are beginning to recognize that reputation, campus culture and even enrollment figures may be impacted by online social networking.

The objective of this chapter is to present the response of university administrators and students to the use of online social networking for non-academic purposes. Qualitative data from student and administrator interviews helps shape the chapter and allows for candid and relevant anecdotes surrounding the topic. The use of primary and secondary quantitative data offers insight and perspective to a compelling, complex and constantly evolving topic. Theories of self-esteem, interpersonal communication, decision making, and innovation diffusion are integrated throughout the chapter.

OSN REIGNING GIANT FOR COLLEGE STUDENTS

The interests of college students are as diverse as the myriad of online social networking (OSN) sites available to them. From Bebo to Classmates.com to Friends Reunied to Friendster, university students have numerous OSN options as they put their technologically savvy skills to use in finding their niche. One network in particular dominates the college scene with over 85% market share of four-year universities in the United States: Facebook.

Originally called *thefacebook,* and targeting college students, Facebook is now the second most trafficked online social networking site following MySpace. In hipper context, Facebook is "…the online hangout of just about every college student in the nation" (Levy, 2007). Mark Zuckerberg, the man credited with Facebook, dropped out of Harvard University to focus full-time on his creation. Like MySpace co-founders Tom Anderson and Chris DeWolfe, Zuckerberg had become frustrated at his own experience and felt he could develop something better than what existed. The story goes that he believed Harvard University was too slow in creating an online student directory, so he made sure his own version was both expedient and impressive. After 6,000 students at Harvard registered with thefacebook, within the first three weeks, Zuckerberg piloted the program at Stanford and Yale (Naposki, 2006). The online social networking site quickly became a sought-after commodity and officially became known as *Facebook* in August 2005.

Facebook initially required a college or university .edu domain extension, but the site has since expanded. High schools and companies now have access to the online social network within certain regions. The official site at www.facebook.com has a section detailing "How this expansion affects you," the Facebook member. It starts by explaining:

Now you can get all your friends on Facebook—people who couldn't get on before because their schools didn't offer e-mail addresses, because they went to work instead of colleges, because they graduated before Facebook even existed, or for any other reason.

Evidently people heeded the call. The site had 24 million members by June 2007 (Kirkpatrick, 2007) and more than 60 million active users as of January 2008, representing an average 3% weekly growth since January 2007. It is no wonder Facebook's originator understands the Millenial generation—Zuckerberg is 23 years old.

SOCIAL MEDIA AND CONNECTIVITY

Facebook has more than three million users aged 25 to 34, and even more users younger than that (Ronn, 2007). With so many online social networking users falling in what is considered the traditional college-age category, there is a need to understand the link between the communication taking place via social networks and how it fits into the larger picture of relationships and overall well-being. Wood's research on personal relationships (1995) determined investment, commitment, trust and comfort with relational dialectics as the four defining characteristics of a successful relationship. Westerners' emphasis on verbal disclosure as an important trust-building mechanism was further noted. This need for verbal acknowledgement and response has important implications for administrators in postsecondary institutions, particularly because many college students feel overwhelmed and lonely as they embark on their first real venture away from home for an extended time. As quoted in *Everyday Encounters* (Woods, 1996), a student stated:

The worst time in my whole life was my first semester here. I felt so lonely being away from my family and friends at home. Back there we were really close, and there was always somebody to be with and talk to, but I didn't know anybody on this campus. I felt all alone and like nobody cared about me. I became depressed and almost left school, but then I started seeing a guy and I made a couple of friends. Everything got better once I had some people to talk to and be with.

The mission statements of postsecondary institutions often center on themes of academic integrity, attaining in-depth knowledge of a particular discipline, well-roundedness and civic-mindedness. But educators and administrators recognize that if students are not content, if they are lonely and depressed and not focusing on their studies, then their self-esteem, sense of responsibility and ultimately their educational experience may be lost or at least substantially weakened.

Theories of self-esteem have established that human beings possess a universal desire to protect and enhance their self-esteem (Rosenberg, Schooler, & Schoenback, 1989). At no point in life are peer acceptance and feedback on one's self more important than in adolescence, and these are two distinct features of online social networking sites (Valkenburg, Peter, & Schouten, 2006). From the college recruitment stage to retaining students through graduation, a recurring theme is connectivity. Students should feel welcome, at ease and comfortable in their home away from home.

Academic Decision-Makers Response to Student Expectations

Academic decision makers must consider new ways of reaching students for recruiting purposes as well as connecting with students as part of retention efforts, and some of these efforts involve technological innovations. The use and need of technology by higher education administrators is altered as the expectations and usage of technology changes by students. In fact, computers, the Internet and social media may be changing so fast that it is impossible to predict the impact. But what is recognized, according to Baase (2003), is that these technological changes in work processing methods have resulted in a loss of community. E-mail, Skype and other mediums are replacing traditional face-to-face conversations. So while technology is often lauded for bringing the global world together, it is simultaneously faulted for creating an unnatural barrier in community.

Many higher education administrators are in the unenviable situation of not having appropriate technology required to act as expert decision makers when it comes to increasingly evolving technology. This is closely aligned to the decision making theory called *incrementalism*, in which individuals may not be able to perform their job responsibilities at the highest level because they do not possess all the facts, information and technology required. In this case, decision makers enact former solutions to current problems and work within a bounded rationality in which they choose an "incremental alternative rather than a fundamentally newly designed approach" for solving problems (Hoy & Tarter, 1995).

But when it comes to constantly changing technology, is an incremental alternative enough to reach students who possess an entirely different set of communication and connection ideals? Typically, the initial decision to have a certain technology available for student use is made at the institutional level (Robinson, Jr., 2006), but in the case of OSN, it may be more an issue of student expectations and current usage driving technology decisions by administrators. Student demand is forcing administrators to play catch-up and create novel ways and approaches for "informative provision and instruction" (Sellers, 2005). Administrators need to not only manage their own collegial community but find ways to encourage community for students.

Communicating with Prospective and Current College Students

Knowing of the growing popularity of Millenials to utilize online social networking sites, it is not surprising that higher education administrators are beginning to view these networks as valid mechanisms to reach student audiences, including prospective students. The broader communicative strategy in this case is referred to as e-recruitment, and the tactics focus on communication with prospects via instant messaging, e-mail and online social network profiles.

It appears prospective college students do not mind this encroachment on their virtual lives, especially if they can control initiating the communication. An E-Expectations Class of 2007 report by Noel-Levitz (2006) discussed the propensity for prospective college students to utilize technology or, in some cases, express a desire to utilize various Web-based applications. Excerpts from the published survey data show student responses to completing certain activities on college Web sites:

- 72% have or would like to exchange instant messages with an admissions counselor or student worker
- 72% have or would like to complete a form to RSVP for a campus event
- 70% have or would like to inquire online
- 64% have or would like to read profiles of faculty
- 64% have or would like to e-mail a faculty member
- 64% have or would like to read a blog written by a member of the faculty
- 63% have or would like to read a blog written by a current student
- 63% have or would like to view a virtual tour
- 62% have or would like to personalize a Web site (meaning they received a unique experience based on information supplied)
- 61% have or would like to e-mail current students from the site (Noel-Levitz, 2006)

These statistics indicate a majority of survey respondents desire activities in Web-based form. A chief benefit to higher education institutions using OSN and other Web-based activities is the relative ease in maintaining connectivity through the posting of information or by e-mailing others, and Millenials have come to expect instantaneous communication. According to Lenhart and Madden (2007), e-mail is the highest ranking Internet activity by teens, with 57% going online to retrieve information about colleges and universities. This underscores a need for colleges and universities to utilize Web-based applications in their recruiting plans. In today's competitive market where each prospective student is crucial to a college or university's full-time equivalent figures, Web sites must be interactive. The more opportunity a Web site has for personalization based on a user's interest, the more likely a Millenial will stay interested.

Once students are enrolled in a postsecondary institution, that interaction must continue. Tinto's predictive model of student integration (1982; 1993) discusses how interactions in both the academic and social realms play a significant role in the attrition process. Factors including peer-to-peer interaction and peer-to-faculty interaction are positively related to degree completion.

Online social networking may prove to be an invaluable tool in assisting students who are easing into college life. Roommates are often introduced to each other through Facebook or MySpace, learning about each other's interests, study habits or partying tendencies through online profiles. Students learn about residence hall life and which clubs might be of interest to them. Once enrolled in college, online social networks prove to be a constant source of information for students. Profiles and groups encourage attendance at campus events, promote specific clubs, fraternities or sororities, and allow college students to view last-minute changes to an academic calendar through bulletin board announcements.

College student Donald Moore thinks it is smart business for organizations to participate in online social networking. "Almost everyone is on some type of social network, so why not communicate an upcoming event this way since so many people check them out constantly? If you send an invitation to 100 people and only one responds, it is still a success because that is one more response than you had before you started. Why not take advantage of free publicity?"

Connectivity in Times of Bereavement

Online social networking remains undeniably constructive as a means of connecting individuals regardless of geographic constraints. The aftermath of the April 16, 2007 massacre occurring on the campus of Virginia Tech University provides insight into a unique value that online social networking provides to college students. Students throughout the U.S. united after the Virginia Tech tragedy by creating online groups and posting comments expressing their concern and grief. The language was often candid, emotional and sentimental. One of the many group descriptors read, "In memory of those lost and those grieving at Virginia Tech. This is a group to honor those who have lost someone just know that you are not alone the world is watching and we are all praying. Today we are all hokies!!"

It was clear that many of the postings originated from those not directly impacted. College students blessed not to have been straightforwardly affected by the incident were nonetheless trying to make sense of the tragedy and working to find a way to reach out and show compassion. One student from Ontario, Canada is a member of a 1,625-member Facebook group titled *A Canadian Tribute To All Those Involved In The Virginia Tech Shooting*. An excerpt from her posting reads, "I don't know any of the people who died in that horrible act, but my heart goes out to each student and all the families involved. You don't need to know anyone to be sad for them." For this individual and others, the Facebook group was a virtual memory wall offering a chance to emotionally embrace.

Until May 2007, Facebook's policy was to delete profiles of the deceased. That policy was altered after online protests and a letter campaign were initiated in response to friends and family of Virginia Tech victims learning that profiles of victims were to be removed (Hortobagyi, 2007). "…these pages are what's left of their voices, and the rest of their voices have been stolen from us," said Virginia Tech student John Woods (Hortobagyi, 2007).

As is the case with the Virginia Tech mourners, it is not just friends or family that are posting comments on online social network sites. Some students who have never interacted with the deceased reach out to find a shared connection in the confusion and despair that comes from the loss of life and the struggle to move on and find meaning from a tragic situation. In a posting for a Facebook group dedicated to remembering a young Midwestern college student who died of heart failure, an individual posted a comment, "He sounds like a great guy. I'm sorry I didn't know him." Others that did know him use everyday vernacular indicative of young people, "he had a heart attack, 26 and dying of a heart attack, that's soooo HORRIBLE! stephen and i worked together like 3 or 4 yrs ago. we would always butt heads but you never want to see this happen to anyone regardless of the relationship you have with them, he's way too young [sic]."

Bereaved college students are an extremely vulnerable cohort to issues of self-confidence and self-efficacy, often feeling a loss of control to external events and factors. These students find their identity formation challenged, and this formation is an important developmental milestone for those in their late teens and early 20s (Balk, 2001). Identity formation challenges mean bereaved students question their own competence and self-worth. Depression, generalized anger, and behaviors categorized as self-destructive are reported outcomes of bereaved students who do not progress through the grieving process in a healthy manner (Silverman, 1987; Tyson-Rawson, 1996).

This issue is critical to colleges and universities as it can influence a student's ability to successfully experience college life. "If for no other reason than a university's interest to increase student retention, graduation, and long-term alumni support, it makes sense for a university to engage systematically in efforts to assist bereaved students" (Balk, 2001).

It is not a mere handful of students impacted by bereavement. Studies indicate that 22-30% of college undergraduates are in the first 12 months of grieving the death of a family member or a friend, and 35-48% of college students are in the first 24 months of grieving the death of a family member or a friend (Balk, 1997; Wrenn, 1999). Colleges and universities have reason to pay attention to bereavement influences and processes as many students are touched by loss during their college years.

One bereavement framework in particular, attachment theory, appears applicable to online social networks. Attachment theory describes bereavement as the outcome of bonds, mainly emotional bonds, sundered by death (Bowlby, 1980). The theory depicts a bereaved's simultaneous process of letting go of emotional attachments to the deceased while striving to invest in other social sources. Peers are often a vital source of social support, yet often are unaware of the critical assistance they can provide. As Barnett (1982; 1987) describes, most college students are incapable of transforming their empathic understanding in a helping fashion because they lack the skills or understanding of what to do. College students untouched by bereavement typically demonstrate both ignorance and fear when in the presence of a grieving peer.

It is in this area that attachment theory and online social networking may prove to find an important association. Talking about grief provides a means to maintain interpersonal relationships and also to invest in attachments with others (Balk, 1997). Many college students are uncomfortable talking about grief or other emotive topics through face-to-face communication. However, over the Internet, they find it soothing and comforting to display sensitivities. For years, funeral homes have offered condolence opportunities via the Internet. Perhaps the posting of comments via online social networking sites is a natural progression.

As online social networking becomes a better researched and highly prevalent mechanism for peer support, higher education administrators will need to determine how to utilize online social networking sites as part of best-practice intervention programs to reach out to or assist bereaved students.

Table 1.Exhibit A (Wandel, 2007)

Exhibit A	
University Use of OSN sites	**Column N%**
Publicizing student organizations	83.3
Planning campus programs	56.5
Announcing upcoming events & deadlines/university calendar	51.6
Publicizing non-university events	19.0
Providing information to current students regarding academics	12.4
Recruitment of new students	9.9
Alumni relations	7.1
Retention efforts	6.3
Distributing information to faculty, administrators and staff	1.3
Fundraising	0.8

HIGHER EDUCATION ADMINISTRATOR USE OF OSN

From serious issues such as bereavement, to simply usesocial media as a means for promotion of campus events, administrators are trying to make sense of how best to utilize technological innovations. To confound the issue, much of the verbiage used by Millenials makes it clear that parents or other adults are the outsiders treading at times on unwelcome ground. Acronyms like PBM, PIR, P911 and POS may seem as innocuous as CUL (see you later), but they can have far more serious implications (PBM = Parent Behind Me; PIR = Parent In Room; P911 = Parent Alert; and POS = Parent Over Shoulder). (Table 1)

It is not surprising given this "keep out" emphasis that, while the larger sphere of online social networking use by higher education administrators is growing, many other administrators are still unsure of how best to approach or utilize social media. A survey of over 1,000 higher education administrators found that fewer than 40% of college or university administrators worked at institutions that had created groups on an online social network site (Wandel, 2007). Groups in this case refer to an element of online social networks, particularly Facebook, in which members can create and join a faction similar to a group or organization in the physical world. Administrators recognized Facebook as the dominant forum used by college students, and 97% of postsecondary officials also chose to access Facebook, while only 23% used MySpace.

For those college administrators participating in OSN, the majority use it as a vehicle to communicate with students about organizational or programming issues. Over 83% said they use Facebook and other sites as a way to publicize student organizations, and over 56%t said they use the forums as a way to help plan campus programs. In addition, over half of the respondents indicated they use online social network sites to announce upcoming events and deadlines as part of a university calendar system. Exhibit A offers a ranking of why university and college administrators stated they use online social network sites.

Rollins College serves as a successful example of using OSN as a tool to promote its orientation/welcome back session. "There wasn't a seat open, because the word went out on Facebook and people actually replied, 'Yeah, I'll be there.' By knowing that other people were going to be participating it started to build steam and build community,"

Table 2. Exhibit B (Wandel, 2007)

Exhibit B	
Perceived Concerns of OSN sites	**Column N%**
Privacy issues	84.6
Student safety	78.1
Liability issues concerning alcohol or drug use	69.5
Legal responsibility	54.4
Freedom of speech issues	43.0
Difficulty regulating the posting of information	41.1
Postings may create social disruptions on campus	35.2
Student access (or lack of) to computers	8.9

said director of Rollins Explorations Doug Little (Santovec, 2006).

Online social networking sites can even be utilized when college or university administrators do not form official groups. Over half of surveyed college administrators report they casually or unofficially monitor student activities, trends and interests (Currie, 2007). Survey respondents reported 36.2% accessed an online social network site on a daily basis, and another 32% accessed a site at least once a week (Wandel, 2007). Higher education administrators are increasingly using online social networks as related to their work. For example, postsecondary institutions such as Utica College, SUNY New Paltz and Colorado State have Facebook groups dedicated to career matters.

CONCERNS AND CONSIDERATIONS GERMANE TO HIGHER EDUCATION

From a higher education perspective, a plethora of considerations exist when students, administrators and educators are involved with online social networks. At the top of the list are concerns of privacy and student safety. Katy Lowe Schneider (personal communication, May 31, 2007), associate dean of students at Hanover College, said she and her staff try to emphasize not only the professional implications of having information posted online, but also the threat to safety that can ensue if students list private and personal information in a public forum. "One thing our director of security often says is if Ted Bundy had been alive today, his murder spree would have included hundreds because stalking would have been much easier. 'I'm blond, early 20s, 5'5" and live at 517 Chi Alpha in Room 3' listed in a student's profile can make her an easy target for crime." (Table 2)

While safety and issues related to cyberstalking have garnered much attention in scholarly journals as well as mainstream media, other concerns exist. Legal, ethical and social implications abound regarding OSN practices. Exhibit B illustrates a ranking of concern as reported by higher education administrators.

Legal Issues

Jessica Binkerd may have been an online social networking participant to achieve a hedonic experience, but the photographs on her MySpace profile ultimately proved anything but pleasurable for her. The photographs were used against her as she was sentenced to more than five years in prison for driving under the influence and vehicular manslaughter. Photographs of the University of

California, Santa Barbara student drinking alcoholic beverages with friends were posted after the date of the fatal accident (Wagstaff, 2007).

Photographs have proved as evidence in numerous other cases. Lowe Schneider describes an example of when a fraternity hosted a philanthropic event in which one participant became so intoxicated that he had to be rushed to the hospital for alcohol poisoning. The fraternity members claimed no alcohol was consumed at the event. "We searched Facebook with the title of the auction and within seconds came up with 20 pictures of students consuming alcohol at the event in plain sight," said Lowe Schneider. "We used these photos in judicial action. We try to be careful not to search Facebook looking for violations, but if information is contradictory, we will use it to assist us."

Cameron Walker became embroiled in a public controversy when he became the first person expelled from a college for Facebook-related activities. Walker, at the time president of Fisher College's Student Government Association, was also an "officer" of a Facebook group that criticized a campus police sergeant and created a petition to get him fired (Stone, 2006). According to Walker, the sergeant had harassed students in order to encourage situations where arrests could be made. Walker claimed the Facebook group he and another student created was a prank. To support this, he pointed to his Facebook group's officer title, which he selected, as "Duke of Propaganda." The administrators at Fisher College in Boston did not see the humor, and they cited Walker as being in violation of the Student Code of Conduct against "verbal, written, graphic, or electronic abuse, harassment, coercion, or intimidation of an individual."

Many college students feel it is unfair to use online social networking profiles or postings against an individual. "I know some universities use Facebook as a tool to bust underage drinkers as well as catch people doing thing they should not be doing," said college student Kathryn Piepho. "I just feel like universities are over-stepping their boundaries by viewing students' Web pages."

Of course, it is not only students that can bring about litigious or public controversy. Vetted by attorneys, Roger Williams University formally adopted a proactive social networking and blogging policy in summer 2007 for faculty and staff when using a university e-mail address (Roger Williams University, 2007). An excerpt from the policy states:

Roger Williams University provides access to the World Wide Web for all of its employees as a privilege and in many cases a necessity to meet the responsibilities of their job. This includes the use of social networking sites, and access to an array of blogs—and even permission to write a blog of one's own—as part of one's professional activities. The University defines "professional activities" as those that advance the University's mission of education, research and public service.

In light of that definition, each employee is reminded when he or she blogs or accesses a social networking site with a Roger Williams University e-mail address, the employee is a representative of the University and must act accordingly. That means an employee can access such sites as Facebook or MySpace to communicate with students, faculty, staff or other professional colleagues in matters related to their teaching and/or professional responsibilities at Roger Williams.

Employees who use a Roger Williams e-mail account must consult their supervisor and/or Dean in advance of their intention to use social networking sites. In addition, staff or faculty using either an RWU address or a personal address to create or post comments to blogs should include this disclaimer: The postings on this site are my own and don't necessarily reflect Roger Williams University's opinion, strategies or policies.

Some activities that would NOT be considered acceptable uses of the Internet from a Roger Williams account include but are not limited to:

- Posting items anonymously or under a pseudonym;
- Conducting personal social relationships unrelated to University activities;
- Using and creating an account with dating and/or matchmaking sites;
- Engaging in partisan political fundraising activity;
- Engaging in online gambling;
- Posting comments or writing blogs that are obscene or untrue;
- Using social networking sites or blog postings to harass others;
- Selling goods or services for personal financial profit.

The policy further details the use of personal e-mail accounts when participating in online social networking sites. It will be interesting to analyze over time how this policy is accepted by faculty and staff. Will it decimate the confidence of faculty by restricting their speech? Will staff appreciate the guidelines to help ensure abuses are limited? It will also be interesting to learn how many other institutions choose to adopt similar policies.

Impact of OSN on the Student-Athlete

In addition to explicitly stating the expectations and responsibilities for employees, many college and university administrators view OSN policies as an opportunity to assist and even benefit another cohort, that of high profile student-athletes. This group is subject to increased scrutiny for participation in online social networking sites. In response to this, the University of Michigan at Ann Arbor is one of many postsecondary institutions electing to take a proactive stance. As of 2007-08, it became mandatory for students to sign a pledge regarding good conduct on social networking sites as part of the student-athlete code of conduct.

Judy Van Horn (personal communication, May 9, 2007), associate athletic director/senior woman administrator at the University of Michigan, said the intent is to use the pledge to educate students. "It's better for us to find inappropriate material on an athlete's profile than for a news reporter to do so," she said. A university representative checks each online account once a semester to make sure all language and photographs are appropriate. As Van Horn explained, it is what is considered appropriate that is often debated. "Using the f-word or having sexually explicit photographs may not be offensive to a student, but it is still shocking to others," she said. If anything inappropriate is found, Van Horn said a process is in place to have the offensive material taken down within 24 hours.

As social networking sites garner increased attention, Van Horn said students are getting smarter and taking advantage of closed groups. Closed groups define members and place restrictions on who can post and view comments within a group. In the past, the University of Michigan had student-athletes "clean up" their personal sites but they remained connected to other questionable groups. "You lose control any time you join a group," Van Horn explained. Identity theft is also a problem. Van Horn said six sites have misrepresented the University's star quarterback as his own, and two other sites misrepresented the head coach.

The University of Michigan's Department of Athletics created the Student-Athlete Conduct Policy as an educational tool, focusing on three areas: Internet Social Networking Community Sites, Athletic Department Policy, and Recommendations. The language from the policy includes:

Internet Social Networking Community Sites. *Internet sites such as Facebook.com, MySpace.com, Xanga.com, Friendster.com and others provides individuals with an opportunity to interact with an extraordinary expansive universe of new* *people and connect with current friends. Postings on personal profiles, groups and chat rooms are in the public domain and easily accessible by anyone including reporters, parents, coaches, groupies, predators, employers, and graduate school admissions officials. Once information is posted, it can be retrieved by computer savvy individuals even after it has been deleted.*

Athletic Department Policy. *Participation in intercollegiate athletics at the University of Michigan is a privilege, not a right. Athletic Department conduct policy currently states, "Student-athletes shall deport themselves with honesty and good sportsmanship. Their behavior shall AT ALL TIMES reflect the high standards of honor and dignity that characterize participation in competitive sports at the University of Michigan." While the Athletic Department does not prohibit student-athlete involvement with internet based social networking communities, this high standard of honor and dignity encompasses comments and postings made to internet sites. The Athletic Department reserves the right to take action against any currently enrolled student-athlete engaged in behavior that violates University, Department, or team rules, including such behavior that occurs in postings on the internet. This action may include education, counseling, team suspension, termination from the varsity team and reduction or non-renewal of any athletic scholarships.*

Recommendations. *Immediately review any internet websites you may have posted on the internet to ensure that the postings are consistent with University, Department, and team rules and that they present you in a way you want to be portrayed. For your safety and privacy, you should refrain from posting and should promptly remove any personally identifiable information such as telephone number, address, class schedule and places frequented as well as any photos you may have posted. Alert the Compliance Services Office of any sites that falsely appear to be yours as this constitutes identity theft, and the University will assist your efforts to have the offensive site removed. Be cautious about which chat groups you join to be sure you want to be publicly associated with that group. Once you become a member, you are linked to the discussion that takes place within that group. Only the group's administrator is able to delete your group membership or postings made to a group site.*

On a broader scale, the NCAA Student-Athlete Advisory committee has discussed the issue of athletes' profiles but, according to assistant director of member services Jess Rigler (personal communication, June 4, 2007), does not set forth policy on the topic. "We leave it up to the individual institutions to set policy on this," he said. While the NCAA Student-Athlete Advisory committee does not track the number of policies that exist, Rigler estimates that "…almost all of the Division I schools have some sort of policy regarding social networks and about half of the Division II schools have a policy in place." He explained the key, however, is in how well written and followed the policies are from one campus to another.

Coaches are striving to find ways to encourage dialogue of OSN usage with the aim that education and awareness of the topic will produce a kind of galvanization of student-athletes. If students are spurred to action and understand the importance of promoting positive images for themselves, their team and their universities, then monitoring sites becomes less of a burden for coaches and administrators. Courtney Felke, a senior playing NCAA Division I women's basketball, said, "Our head coach told us to modify the information that we had posted online because of how easily the information is accessible to other people and how information can be misconstrued. We haven't had any issues, but we're working to be proactive. More than once there have been discussions about this."

Other colleges are hosting guest speakers to introduce the topic of OSN, and still others choose to approach the issue through written correspondence. A letter from Bill Maher (Canisius, 2007), director of athletics at Canisius College, is sent to each student-athlete to educate them regarding online social networking and to remind them that unique responsibilities and expectations come with serving as a student-athlete.

Dear Canisius Student-Athlete:

Facebook.com and other similar websites have generated national concern about the safety and welfare of high school and college students. This concern has created intense discussions particularly on college campuses and more specifically, within athletic departments.

The focus of these discussions has been on the posting of student-athlete profiles and photographs on these websites. Many student-athletes have elected to post pictures of themselves and teammates engaging in inappropriate activity. Examples of this activity includes: underage drinking, hazing rituals, drug use, smoking, and even questionable sexual behavior. In some instances, these photos have led to disciplinary action against student-athletes and against teams including forfeitures of contests at institutions across the country.

The media has become aware of these sites and has gained access to some of this information posted. These outlets have been able to exploit student-athletes by simply copying what has been posted and allowing scrutiny of student-athlete behavior in a grander scheme. It also draws attention to the institution in a negative fashion. Opposing teams have even capitalized on the website by downloading pictures and using them as motivation for themselves or to taunt a specific student-athlete.

All of our athletic teams have policies on underage drinking, hazing and inappropriate behavior. Your decision to post items on facebook.com or similar websites is a personal one; however, the Athletic Department and your individual team policies should serve as a filter for what you decide to put on line. Any public pictures or comments determined to be contrary to these departmental policies and/or the Student-Athlete Code of Conduct will be treated as violations of said policies and handled accordingly.

Your coaching staff has explained the Department's expectations in this area, so please ensure that you take the appropriate steps to avoid additional consequences. If this behavior continues, your coach will be in a position to suspend you from competition and potentially recommend a dismissal from the program and a non-renewal of your athletic scholarship.

You must remember that you represent Canisius College at all times. Do not post pictures, comments or information on the websites that would/could embarrass you, your team, or Canisius College, or that are clearly contrary to the expectations for the student-athletes. It is a privilege to represent Canisius College in athletic competition, so your good personal judgment in this area is expected.

Our competitive goals are clear – to win Championships within the Metro Atlantic Athletic Conference. For us to reach these goals, it takes a level of personal commitment from each student-athlete in our program. The personal decisions you make on a daily basis will determine our overall success. Do your part to help us win MAAC Championships.

After controversial photographs of several student-athletes appeared publicly due to postings on online social networking sites, the athletic office determined it best to educate students and limit future problems. Some institutions, including Loyola University Chicago and Kent State, have moved in an even more aggressive manner, completely banning student-athlete membership in online social networks. These types of bans do have critics who question the First Amendment rights of students being violated by such blatant prohibition. To date, any violation appears to be dismissed as the expectations of student-athletes are significantly higher than that of other students. This is not only the case with online social networks, but also in other rights-restriction capacities such as drug testing. However, the issue of First Amendment concerns is far from clear-cut and precedent-setting cases are likely to emerge in the next few years.

Employer Ethics and Expectations

"Have you checked your Facebook page lately?
I have."

Imagine being 18 years old, seeking your first relevant work experience, and receiving that message. Through mock interviews with Hanover College's Center for Business Preparation, Lowe Schneider saw this very statement written by an employer on a student's evaluation.

Public access to what many feel is private information is causing concern and discussions on college campuses nationwide. Ethical questions abound as to whether it is fair for employers to look at online social networking sites to gain information about job candidates. To what degree students and prospective employees are protected under privacy laws and ethical boundaries when it comes to accessing these profiles is at the core of the debate. Is viewing an online profile considered the same as reading an article in a newspaper about a person and learning information about him or her? Is it a matter of being entitled to as much information about job candidates as possible, regardless of how the information is obtained?

"I hate the fact that universities are getting involved in online networks," said college student Lauren Deas. "I have so many great pictures that I can't even show in fear of losing a potential job or scholarship."

But despite such concerns, 40% of companies say that they would at least consider using Facebook profiles before making a hiring decision (Read, 2007). Thirty-two percent of students think it is unethical for companies to scan the Facebook profiles of job candidates, but only 17% of employers feel the same way. Chris Wiley and Mark Sisson, authors of the widely cited University of Dayton study, found that many students tend to draw sharp lines between their personal and professional lives and see Facebook as a tool to be used in a personal manner. One reason students may feel this way is that they often embellish on their online postings or profiles. Many college students acknowledge they purposefully misrepresent themselves. For example, 8% of students say they exaggerate their alcohol or drug use in Facebook postings. But should employers have to decipher reality from fantasy? Of businesses polled in the University of Dayton study, 326 said they were not convinced that students could make a clean break between their Facebook personas and their professional demeanor, so these employers see value in viewing online social networking sites to learn about job candidates.

Company officials do not appear apprehensive about Internet searches jeopardizing the law. Employment attorneys say it is not illegal for employers to search the Internet or publicly available Web sites created by applicants to see what information they can find. Moreover, the attorneys note the privacy issue is even ethically minimal if someone has put information about themselves on the Internet where millions of people have access to it (Pitfalls, 2006). Of course, employers could use Facebook to determine students' gender, race or sexual preference, but only 13% of the officials said they felt that scanning Facebook might violate equal opportunity employment laws.

The National Association of Colleges and Employers found that 27% of employers surveyed had reviewed job candidates' personal information on sites such as MySpace or Facebook or had conducted broader Internet searches on applicants (NACE, 2006). These non-comprehensive, unofficial background checks are easy to conduct. Most often, the reviews are conducted by interns or employees who are recent graduates since both groups have college e-mail addresses, enabling them to easily view online profiles (Finder, 2006).

As the senior associate director of the career center at Duke University, Kara Lombardi (personal communication, April 24, 2007) finds most human resource personnel "take an official stance that they do not formally use online social networks, but we do know that many are unofficially using it. Many of the employers that recruit on campus will bring young alums to campus to help interview. These alums, who do not work in HR, will look up candidates on Facebook. We have heard back from alums about deciding not to interview students based on what is posted in their profile."

Similar to the experiences of many college administrators, Lombardi was first introduced to the world of online social networking not by colleagues but by students. Peer educators in her office first acquainted her with Facebook, and she quickly garnered interest after learning the exorbitant amount of time students spend on OSN. Since then, Duke University's career center has embraced an appreciation for the benefits of online social networking, while working to ensure students understand the potential consequences associated with them. The career center posts on its Web site a statement developed in summer 2006:

Considerations for Blogs and Social Networks like MySpace and Facebook

Duke University takes free expression seriously and goes to great lengths to protect that right. Social networks such as Facebook and MySpace have expanded opportunities to express yourself, connect with friends and to build your network. Still, there are several responsibilities to consider when you create your persona and post messages online.

- **What you post is public information.** You have a much larger audience than you might be aware.
- **What you post is going to be around for a while.** Because caching and other forms of technology can capture your postings, information is accessible even after you've removed it.
- **What you post can harm others.** You are free to express yourself on social networks in ways that you feel are appropriate for you. However, it is important that you respect the privacy and rights of others. Posting things about others can place both you and your subject in a contentious situation.
