List of Contributors

Contents

Volume 1

Section I. Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference source by addressing crucial theories essential to the understanding of social computing. Chapters found within this section provide a framework in which to position social computing within the field of information science and technology. Individual contributions provide overviews of computer-mediated communication, social networking, and social software. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of social computing.

Section II. Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design of social computing tools and technologies. Throughout these contributions, fundamental development methodologies are presented and discussed. From broad examinations to specific discussions of particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful e-learning environments, social search engines, and social software are examined.

Volume II

Section III. Tools and Technologies

This section presents extensive coverage of the tools and specific technologies that change the way we interact with and respond to our environments. These chapters contain in-depth analyses of the use and development of innumerable devices and also provide insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of specific tools, such as social television, wikis, mobile photo galleries, and personal digital libraries. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Volume III

This section includes a wide range of research pertaining to the individual and organizational impact of social computing tools and technologies. Chapters included in this section analyze the usability of social software, the creation of social relationships in virtual communities, and social networking in educational settings. The inquiries and methods presented in this section offer insight into the implications of ubiquitous and pervasive computing at both an individual and organizational level, while also emphasizing potential areas of study within the discipline.

Section VI. Managerial Impact

This section presents contemporary coverage of the managerial implications of social computing. Particular contributions address the importance of guarding corporate data from social engineering attacks and explore a professional social network system. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how social computing can impact and inform practices and behavior.

Section VII. Critical Issues

This section addresses conceptual and theoretical issues related to the field of social computing. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters discuss ethical issues in social networking, security concerns that arise when individuals share personal data in social networks, and reducing social engineering impact. Overall, contributions within this section ask unique, often theoretical questions related to the study of social computing and, more often than not, conclude that solutions are both numerous and contradictory.

Volume IV

Section VIII. Emerging Trends

This section highlights research potential within the field of social computing while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section discuss social bookmarking, the emergence of virtual social networks, and new trends in educational social software. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Preface

With increased access to social networking tools, the development of Web 2.0, and the emergence of virtual worlds, social computing crosses cultural boundaries to join people in the digital landscape.

As the world moves closer and closer to the integration of technology into traditional social behaviors, there is a greater need for innovative research and development into the various aspects of social computing. Information Science Reference is pleased to offer a three-volume reference source on this rapidly growing discipline, in order to empower students, researchers, academicians, and practitioners with a wide-ranging understanding of the most critical areas within this field of study. This publication uncovers the growing and expanding phenomenon of human behavior, social constructs, and communication in online environments and provides the most comprehensive, in-depth, and recent coverage of all issues related to the development of cutting-edge social computing technologies. This reference work presents the latest research on social change, evolving networks, media, and interaction with technology to offer audiences a comprehensive view of the impact of social computing on the way cultures think, act, and exchange information.

This collection entitled, "**Social Computing: Concepts, Methodologies, Tools, and Applications**" is organized in eight (8) distinct sections, providing the most wide-ranging coverage of topics such as: 1) Fundamental Concepts and Theories; 2) Development and Design Methodologies; 3) Tools and Technologies; 4) Utilization and Application; 5) Organizational and Social Implications; 6) Managerial Impact; 7) Critical Issues; and 8) Emerging Trends. The following provides a summary of what is covered in each section of this multi-volume reference collection:

Section 1, **Fundamental Concepts and Theories**, serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of social computing. Chapters such as, "Computer-Mediated Communication Learning Environments: The Social Dimension" by Stefania Manca, as well as "Online Communities and Social Networking" by Abhijit Roy, provide foundational overviews of how individuals interact with social computing tools and the impact these tools have on shaping and influencing behavior. "Mobile Social Networks: A New Locus of Innovation" by Nina D. Ziv and "Mobile Social Networks and Services" by Lee Humphreys offer investigations into the recent emergence of mobile social networks, reviewing current trends and technologies and offering suggestions for future research. As this section continues, authors explore the many uses of social software and its implications in contributions such as "Social Software (and Web 2.0)" by Jürgen Dorn, "Self-Organization in Social Software for Learning" by Jon Dron, and "Living, Working, Teaching and Learning by Social Software" by Helen Keegan and Bernard Lisewski. These and several other foundational chapters provide a wealth of expert research on the elemental concepts and ideas which surround investigations of social computing technologies.

Section 2, **Development and Design Methodologies**, presents in-depth coverage of design and architectures to provide the reader with a comprehensive understanding of the emerging technological developments within the field of social computing. A number of contributions, including “Distributed Learning Environments and Social Software: In Search for a Framework of Design” by Sebastian Fiedler and Kai Pata, “Electronic Classroom, Electronic Community: Designing eLearning Environments to Foster Virtual Social Networks and Student Learning” by Lisa Harris, and “A Methodology for Integrating the Social Web Environment in Software Engineering Education” by Pankaj Kamthan highlight the many methods for the effective design of social software and networks that support education. With contributions from leading international researchers, this section offers developmental approaches and methodologies for social computing.

Section 3, **Tools and Technologies**, presents extensive coverage of the various tools and technologies that define and continue to redefine social computing research and implementation. This section begins with “A Modern Socio-Technical View on ERP-Systems” by Jos Benders, Ronald Batenburg, Paul Hoeken, and Roel Schouteten, which discusses a specific approach to creating socio-technical systems. This section continues with an in-depth investigation of social television, contained within the selections “In Search of Social Television” by Gunnar Harboe, “Asynchronous Communication: Fostering Social Interaction with CollaboraTV” by Brian Amento, Chris Harrison, Mukesh Nathan, and Loren Terveen, “Examining the Roles of Mobility in Social TV” by Konstantinos Chorianopoulos, and “From 2BeOn Results to New Media Challenges for Social (i)TV” by Konstantinos Chorianopoulos and Pedro Almeida. With more than a dozen additional contributions, this section provides coverage of a variety of tools and technologies under development and in use in social computing and social networking communities.

Section 4, **Utilization and Application**, describes the implementation and use of an assortment of social computing tools and technologies. Including 20 chapters such as “Social Networking Sites and Critical Language Learning” by Andy Halvorsen, “Using Social Networking to Enhance Sense of Community in E-Learning Courses” by Steve Chi-Yin Yuen and Harrison Hao Yang, “Publishing with Friends: Exploring Social Networks to Support Photo Publishing Practices” by Paula Roush and Ruth Brown, this section provides insight into the utilization of social computing tools and technologies for both personal and professional initiatives. “Social Software Use in Public Libraries” by June Abbas offers suggestions for applying social software techniques such as tagging and cataloguing in library settings. “Designing for Disaster: Social Software Use in Times of Crisis” by Liza Potts presents another interesting application of social software, illustrating the need for sociotechnical interventions in systems design. Contributions found in this section provide comprehensive coverage of the practicality and present use of social computing by organizations and individuals.

Section 5, **Organizational and Social Implications**, includes chapters discussing the impact of social computing on organizational and individual behavior, knowledge, and communication. This section begins with an examination of organizational knowledge, investigating its foundations and management in chapters such as “Managing Organizational Knowledge in the Age of Social Computing” by V. P. Kochikar, “Social Software for Bottom-Up Knowledge Networking and Community Building” by Mohamed Amine Chatti and Matthias Jarke, and “The Essence of Organizational Knowledge: A Social Epistemology Perspective” by Fei Gao. “The Usability of Social Software” by Lorna Uden and Alan Eardley argues that despite the prevalence of Web 2.0 tools and technologies, there is little research on usability evaluation. Successful virtual communication and collaboration are explored in chapters including “Building Social Relationships in a Virtual Community of Gamers” Shafiz Affendi Mohd Yusof and “Entering the Virtual Teachers’ Lounge: Social Connectedness among Professional Educators in Virtual Environments” by Randall Dunn. While these two chapters present very different applications of virtual collaboration, they both offer definitions of virtual communities and offer depictions of how virtual environments both differ from and resemble face-to-face communities.

Section 6, **Managerial Impact**, presents focused coverage of social computing in the workplace. Fernando Garrigos' chapter "Interrelationships Between Professional Virtual Communities and Social Networks, and the Importance of Virtual Communities in Creating and Sharing Knowledge" analyzes, as the title suggests, the relationship between professional virtual communities and social networks, and describes how these communities create and share knowledge. "Managing Relationships in Virtual Team Socialization," by Shawn D. Long, Gaelle Picherit-Duthler, and Kirk W. Duthler provides an overview of the emergence of virtual teams in the workplace and explores the specific issues virtual employees must overcome in order be efficient and productive. Also included in this section are chapters addressing topics related to social engineering attacks and enterprise social software, presenting an empirical view of managerial considerations for social computing.

Section 7, **Critical Issues**, addresses vital, conceptual issues related to social computing such as ethical considerations, security, and privacy. Chapters such as "Security and Privacy in Social Networks" by Barbara Carminati, Elena Ferrari, and Andrea Perego and "Emerging Cybercrime Variants in the Socio-Technical Space," by Wilson Huang and Shun-Yung Kevin Wang tackle the difficult question of privacy and data security in online environments. In "The Emergence of Agency in Online Social Networks," by Jillianne R. Code and Nicholas E. Zaparyniuk, the authors explores how agency emerges from social interactions, how this emergence influences the development of social networks, and the role of social software's potential as a powerful tool for educational purposes. "Social Network Structures for Explicit, Tacit and Potential Knowledge" by Anssi Smedlund highlights the role of knowledge, asserting that it is embedded in relationships between individuals rather than possessed by these individuals. These and other chapters in this section combine to provide a review of those issues which are the subject of critical inquiry in social computing research.

The concluding section of this authoritative reference tool, **Emerging Trends**, highlights areas for future research within the field of social computing, while exploring new avenues for the advancement of the discipline. "Legal Issues Associated with Emerging Social Interaction Technologies" by Robert D. Sprague depicts potential legal issues that can arise from social interaction technology use, such as employee behavior online impacting the ability to get or maintain a job. Similarly, "Public Intimacy and the New Face (Book) of Surveillance; The Role of Social Media in Shaping Contemporary Dataveillance" by Lemi Baruh and Levent Soysal investigates privacy implications of sharing personal data in a public environment. Other issues, such as codes of conduct in social networking sites, are explored in chapters such as "Conceptualizing Codes of Conduct in Social Networking Communities" by Ann Dutton Ewbank, Adam G. Kay, Teresa S. Foulger, and Heather L. Carter. New opportunities for using technology to maintain a healthy social network are demonstrated in "Using Ambient Social Reminders to Stay in Touch with Friends" by Ross Shannon, Eugene Kenny, and Aaron Quigley. These and several other emerging trends and suggestions for future research can be found within the final section of this exhaustive multi-volume set.

Although the primary organization of the contents in this multi-volume work is based on its eight sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore to ensure that the scholar, researcher and educator have access to the entire contents of this multi volume set as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited multi-user electronic access to the online aggregated database of this collection for the life of the edition, free of charge when a library purchases a print copy. This aggregated database provides far more contents than what can be included in the print version in addition to continual updates. This unlimited access, coupled with the continuous updates to the database ensures that the most current research is accessible to knowledge seekers.

The diverse and comprehensive coverage of social computing in this three-volume authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field, resulting in a greater understanding of the fundamental concepts and technologies while fueling the research initiatives in emerging fields. We at Information Science Reference, along with the editor of this collection and the publisher, hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of all aspects of social computing research.

Social Computing:
Concepts, Methodologies, Tools, and Applications

Subhasish Dasgupta
George Washington University, USA

The World Wide Web has been widely used for a number of applications over the years. It has altered the way businesses work and connect to their customers. E-commerce and e-business applications are widespread with these transactions making up a significant part of the economy. In recent years, another phenomenon called social computing has changed the Web. Common citizens have flocked to social computing websites such as Facebook, MySpace and Twitter in the millions, making these sites the fastest growing properties on the Web.

In this editorial I provide an overview of the area of social computing. We first define the concept of social computing. Then I present an overview of the fundamental concepts and theories in the area of social computing, research in the area of social computing that includes tools and applications in this field, systems development and design applications, utilization and application of social computing, organizational impact of social networks, critical issues in the area, and emerging trends in the area of social computing. Please note that the material provided in this editorial in each of the areas discussed above is not exhaustive but a representation of the most important research and ideas related to social computing.

INTRODUCTION TO SOCIAL COMPUTING

Social computing refers to an area of computer science that is the intersection of social behavior and computational systems[1]. So, social computing implies two components: a social behavior component and a computational system or technical component. The technical component provides the environment in which people interact. Another definition of social computing is, "Social computing is the use of technology in networked communication systems by communities of people for one or more goals."[2] Social computing takes many forms including social networks, RSS, blogs, search engines, podcasts, wikis, and social bookmarking (or tagging). A number of other terms are used loosely to refer to social computing. They are: online communities, Web 2.0, virtual communities and social networking. These terms have similar definitions, and these definitions sometimes overlap (Parameswaran and Whinston 2007). Online communities are defined as groups of people who meet and interact with others, are connected by a specific interest, are brought together by means of a technical platform, and can establish social relationships or a sense of belonging to the group (Leimeister et al 2008). According to Preece (2000), a virtual community refers to people with a common or shared purpose, whose interactions are governed by policies in the form of tacit assumptions, rituals, protocols, rules and laws and whose use of computer systems to support and mediate social interaction and to facilitate a sense of togetherness. We see that the definitions of online communities, virtual communities and social computing are overlap. We use the social computing as the overarching concept that includes online and virtual communities, RSS, blogs, wikis, and other systems as stated earlier. But, I do use the terms social computing and social networking interchangeably.

In the next section I present some fundamental concepts and theories in information systems.

FUNDAMENTAL CONCEPTS AND THEORIES

The underlying theories and concepts in social computing include social network analysis, and social identity theory. The foundation of social computing lies in the underlying social network. A number of researchers have studied the social network using a technique called social network analysis. Social network analysis is based on the assumption that the relationships between interacting units are important. The social network perspective encompasses theories, models, and applications that are expressed in terms of relational concepts or processes. Along with growing interest and increased use of network analysis has come a consensus about the central principles underlying the network perspective. The following are some of the characteristics of social network analysis:

- Actors and their actions are viewed as interdependent rather than independent, autonomous units
- Relational ties (linkages) between actors are channels for transfer or "flow" of resources (either material or nonmaterial)
- Network models focusing on individuals view the network structural environment as providing opportunities for or constraints on individual action
- Network models conceptualize structure (social, economic, political, and so forth) as lasting patterns of relations among actors

The unit of analysis in network analysis is an entity consisting of a collection of individuals and the linkages among them (Wasserman and Fraust 1994).

Social identity theory states that a social category (e.g. nationality, political affiliation, sports team) into which one falls, or to which one believes one belongs, defines who one is in terms of the defining characteristics of the category (Hogg et al, 1995). Social networks either provide individuals with the social identity, or draw people in because they already belong to a social category that is represented in the social network. Social identity theory provides the basic explanation of an individual's behavior in social computing.

Social network analysis (or structure) and social identity theory are, in my opinion, the fundamental concepts of social computing. We examine research in social computing in the next section.

Table 1. A Sampling of social computing research

Research	Independent Variables	Dependent Variables
Chen, et al (2008)	National Culture	Trust
Ardichvili et al (2008)	Culture in virtual communities	Knowledge Sharing
Gupta and Kim (2007)	Cognition, Affect	Attitude
Shang et al (2006)	Involvement, Trust, Participation, Perceived Attitude	Loyalty
Talukder and Yeow (2007)	Usability, Marketing, Languages	Virtual Community Characteristics

SOCIAL COMPUTING RESEARCH

Most of the research in social computing examines social and managerial issues with the adoption and use of social networks. Here I will examine social variables that were considered in research studies on social computing. Table 1 provides a sampling of representative research in this field.

In the social computing research area, some studies have explored the diffusion of virtual communities. Lin (1998) extended the Technology Acceptance Model (TAM) to study the role of online and offline features in sustaining virtual communities. Based on a survey of 165 community members, Lin examined the role of online factors such as information quality, system quality, and service quality, and offline features such as offline activities on the sustainability of virtual communities. The researcher found that perceived usefulness, perceived ease of use, and offline activities are determinants of sustainability of virtual communities. Since this research was conducted in a non-profit virtual community, Lin recommends additional research for profit-oriented virtual communities. In another study of virtual community adoption, Song and Kim (2006) adapted a different theory in information technology acceptance. They used the Theory of Reasoned Action (TRA) examined the effect of subjective norms, tendency to social comparison, and social identity on a behavioral intention to use an Avatar service.

Leimeister (2008) developed and tested a model to examine antecedents of the formation of virtual relationships of cancer patients within virtual communities. They found that virtual communities provide an environment in which virtual relationships among patients is established and these relationships play an important role in meeting patients' social needs. Internet usage intensity (active posting versus lurking) and perceived disadvantages of computer-mediated communication are determinants of the formation of virtual relationships. These relationships have a strong effect on the virtual support of patients. This research did not support earlier research that had found that the effect of marital status, education, and gender were strong determinants of the formation of virtual relationships in virtual communities.

Since social computing takes place across national boundaries, global issues such as culture are very important. Culture refers to shared values and beliefs of individuals in a unit. The unit could be a nation, a region or even an organization. These different levels of culture impact how individuals operate in a social network. Chen et al (2008) investigated the role of national culture on trust and compared this across virtual communities in China, Hong Kong, and Taiwan. They found that there exists significant differences in individual trust, social presence, stickiness, and word-of-mouth. Ardichvili et al (2006) examined the role of culture on knowledge sharing across different countries such as US, Russia and Brazil. Other research has looked at the impact of individual variables on the individual's attitude towards the social network.

This sample of research in social computing shows that studies in this area are basically of two types. Some researchers are extending theories that already exist in other areas of information systems to include social computing. For example, researchers are testing the technology acceptance models such as the TAM and TRA to see if they are valid in a social computing environment. Other researchers are developing and testing theories and concepts that are unique to the social computing environment. They are using concepts from the social sciences such as social network analysis and social identity theory to explain the structure and working of social networks. This multi-volume collection will provide readers with an overview of the kinds of research that is being done so far in the area of social computing. But, this is a young research area with lots of research to be done.

EMERGING TRENDS

I believe that social computing will grow at a feverish rate for another couple of years. Newer applications will be developed and distributed on social networks. We will see more mobile applications of social computing in the years to come. Facebook, Twitter and LinkedIn already have applications for the iPhone, but newer applications will utilize the capabilities of mobile computing.

THIS COLLECTION

This multi-volume set is a collection of latest research in the area of social computing. The research covers all aspects of social computing: the social dimension and the technical dimension. Studies report on various cultural, social and individual factors that have an impact the success of virtual communities and social computing.

About the Editor

Subhasish Dasgupta is Associate Professor of Information Systems and Director of the Master of Science Program in Information Systems Technology in the School of Business at George Washington University. Dr. Dasgupta received his BS (Physics) and MBA (MIS and Operations Research) degrees from the University of Calcutta, India, and PhD (Information Systems) from the City University of New York. His research interests include information technology adoption and diffusion, global information systems, virtual communities and social networking, and open source architectures. Dr. Dasgupta has published his research in journals such as *Journal of Strategic Information Systems*, *European Journal of Information Systems*, *Journal of Global Information Management* and *Journal of Information Education and Research* (now *Journal of Information Systems Education*). He has also presented many papers at international, national and regional conferences. Dr. Dasgupta serves as Editor-in-Chief of the *International Journal of Virtual Communities and Social Networking*.

Section I
Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference source by addressing crucial theories essential to the understanding of social computing. Chapters found within this section provide a framework in which to position social computing within the field of information science and technology. Individual contributions provide overviews of computer-mediated communication, social networking, and social software. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of social computing.

Chapter 1.1
Social Influence and Human Interaction with Technology

Robert S Friedman
New Jersey Institute of Technology, USA

Desiree M. Roberts
Rensselaer Polytechnic Institute, USA

Jonathan D. Linton
Rensselaer Polytechnic Institute, USA

INTRODUCTION

This chapter discusses how information that supports innovation flows throughout an organization, the construction and effects of team composition, the innovative processes that teams employ, and the development, implementation, and evaluation of systems used to manage the flow and distribution of information. As Allen and Cohen (1969) point out, effective communicators rise in their organizations as a result of their willingness to engage information—by reading and conversing outside of their immediate settings, but as Tushman (1977) explains, that kind of outreach precipitates special boundary roles, which come about to satisfy an organization's communication network's role of bridging an internal information network to external sources of information. Thompson (1965) investigates the conditions necessary to move an organization from a single-minded focus on productivity to one of those that facilitate innovation. At times, that means engaging rival firms, and von Hippel (1987) demonstrates that information sharing is economically beneficial to the organizations doing the trading. Freeman's (1991) finding that information regarding innovative processes entails the development of effective information networks confirms how important it is for successful innovation that there exist effective external and internal communication networks, and that individuals collaborate to share information. von Hippel (1994) returns later in the chapter to qualify this point by showing that there is a direct correlation between the level of stickiness and the expense related to moving that information to a location where it can be applied to solving a problem.

Bantel and Jackson (1989) begin the section on team composition by suggesting that certain demographic factors affect a team's ability to be innovative, but resource diversity—including communication ability—is ultimately essential to innovation. For Howell and Higgins (1990), identifying a champion among a team's members will facilitate innovation, while Anconia and Caldwell (1992) find that the greater the functional diversity, the more team members communicated outside of

DOI: 10.4018/978-1-60566-038-7.ch004

their teams' boundaries. Scott and Bruce (1994) take a different vantage point, focusing on the individual and his or her influence on and adaptation to an organization's climate for innovation. The section on innovation process begins with Hage and Dewar (1973), who conclude that ultimately, the values held by an organization's elite group are more significant when predicting innovation than the values of any single leader or even the entire staff, but the correlation between a single leader and innovation should not be dismissed as a valid predictor of an organization's ability to innovate. Even so, as Daft (1978) has found, there is evidence to support the theory that there can be opposing innovative processes in an organization: one that begins at the lower levels of its hierarchy, and one that percolates down from upper levels. Even more radical, Quinn (1985) proposes that corporate executives understand and adapt to the fact that the innovation environment is filled with surprise, characterized by chaos, and virtually immune to control. The chapter concludes with Porter and Millar's (1985) article describing how information technologies affect management strategies and how these strategies are disseminated throughout a firm.

FLOW OF INFORMATION

In 1969, Allen and Cohen set out to explain the course that scientific and technological information takes in research centers and laboratories. Are there distinct pathways that information travels as it moves from external sources to people working with research labs? Their study, premised on the idea that research done while excluding outside information into the lab will ultimately fall short, consisted of examining patterns of technical communication in two different research labs, each of which had identifiable technical communication networks that arose from the nature of social interaction and work structure. The most effective communicators, those the authors refer to as the "sociometric stars," rose to prominence in the lab environment through their willingness to "either make greater use of individuals outside the organization or read the literature more than other members of the laboratory" (p. 12). In other words, either all members of an R&D team proactively seek the latest information regarding recent developments in the field, or managers bring in knowledgeable people to serve as consultants to the staff.

They also found evidence in existing literature that the lesser the rate of internal communication in an organization, the more chance there is that the research team will perform poorly, suggesting to managers that there is a need for external sources of information. Managers and project leaders can stave off the need for external consultants by recognizing that there are different rates of information flow when one considers the different demands spurred by organizational loyalty and structure, and the value of shared experience as opposed to the organizational schema that are inculcated in an academic setting. In other words, the affiliations, loyalties, and social relationships that develop among team members can be thought of as one way to see how the world works; conversely, training and information received in an academic setting and then brought into a research facility can be thought of as a different coding scheme that "introduces the possibility of mismatch and attendant difficulties in communication between organizations" (p. 12). Having team members who understand both schema, and therefore serve as translators, can mitigate the negative effects of such a mismatch.

Allen and Cohen identify previous literature concerning the effect of "prestige or status hierarchies in a social system [on] the flow of information." Essentially, those of high status will be more sociable and therefore more communicative with one another, whereas those of lower status tend not to like one another or communicate effectively with one another, "direct[ing] most of their communication toward the higher-status members, without complete reciprocation" (p. 16). At the time of their writing, Allen and Cohen believed that gatekeepers—those who could translate and facilitate communication among different hierarchical levels of an organization—would continue to transmit information, but management of the laboratories studied failed to see the value in that role, and therefore either discourage[ed] this activity by failing to reward it, or to reward the gatekeeper by promotion and thereby [made] it impossible for him to continue as a transmitter of information" (p. 19).

Boundary Roles and Innovation

Tushman (1977) uses previous organizational behavior and research and development literature to inform his understanding of how "special boundary roles" serve as a way for innovative organizations to facilitate necessary "cross-boundary communication" in a research and development lab. Particular attention is paid to the "distribution of these special boundary roles within the organization and their impact on subunit performance," and how boundary roles factor into the innovative process (p. 587).

There is often a strong need for an innovating organization to provide information to a variety of external information areas. This need precipitates special boundary roles, which come about to satisfy an organization's communication network's role of bridging an internal information network to external sources of information. These boundary roles occur at several places in the organizational structure, and the nature of their distribution depends on the type of work occurring within the organization. Tushman's findings are consonant with other research "on boundary spanning in general and highlights the importance of boundary roles in the process of innovation" (p. 587).

Tushman summarizes previous literature on the process of innovation development and dissemination, identifying the variety of steps and phases that result in decisions and coordinative efforts, and by communication patterns. Ultimately, however, Tushman focuses on the three-step innovation process offered by Myers and Marquis (1969): "idea development (the generation of a design concept), problem solving (technical efforts and problem solving in developing the proposed idea), and implementation (pilot production, inter-area coordination)" and point out that among the various positions and descriptions of these communicative patterns, "one important difference is the locus of critical information and feedback" (Tushman, 1977, p. 588).

Although Tushman recognizes the importance "of extra-organizational communication since the laboratory must receive up-to-date information about market and technological developments," he also points to other researchers' findings regarding the relevance of understanding external information such as user or market need, as well as maintaining an awareness of trends related to "new technological products, processes, and knowledge" (p. 589).

Special boundary roles are crucial to the flow of technical information between R&D labs and the larger organizations of which they are a part. The success of new projects is due, in large part, from an effective interaction between R&D teams and units such as sales, marketing, and the factory floor. Understanding that there are blocks to information flow and the hazards that complicate "transferring information across organizational interfaces," Tushman looks to systems theory research for reasons why such problems develop. The more complex any organization becomes, the more subgroups differentiate not only their tasks and goals, but their methods of accomplishing them and the social norms and behaviors that define them. Problems arise when there are discordant norms and coding schemes. When there is an overt disconnect between subgroups, and information cannot flow across organizational boundaries, yet project success is dependent upon effective communication, it is crucial that organizations "develop special boundary roles" (p. 590).

Referring to Allen and Cohen's (1969) point that the identification of key nodes in a communication network serve as a conduit for relevant external information into an internal communication system, "communication stars" must be identified and empowered to connect external sources of information to the R&D lab, as these stars are capable of translating and applying external information to the specific needs of the project team. At the same time, Tushman raises the question of how important it is to keep the boundaries between R&D and the larger organization clearly defined, as the difficulties inherent to differing coding schemas of different subgroups, even in an R&D setting, can hinder the integration of product development. Having information flow through agents who can effectively communicate and mediate—those occupying special boundary roles—will result in progress in innovative product development. Tushman's 1977 research "indicates that special boundary roles function to link the innovating system with various sources of external information and feedback. Thus, communication with external areas is not distributed equally among the innovating unit's staff but takes place through a limited set of individuals able to translate between several coding schemes. These individuals, or special boundary roles, are well connected to external information areas and are frequently consulted within the innovating unit. These boundary roles exist to mediate communication across several organizational interfaces" (p. 602).

Productivity and Innovation

Thompson's 1965 article reminds us of the enormous efforts toward structural changes in organizations that are necessary to initiate and promote innovative thinking. Before beginning his overview of contemporary organizational design and the forces behind it, he offers one premise and one definition: "No attempt is made to answer the question as to whether innovation is desirable or not," and by "innovation is meant the generation, acceptance, and implementation of new ideas, processes, products or services. Innovation therefore implies the capacity to change or adapt" (p. 2). His approach is comparative, taking typical bureaucratic architectures and juxtaposing them to what organizational and behavioral psychologists would suggest as conditions "conducive to individual creativity" (p. 1). What are the conditions necessary to move an organization from the rigid hierarchical structures that promote productivity to a variety of levels of hierarchy to facilitate innovation?

The typical successful organization can be viewed as "high [on] productive efficiency but low [on] innovative capacity" (p. 1). However, there is no synonymous relationship between adaptive and innovative organizations: a firm can adapt to new and varied pressures but fail to come up with new ideas. The distinction made between adaptive and innovative firms does not mean there is a void in terms of innovative practices. The innovative firm is capable of putting new ideas into practice. However, in order for any organization to function effectively, a "production ideology," the set of goals, objectives, and methods that "legitimizes the coercion of the individual by the group," needs to be articulated. In a vertical organization, this would mean goals set by an owner or executive group carried out through the efforts of employees who have been hired to do specific, discrete, and non-overlapping functions (p. 2).

Thompson characterizes "this [stereotypical] organization [as] a great hierarchy of superior-subordinate relations in which the person at the top, assumed to be omniscient, gives the general order that initiates all activity [and] authority and initiation are cascaded down" the chain of command, much like the military, where "complete discipline [is] enforced from the top down to assure that these commands are faithfully obeyed…each position is narrowly defined as to duties and jurisdiction, without overlapping or duplication[, and problems] that fall outside the narrow limits of the job are referred upward until they come to a person with sufficient authority to make a decision" (p. 3). While the egalitarian and horizontal organizational structure may seem to suggest that there is value in considering "the organization as a coalition" of people, skills, and efforts to achieve agreed-upon goals, "according to the Monocratic stereotype, the organization as a moral or normative entity is the tool of an owner, not a coalition" (p. 4).

How can members of stereotypical organizations adopt innovative methods when the "extrinsic reward system, administered by the hierarchy of authority, stimulates conformity rather than innovation"? The answer is to create an environment in which each member is personally committed to the organization's goals so that the rewards for creative thinking and action are primarily intrinsic rather than material. In such an environment, the concept of success is defined by the synergy between the individual and the organization's goals rather than the completion of a specific task, often preceded by the "normal psychological state…of…anxiety" (p. 6). Success eventually becomes synonymous with conformity, but that conformity is antithetical to creativity. Therefore, to "gain the independence, freedom and security required for creativity, the normal individual has to reject this concept of success" (p. 6). The "traditional bureaucratic orientation is conservative," a condition not conducive to innovation, which is in fact perceived as "threatening." Its primary concern is "the internal distribution of power and status" resulting in "the distribution of… extrinsic rewards." Reaction to innovative ideas is first and foremost characterized as "How does it affect us?" (p. 7).

To move toward an organizational structure that promotes innovation, several basic resources are needed, including "uncommitted money [and] time, [but also the human resources of] skills and good will," which inculcate a positive and unbounded sense of an individual's "limits of his capacities, so that he has that richness of experience and self-confidence upon which creativity thrives—a professional" (pp. 10-11). This will promote a "structural looseness" in the organization that puts "less emphasis on narrow, non-duplicating, non-overlapping definitions of duties and responsibilities," defines people by their "professional type rather than the duties type," creates a more open and freer sense of communication and "decentralizes…assignment and resource decisions" (p. 13). How costly this approach would be is something that Thompson, in 1965, simply could not predict, as management theorists "do not know the value of the novel ideas, processes, and products, which might be produced by the innovative organization, and we do not know that our present methods of costing and control are the best approach to achieving low-cost production" (p. 20). He believes, though, "that bureaucratic organizations are actually evolving in this direction," and that evolution is manifesting itself in attempts toward "increased professionalization, a looser and more untidy structure, decentralization, freer communications, project organization when possible, rotation of assignments, greater reliance on group processes, attempts at continual restructuring, modification of the incentive system, and changes in many management practices" (p. 20).

Informal Trading Knowledge

In von Hippel's 1987 article, his focus is on "the informal trading of proprietary know-how between rival (and non-rival) firms." Presaging the positive, cooperative spirit of the open source movement, von Hippel suggests that such information sharing is economically beneficial to the organizations doing the trading, but also that such activity is potentially beneficial in "any situation in which individuals or organizations are involved in a competition where possession of proprietary know-how represents a form of competitive advantage" (p. 291).

Innovation and Information Networks

Freeman's 1991 article begins by identifying and summarizing a major focus of 1960s empirical research on the flow of information from external sources into innovative business organizations, resulting in a reiteration of "the vital importance of external information networks and of collaboration with users during the development of new products and processes…whilst recognizing the inherent element of technical and commercial uncertainty" (p. 499). Freeman builds on von Hippel's sense of benefit deriving from industry-wide cooperation and seeks new ideas related to the process of networking innovators and their ideas. He discusses the development, in the 1980s, of flexible, regional networks that promote cooperative research among competing organizations, "and whether they are likely to remain a characteristic of national and international innovation systems for a long time to come, or prove to be a temporary upsurge to be overtaken later by a wave of takeovers and vertical integration" (p. 499).

By identifying and comparing innovations that succeed, and juxtaposing them against those that fail, Freeman finds that the failures both had lower resource investment and resulted in poorer product development. Comparative components included the size of the firm, which did not "discriminate between success and failure" (p. 500), and the size of a distinct research and development project, which did discriminate. Information regarding the design, manufacture, and sale of new products, and the innovative processes embedded therein, entailed the essential role of information networks "both in the acquisition and in the processing of information inputs" (p. 501). This confirms how important it is for successful innovation that there exist effective external and internal communication networks, and that they collaborate to share information.

How these networks are organized affects how an organization addresses systemic innovation, as the information networks themselves are "an inter-penetrated form of market and organization" that contain differing levels of cohesiveness among their members. Freeman defines a "network" as "a closed set of selected and explicit linkages with preferential partners in a firm's space of complementary assets and market relationships, having as a major goal the reduction of static and dynamic uncertainty." Freeman indicates that cooperation among regional firms, "as a key linkage mechanism of network configurations," can take a variety of forms, including "joint ventures, licensing arrangements, management contracts, sub-contracting, production sharing and R&D collaboration" (p. 502). Allowing that "in the early formative period of any major new technology system, almost by definition there are no dominant designs or standards and a state of organizational flux" (p. 510), it is logical that innovative business groups are not weighed down or restricted by industry standard or characteristic R&D techniques, but as adoption of technologies and methodologies takes place, "economies of scale become more and more important and standardization takes place," thus reducing the number of competing firms. However, Freeman points out that there is an alternative outcome to such standardization, particularly when one includes information networks as essential components to innovation, and that is that the number and productivity of autonomous firms "will grow still more important and will become the normal way of conducting product and process development" (p. 510).

Sticky Information

von Hippel returns to this cohort of top-cited articles on information flow in his 1994 piece on "sticky information" and its role in problem solving in innovative environments. He stresses the importance of uniting information and problem-solving skills in one location, be it on site in a lab or virtually via the Internet, as a prerequisite to solving any problem in the scope of product innovation. As long as information is easily available and inexpensive or free to get and share with others, where the information needed to solve a problem is used, is not at issue; but "when information is costly to acquire, transfer, and use—is, in our terms, 'sticky'—we find that patterns in the distribution of problem solving can be affected in several significant ways" (p. 429). There is a direct correlation between the level of stickiness and expense related to moving that information to a location where it can be applied to solving a problem. The thrust of the paper is on "four patterns in the locus of innovation-related problem solving that appear related to information stickiness" (pp. 429-430). Underlying these patterns are a few basic premises. First, when sticky information that problem solvers need is located in one place, the people will gravitate toward the information. When that information is distributed, problem solvers may do portions of their work at each of the locations. The third pattern is driven by cost: when the information is particularly sticky (expensive to obtain and/or share), problem solvers will divide their goal into sub-problems that can be addressed using the information held at any individual site. Lastly, not all locations of sticky information will receive the benefit of investment intended to reduce the expense of information at that location. Issues arising from the sticky information phenomenon result in the following four patterns, according to von Hippel (1994, p. 429): "patterns in the diffusion of information, the specialization of firms, the locus of innovation, and the nature of problems selected by problem solvers."

von Hippel draws an analogy between the costs of information transfer in problem solving and those of the physical manufacture of a product. Just as when there is sticky information needed to solve a problem, drawing the activity to the information to keep expenses low, a manufacturing firm will try to locate its facilities in such a way as to keep its transportation costs as low as possible. Citing research that indicates trial and error as a significant component of problem solving in cases in which sticky information is located at multiple sites, von Hippel suggests that problem solving will "sometimes move iteratively among these sites" or efforts will be extended toward "reducing the stickiness of some of the information" (pp. 432, 436).

TEAM COMPOSITION

Information Processes and Innovation

Bantel and Jackson's 1989 paper takes a demographic approach to investigating the leadership characteristics that result in a tendency to innovate, rather than avoid new approaches to both technical (products, services, and systems) and administrative (human and organizational) innovation. Previous research in this domain approached top decision makers such as CEOs as individuals making decisions on their own. Bantel and Jackson's demographic approach focused on characteristics as variables of top management teams: "We assume this dominant coalition acts as a decision-making unit for the organization" (p. 107). The authors looked at the demographics of top decision-making teams in 199 banks to discover the elements of team composition that supported innovative activity. Innovations "were identified through reference to the state of the art in the industry" (p. 108).

"The demographic characteristics of top management teams [that] were examined [included]: average age, average tenure in the firm, education level, and heterogeneity with respect to age, tenure, educational background, and functional background. In addition, the effects of bank size, location (state of operation), and team size were assessed. Results indicate that more innovative banks are managed by more educated teams who are diverse with respect to their functional areas of expertise. These relationships remain significant when organizational size, team size, and location are controlled for" (p. 107).

There are two basic organizational theory approaches to understanding the role that leaders play in effectuating a company's performance. Some hold that leaders and their abilities are environmentally determined (and therefore have relatively little ability to control organizational structure or reshape factors that support action), while others look at leaders as proactive decision makers who have a great deal of power over the direction of a firm. However, there is a middle position, which views organizational leaders as conduits that allow external influences into their firms, "thereby facilitating adaptation to the environment" (p. 107). These perspectives have shaped organizational behavior research, resulting in yet another opposition of approaches. Bantel and Jackson divide the field into the "direct assessment approach," which "directly assess[es] the psychological attributes of decision-makers and examine[s] their relationship to outcomes," and the "demographic approach," which the authors view as being more practical, but in terms of statistical analysis, has the disadvantage that "characteristics do not co-vary perfectly with the psychological attributes of interest" (pp. 107-108). These different approaches suggest differing hypotheses to study, with the psychological approach stressing "the role of cognitive resources in group problem solving," while the demographic approach suggests significant value in "the role of cohort effects in organization processes" (p. 108).

Perhaps more fundamental than the divergence of research approaches, the authors point out that there is not agreement on what "innovation" means. They describe the term as being actively inflected (innovation as process), as nominally inflected (innovation as the end product, a program or a service), and adjectivally (innovation as an descriptive attribute that an organization manifests). Their review of the literature indicates that most references to the term often take the nominal sense—the thing the firm sells. "In other words, the innovation 'process' culminates with innovation 'items', and firms that cycle through the process relatively frequently are described as 'innovative'" (p. 108).

The authors' analyses resulted in identifying "three phases of the decision process: (1) problem identification and formulation; (2) exploration, formalization, and problem solving; and (3) decision dissemination and implementation" (p. 108). The second phase has an impact on the number, nature, and effectiveness of solutions generated, as well as the scope and content of the discussions. If one focuses on differences of degree among group members in any factor, one will find that groups consisting of members at higher levels of "knowledge and ability" will out-perform those with lower levels when the shared task involves creative problem solving. When the factors studied are different in kind, when faced with "complex, non-routine problems," the more "variety in skills, knowledge, abilities and perspective," the more effective the team (p. 109).

Regarding team composition and its effect on the exchange of information, diverse groups in terms of organizational experience often suffer from limited communication. While there is an assumption that age and organizational tenure are positively correlated, demographic evidence dispels it. The authors caution researchers "to separate the effects of age and tenure because explanations differ for why age and tenure might be related to innovation" (p. 110). Their study resulted in the following demographic factors of team composition affecting a team's ability to be innovative: age, organizational tenure, educational background, and functional experience, but ultimately, their "results suggest support for the cognitive resources perspective, which posits that both resource level and diversity are important for innovation" (p. 120).

The Role of the Champion

Howell and Higgins (1990) take a different perspective on demographics, seeking empirical evidence to support the hypothesis of champions, individuals within an organization who take risks by introducing new ideas and innovative techniques to a group, process, or industry to promote their ideas. They sought evidence that "personality characteristics, leadership behaviors, and influence tactics…influence the emergence of champions in organizations" (p. 318). Their study relied on previous literature in entrepreneurship, transformational leadership, and influence, as there is a perceived positive correlation between entrepreneurs and champions. Champions often inspire others, and therefore they are perceived as leaders even though they do not have the hierarchical stature or title.

Howell and Higgins developed questionnaires and survey instruments that were completed by 25 matched pairs of perceived champions and non-champions, seeking responses concerning the personality characteristics, leadership behaviors, and influence tactics of champions of technological innovations. In sum, "champions exhibited higher risk taking and innovativeness, initiated more influence attempts, and used a greater variety of influence tactics than non-champions [and] showed that champions were significantly higher than non-champions on all paths in the model" (p. 317).

As the business environment becomes increasingly complex and competitive, finding leaders who can contribute positively to technological innovation—its identification, evaluation, and adoption—is an essential factor in productivity, competition, and survival. Success is in part reliant on there being a champion, someone who is not necessarily a corporate figurehead, but more often an individual who can contribute to an organization's success by promoting significant ideas and methods in an enthusiastic manner at critical points in that firm's or in a specific product's lifespan. As previous research has shown, "in order to overcome the indifference and resistance that major technological change provokes, a champion is required to identify the idea as his or her own, to promote the idea actively and vigorously through informal networks, and to risk his or her position and prestige to ensure the innovation's success" (p. 317). Champions should not be confused with gatekeepers, as their roles are quite different. The gatekeeper moves information from external sources to the cohorts within a project that will benefit by it. The gatekeeper is not necessarily a member of any of the project groups. Champions, on the other hand, as members of a project's cohorts, go outside the project and its sponsoring organization to find external information deemed beneficial, then uses their enthusiasm for the project as a tool aimed at convincing peers as to the use of the new idea.

Not all enthusiasts are champions. There are personality traits that contribute to one's ability to be a champion, including those resulting in being able to lead and influence others. Previous research has shown that "since innovation adoption is largely a process of influence… both with subordinates, as indicated by leadership behavior, and with peers and superiors, as indicated by influence tactics," champions are essential to innovation adoption (pp. 318-320). Transformational leaders, sometimes referred to as change agents, "use intellectual stimulation to enhance followers' capacities to think on their own, to develop new ideas, and to question the operating rules and systems that no longer serve the organization's purpose or mission" (p. 321). They boost the confidence levels and enhance the skill sets of their subordinates to the degree of their assisting in promoting and executing innovative strategies in response to challenges.

Howell and Higgins reviewed the literature on entrepreneurial personalities and found "that entrepreneurs desired to take personal responsibility for decisions, preferred decisions involving a moderate degree of risk, were interested in concrete knowledge of the results of decisions, and disliked routine work," and are often involved in innovative activities (p. 322). This is a profile consistent with that of innovators who display confidence in their abilities and seek opportunities to test and demonstrate them.

The recipe for a champion is a combination of personality traits such as enthusiasm and risk-taking, leadership skills strong enough to move people from accepted and comfortable practices to new and untested behaviors, and organization-wide vision that can result in the adoption of innovative practices. The authors believe that their study, as a concatenation of empirical evidence and established theory "in the domains of entrepreneurship, transformational leadership, and influence…provide organizational implications for the detection, selection, and development of champions." Champions are risk-takers, innovators, and informal transformational leaders, in their view, as opposed to what other researchers have suggested. It is not "that dispositional effects are less important than situational effects in influencing people's attitudes in organizational settings, [but that] our results suggest that by ignoring individual differences, one neglects major variables relevant to an important organizational human resource" (p. 336).

Functional Diversity

Anconia and Caldwell (1992) seek to understand the impact of functional diversity on product development teams, challenging the accepted wisdom that, as the complexity of tasks suggests an increase of the use of cross-functional and diverse teams, innovation in product development will be enhanced by combining engineers with other specialists. The authors looked at the performance of 45 high-tech new product development teams by integrating "group demography with other aspects of group theory to predict [their] performance." They looked at "the direct effect of group demography and the indirect effects created by demography's influence on internal processes and external communication" (p. 322). Specifically, their "study investigates two things: the direct effects of group heterogeneity on ratings of new product team performance, and the indirect effects of heterogeneity attributable to internal group process and to communication with non-group organization members" (pp. 325-326).

Their findings include different effects resulting from functional diversity (job tasks, domains, and limitations) and tenure diversity (length of time in a position) on team communication. The more functional diversity there was, the more team members communicated outside of their teams' boundaries, with groups such as marketing and management. Moreover, "the more the external communication, the higher the managerial ratings of innovation" (p. 321). When looking at tenure diversity, its effects were centered on how team members interacted rather than how and how much they communicated with external groups. The more diverse the tenure, the greater the level of improvement in group dynamics such as setting and buying into group goals and priorities, which yielded positive team assessments of performance. Sometimes, though, diversity is not wholly good and not solely positive, as it can also directly impede team performance. As the authors found, "Overall the effect of diversity on performance is negative, even though some aspects of group work are enhanced. It may be that for these teams diversity brings more creativity to problem solving and product development, but it impedes implementation because there is less capability for teamwork than there is for homogeneous teams" (p. 321). It is up to the team to navigate the negative functions of diverse teams so that the positive effects that diversity has on team interaction can be realized; this can be accomplished through increased communication and proactive resolution of conflict. Concurrently, it is up to management to recognize the tensions and impediments of diverse team composition so that the team does not suffer from organizational pressures from above, and the team is rewarded for its combined outcomes rather than individuals' functional outcomes.

Previous research has established that different demographic factors affect different variables. Age and sex affect economic states, geographic movement patterns, and crime rates, for example. How do demographic factors affect organizations and teams? Researchers have related demographic composition to employee turnover, to supervisors' performance evaluations of subordinates, and to types and levels of innovative practice within organizations. "For product development teams, two variables are likely to be of particular importance: the homogeneity of organization tenure and the mix of functional specialties" (p. 322). If a team is cross-functional, it has greater access to a wider array of expertise than if it were uni-functional. If a cross-functional team includes representatives from other departments of an organization, such as marketing, product transfer is facilitated. The authors also suggest that similarity in organizational tenure leads to enhancement of team integration because of increased "attractiveness of members to one another" (p. 323). Previous research also indicates that demographic diversity results in more conflict, and less team cohesion and ineffective communication than a homogenous team. Research on team conflict indicates that there will be more conflict among team members when individuals are relying on each other for task completion but they share different goals; the literature on group formation and effectiveness indicates that teams with diverse members often have difficulty integrating different values and cognitive styles. Their conclusion is that, if "not managed effectively, this diversity can create internal processes that slow decision making and keep members from concentrating on the task" (p. 323). Tenure diversity, for a new team member, also poses such negative factors as fewer opportunities to interact, differences in experience and perspectives, and a sense of exclusion from those group members who were teamed together at the same time. These distinctions hinder a team's ability to establish goals or set priorities.

The research literature on innovation also finds that diverse teams suffer from difficulties in reaching agreement or setting goals and establishing priorities. As new product teams have to obtain and share resources and information from other entities within an organization so that their tasks and goals can be accomplished, understanding the role of team communication—both internal and external—is important. High performing teams have greater amounts of communication among team members than low performing teams and organizations. If a team has a member that can translate and transmit information from the outside to the other team members, group performance can be enhanced.

The authors conclude by indicating that team productivity can increase when a team is composed of people with diverse sets of skills, knowledge, and interpersonal relationships with others in the organization. Tenure diversity can also be a positive factor, if the team takes advantage of its "range of experiences, information bases, biases, and contacts. Members who have entered the organization at different times know a different set of people and often have both different technical skills and different perspectives on the organization's history" (p. 325). However, "from a managerial perspective these research findings suggest that simply changing the structure of teams (i.e., combining representatives of diverse function and tenure) will not improve performance. The team must find a way to garner the positive process effects of diversity and to reduce the negative direct effects. At the team level, training and facilitation in negotiation and conflict resolution may be necessary. At the organization level, the team may need to be protected from external political pressures and rewarded for team, rather than functional, outcomes. Finally, diverse teams may need to be evaluated differently than homogeneous teams" (p. 338).

Individual Adaptation

Unlike Anconia and Caldwell, Scott and Bruce (1992) focus on the individual and his or her influence on and adaptation to an organization's climate for innovation. The authors ground their research in social interactionist theory and address the questions of how "leadership, work group relations, and problem-solving style affect individual innovative behavior directly and indirectly through perceptions of a "climate for innovation" (p. 581). Does the actual job or task that an individual is working on influence innovative behavior? Previous research has indicated that there is a "moderate relationship between climate and performance." To ascertain whether or not a job task proves to be a facilitator or hindrance to creativity, the authors "tested whether type of job assignment moderated the relationship between innovative behavior and each of the predictors in the model" (p. 581). They hypothesize that an individual's perception of the organizational climate for innovation is affected by the variables of leadership, work group relations, and problem-solving style, and used structural equation analysis to determine that the model proposed explained 37% of the variance in innovative behavior, concluding that task type actually does moderate the relationship between leader role expectation and innovative behavior (p. 580).

Referring to the accepted belief that managing innovation grows more difficult as an individual's attention is diverted from assigned task or goal, understanding both the motivation for innovative behavior and the nature of an environment that can foster motivation is essential. "Managing attention is difficult because individuals gradually adapt to their environments in such a way that their awareness of need deteriorates and their action thresholds reach a level at which only crisis can stimulate action" (p. 580).

There are three stages of individual innovation: problem recognition and the beginnings of solution generation, seeking of sponsorship or buy-in for that solution from those within the innovative environment, and the production of a model or prototype that can be used by a wider array of stakeholders. Innovation turns out to be the outcome of four interacting systems: an individual, a leader, a work group, and the climate for innovation (p. 582). What distinguishes Scott and Bruce's research from the literature addressing the relationship among tasks, technology, perception of climate, and effectiveness is their attention to how a task affects the moderation of the climate of innovation at the individual level. "When a task is routine or when individual discretion is low, the relationship between climate and innovative behavior is likely to be weaker than when the task is non-routine and high discretion is granted" (p. 588). Their summary of findings includes "leadership, support for innovation, managerial role expectations, career stage, and systematic problem-solving style to be significantly related to individual innovative behavior, and the hypothesized model explained almost 37 percent of the variance in innovative behavior" (p. 600).

The Innovative Process

Hage and Dewar (1973) elucidate the practicality of "elite values" as a concept and discuss how to go about measuring them empirically. "There are both formal and behavioral criteria, and one can easily imagine a continuum of elite participation with the precise cutting point of membership and non-membership remaining indistinct. Therefore, various definitions of membership need to be explored" (p. 279). To do so, the authors juxtapose for comparison concepts of elite values and those identified as criteria for leaders and members with the "three structural variables of complexity, centralization, and formalization" (p. 279). The amount of variance among these terms supported their being considered as independent variables. Hage and Dewar present the hypothesis that what the elites of an organization value has a direct effect upon what the organization accomplishes, but complicate the question by suggesting four alternative explanations for an organization displaying behaviors associated with elite values.

The first explanation involves organizational structure, as previous research has shown that structural variables such as complexity, centralization, and formalization are related both to rates of program change and the prediction of other organizational performances. One should also consider task structure, the second explanatory idea, as an organization maintaining a diversity of tasks will have a diversity of perspectives applied to them. This interplay of task and perspective "produces a creative dialectic that results in the development of innovative products and services," as a diversified task structure necessitates a diversified pool of professionals, each having access to specialized knowledge and sources of information (pp. 279-280). Third, Hage and Dewar note the "inverse relationship between centralization and program innovation." The more influential, elite members of an organization who can effect change and retain that power, the less opportunity there will be for non-elites to implement innovative ideas, as their suggestions would be concomitant with suggestions for change in "power, privilege and reward." Fourth, if power is centralized, there is less opportunity for innovation resulting from exchange of ideas or "the creative dialectic implied by complexity or diversity of tasks" (p. 280). Hage and Dewar gauged the degree of centralization by asking staff to describe the amount of participation they had in decision making, aggregating their responses as an average of positional means, with staff classified according to task assignment and hierarchical position in the organization (p. 283), suggesting that there is complementarity between elite size and degree of centralization.

There is a truism in organizational research that leaders are the source of strong influence. The authors describe leadership in organizations as "an interactive process wherein the leader provides certain services to the organization in exchange for legitimacy, respect, and compliance with his wishes by the staff" (p. 280). But leaders also act as mediators, spokesmen, and decision makers, and therefore the value they bring to an organization can be summarized as an agent of uncertainty reduction; power and influence increase as the general level of uncertainty among the staff decreases.

The authors conclude that ultimately, the values held by the elite group are more significant when predicting innovation than the values of any single leader or even the entire staff, but the correlation between a single leader and innovation should not be dismissed as a valid predictor of an organization's ability to innovate. "The association between Elite values and performance gives one some basis for arguing that statements about the goals of an organization from members of the Elite are probably more adequate than the executive director's perceptions alone" (p. 287).

A Dual-Cored Model of Organizational Innovation

Daft (1978) investigated the innovative process in an educational setting and examined the "behavior of administrators' vis-à-vis lower employees as innovation initiators…for a sample of school organizations [and relates his findings] to the professionalism of organization members, organization size, and frequency of innovation adoption" (p. 194). What leads administrators and other technical employees in this domain to adopt innovative approaches to problem solving? Daft offers findings of previous research to support the theory that there can be opposing innovative processes in an organization: one that begins at the lower levels of its hierarchy, and one that percolates down from upper levels. Therefore, his "findings are used to propose a dual-core model of organizational innovation" (p. 193).

Do organization leaders have primary impact on organizational innovation, as Hage and Dewar (1973) propose, linking innovation adoption to the "status and sociometric centrality of organization top administrators," or to top administrators' "cosmopolitan orientation," or perhaps with individual administrator's "motivation to innovate" (Daft, 1978, p. 193)? The answer is elusive, but much of the accepted research on innovation to the time of Daft's article suggests that leaders are active in the innovation process, acting as the connection between the organization's hierarchy and the technical environment in which staff and administrators work. By mere status and rank, organizational leaders are in position to innovate, and they can serve in supporting roles as well, by finding funds to implement new programs. By virtue of their leadership status, top administrators also influence innovation by setting priorities and goals (p. 193). Daft's concern is to find "underlying organization processes" that support innovation, as such information would be beneficial in providing knowledge that supports innovative alternatives to existing problems, and basic knowledge of organizational innovative processes would facilitate new ideas that may eventually provide innovative techniques that can be adopted (p. 194).

The two components of Daft's dual-core model derive from the organizational/human and the technological/mechanical orientations of a firm. This dichotomy is illustrative of how innovative ideas can come from either end of an organization's hierarchy, with administrative innovations moving from top to bottom, and technical innovations moving from bottom to top; therefore, innovative "ideas follow different paths from conception to approval and implementation" (p. 195). Keeping in mind that the larger an organization is, the more complex and refined the division of labor, it is not unusual that technical staff will be most concerned with technical innovations that are within their scope of work. This is in keeping with the elements of professionalism that define this group as a working unit, as they base the esteem they offer on team members' "education and training, participation in professional activities, exposure to new ideas, autonomy, and the desire for recognition from peers rather than from the formal hierarchy" (p. 196).

Daft summarizes the different roles that administrators and technical staff play in the innovation process, with the basic distinctions in definition of the groups being that a "technical innovation is an idea for a new product, process or service. An administrative innovation pertains to the policies of recruitment, allocation of resources, and the structuring of tasks, authority and reward. Technical innovations usually will be related to technology, and administrative innovations will be related to the social structure of the organization." This being the case: "(1) Each group is expected to initiate innovations pertaining to their own organization task; (2) this division of labor is expected to heighten as employee professionalism and organization size increase; (3) the absolute number of proposals initiated by each group is also expected to increase as professionalism and size increase; but (4) the greater number of proposals may not lead to greater adoptions because professionalism and size may be associated with greater resistance to adoption" (p. 197).

This does not mean that there are barriers between the two domains in terms of initiation and development of innovative strategies and solutions. In both the administrative and technical components of an organization, the process of innovation is often based on the professionalism of the employees and offered by individuals who are domain experts who will most likely use and benefit from the innovation proposed. In some organizations, "the amount of innovation and the degree of coupling between the two cores may be a function of technology, rate of change, and uncertainty in the environmental domain as well as employee professionalism" (p. 206). However, Daft finds that administrative innovation tends to happen in anticipation of changes in factors in the administrative domain, such as new goals and objectives, hierarchy, and control structures. In sum, organizations usually adopt more administrative than technical innovations, and the "technical core appears to be subordinate and tightly coupled to an active and influential administrative core" (p. 207).

Innovation Success Factors

Quinn's 1985 article opens a window onto the results of a multi-year, worldwide study of innovative companies, and highlights some of the "similarities between innovative small and large organizations and among innovative organizations in different countries" in an effort to understand the pervasive perception that world technological leadership is passing from the United States to our international rivals in Europe and the Far East (p. 73). While some would hold bloated U.S. corporate bureaucracies responsible for stifling innovation, Quinn suggests that there are large companies that understand what it takes to promote the innovative process and reap its rewards, like so many entrepreneurs who accept "the essential chaos of development, pay close attention to their users' needs and desires, avoid detailed early technical or marketing plans, and allow entrepreneurial teams to pursue competing alternatives within a clearly conceived framework of goals and limits" (p. 73). Small companies are associated with successful production of innovative ideas and products for several reasons, including that "innovation occurs in a probabilistic setting." Quinn refers to the very high percentages of venture failure—failures that the general public and corporate competitors never see—as one reason. On the opposite end of the spectrum are large corporations that might want to promote a new concept or product but are limited by the knowledge that innovation brings with it the real costs of failure. Unlike a new, small business, a large corporation does not want to "risk losing an existing investment base or cannibalizing customer franchises built at great expense" or attempt to "change an internal culture that has successfully supported doing things another way" or dismiss "developed intellectual depth and belief in the technologies that led to past successes." Emergent companies are not scrutinized and restricted by "groups like labor unions, consumer advocates," and should their venture fail, they "do not face the psychological pain and the economic costs of laying off employees, shutting down plants and even communities, and displacing supplier relationships built with years of mutual commitment and effort" (pp. 73-74).

Quinn's findings, supported by previous research in the management of innovation, yield a list of "factors [that] are crucial to the success of innovative small companies," including:

1. **Need orientation**: A personality trait held by inventor entrepreneurs. "They believe that if they 'do the job better,' rewards will follow."
2. **Experts:***and fanatics* are two adjectives applicable to company founders "when it comes to solving problems."
3. **Long time horizons:** Unlike their large corporation counterparts, inventor entrepreneurs, fanatics that they are, tend to "underestimate the obstacles and length of time to success. Time horizons for radical innovations make them essentially 'irrational' from a present value viewpoint."
4. **Low early costs:** Innovators often are not burdened by large fixed costs such as rent, payroll, and employee health care plans, tending to minimize expenses by maximizing existing space.
5. **Multiple approaches:** "Technology tends to advance through a series of random—often highly intuitive—insights frequently triggered by gratuitous interactions between the discoverer and the outside world. Only

highly committed entrepreneurs can tolerate and even enjoy this chaos."

6. **Flexibility and quickness:** Two traits associated with and resultant from each of the items above, with the added benefit of being undeterred "by committees, board approvals, and other bureaucratic delays, [allowing] the inventor-entrepreneur [to] experiment, test, recycle, and try again with little time lost."
7. **Incentives:** While small-scale innovators realize that they will personally reap the benefit of their success, Quinn recognizes that they "often want to achieve a technical contribution, recognition, power, or sheer independence, as much as money."
8. **Availability of capital:** Quinn's assessment at the time of publication posits "America's great competitive advantages [to be] its rich variety of sources to finance small, low-probability ventures" (pp. 75-76).

Juxtapose these eight factors for innovative success against what Quinn terms "bureaucratic barriers to innovation," and one has a comprehensive picture as to how and why many in 1985 viewed America as losing its role as the world's technological leader:

1. **Top management isolation:** Similar to what Bantel and Jackson would posit five years later, Quinn suggests that "senior executives in big companies have little contact with conditions on the factory floor or with customers who might influence their thinking about technological innovation."
2. **Intolerance of fanatics:** As is often the case in many domains where an unknown challenges the status quo, Quinn finds that large "companies often view entrepreneurial fanatics as embarrassments or troublemakers."
3. **Short time horizons:** Ladened with the weight of public perception and stockholder expectation, corporations often feel the "need to report a continuous stream of quarterly profits," which is antithetical to "the long time spans that major innovations normally require."
4. **Accounting practices:** "By assessing all its direct, indirect, overhead, overtime, and service costs against a project, large corporations have much higher development expenses compared with entrepreneurs working in garages."
5. **Excessive rationalism:** Large entities need to be managed and often via cautious business practices that are prescriptive and constrained in comparison to free-wheeling entrepreneurial techniques. "Rather than managing the inevitable chaos of innovation productively, these managers soon drive out the very things that lead to innovation in order to prove their announced plans."
6. **Excessive bureaucracy:** As a direct result of excessive rationalism, "bureaucratic structures require many approvals and cause delays at every turn."
7. **Inappropriate incentives:** The process of innovation is rife with surprise, which is poisonous to the "reward and control systems in most big companies." Large, bureaucratic organizations cannot permit challenges to their "well-laid plans, accepted power patterns, and entrenched organizational behavior" (pp. 76-77).

Quinn proposes that corporate executives understand and adapt to the fact that the innovation environment is filled with surprise, characterized by chaos and virtually immune to control. If they begin to adopt and implement some of the techniques and perspectives that successful entrepreneurs practice, and bring "top-level understanding, vision, a commitment to customers and solutions, a genuine portfolio strategy, a flexible entrepreneurial atmosphere, and proper incentives for innovative champions, many more large companies can innovate to meet the severe demands of global competition" (p. 84).

IT Use for Competitive Advantage

Porter and Millar (1985) address the role of information technology in an organization's strategy for competitive advantage. It is not insignificant or obvious to point out that at the time of this article's publication, information technologies fulfilled primarily quantitative functions. 1985 preceded ubiquitous e-mail, graphical user interfaces, and the Internet as a global communication network. As the authors indicate, "Until recently, most managers treated information technology as a support service and delegated it to EDP departments." Porter and Millar's goal is to "help general managers respond to the challenges of the information revolution" such as it was in 1985. Presciently enough, they are quick to point out that "managers must first understand that information technology is more than just computers." Indeed, understanding how managers can put these tools to use for competitive advantage is essential, as IT is "transforming the nature of products, processes, companies, industries, and even competition itself" (p. 149).

How should managers view information technologies in order to assess and implement their strategic significance? How and why do these technologies change "the way companies operate internally as well as altering the relationships among companies and their suppliers, customers, and rivals"? They should begin by recognizing the general ways in which technology affect business competition: "it alters industry structures, it supports cost and differentiation strategies, and it spawns entirely new businesses." Once these outcomes have been recognized, managers can follow the authors' five-step plan to "assess the impact of the information revolution on their own companies." Looking back with over 20 years of growth and change in information technologies, it is to the authors' credit for indicating early on how business advantage will derive from our abilities to make strategic use of the increasingly convergent and linked technologies that process the information (p. 149).

Porter and Millar urge managers to understand that the "role of information technology in competition is the 'value chain,' [a] concept [that] divides a company's activities into the technologically and economically distinct activities ['value activities'] it performs to do business." Profitability derives from a business's ability to create more value than "the cost of performing the value activities." Competitive advantage is achieved when "a company…either perform[s] these activities at a lower cost or…in a way that leads to differentiation and a premium price (more value)" (p. 150).

One can assess the potential profitability of a company by understanding its structure, which Porter and Millar contend is "embodied in five competitive forces…the power of buyers, the power of suppliers, the threat of new entrants, the threat of substitute products, [and] the rivalry among existing competitors." The degree to which the strength of these five forces coalesces obviously "varies from industry to industry as does average profitability." What managers need to keep in mind, however, is that the "strength of each of the five forces can also change, either improving or eroding the attractiveness of an industry" (p. 155). Moreover, given that "information technology has a powerful effect on competitive advantage in either cost or differentiation…technology affects value activities themselves or allows companies to gain competitive advantage by exploiting changes in competitive scope" (p. 156).

What specific steps can managers take to avail themselves and their companies of the strategic advantages for which information technologies have already provided positioning? Porter and Millar offer the following five:

1. **Assess information intensity:** "A company's first task is to evaluate the existing

and potential information intensity of the products and processes of its business units."

2. **Determine the role of information technology in industry structure:** "Managers should predict the likely impact of information technology on their industry's structure."
3. **Identify and rank the ways in which information technology might create competitive advantage:** "The starting assumption must be that the technology is likely to affect every activity in the value chain."
4. **Investigate how information technology might spawn new businesses:** "Managers should consider opportunities to create new businesses from existing ones."
5. **Develop a plan for taking advantage of information technology:** "The first four steps should lead to an action plan to capitalize on the information revolution" (pp. 158-159).

Ultimately, "companies that anticipate the power of information technology will be in control of events. Companies that do not respond will be forced to accept changes that others initiate and will find themselves at a competitive disadvantage" (p. 160).

CONCLUSION

A laboratory that places a reliance on internal information, while excluding outside information from flowing into the lab, will ultimately fall short of its potential for discovery. This is demonstrated by the success of researchers inside a laboratory, who make greater use of individuals outside the organization and/or the literature (Allen & Cohen, 1969). This work lays a critical foundation for the need to boundary-span and the existence and importance of different types of roles within a research environment, and for organizations involved with innovation in general. These boundary roles satisfy an organization's communication network's role of bridging an internal information network to external sources of information (Tushman, 1977). Boundary roles and the interface between employees inside an organization with employees outside of an organization are highlighted in the discussion of the importance of informal trading of proprietary know-how between members of rival (and non-rival) firms (von Hippel, 1987). This work arguably sets the theoretical ground for the open source movement, while Freeman's (1991) consideration of benefit derived from industry-wide cooperation and networks of innovators similarly sets the theoretical stage for industry/government consortia focused on pre-competitive research. While the importance of boundary spanning and working/interacting with individuals outside the organization has been discussed, the criticality of close proximity is stressed, due to the "stickiness of information" (von Hippel, 1994).

Enormous structural changes in an organization are necessary to initiate and promote innovative thinking (Thompson, 1965). The focus on structural change is to move an organization away from one being highly efficient but low on innovation, to one that is high on innovation while retaining as much efficiency as possible. Some of these changes are illustrated by findings associated to the nature of team structures that support innovation. Leadership characteristics that result in a tendency to innovate are suggested to be a function of the top management team, rather than the CEO (Bantel & Jackson, 1989). A critical part of the management team, in relation to a specific innovation, is that of the *champion*. Champions are identified as the key individuals within an organization who take risks by introducing new ideas and innovative techniques to a group, process, or industry to promote their ideas (Howell & Higgins, 1990). Moving from managers to team members, it was found that the more functional diversity in an organization's product development team, the more team members communicated outside of their teams' boundaries with groups such as marketing and management. External communication corresponded to higher managerial ratings of innovation (Anconia & Caldwell, 1992). Also important is focusing on the individual's influence on and adaptation to an organization's climate for innovation. It is found that organizational climate for innovation is affected by the variables of leadership, work group relations, and problem-solving style, concluding that task type moderates the relationship between leader role expectation and innovative behavior (Scott & Bruce, 1994). Having considered teams, some final thoughts are offered on the innovative process.

There is complementarity between elite size and degree of centralization, and this is important for the acceptance and integration of innovation (Hage & Dewar, 1973). In other words, the upper management or elite are the enablers or disablers of innovation. This view is expanded on from findings that there can be opposing innovative processes in an organization: ones that begin at the lower levels of an organization's hierarchy, and ones that percolate down from upper levels—a dual-core model of innovation (Daft, 1978). The consideration of the differences associated with firm, size, region, and incumbent vs. emergent companies is offered though a multi-year study (Quinn, 1985). Finally, early advice was offered on the role of information technology in obtaining competitive advantage (Porter & Millar, 1985):

1. Evaluate the existing and potential information intensity of products and processes.
2. Predict the likely impact of information technology on industry structure.
3. Identify and rank the ways that information technology may offer competitive advantage.
4. Embrace the idea that information technology promotes the spawning of new businesses from existing ones.

Chapter 1.2
Social and Human Elements of Information Security:
A Case Study

Mahil Carr
Institute for Development and Research in Banking Technology, India

ABSTRACT

This chapter attempts to understand the human and social factors in information security by bringing together three different universes of discourse – philosophy, human behavior and cognitive science. When these elements are combined they unravel a new approach to the design, implementation and operation of secure information systems. A case study of the design of a technological solution to the problem of extension of banking services to remote rural regions is presented and elaborated to highlight human and social issues in information security. It identifies and examines the concept of the 'Other' in information security literature. The final objective is to prevent the 'Other' from emerging and damaging secure systems rather than introducing complex lock and key controls.

DOI: 10.4018/978-1-60566-036-3.ch008

AI can have two purposes. One is to use the power of computers to augment human thinking, just as we use motors to augment human or horse power. Robotics and expert systems are major branches of that. The other is to use a computer's artificial intelligence to understand how humans think. In a humanoid way. If you test your programs not merely by what they can accomplish, but how they accomplish it, they you're really doing cognitive science; you're using AI to understand the human mind.

-Herbert Simon

INTRODUCTION

Information security falls within the broad category of security. All the while when designing systems, designers employ an underlying model of the "human being" who is either an "attacker," "adversary," "eavesdropper," "enemy," or "opponent," apart from the normal user of a system who is a "beneficiary," "customer," or "user." For the sake of simplicity, let us call the human being who interacts with the information system in the normal, authenticated, and authorized user mode as a legitimate "user." Let us call a human being who interacts with the system performing some illicit operations not within the legitimate framework as the "other." It is important to understand that the same person may switch between different modes from user to the other depending on the context. Most security systems employ a model of the "other" in relation to which the security features of systems are designed.

This chapter focuses on fundamental underlying premises that are implicitly or explicitly employed while constructing secure information systems. This chapter attempts to open the door for a new approach to the study of information security. It examines the human and social factors in information security from the perspective of a model of human behavior and cognitive science. A real world case study is the basis from which insights are drawn from the process of its design (but not actual implementation). We attempt to outline three distinct universes of discourse and frames of reference and try to relate them together. First, we look at the underlying broad philosophical assumptions of security frameworks in general. Second, we choose a model of human behavior from a systems perspective and situate a cognitive science approach within it. Third, we analyze the technical fabrication of information security protocols in the context of human and social factors, drawing insights from a case study. We discuss and highlight issues in providing secure messaging.

The philosophy of security section discusses the reason why at all we need secure systems. Secure systems are products of a particular time, space, and the level of technology currently available in a society. From the nature of humanity we draw the conclusion that all human beings have the potential to create security hazards. However, whether a person is a legitimate user of the system or the "other" (at the individual level) is determined by his or her cognitive (rational) capacities, emotions (affective states), intent (will), spirituality (belief systems adhered to), and the overt behavior of the individual that is expected of him or her. This provides an explanatory framework to understand why individuals who are intelligent opt to undertake malicious activities (e.g., "hackers" and "terrorists"). The social setting in which the individual is embedded to a great extent determines his or her predisposition to choose act the role of "the user" or the "other." The expression of the "collective conscience" of the community to which he or she belong gives sustenance to the emotional basis, the formation of will, the spiritual basis, and specifies public action that is encouraged. Though these particular human and social factors are not treated in depth in this chapter, it points out that these factors have to be studied seriously and an approach should be taken to prevent the emergence and continued presence of the "other" in the social space. This probably is a more secure way of ensuring implementation of security features.

We look at a case study where information security is of key concern in a modern financial system. The case study outlines a design process for remote banking that offers several technical and managerial challenges. The challenge is to be able to extend banking to communities that hitherto have had no experience in banking and to those who are illiterate. This chapter outlines the technical issues that need to be addressed to make remote banking a reality. From this case study, we draw conclusions of how the "other" is present in the design of the project. We have only emphasized and dealt with the cognitive model of the "other" among the several human and social factors involved in providing a secure financial system. We conclude the chapter paving the way for a deeper social science research that needs to the address the problem of the causes of formation of malicious or subversive intent, process of its sustenance, its expression, presence, and persistence. This will enable creation of secure systems.

PHILOSOPHY OF SECURITY

To understand human factors in information security we must have a framework to comprehend both the "human" and "security." Let us first address the question "Why security?" A simple description of the human being and human nature gives us the answer. Human beings are products of nature and interact with nature. Humans have the ability to create or fashion things out of natural material. They have the power to destroy forms and recreate newer forms, for example, they can melt iron, make steel, build edifices, and construct cars and aircrafts. Humans have the power to break and make things. This human potentiality makes them destroyers while at same time being creators (e.g., cutting trees to make furniture). The potential threat while safeguarding an artifact or a possession comes from other humans (and possibly from his or her own self too). A layer of security is therefore necessary to protect an entity from being destroyed accidentally or deliberately. Borders are an essential security feature that preserves the form of an entity and provides an inner secure space ("privacy"). Borders delineate and define distinct spaces. What is within and what is outside. Humans have the capability to break open "security" features (the husk, shell, case, or skin that covers and protects a seed or fruit).

In their quest to attain mastery over the universe, humans have developed tools that are efficient in interacting with nature intimately. Whenever humans develop a new tool that is technologically advanced than the current level of technology, then the new technology can also be deployed as a weapon. The invention of knives gave rise to swords, dynamite for mining gave rise to grenades, the capability to generate nuclear power gave rise to nuclear weapons, and so on. When a certain technology becomes out of date the weapons also become outdated, for example, we no longer use bows and arrows, swords and even firearms—we no longer witness duels or fencing. Security frameworks of yesteryears are no longer meaningful today—castles and fortresses are no longer strongholds, they have been replaced by different types of defense establishments (e.g., the Windsor castle and many fortresses dotted all over India). Previously, photographing a dam was thought to be a security risk. But with today's satellite capabilities and inter continental ballistic missiles, the information of the location of a dam cannot be kept secret (e.g., Google Earth). The security frameworks of a particular time are contingent upon the level of technology that the society has achieved.

Since humans have the innate potentiality to destroy and consume, if something is to be preserved from destruction then it is necessary to safeguard it with a layer of security. Particularly with respect to information security, one needs to be clear whom you need to protect information from. What are the threats to information security—where does it arise from? The employee, customer, the competitor, or the enemy? Malicious attacks from "hackers" or even from your own self? While constructing systems, it has to be taken into account that:

A human being will exploit a vulnerability in a system, if there is a vulnerability existing in the system, to his or her advantage at cost of the system.

All security frameworks are built with the *other* and the *other's* capability in mind.

HUMAN FACTORS: A BEHAVIORAL MODEL

When we talk about "human" factors that influence information security, we first need to identify and define what we mean by "human" factors. Human factors are taken into account in a wide variety of fields, for example, aeronautics, ergonomics, human-computer interaction, medical science, politics, economics, and so forth. Each of these fields considers human factors from several different aspects. In aviation, human factors mean cognitive fidelity, whole body motion, and physiological stress (Garland, 1999). Ergonomics deals with user interface design, and usability—making products in the workplace more efficient and usable. Anthropometric and physiological characteristics of people and their relationship to workspace and environmental parameters are a few of the human factors taken into consideration in ergonomics. The other factors may include the optimal arrangement of displays and controls, human cognitive and sensory limits, furniture, and lighting design.

We need a model of the "human" in the context of information security. Models provide us with important relationships between variables. Philosophical positions give us a foundation to construct scientific models over empirical data. While scientific models are often reductive in nature (i.e., entities are studied in isolation), systems models study interactions between components. The sum of parts is greater than the whole. The systems model of human behavior gives us a possible basis to identify the sources of threat to information security. Information security cannot be achieved purely from the standpoint of cryptographic algorithms (lock and key mechanisms) alone, but from understanding human behavior and the social context in which humans are embedded (Dhillon, 2007).

The systems model of human behavior identifies three major components of the mind as well as the biological and spiritual underpinnings (Huitt, 2003). Eysenck (1947), Miller (1991), and Norman (1980) provide empirical support for the three dimensions of mind (or human personality) for example:

1. Cognition (knowing, understanding, thinking—processing, storing, and retrieving information);
2. Affect (attitudes, predispositions, emotions, feelings); and
3. Conation (intentions to act, reasons for doing, and will).

These three components of the mind can be used to address several issues that can arise in the context of information security. An individual's thinking (cognition), feeling (affect), and willingness (volition, conation), as well as overt behavior and spirituality are constituents that interact to give appropriate human responses to stimuli from the environment. A second characteristic of the systems model of human behavior is that human beings do not operate in isolation; they are products of a variety of contexts—environments that surround the individual human being that he or she is in constant interaction play a major role in the individual's responses and interactions with the world (see the next section on social factors for a detailed discussion).

There are therefore five major components of the human being in the systems model of human behavior (Huitt, 2003):

1. **Cognitive component:** Perceives, stores, processes, and retrieves information
2. **Affective component:** Strongly influence perceptions and thoughts before and after they are processed cognitively
3. **Conative component:** The intent of the human actor
4. **Spiritual component:** How humans approach the mysteries of life, how they define and relate to the sacred and the profane

5. **Behavioral system:** Explicit action of the human being and the feedback received from other members of the community.

Of these, the major component that we are concerned with is the cognitive component. We would like to explore this cognitive component from the framework of cognitive science. Briefly, here we will outline how other components are influential in information security. Human emotions, the basis of the affective component is a subject that has been explored in psychology (Huitt, 2003). A variety of emotions impact how humans relate with information systems. Anger, fear, and anxiety are known to influence the adoption and usage of information systems (Athabasca University, 2000), for example, the introduction of computerized systems in the banking industry in India faced organized, stiff resistance during the initial phases as bank employees had apprehensions of threats of job loss and retrenchment (Goodman, 1991). The conative component (human will) determines at what level an individual or a group of people will adopt information technology. The human being can be influenced by cultural factors ("we" and "they"), the religious position he or she has abided by (spirituality), and also the collective memory (social factors) in which he or she has been contextualized.

While this chapter essentially focuses on a cognitive science perspective, it also admits the limitations of cognitive science in general. In this chapter we have taken a limited attempt to study only the cognitive component of the mind as opposed to treating other components such as the affective, the conative, the spiritual, and the overt action of the human being. There are philosophical criticisms raised by Dreyfus (1992) and Searle (1992) to cognitive science. They claim that this approach is fundamentally mistaken in the sense that cognitive perspective does not take into account (Thagard, 2004):

- The ***emotion*** challenge: Emotions can be the basis for action in human thinking.
- The ***consciousness*** challenge: The ability to do what is good and what is evil influences the cognitive model of the human being.
- The ***world*** challenge: The physical environment in which a human being is located influences his or her thought.
- The ***body*** challenge: Health conditions can determine one's thought patterns.
- The ***social*** challenge: Human thought is always embedded in symbol, ritual, and myth and is part of a collective conscience.
- The ***dynamical systems*** challenge: The human mind is a continuous dynamic system, and does not always compute in the traditional sense.
- The ***mathematics challenge***: Human thinking is not mathematical—the brain does not compute using numeric quantities will making calculations, for example, the speed at which a human being drives a car is not computed using equations.

The systems model of human behavior does accommodate all the criticisms to a pure cognitive science approach.

SOCIAL FACTORS (SYSTEMS AND ECOSYSTEMS)

Systems cannot be completely understood without understanding the ecosystem within which they are embedded. Human behavior is not merely a function of an individual's cognitive components. There are three levels of ecology that are identified by the systems model of human behavior (Huitt, 2003). Huitt's framework is discussed. The first level of the ecology or the context of human behavior is the micro-system. The family, the local neighborhood, or the community institutions such as the school, religious institutions, and peer groups form part of the micro-system where individual formation occurs. The second level is the meso-system. This influence arises from social institutions or organizations where the human being does work (employment) or obtains pleasure (entertainment). The micro-system institutions filter and mediate the influence of these meso-systems and institutions with which the individual interacts. The third level is the macro-system. The third level of influence relates to the international region or global changes or aspects of culture. Ecological parameters can influence human behavior significantly. The German defeat in the First World War that led to an economic catastrophe leading to the Second World War is a case in point. All human actions of individuals in the German world or the Allied world had to be influenced by the war during the world wars.

The sources of security threats can emerge from the global environment, the meso-system, or the micro-system. An individual's motivation to destroy can emerge from any of these sources. In a context of war between two communities, each may perceive the other as a threat (e.g., world wars). Two organisations may compete against each other for their share of the market (e.g., Microsoft vs. Apple). Families may have animosities with other families (e.g., the Capulets and the Montagues). Therefore, each of these of these ecological levels may strongly impact as to whom the individual treats as the "other."

Cognitive Science and Security

Cognitive science emerged when researchers from several fields studied complex representations and computational procedures of the mind. Cognitive science is the interdisciplinary study of mind and intelligence, embracing philosophy, psychology, artificial intelligence, neuroscience, linguistics, and anthropology (Thagard, 2004). The computational-representational approach to cognitive science has been successful in explaining many aspects of human problem solving, learning, and language use.

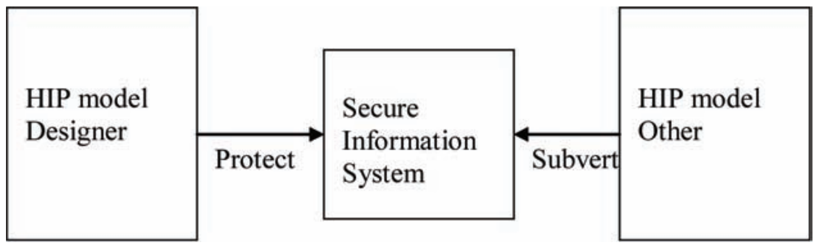
Cognitive scientists build computer models based on a study of the nature of intelligence, essentially from a psychological point of view. This helps comprehend what happens in our mind during problem solving, remembering, perceiving, and other psychological processes. AI and cognitive science have been able to formulate the information-processing model of human thinking (Association for the Advancement of Artificial Intelligence, 2007). Rapaport (2000) puts it this way:

The notion that mental states and processes intervene between stimuli and responses sometimes takes the form of a 'computational' metaphor or analogy, which is often used as the identifying mark of contemporary cognitive science: The mind is to the brain as software is to hardware; mental states and processes are (like) computer programs implemented (in the case of humans) in brain states and processes.

Whereas when we talk about human factors in information security, we are primarily interested in the human information processing model. An understanding of human information-processing characteristics is necessary to model the *other's* capability and action. Characteristics of the human as a processor of information include (ACM SIGCHI, 1996):

- Models of cognitive architecture: symbol-system models, connectionist models, engineering models
- Phenomena and theories of memory
- Phenomena and theories of perception
- Phenomena and theories of motor skills
- Phenomena and theories of attention and vigilance
- Phenomena and theories of problem solving

Figure 1. Cognitive model of the designer of secure information systems



- Phenomena and theories of learning and skill acquisition
- Phenomena and theories of motivation
- Users' conceptual models
- Models of human action

While cognitive science attempts to build a model of the human as an information processor (HIP model), it deals with only one individual unit as its basis. However, the design of security features in information systems design has to take into account two or more processing units as the basis of the model. The technical fabrication of secure systems incorporates a model of the "Other." A careful analysis of the Global Platform (see case study) or EMV standards reveals the process of how the designer attempts to build secure financial information systems where the "attacker" is always present in the scenario. The cognitive model of the "attacker" is the human factor that the system attempts to protect itself against (Fig. 1). The *other's* technical competence is assumed to be equivalent to that of the designer. The destructive capability—the computational-representational model of the "other" is the source of threat for the designer, to protect against whom the designer designs his or her security features.

THE CASE STUDY: FINANCIAL INCLUSION USING INFORMATION TECHNOLOGY

Financial inclusion means extending banking services at an affordable cost to the vast sections of disadvantaged and low-income groups. Financial Inclusion Task Force in the UK has cited three priority areas requiring serious attention: access to banking, access to affordable credit, and access to free face-to-face money advice (Kumar, 2005). The Reserve Bank of India (RBI) has noticed that more than eighty percent of adult rural Indians (245 million, roughly the size of U.S. population) do not hold a bank account (Nair, Sofield, & Mulbagal, 2006). The Reserve Bank of India has mandated that banks extend their outreach taking banking service to the common man (Reserve Bank of India, 2005).

Extending banking to the rural areas where there are no bank branches, consistent power supply, or communication links such as telephones or Internet is a daunting task. This calls for newer approaches in taking banking to remote regions. One solution that RBI has come up with is to enable customers' intermediate banking facilities through business correspondents who act as agents on behalf of banks (Reserve Bank of India, 2006). As law mandates, any transaction on an account involving cash has to be made within the physical premises of the bank. The business correspondents are appointed by the banks and have the authority to accept deposits or make cash payments when customers would like to withdraw or deposit money from or to their accounts at locations other than bank premises.

The experience of microfinance institutions in India while taken into account suggested that cash management is a problem in rural India. The transport of cash is expensive and dangerous. A solution was sought whereby the cash that is available in the villages could be circulated and kept within the region would lead to less security hazards in cash management. Instead of opening full-blown brick and mortar bank branches in remote districts (an expensive proposition), it was proposed that with the help of modern information technology and managerial capabilities of business correspondents, banking functionalities could be extended to remote regions. It is known that information technology solutions to deliver banking services have been able to reduce transaction costs (e.g., ATMs). The business requirements for the proposed solution are outlined. We also discuss in the next section how these requirements could possibly be implemented using information technology as a vehicle.

Business Requirements for the Financial Inclusion Initiative

The basic idea of the financial inclusion initiative is to extend banking services to the un-banked and under-banked rural population. The rural communities that reside in remote regions were the target beneficiaries of the scheme.

Information technology should enable banks to provide services that have the following business requirements:

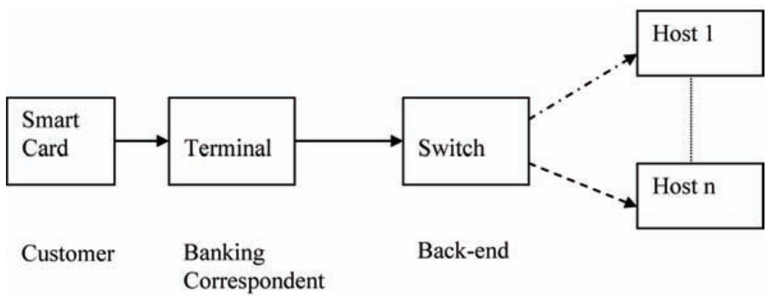
- Banking services such as deposits, withdrawals, and funds transfer are to be provided.
- Each customer must be identified uniquely by some means especially fingerprints. Biometric authentication using fingerprints proved to be more secure than personal identification number (PIN) based authentication. As most customers are illiterate, they would not be able use PINs to authenticate themselves (in some pilots it was noticed the rural customers who could not keep their PIN secret had written it down on the card itself!).
- Both online and off-line transactions must be possible.
- Balance enquiry and mini-statement showing last ten transactions must be possible at all terminal locations.
- No transaction should be lost in the entire system.

Technical Implementation Issues (Problems and Solutions)

The model solution proposed for the financial inclusion initiative is outlined in Figure 2. Each customer is given a smart card with his primary account number and other personal details such as address, nominee details, and contact information stored within it. The smart cards are to be used at bank terminals owned by banks and operated by business correspondents. The customer is authenticated using the biometric fingerprint of the customer stored in the smart card. These terminals have connectivity through GSM, CDMA, PSTN, or Ethernet depending upon the type of connectivity available at the local place of operation. However connected, the communication finally happens through an IP connectivity to the back-end switch. The network switch connects a particular terminal with an appropriate bank host. All customer details and account information including current balance is held at the bank host. The smart card is used for customer authentication whenever transactions are made at bank terminals. Figure 3 provides an overview of the technological solution to the financial inclusion initiative.

The technical issues addressed in the design of the system:

Figure 2. Model solution for the financial inclusion initiative



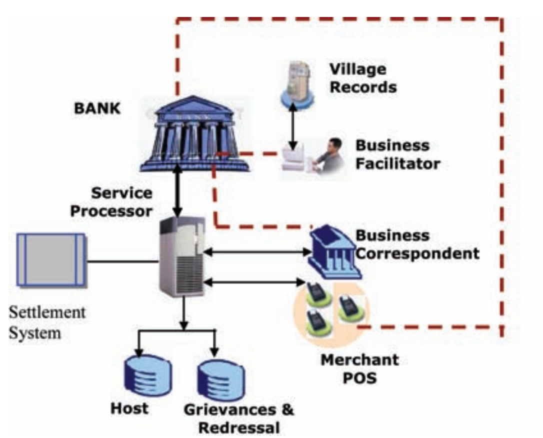
- The choice of the appropriate smart card (ISO 7816, Global Platform)
- The internal layout and file structure of the smart card (personalization)
- The choice of the terminal (Level 1—EMV certified)
- The communication protocol between the terminal and the smart card (EMV)
- The communication protocol between the terminal and the switch (ISO 8583)
- The customization of the switch software
- A card management system
- A terminal management system

The Smart Card

Smart cards have been widely used in various sectors such as transport, retail outlets, government, health (insurance), mobile telecom, and in the financial sector. Smart cards come in different flavors with differing operating systems, memory capacities, and processing power (Rankl & Effing, 2003). Smart cards come with different operating systems like MultOS, Payflex, or Java. Certain operating systems are vendor specific. Smart cards differ in terms of the memory capacity that is available within them. There is a tradeoff between the cost and the level of security required. A crypto card that uses public key infrastructure (PKI) offers more security and is relatively more expensive than a smart card that permits only static data authentication.

A wide range of smart card with different memory capacities exist from 8K, 16K, 32K, and 64K. It was a business requirement specification that the customer's fingerprint templates need to

Figure 3. Technological solution for financial inclusion—an overview



be stored in the smart card. Also, since the last 10 transaction details had to be stored within the smart card for balance enquiry and mini-statement, a smart card with as much EEPROM memory as possible was needed. The fingerprint template ranges from half a kilobyte to one kilobyte in size. Considering the storage of templates for four fingers, this would take about four kilobytes of space. A normal, rudimentary software application on the smart card takes about four kilobytes. Therefore, the final choice was a 32K card. Smart cards were specified to adhere to ISO 7816 standards (physical characteristics and cryptographic requirements).

The information contained in the smart card is to be held securely, only to be read and updated using secure symmetric keys. This solution using symmetric keys, though weaker than a PKI solution, was adopted mainly due to cost considerations. A PKI enabled, Europay MasterCard Visa (EMV) compliant cryptographic smart card costs four times as much as a normal card. The affordability of the customer determined the level of security that could be offered. Since the account balances were anticipated to be low—a lock costlier than the value it protects was discarded. A secure access module (SAM) at the terminal provided the necessary computational security to read and access the information in the smart card. Derived keys and diversified keys are used for this purpose (Rankl & Effing, 2003).

Smart cards can contain multiple applications. Global platform is an industry wide standard that provides a layer of management while handling multiple smart card applications. Global platform specifies the security requirements that a card and the application should have while making secure smart card applications. Table 1 samples

Table 1. Sample from global platform perception of security threats

1.	High level threats are classified security concerns as: - The manipulation of information on card including modification of data, malfunction of security mechanism, - The disclosure of information on card - The disclosure of information of card as design and construction data.
2.	*The cloning of the functional behavior of the smart card on its ISO command interface is the highest-level security concern in the application context.*
3.	The attacker executes an application without authorization to disclose the Java card system code.
4.	An applet impersonates another application in order to gain illegal access to some resources of the card or with respect to the end user or the terminal.
5.	The attacker modifies the identity of the privileged roles.
6.	An attacker prevents correct operation of the Java card system through consumption of some resources of the card: RAM or NVRAM.
7.	The attacker modifies (part of) the initialization data contained in an application package when the package is transmitted to the card for installation.
8.	An attacker may penetrate on-card security through reuse of a completed (or partially completed) operation by an authorized user.
9.	An attacker may cause a malfunction of TSF by applying environmental stress in order to (1) deactivate or modify security features or functions of the TOE or (2) deactivate or modify security functions of the smart card. This may be achieved by operating the smart card outside the normal operating conditions.
10.	An attacker may exploit information that is leaked from the TOE during usage of the smart card in order to disclose the software behavior and application data handling (TSF data or user data). No direct contact with the smart card internals is required here. Leakage may occur through emanations, variations in power consumption, I/O characteristics, clock frequency, or by changes in processing time requirements. One example is the differential power analysis (DPA).

some of the security requirements that global platform card security specification addresses (GlobalPlatform, 2005).

Corporations such as Visa and MasterCard have built their own EMV standard applications such as Visa Smart Debit/Credit (VSDC) or MChip, respectively. The design issue is whether to adopt one of these applications (with suitable customization) or to build a custom application from scratch. Adopting any of these standard applications has the advantage of worldwide interoperability. But the price is heavy in terms of licensing and royalty fees that the poor rural customer has to bear when every transaction is made.

Issues in Storing Value in the Smart Card

Permitting off-line transactions (as connectivity is poor) require that account balance information be carried within the smart card. The value stored in the cards has to be treated as electronic money or currency. However, apart from technicalities of implementing an electronic purse, there are legal constraints. Electronic currency has not yet been afforded the status of legal tender. Electronic wallets have so far been unsuccessful in the market in Europe (Sahut, 2006).

Certain types of smart cards have an e-purse facility implemented in the card itself. The common electronic purse specifications (CEPS) standard outlines the business requirements, the functional requirements and the technical specifications for implementing e-purses. However, CEPS is considered as a dead standard in the industry. Whenever there is a situation where the value of currency can be written by the terminal onto the card, the security risk dramatically increases. Therefore, the possibility of offering offline transactions as a business requirement had to be compromised.

Issues in Customer Authentication using Biometric Identification

In today's payment systems scenario in India, a normal magnetic stripe card that is used for debit or credit applications. The magnetic stripe card holds the customer's primary account number (PAN), name, and some authentication information (such as enciphered PIN). No account balance information is held in the card. These cards facilitate only online transactions.

The business requirements for this initiative demanded that off-line transactions should be accommodated since connectivity is poor in rural India. This meant that the card needed to carry the account balance to allow offline transaction facilities. Therefore, the option of a smart card was taken. The smart card is to carry biometric (fingerprint) identification details, customer information, and bank account information. However, since the card should also possibly be used with other existing financial networks, a magnetic stripe was also needed in the card (e.g., using the same cards in ATMs apart from the terminals). So a combination of chip and magnetic strip solution was proposed.

The fingerprint template was to be stored in the card so that every time the customer wanted to do a transaction, a fingerprint scanner could extract the image and terminal could compute the template for feature matching. The biometric validation process could either take place at:

- **The Card:** The biometric fingerprint template is held within the card. The terminal reads the fingerprint and creates the template. The templates are compared inside the card using the intelligence within the card.
- **The Terminal:** The terminal reads the biometric fingerprint and converts it to a template, and it is compared with the template stored read from the smart card into

the terminal. Terminals also have memory requirements and limitations.

- **The Back-end Host:** The back-end stores both the image and the template. The comparison is made with the biometric template stored within the smart card. This solution is costly in terms of telecommunication costs since the fingerprint template needs to be communicated to the back-end host over wired or wireless telecommunication networks for every transaction the customer makes.

The Terminal

The interaction between the card and the terminal is specified in the Europay, MasterCard, and Visa (EMV) standard. The terminal was chosen to be one with Level 1—EMV compliant hardware. The software on the terminal had to be Level 2—EMV compliant software. An EMV Level 2 certification guarantees software on the terminal that is reasonably secure. The software handles the communication between the smart and the terminal communication. The EMV process is discussed in section below.

EMV Standards for Smart Card: Terminal Communication

EMV standard is a specification of a protocol that governs the communication between the terminal and the smart card (EMVCo, 2004). Essentially, terminal verifies whether the card belongs to the acceptable family of cards, the card authenticates whether the terminal is a genuine one, and finally, the cardholder has to be authenticated, that is, whether the cardholder is the one whom he/she claims to be. There are several steps in the EMV process:

- Initiate application
- Read application data
- Data authentication
- Apply processing restrictions
- Cardholder verification
- Terminal action analysis
- Card action analysis
- Online/off-line processing decision
- If online, then issuer authentication and script processing—go to step 11
- If off-line process the transaction
- Completion.

Though there are several steps (we will not delve into the details here), we discuss only the process of static data authentication (SDA) as an example of an EMV process. The terminal verifies the legitimacy of the data personalized in the card. This is to detect any unauthorized modification or tampering of the data after personalization of the card (Radu, 2003).

The public key of the certificate authority (CA) is stored in the terminal. The CA signs the public key of the card issuer (e.g., a bank) using the CA's private key and this certificate is stored in the smart card. The issuer uses its private key to digitally sign the static data (those data items that are to be protected from tampering). The signed static data is stored on the card. When the terminal wants to verify the authenticity of the data the following steps are done:

- The terminal retrieves the certification authority's public key.
- The public key of the issuer is retrieved from the certificate.
- Retrieve the signed static data.
- Separate the static data and its signature (hash result).
- Apply the indicated hash algorithm (derived from the hash algorithm indicator) to the static data of the previous step to produce the hash result.
- Compare the calculated hash result from the previous step with the recovered hash result. If they are not the same, SDA has failed. Else SDA is successful.

Table 2. Sample ISO 8583 messages (Source: http://en.wikipedia.org/wiki/ISO_8583)

Message Type Indicator	Type of Request	Usage
0100	Authorization request	Request from a terminal for authorization for a card-holder transaction
0200	Acquirer financial request	Request for funds
0400	Acquirer reversal request	Reverses a transaction
0420	Acquirer reversal advice	Advises that a reversal has taken place

This procedure verifies whether the card has been tampered with or not. The cardholder verification method (CVM) verifies whether the card belongs to the cardholder or not. Traditionally, the cardholder uses a personal identification number (PIN). In the financial inclusion project it is envisaged to use biometric fingerprint authentication for the CVM.

Terminal: Host Communication

Once the user is authenticated, the terminal communicates with the host to make transactions. The transactions include deposit, withdrawal, and funds transfer or utility payments. ISO 8583 is the protocol that governs this communication between the smart card and the terminal. ISO 8583 defines the message format and communication flows. ISO 8583 defines a common standard for different networks or systems to interact. However, systems or networks rarely directly use ISO 8583 as such. In each implementation context, the standard is adapted for its own use with custom fields and custom usages. In the financial inclusion project, the message arrives in the switch in the EMV format. The message is stripped of EMV formatting and encryption; a customized ISO 8583 message is generated and passed on to the host. The communication between the terminal and the switch happens over the air or over the wire using a telecommunication network. Table 2 provides a small sample of messages.

HUMAN AND SOCIAL FACTORS IN INFORMATION SECURITY

Before outlining the possible abuses of the system by its various participants, it is important to note that in a complex information system as discussed in the case could be compromised by both the insider (personnel who construct and maintain the system) and people who are end users of the system (outsiders). We briefly dwell upon the problem of insider threats before addressing the possible problems created by outsiders to the system.

The Insider

Shaw, Ruby, and Post (1998) identify the sources of threats can emerge from employees (full time and part time), contractors, partners, and consultants in the system. People who are emotionally distressed, disappointed, or disgruntled can be manipulated and recruited to commit damaging acts. Introverts (people who "shy away from the world while extroverts embrace it enthusiastically"—H. J. Eysenck) like intellectual pursuits rather than interpersonal relationships are vulnerable to act destructively. Profiles of possible perpetrators of security threat are people who are socially isolated, computer dependent, and gain emotional stimulation and challenge through breaking security codes consequently beating security professionals. High rates of turnover reduce loyalty of employees to particular organizations. Moreover, computer professionals have weak ethics and they see any unprotected data as fair game for attack. Certain predisposed traits in individuals when exposed to acute, stressful situations produce emotional fallout that leads them to act in ways subverting the system.

A study of illicit cyber activity in the banking and financial sector (United States Secret Service, 2004) reveals that most of the security incidents required very little technical training and skills. In 87% of the cases studied, simple and legitimate user commands were used to create the security incidents and 13% of cases involved slightly more sophistication like writing scripts or creating "logic bombs." About 80% of the users were authorized users. Only few (23%) were employed in technical positions. Most of the system subversion activities were planned in advance by the perpetrators and their intent of the actions were known to other people such as potential beneficiaries, colleagues, friends, and family. Most of the attacks were carried out during normal business hours and at the work place. Revenge, dissatisfaction with company policies, desire for respect, and financial gain were some of the motivating factors identified by the study.

Threats, whether they emerge from inside or outside, whatever be the source of their motivations (the different ecological levels and individual dispositions that influence human behavior), at the point of attack the perpetrator applies logic or a heuristic strategy to make his or her move. Therefore, the designer needs to anticipate the possible scenarios where the system can be compromised. The designer therefore has an anticipated intricate model of the *other's* cognitive thought processes and possible "moves." Against this backdrop, the designer secures the system in the best possible manner (like building a fortress), for example, "bus scrambling"—individual bus lines are not laid out in sequence in a smart card microcontroller, rather they are scrambled so that the potential attacker does not know which bus line is associated with which address bit or function (Rankl & Effing, 2003). In this respect, cognitive science can play a significant role in uncovering, mapping, and addressing the heuristics, the strategies, and the logic employed by potential attackers.

The modern banking system, on the whole, is rather vulnerable as it is heavily dependent and exposed to various consultants and vendors. Vendors take care of security risks within their organizations, for example, smart card manufacturers have to secure the entire process of production of smart card, key management process, transport and distribution process, and card personalization process. The banking electronic system relies heavily on outsourcing certain key functionalities such as database management where "ethical" and regulatory aspects do not govern the interface and interaction. Every time a vendor "opens" a banking database either for maintenance or for troubleshooting, the risks of exposure are quite phenomenal.

We have discussed the technicalities of secure financial transactions that can happen in the financial inclusion project in the earlier section. If there occurs a security breach or incident, either in the authentication process using the smart card or in the interaction between the cardholder and the business correspondent, the entire system will collapse. Any of the human participants in the financial system can attempt to subvert the system—the outsider to the system, the customer, or the business correspondent. We discuss three possible scenarios that could lead to comprising of the financial system.

First, we look at a masquerader who either steals or obtains a smart card that is in use in the project. Second, we look at problems a customer can create when offered facilities for off-line transactions. Third, we consider the case of a dishonest business correspondent who can exploit the illiteracy (vulnerability) of the customer.

The Outsider

The outsider to the system who obtains a card may be able to use the card to his or her advantage. Since the EMV standard does not provide for biometric fingerprint authentication, this has to be incorporated with the cardholder verification method (CVM). In the extreme case, it may be possible for the outsider to alter the biometric of a card and use it to masquerade as the user.

The Other Customer

Secondly, in the case where off-line transactions were to be permitted, the card has to carry financial information such as account balance. The possibility of abuse or misuse by the customer had to be accounted for. The customer could make several offline transactions and claim to loose the card. If the card were to be reissued to customer with balances available at the host (not as yet synchronized with the offline terminal information), then the bank stands to loose financially. One could not trust the customer not to resort to this avenue.

The Other Banking Correspondent

Thirdly, the problem of dishonest business correspondents (those operating terminals doing transactions on behalf of the bank) came to the fore. Suppose a rural customer who was illiterate would like to withdraw cash from his/her account then the business correspondent can debit a larger value than what was disbursed to the customer. Though a printed receipt would be made available to the customer, since the customer is illiterate this would not be of any practical use. This gives rise to a flaw in the system. This technical loophole could only be overcome with some form of social surveillance as well as taking care to appoint trustworthy business correspondents. A possible administrative solution was to provide a hotline for customer complaints of this kind of system abuse by business correspondents. Once a business correspondent is identified as committing fraud, the bank authorities could take appropriate action.

This financial inclusion project highlights the limitations of approaching information security from the viewpoint of technicalities alone. It requires a solution whereby all the parties involved are bound by ethics as well appropriate social controls (administrative procedures to handle disputes and violations). Human and social factors have to be taken into account to be able to provide a good solution to the problem of remote banking.

CONCLUSION

This chapter attempts to place the human and social elements of information security within a wider context. It discusses some philosophical underpinnings underlying security ventures. The chapter takes the systems model of human behavior as a basis and situates a cognitive science approach within. It discusses the design a real world case of a secure financial system of how it characterizes and accounts for the "other." The design of the technical system is entirely based on the current level of information technology today and how it is employed in a remote banking application scenario.

The source of much of our technical aspects and capabilities (e.g., cryptography) in information security emerged in the historical context of world wars—battling with a real, flesh and blood "enemy." But today systems designers' battles with the "other" in their imagination to construct secure systems. This chapter attempts to outline the need for a broader approach to information security incorporating philosophy, social and cognitive sciences. Security should be approached from first principles. This approach may provide different ways to handle security. The implications for information security may be derived from a general philosophy of security. Since security is essentially a psychological, political, social, and historical phenomenon, there is a need to "model" the human (and the "other") in the frames of references of these sciences. This will better able societies and organizations to understand the source and nature of threats and deal with them at that level, rather than at the level of technical fabrication alone, for example, deep-seated emotional memory wounds of lost battles long ago may stir and motivate a "hacker" or a "terrorist." The philosophical question to address is "How do you prevent the "other" from emerging and operating adversely in the world?" The social and moral fabric of society needs as much attention as the design of security of protocols.

Chapter 1.3
Computer-Mediated Communication Learning Environments:
The Social Dimension

Stefania Manca
Institute for Educational Technology, National Research Council, Italy

INTRODUCTION

The social, relational, and affective dynamics are receiving more and more attention in the study of learning processes, as cognitive, affective, and emotional dimensions of learning seem to be closely related. This kind of co-origination, borne out in the context of neurosciences, artificial intelligence, cognitive psychology, and education, has also been recognized in the field of Web-based learning. The research framework of computer supported collaborative learning (CSCL) has emphasized the role that a well-established social dimension plays in collaborative learning and group-based working within communities of learners. According to the socioconstructivist model, learning always implies a social dialogical process where individuals are mutually engaged in the construction and sharing of new knowledge (Scardamalia & Bereiter, 1994; Wenger, 1998). Pedagogical approaches based on these assumptions combine the advantages of a learning strategy that promotes deeper level learning, critical thinking, and shared understanding with those related to the development of social and communication skills (Garrison & Anderson, 2003).

What characterizes the intertwining of the educational and sociopsychological dimensions in these settings is that they are strictly linked to the dialogues that participants mutually construct. Most of the learning experiences that occur on the Internet are characterized by written and asynchronous communication (Lapadat, 2002). And the written discourse deeply influences also the socio-affective dimension of learning.

The present review aims at presenting the most recent and promising research studies that tackle the linguistic nature of the emotional and affective dimension of learning in Web-based learning environments. Its purpose is to emphasize how computer-mediated communication (CMC) may convey specific social affordances in the expression of affective and social domain of learning.

DOI: 10.4018/978-1-59904-845-1.ch016

BACKGROUND

Early approaches in the study of CMC noted that the lack of nonverbal cues (e.g., facial expression, posture, gesture, proximity) would limit the richness and scope of communication (Short, Williams, & Christie, 1976). CMC was thought to be an impoverished means of communication giving little chance to gather important information about the context, the commonly shared rules of conduct and their influence on communication, all of which foster uninhibited speech and flaming. Moreover, as anonymity, which is a frequent feature of online interactions, reduces these control indicators, communication would be more de-individualized and de-personalized, and that would have different and unpredictable consequences on the various speech contexts. Lacking nonverbal indicators, CMC was seen to be characterized by a very low level of social presence, and it was thought that this feature could invalidate the learning purpose.

In recent times, a number of studies have shown that with written communication alone, typically used in chat and e-mail, it is possible to stimulate social and affective presence, provided that interlocutors are allowed to manage their time freely. Other authors underlined the similarity between the development of relationships in both face-to-face and online contexts, showing that although the latter need more time to grow, they can be more socially oriented than the former (Walther, 1996). Users compensate for the communicative lack of written discourse with linguistic inventions and adaptations (e.g., emoticons, typographical marks, and other textual features, including the use of capital letters, ellipses, exclamation marks, as well as typing errors) in order to express with appropriate orthographical strategies the aspects of nonverbal communication (Crystal, 2001). In this way, a higher degree of familiarity and intimacy in content, style, structures, and timing of the exchanged postings would not only be a linguistic adaptation able to incorporate colloquial and informal registers, but it could also strike a balance between the features of the medium and an acceptable level of immediacy.

In the context of distance learning, social presence has been recently redefined as "the ability of participants in a community of inquiry to project themselves socially and emotionally, as 'real' people (i.e., their full personality), through the medium of communication being used" (Garrison, Anderson, & Archer, 1999, p. 94). According to this reformulation, social presence seems to support cognitive objectives as it encourages and supports meaningful critical thinking processes in a community of learners. Emotion arousal influences the cognitive, metacognitive, and motivational aspects of the learning process, especially when socially oriented (Wosnitza & Volet, 2005) and affective objectives that result in engaging and rewarding group interactions may lead to an increase in academic, social, and institutional integration and results (Rourke, Anderson, Garrison, & Archer, 1999).

The studies that have adopted this new conceptual perspective have investigated social presence, among other characteristics, as a predictor of satisfaction and perceived learning (Richardson & Swan, 2003) and as an indicator of success and quality of the learning experience (Swan & Shih, 2005). Others underline the relationship between the role of the tutor/instructor and the affective and cognitive learning in the online classroom (Baker, 2004). All of them focus on the fundamental connection between the cognitive and affective elements of learning processes.

THE LINGUISTIC EXPRESSION OF THE SOCIAL DIMENSION OF LEARNING

If traditional approaches to measuring social presence and the affective dimension of learning used different combinations of survey instruments (e.g., scale-graduated questionnaires and semistructured or unstructured interviews) and analyses of students' online interactions through quantitative methods (e.g., frequency of messages, etc.), in recent times, the expression of the social dimension has been investigated through other means. Since the pioneering work of Henri (1992), the content analysis approach has become one of the most valuable ones. Classifications of text features into categories and indicators have been proposed, with the aim of capturing the new styles and characteristics of human communication which rely on asynchronous written discourse.

There are a number of ways in which textual indicators are able to manifest social presence and express representation of learners' affective domain. Rourke et al. (1999), for instance, identified 12 indicators of social presence belonging to three categories (affective, interactive, and cohesive), based on previous research, literature, and analysis of transcripts, which were applied to transcripts of online communication. To these, Swan and Shih (2005) added new indicators that match quite well with the ones derived both from face-to-face analysis and research on previous online learning.

Job-Sluder and Barab (2004) examined how participants in a community of practice express a shared group identity in their discussions on the basis of the use and frequency of singular and plural first person pronouns; the aim of the study was to investigate the role of identity formation in learning processes in the context of preservice and in-service teacher development. Inductive methodology guided the approach of a research study that proposes a model of engagement able to capture the dynamic nature of learners' interaction by means of the philosophical hermeneutic circle (Ziegler, Paulus, & Woodside, 2006). These studies have contributed to emphasize the importance that linguistic specificities of written communication have in the expression of social presence and affective dimension of learning. Linguistic creativity is indeed what distinguishes writing in CMC settings from written language in other kinds of communicative contexts (Crystal, 2001). Yet, the examination of specific features of language in creating an effective climate of social presence has not been carried out adequately.

Only in recent times, for instance, the role that metaphors and figurative language in facilitating the expression of emotions and affective domain in Web-based learning environments has been investigated. Literature in linguistics and cognitive science state that metaphoric language has a central role in every day discourse, because it seems to shape the ways in which we think, creating a bridge from abstract domains to perceptual experience and helping to understand a new domain of experience in terms of what is already familiar. Moreover, figurative language has a central role in establishing a climate of closer intimacy between speakers, as the power of imagery seems to facilitate the sharing of personal experience and to create emotional involvement. Studies in Web-based learning settings have shown that figurative language may be a creative way through which students at a distance may give substance and concreteness to the immaterial place of the Web. It can allow participants to represent their affective domain (their emotions and feelings) and to conceptualize the main learning components on the Web (Manca & Delfino, 2007). In this study, the use of figurative language, as a special communicative tool that creates that sense of closeness and intimacy that literal language cannot achieve, is shown to be an original and creative way to communicate through the written expression of emotions and social presence.

NEW HORIZONS OF EXPLORATION

In an online learning community, cognitive and metacognitive processes are closely linked with the social and affective dimensions. Learning always involves a deepening process of participation in a community, and it is closely connected to that of construction of identity. Being part of a group or a community means, most of all, building a common and shared identity with the other members. Indeed, participation especially implies the reorganization of individual identities and the construction of a collective and shared identity within the community (Wenger, 1998).

If we assume that participants are able to construct individual and collective identities, as well as to express their emotional and affective horizons through writing processes, we need to ask how one projects oneself on the Web and which images of self are constructed and proposed to others. In the context of learning settings, cyberspace may be a "space" where the narratives of the self usually maintained in a face-to-face situation are more readily disrupted. Hence, there is more possibility of exploring modes of identity formation, both on the students' and tutors' side (Bayne, 2005).

From this perspective, narrative is being recognized as one of the most promising and emerging areas of interest in digital learning environments (Dettori, Giannetti, Paiva, & Vaz, 2006). Narrative has been shown to be a powerful cognitive tool for meaning construction in organizing external knowledge representation and as a way to structure human experience. Storytelling, as a means through which people may communicate their emotions and feelings, is strictly intertwined with those aspects of learning related to motivation, engagement, social interaction, and personal meaningfulness. In CMC learning contexts, the use of narratives can improve the social dimension of online learners and contribute to collaborative student learning through the sharing of personal experiences and the construction of a common identity.

Another promising approach is based on the theory of dialogical self. The relatively new concept of dialogical self in psychology is closely related to narrative psychology, constructivism, and cultural psychology. It explores the reciprocal influences that occur between the construction of the self and the cultural environment, as well as the specific impact of digital environments. In an online learning environment, self-positioning strategically supports the creation of a virtual learning community and also stresses the relationship of individual development with the sense of belonging to a community (Ligorio & Pugliese, 2004).

From a methodological perspective, along with approaches that tackle the content analysis of written communication, other methods are gaining further consideration. Among others, social network analysis focuses more on the study of the whole learning community, rather than on the individual who takes part in it. It examines the ways in which participants communicate with each other by exploring the depth of collaboration and the frequency of communication between participants, considering notions such as relation and structure of a network. The first applications of these notions to online communities have revealed that this method is especially helpful for understanding how a community is born and grows through the complexity and density of the network nodes and links (e.g., Aviv, Zippy, Ravid, & Geva, 2003).

CONCLUSION AND IMPLICATIONS FOR PRACTICE

The constant growth of online education is rapidly changing how and when people, especially adults, choose to engage in a learning experience. Today, it is more a question of choosing the most convenient and personally suitable way to receive "instruction" and training rather than attending a traditional "physical" institution. This shift of perspective is gradually changing our view of the social nature of learning processes, too. The latter, as we have seen, are always deeply intertwined with the affective, emotional, and relational factors that usually emerge in a community of learners. In contexts of such a nature, the process of learning is mostly interrelated with that of becoming, the process of sharing practices and knowledge with that of constructing a common and shared identity.

Identifying new and more suitable methods with which to investigate how these relationships are constructed is becoming an imperative in the field of ICT. More conservative views of the ways people experience the immaterial dimension of learning in cyberspace should be accompanied by, if not substituted with, new and more appropriate methods. This sort of paradigm shift also affects how affectivity and sociability, which influence and transform the learning dimension, should be investigated. Becoming aware of the potentialities of learning communities that rely on written discourse communication would enhance our exploration of these processes and help us to design and support more effective learning environments based on ICT use.

Previous sections have enlightened how written communication is able to convey specific and unique social and emotional affordances in the context of Web-based learning. For this reason, rather than comparing face-to-face and online settings and seeing the latter as characterized by an impoverished communication, researchers should look at how the pragmatic needs of an online setting might be satisfied thanks to the richness of written language. These considerations have profound implications for practitioners as well. The examples shown above underline that numerous are the textual indicators of social presence in Web-based learning environments that could be adopted in the design and conducting phases. The use of figurative language (in the forms of metaphors, analogies, etc.), for instance, may be encouraged and adopted during the design and conduct of online learning courses as a stimulus to manifest and share those personal emotions and feelings that are always deeply rooted in any new learning experience. The adoption of metaphors by tutors may foster students' sense of belonging to a larger community and provide a framework for role assignment, identity, and responsibility. Along with other facilitation measures, tutors/instructors would be able to use a further feature of aiming at encouraging interaction based on figurative language that would serve as a stimulus to facilitate the intertwining of the social dimension with learning processes.

On the narrative side, measures of this kind may be adopted as a more effective means of achieving quality discussions more than using traditional materials. Online instructors could combine encouragement of personal storytelling with the utilization of stories as a designed teaching strategy to deliver content, to discuss post assignments, or to tackle negative feelings of frustration and of being overwhelmed. A narrative pedagogy goes indeed beyond the information dimension of learning and renders apparent the social basis of learning and knowledge.

KEY TERMS

Community of Practice: First used in 1991 by Jean Lave and Etienne Wenger, the concept refers to the process of social learning that occurs among people who share a common interest in some subject or problem and are linked to each other over an extended period to share ideas, find solutions, and build innovations. The concept of community of practice has been recently associated with knowledge management and organizational development.

Computer-Mediated Communication: CMC is any form of communication between two or more people who interact via computer on the Internet. CMC mostly occurs through e-mail, chat, instant messaging, bulletin boards, list-servers, and MUDs (some also include audio and video communication). Today Wiki and Weblogs emerged as special forms of socially-oriented collaborative writing.

Content Analysis: This is a research technique based on the analysis of transcripts of interactions. Specific indicators are counted, classified, and interpreted as descriptive data to create an understanding of the content. It is a crossover technique that combines qualitative and quantitative methods. It includes the following phases: unitization, coding, inter-rater reliability tests, analysis and interpretation.

Social Constructivism: Social constructivism emphasizes the importance of culture and context in the process of knowledge construction. Learning is meant to be a social process that occurs when individuals take part in social activities. Instructional models based on this perspective stress the need for collaboration among learners and with practitioners in society.

Social Network Analysis: SNA has emerged as a new approach for understanding relationships among participants in an online learning environment. It serves to identify a set of structural variables such as density, connectivity, and heterogeneity that are implied in a network, and incorporates mathematical and statistical devices to measure individual positions within a network of participants.

Social Presence: Social presence was initially defined as the degree of other person salience in a mediated communication and the consequent salience of their interpersonal interactions. The term was soon after associated with the concept of media richness, according to which social presence is a quality of the communication medium itself. In more recent times, it has been redefined as the ability of participants in a community of inquiry to project themselves socially and emotionally, as "real" people, through the medium of communication being used.

Chapter 1.4
Online Communities and Social Networking

Abhijit Roy
University of Scranton, USA

INTRODUCTION

Technology has enabled communities to move beyond the physical face-to-face contacts to the online realm of the World Wide Web. With the advent of the highways in the 1950s and 1960s, "communities" were created in suburbia. The Internet, on the other hand, has over the last two decades, enabled the creation of a myriad of "online communities" (Green, 2007) that have limitless boundaries across every corner of the globe.

This essay will begin by providing a definition of the term "online communities" and then describing several typologies of this phenomenon. The various motivations for joining communities, how marketers create social bonds that enhance social relationships, as well as strategies used by firms in building online communities are also discussed. We conclude by discussing strategies for managing online communities, leveraging them for social networking, researching them, as well as directions for future research.

DOI: 10.4018/978-1-60566-014-1.ch145

DEFINITION

A "community" refers to an evolving group of people communicating and acting together to reach a common goal. It creates a sense of membership through involvement or shared common interests. It has been considered to be a closed system with relatively stable membership and demonstrates little or no connection to other communities (Anderson, 1999).

With the rapid growth of the Internet, the geographic boundaries constraining the limits of communities are no longer a factor, and the functions of maintaining a community can be fulfilled virtually from anywhere in the globe. This is the basic essence of an online community, which is also synonymous with e-community or virtual community. Several authors have attempted to provide a formal definition of the term for semantic clarifications. The major definitions are as follows:

- Social aggregations that emerge from the Net when enough people carry on public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace. (Rheingold, 1993)

- Groups of people who communicate with each other via electronic media, rather than face-to-face. (Romm, Pliskin, & Clarke 1997)
- Computer mediated spaces where there is a potential for an integration of content and communication with an emphasis on member generated content. (Hagel & Armstrong 1997)
- Online Publics are symbolically delineated computer mediated spaces, whose existence is relatively transparent and open, that allow groups of individuals to attend and contribute to a similar set of computer-mediated interpersonal interactions. (Jones & Rafaeli, 2000)

While Rheingold (1993) provides one of the earliest definitions of the term, and one that is most quoted in the literature (Kozinets, 2002), many may question whether "with sufficient human feeling" is a necessary condition for online community formation. Romm et al.'s (1997) definition may not sufficiently distinguish it from general Web sites. Hagel and Armstrong (1997) emphasize member generated content, while Jones and Rafaeli (2000) use the term "virtual publics" instead of online community. Others, like Bishop (2007), have pointed to the phenomenon of "de-socialization" or less frequent interaction with human in traditional settings, as a consequence of an increase in virtual socialization in online communities. Based on the above definitions the term may be simply defined as a group of individuals with common interests who interact with one another on the Internet.

TYPOLOGIES OF ONLINE COMMUNITIES

Online communities come in different shapes and sizes and may have memberships of a few dozen to millions of individuals. These communities may extend from active forums like discussion groups and chat rooms to passive ones like e-mails and bulletin boards. Given that these communities are not geographically constrained, their size can be much bigger than typical physical communities and many millions of them exist on the Internet. Uncovering archetype or gestalt patterns is fundamental to the study of social science and research, and several authors have proposed classification schemes for configurations of online communities.

Lee, Vogel, and Limayem (2003) in their review of classification schemes of online communities identify Hagel and Armstrong's (1997) and Jones and Rafaeli's (2000) typologies as being the most popularly referenced. Kozinets (2002) too delineates four kinds of online communities. These three typologies are reviewed, and a further popular typology of affinity groups proposed by Macchiette and Roy (1992) as applied to the online environment is also proposed.

Hagel and Armstrong (1997) propose four major types of online communities based on people's desire to meet basic human needs: *interest, relationship, fantasy,* and *transaction.* Jones and Rafaeli (2000) further segment these communities by *social structure*, that is, communities formed based on social networks, for example, online voluntary associations, cyber inns, and so forth, and *technology base*, that is, types of technology platforms, for example, e-mail lists, Usenet groups, and so forth.

Kozinets (2002) proposed the four types of communities as *dungeons*, that is, online environments where players interact, such as for online video games, *circles,* (interest structured collection of common interests), *rooms* (computer-mediated environments where people interact socially in real time), and *boards* (online communities organized around interest specific bulletin boards).

Finally, Macchiette and Roy (1992) proposed a typology of affinity communities that can also be used for classifying online communities. They defined communities as either being: *professional* (e.g., doctors, lawyers, etc.), *common interest* (e.g., hobbies, interests), *demographic* (e.g., by gender, age, etc.), *cause-based* (e.g., Sierra Club, Green Peace), and *marketer generated* (e.g., Disney, Nintendo) communities. These communities may also be constructed in the online environment.

It is also interesting to make other dichotomous distinctions of online communities such as: (a) between *formal* (e.g., associations) vs. *informal* communities, (b) *commercial* (which offers goods and services to make revenues that in turn fuels community operations) vs. *noncommercial* (communities created from the ground up by a group of individuals, e.g., with an interest in stamp collection), and (c) *open or public* (where everyone regardless of their qualifications and individual profile can enter the community and participate) vs. *closed or private* (where outsiders are not allowed into the community, or where membership is very difficult to obtain).

ONLINE COMMUNITIES: MOTIVATIONS, MODE OF PARTICIPATION, CHARACTERISTICS, AND BENEFITS

Rayport and Jaworski (2004) present a model of how the various components of an online community can be integrated. An adapted version of the model is shown in Figure 1.

The model illustrates how members' motivations for joining the online community, their mode of participation, and the community's degree of connectedness in many ways determine the characteristics of the community, which in turn influences the benefits sought by the members in these communities. The various components of the model are discussed next.

Motivations

A member's reasons for joining a community may depend on a wide range of factors, such as affiliation (others like them are members of the community), information (about experiences, ideas, and issues), recreation (meeting people, playing around, sharing stories, etc.), or transaction (e.g., those who join a Web site for buying and trading possessions).

Mode of Participation

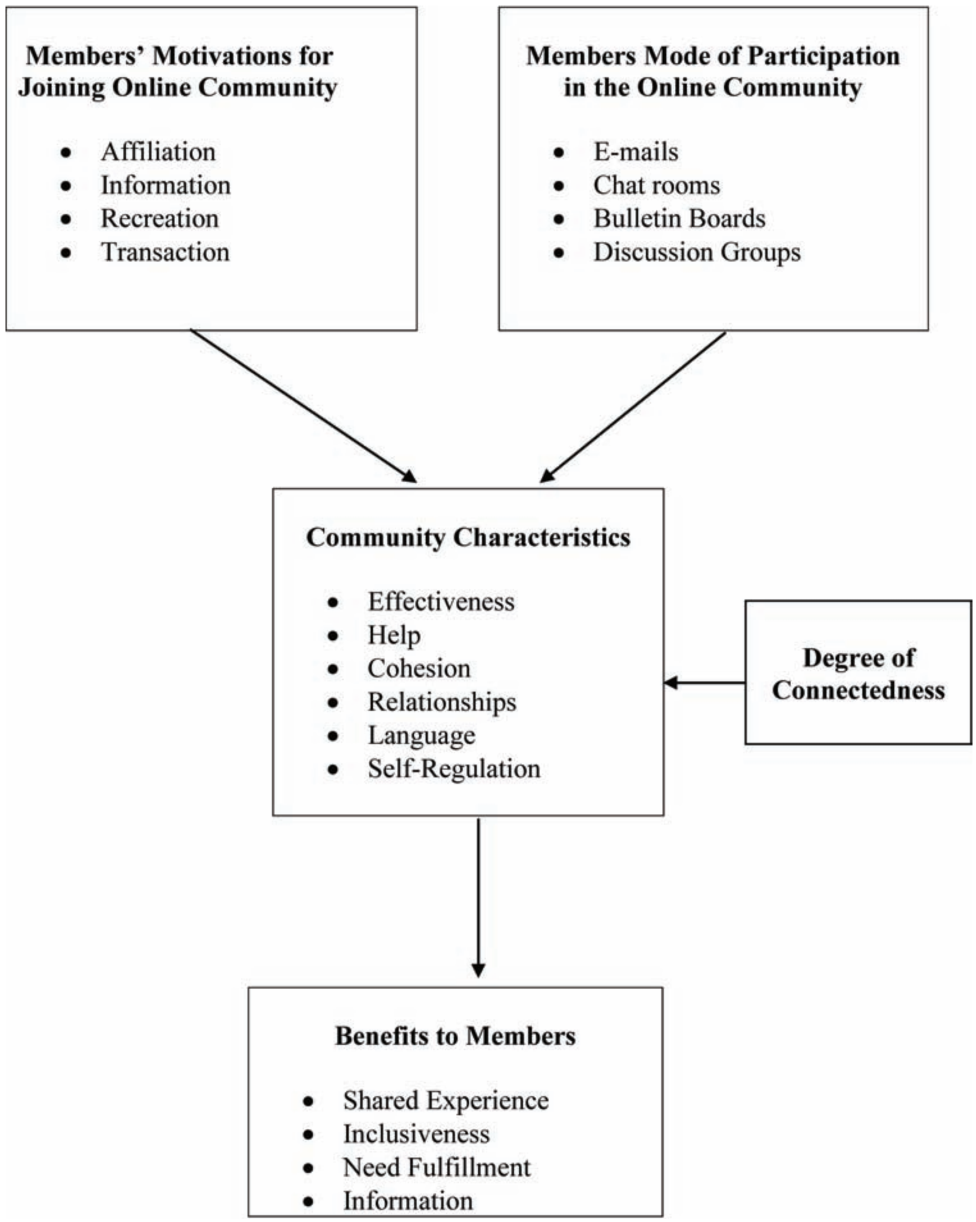
Participation can occur in a myriad of ways, for example, through e-mails, chat rooms, discussion groups, online events, blogs, social networking Web sites (e.g., *MySpace, Facebook, Orkut,* etc.), sharing photographs (e.g., *Flickr*), wikis (e.g., *Wikipedia*), bulletin boards, and so on. Some (such as discussion groups, chat rooms) have more active members than passive members (e.g., e-mail, bulletin board or posting, or watching viewing content on *You Tube*).

Characteristics of Online Communities

With the growth and maturity of online communities, certain characteristics are prevalent. Adler and Christopher (1999) identify six such characteristics:

- **Cohesion:** Members seek a sense of belonging and develop group identity over time.
- **Relationships:** Community members interact and develop friendships over time.
- **Effectiveness:** The group has an impact on members' lives.

Figure 1. Online communities: Motivations, mode of participation, characteristics, and benefits



- **Help:** Community members feel comfortable asking and receiving help from each other.
- **Language:** Members develop shared communication tools that have a unique meaning within the community.
- **Self-Regulation:** The community develops a system for policing itself and sets ground rules of operation.

Benefits to Members

Adler and Christopher (1999) further point out that the members of the online community develop various emotional benefits depending on the communities that they join. They include inclusion, shared information and experiences, need fulfillment, and mutual influence among others.

Degree of Connectedness in Online Communities

The degree of connectedness in online communities also plays a significant role in how a online community develops. They can be classified as weak, limited, or strong. This primarily depends on the degree of interactivity between and among members.

- **Weak:** Members of these sites have no opportunities of interacting with each other on an one-on-one basis, for example, newspaper Web sites and corporate Web sites.
- **Limited:** These communities offer limited opportunities for members to interact with other, for example, reading and posting information or opinions.
- **Strong:** These communities offer chat rooms and message boards and allow users to form strong bonds with each other.

Research has shown that both strong and weak connectednesses have their own advantages. While weak ties are shown to facilitate such tasks as finding jobs (Granovetter, 1973), strong ties are required to facilitate major changes in the communities (Krackhardt, 1992).

Stages of Online Community Life Cycle

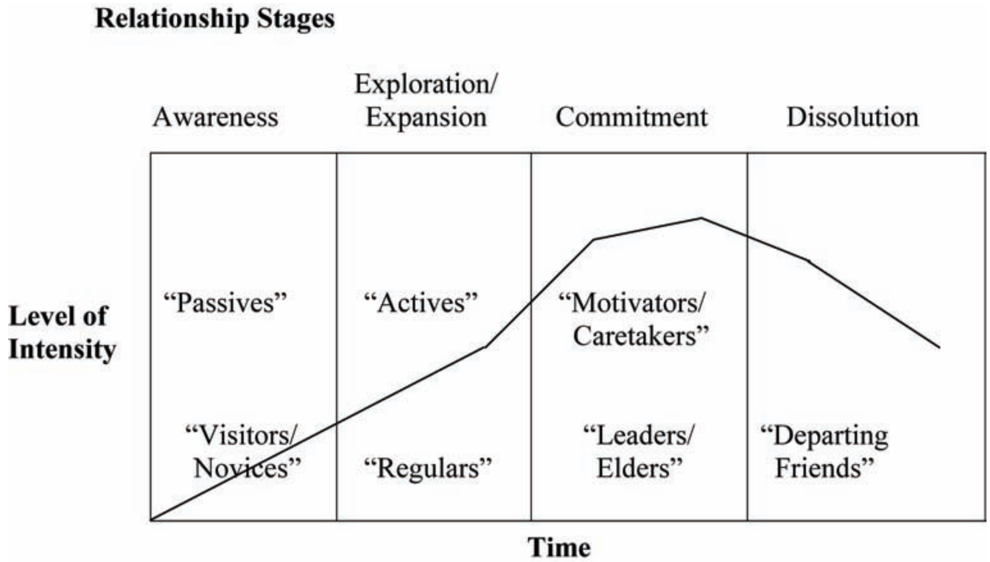
Kim (2000) proposes a five stage online community building process which progresses as follows:

1. **Visitors:** These are individuals who "lurk" in the online community, yet do not participate in them.
2. **Novices:** They are new members or "newbies" who are usually passive and are busy learning the rules and culture of the online community and thus are not actively engaged in it.
3. **Regulars:** They are established members comfortably participating in the exchanges and make up the largest segment of the online community.
4. **Leaders:** These members are volunteers, contractors, and staff who create topics and plan activities that keep the online community running.
5. **Elders:** They are respected members of the online community who are always eager to share their knowledge and pass along the culture of the community to the newer members.

Mohammed, Fisher, Jaworski, and Paddison (2004) further suggest four relationship stages: awareness, exploration/expansion, commitment, and dissolution, and the varying level of intensity patterns as online community members go through membership life cycle. At the initial "awareness" stage, members have the lowest intensity levels and are likely to be considered visitors up until the exploration stage. At this second stage, these novices develop greater intensity and commitment to the site. The equity building efforts over time translate into the online members becoming regulars and subsequently leaders or elders. Finally, over time even the most committed members outgrow a community and become "departing friends." Figure 2 illustrates these stages.

Farmer (1994) had earlier described four similar stages through which individuals in online communities mature. According to him, members begin as *passives* (attending a community, yet not actively engaging in it), and then go on to become *actives* (participating in communities and taking part in conversations). The highest levels of participation are displayed by *motivators* (those who create conversation topics and plan activities)

Figure 2. Intensity patterns of the different types of online communities at various relationship stages (adapted from Mohammed et al., 2004)



and *caretakers* (those who act as intermediaries between members).

The "passives" are analogous to the "visitors" and "novices." the "actives" are similar to the "regulars," while the "motivators" and "caretakers" are equivalent to the "leaders" and "elders" in the Mohammed et al. (2004) model.

STRATEGIES FOR MANAGING SUCCESSFUL ONLINE COMMUNITIES

Duffy (1999) outlines the eight critical factors for community success as recommended by *Accenture*, the Management Company. They are:

- Increasing traffic and participation in the community.
- Focusing on the needs of the members by using facilitators and coordinators.
- Keeping the interest high by provoking controversial issues.
- Involving the community members in activities and recruiting.
- Providing tools and activities for member use.
- Managing the cultural environment.
- Encouraging free sharing of opinions and information.
- Obtaining financial sponsorship.

Social Networking in Online Communities

In the last few years, several social networking sites like *My Space, FaceBook,* and *Orkut* have come up which allow individuals to build up the equivalent of their circle of friends (Scott, 2007). Some communities allow simple access to friends or acquaintances, while others have provisions for improving skills or contacting people with particular types of expertise.

A recent study reported by Steel (2007) showed that *Webkinz.com, Clubpenguin.com,* and *Zwinky.com* received the virtual world sites to most unique visitors with 6.0, 4.7, and 4.4 million visitors in

September 2007. Most notably, all three sites primarily target young teenagers, who happen to be the most active participants of these communities.

Researching Online Communities

Kozinets (2002) suggests using "netnography," involving ethnographic techniques in studying online communities for providing insights into the symbolism, meanings, and consumption patterns of online communities. The method is derived from "ethnography" which was developed in the field of anthropology. Netnography, or ethnography on the Internet, involves the study of distinctive meanings, practices, and artifacts of online communities.

Rather than approaching the problem from a positivistic or scientific point of view, where a researcher begins with a theory, develops and tests hypotheses, and draws conclusions, netnography approaches the construction of meaning in online communities in an open ended manner using inductive techniques using grounded theory. Since the research technique by nature is unobtrusive, ethical research guidelines must strictly be followed such as: (a) fully disclosing his or her presence, affiliations, and intentions to online community members; (b) ensuring confidentiality and anonymity to respondents; and (c) seeking and incorporating feedback from the online community being researched.

Market research firms are increasingly following individuals into virtual communities such as *My Space, FaceBook* and *Second Life* (Story, 2007). By using online focus groups and questionnaires, they are able to get immediate feedback and make decisions about how best to target them in these environments. For example, at CC Metro, an imagined island on the Web, visitors can set up an "avatar" or a virtual alter ego, which can then shop and dance at the *Coca Cola* diner, visit a movie theater, as well as buy clothes and other accessories for their avatars, while surreptitiously being monitored by the firm.

FUTURE RESEARCH ISSUES

There are several issues relating to online communities that are worth investigating (Maclaran & Catterall, 2002). First and foremost is the issue of whether or not they facilitate socialization or whether they are a threat to civilization. Some see them as a way of enhancing social capital between families, friends, and acquaintances, empowering individuals and organizations, creating new ways of relating to each other. Innovative firms leverage this power to create growth and create loyal customers. Others see them as a far cry from the regular face-to-face interactions, creating weak ties between strangers instead of strengthening existing ties between friends and neighbors.

Other issues deal with how to integrate online and off-line communities and developing appropriate metrics for such integration. How can these communities reduce member churn and build loyalty? What are the appropriate metrics for measuring community strength? Hanson (2000) suggests using content attractiveness, member loyalty, member profiles, and transaction offerings as possible metrics for measuring this phenomenon. Under what circumstances is loyalty developed through member-to-member relationships vs. content attractiveness vs. the transaction offerings? What is the most appropriate way of classifying the typologies and taxonomies of these communities? How are intentional social actions generated in such communities (Bagozzi & Dholakia, 2002)? How can stronger brands be built through the use of such communities (McWilliam, 2007)? Are online communities likely to replace regular face-to-face associations in the long run?

Other related research issues pertain to motivation aspects (Igbaria, 1999) and network dynamics (Wellman, Salaff, Dimitrova, Garton, Gulia, & Haythornwaite, 1996) and effects. What business models are likely to work the best for various types of online communities (Hanssens & Taylor, 2007; Reid & Gray, 2007)? How are trust, privacy (Luo, 2002), and satisfaction issues (de Valck, Langerak, Verhoef, & Verlegh, 2007) different between off-line and online environments? What rules of engagement and social structure governs such networks (Cindio, Gentile, Grew, & Redolfi, 2003), and what factors impact the members' continuance in these communities? How do various forms of market structure impact member interaction in these communities (Sohn & Leckenby, 2007)? What ethical dilemmas and challenges do researchers face in researching electronic communities (Hair & Clark, 2007)? What differences are there in online communities across countries? For example, Talukdar and Yeow (2007) have identified interesting differences in such communities in Bangladesh and the United States. Finally, has the balance of power shifted to consumers over firms, with the rapid growth of virtual communities? (Chen, 2007).

Online communities of all shapes and forms are rapidly evolving and creating values for their respective members. Many such communities have over millions of members. These communities will continue to attract the interest of researchers from a wide range of academic fields in the future.

KEY TERMS

Affinity Communities: Communities that are based on profession, common interest, cause, demographic, or marketer generated phenomenon.

Characteristics of Online Communities: Online communities are characterized by their level of cohesion, effectiveness, helpfulness of members, quality of the relationships, language, and self-regulatory mechanisms.

Netnography: Using ethnographic techniques to study online communities.

Online Community: A group of individuals with common interests who interact with one another on the Internet.

Online Social Media: Uses online community members' collaborative attempts in connecting information in various forms including internet forums, Weblogs, wikis, podcasts, pictures, and video. Examples of such applications include *MySpace* and *Facebook* (social networking), *You Tube* (video sharing), *Second Life* (virtual reality), and *Flickr* (photo sharing).

Online Social Networking: Necessitates the use of software to involve communities of individuals who share interests and activities. *MySpace, Facebook*, and *Orkut* are currently some of the most popular online social networking sites.

Stages of the Online Community Life Cycle: Online community members go through four relationship stages: awareness, exploration/expansion, commitment, and dissolution.

Chapter 1.5
IT and the Social Construction of Knowledge

Elena Revilla
Instituto de Empresa, Spain

José Sánchez-Alarcos
Quasar Aviation, Spain

INTRODUCTION

In a dynamic environment, knowledge is the only valid asset that allows organizations to adapt and change. That is why knowledge is one of the few resources on which any organization can support its sustained success. This resource, in its turn, appears as a result of a repetitive process of learning.

Learning is a social product—knowledge is social and has synergic possibilities—therefore, its value increases when it is shared, enriched, and developed beyond the individual, proportioning coherence to the interpretations of the members of the group (Brown & Duguid, 2001; Nonaka & Takeuchi, 1995). Many researchers have pointed out that the capacity of an organization to get into the environment, interpret it, and understand it, in short, to learn it, requires dialogue and discussion among its members. Through dialogue (Isaacs, 1993), each member exhibits a perception or personal image of the world, and these perceptions will affect the other members when they are shared during interaction. Together, the discussion of individual perceptions produces a shared image of reality.

In addition, collective knowledge is a needed complement to the individual (Brown & Duguid, 1991). First of all, there are problems that require the integration of individual knowledge. Second, and not less important, collective knowledge implies that the members of an organization that share it are going to act according to the same criteria and that makes the organization predictable beyond individual contingences. For example, it is of little use for a driver to know the obligation to drive on the right if the others do not know such obligation (as anyone who has driven in countries where they drive on the left will have been able to confirm at the slightest distraction). It is collective knowledge that supplies standards of conduct whose validity stems precisely from the fact that it is collective.

The idea of social construction of knowledge links it to the communities that create, use, and transform it. According to this, if learning is the result of personal experience and processes of interaction

DOI: 10.4018/978-1-59904-883-3.ch084

among individuals, this should be understood in relation to the social and cultural context in which these experiences and interactions take place, that is, in relation to communities of practice.

Over the last decades, the popularity of communities of practice has grown considerably in literature related to knowledge management as a consequence of the importance that an environment of collaboration has had in the generation of knowledge (Cox, 2005; Garavan & Carbery, 2007; Roberts, 2006). They are emerging as a complement to the existing structures and radically galvanize knowledge sharing, learning, and change. In the present-day society of knowledge, these are becoming essential.

Experience has shown over and over that what makes for a successful community of practice has to do primarily with social, cultural, and organizational issues, and secondary only with technological features (Peltonen & Lämsä, 2004). However, an increasing number of communities of practice are geographically distributed and must rely on some kind technology for keeping in touch. And even those that are colocated often need to process data, information, or knowledge. So, appreciation of this central role of technological has emphasized technical initiatives to promote collaboration in communities of practice (Cross, Laseter, Parker, & Velasquez, 2006).

On this basis, this chapter begins with a description of the communities of practice. This is followed by a review of the role of information technology management. The challenges of managing communities of practice are subsequently discussed and brief conclusions drawn.

BACKGROUND

The concept of community of practice was originated in the context of a social theory of learning. Contrary to the idea that human learning occurs in isolation, a social theory of learning insists on the situated nature of human cognition and, thus, in learning as embedded in social practice (Brown, Collins, & Duguid, 1989).

Originally, the term was coined by Jean Lave and Etienne Wenger (1991) based on work in the late 80s when they investigated apprenticeship in various types of communities ranging from midwives in Mexico to butchers in U.S. supermarkets and quartermasters on U.S. Navy ships. Their idea of a community of practice is close the sociology of Tönnies, as noticed by Brown and Duguid (2001).

In particular, Wenger, McDermott, and Snyder (2002) define communities of practice as groups of individuals who share a worry, a set of problems under similar perspectives, or a common interest about a subject, and through communication among its members, share and generate a body of group knowledge. The operative of the communities is totally different. When there are not geographic barriers among its members, they can meet periodically; in other cases, when there is a long distance or the members' agendas are full, they may opt for interchange of ideas through the Internet, video conferences, or any other resource.

They may or may not have an explicit agenda or they may not even follow the agenda closely. Equally, they may or may not go beyond the limits of an organization. Whichever way they choose, communities of practice have something in common (Wenger, 1998):

The domain: A community of practice is not a merely a club of friends or a network of connections between people. It has an identity defined by a shared domain of interest.

The community. In pursuing their interest in their domain, members engage in joint activities and discussions and help each other to share information. They build relationships that enable them to learn from each other.

The practice. Members of a community of practice are practitioners. They develop a shared repertoire of resources: experiences, stories, tools, and ways of addressing recurring problems. This takes time and sustained interaction.

Belonging to a community of practice implies the existence of mental models shared by its members that often lends to a series of unspoken understandings within the actions, social relationships, and experiences of the community (Brown & Duguid, 2001). Handley et al. (2006) suggest that communities of practice emphasize interaction, interpretation, and the ongoing process of sense-making, story telling, and representation. Therefore, the decisions that characterize the members of the group are only slightly formalized and arise from their own tradition.

Throughout this process a high level of confidence is generated based on the knowledge that each has of his/her own potential and of those members of the group. This model of performance creates, in addition, a strong tie among the members of the community that lets both ideas flow within its womb and people work together in a more efficient way. So, an informal atmosphere is created that offers its members the needed support and stability to be able to seek new ways of acting, taking risk, and, in a nutshell, having initiative. Thus, the communities of practice can be described as a "playful community," characterized by a strong work ethic around collective knowledge sharing, mutual challenging, and ongoing learning (Garavan & Carbery, 2007).

Because its primary product is knowledge, the concept of community of practice has been identified as the setting for effective knowledge sharing. Calling them "knowledge communities" might sound like another "soft" management fad, as if they were our first knowledge-based social structure. But that is not the case. Communities of practice are deeply rooted in the real world. They are formed through practice.

Communities of practice refer to groups that have been practising together long enough to develop into a cohesive community with a relationship of mutuality and shared understanding (Lindkivist, 2005). According to Seely Brown the word "practice" is fundamental because in a community of practice the creation of knowledge, innovation, and learning is produced while one does daily work. This converts the communities of practice into a key concept as a basic unit of analysis especially in the most knowledge-intense enterprises.

In this way, communities of practice take the analysis of research to the point where things happen, where work is developed, and where one can work and observe individual behaviour, resolution of interests, and the creation of identity. Communities of practice are natural constructions that respond to the need that the people in a practice recognize each other as colleagues and it is that mutual recognition that gives the community a meaning and lets it be useful. It emerges from a work-related or interest-related field and its members volunteer to join (Arbonies, 2005).

Thus, we see how the communities differ for other work teams. Communities of practice must not be confused with other work teams, which are formal and work together, assigned by a superior, to develop a concrete project or task and are subject to the duration of such project or to changes that can arise in the organization of the enterprise. Communities of practice are informal, however, they can lend to the formation of work or project teams, especially if they are made up of members of a particular organization. They organize themselves, meaning they set their own agendas and establish their own leadership. Membership in a community is self-selected. They know if they have something to give and whether they are likely to take something away (Wenger & Snyder, 2000). What keeps their members together is the passion, the compromise, and the identification of their components with the subject matter of the community of practice. Their duration is infinitely tied to the interest of the members to keep the team alive.

Storck and Hill (2000) suggest that the differences between teams and communities can be characterized as follows:

- Team relationships are established when the organization assigns people to be team members. Community relationships are formed through practice.
- Similarly, authority relationships within the team are organizationally determined. Authority relationships in a community emerge from interaction through expertise.
- Teams have goals, which are often established by people not on the team. Communities of practice are only responsible to their members.
- Teams rely on work and reporting processes that are organizationally defined. Communities develop their own processes.

THE ROLE OF INFORMATION TECHNOLOGIES IN COMMUNITIES OF PRACTICE

Information technologies are often pointed out as the anchor to achieve collaboration (Alavi & Leidner, 2001; Gold, Malhotra, & Segars, 2001) and thus to develop the communities of practice (Cross et al., 2006). The advantages of modern information technologies as a major issue for learning and knowledge in organizations have been widely recognized in literature (Alavi & Leidner, 2001; Nonaka & Takeuchi, 1995). They are accepted as a real pipeline to codify, organize, and disseminate information and knowledge, thereby removing barriers of time and location. At the same time, they create an interconnected environment that is a medium to vertically and horizontally integrate efforts within communities of practice, and in this way to shorten the length of the transformation cycles. As result, and based on the works of Van den Brink (2003), an effective information technology infrastructure demands a combination of two related dimensions: the convergent and the divergent dimension.

The divergent dimension is about having information and explicit knowledge components online, indexed and mapped, with easy access and accurate retrieval for all members of communities of practice. It greatly affects how data and information are gathered and stored. In this situation the emphasis is put on explicit knowledge. The convergent dimension plays the role of enhancing analysis and discourse, and supports a virtual network that is not constrained by barriers of time and place. It improves coordination and communication between members of communities of practice by transferring knowledge from those who posses it to those who need or can use it. Here the emphasis is on tacit knowledge.

Several tools are present at the divergent dimension: integrated document management, document imagining, data warehouse, data mining, business intelligence, Intranet, and Internet. These tools hold collections of knowledge components that have a structured content like manuals, reports, articles, best practices, customer inquiries and needs, competitor analysis, and experience with production. A content classification scheme or taxonomy is used to organize knowledge, facilitate grouping, sort visualization, searching, publication, manipulation, refinement, and navigation. It mostly helps to explicit knowledge, since it can be expressed in symbols and communicated through these symbols to other communities of practices members. It can be easily accessed and used by communities of practice's members.

Regarding the convergent dimension, its functionality is incorporated in tools as e-mails, calendaring and scheduling, groupware, work management system, process support system, and so forth. Its goal is to facilitate group and teamwork regardless of time and geographic location. It offers communities of practice's members the opportunity to interact and exchange views and thoughts with each other. It is thus useful to transfer tacit knowledge, the one that is difficult to express and communicate to other people because it cannot be codified and articulated.

Both the convergent dimension and the divergent dimension configure the potential of information technologies to support communities of practice' capability to generate and utilize knowledge. Therefore, it is feasible to presume that the relationship between the convergent dimension and the divergent dimension may produce variations in the communities of practice. While some communities of practice tend to emphasize one dimension over other, other companies are able to manage the correct balance between both dimensions, or even adjust them in accordance with knowledge characteristics or environmental conditions.

FUTURE TRENDS

In some organizations, the communities themselves are becoming recognized as valuable organizational assets. Whereas the value was previously seen as being relevant to the individual members of a community, it is now often recognized that benefits can also accrue to the organization itself (Lesser & Storck, 2001). Communities of practice can drive strategy, generate new lines of business, solve problems, promote the spread of better practices, develop people's professional skills, and help organizations to recruit and retain talent (Wenger & Snyder, 2000). They are advocated as an innovative collaborative strategy for combining working, learning, and innovation (Gongla & Rizzuto, 2001; Palinscar & Herrenkohl, 2002).

Given the importance of these outcomes, many organizations have spent time and resources designing and implementing communities of practice in an attempt to connect people to others with similar issues and to collect knowledge valuable to the organization. To get communities going—and to sustain them over time—managers should align communities and their members with business needs (Vestal, 2006). In this way, communities of practice remain vibrant and attractive to members and important to the business. Fluctuating business strategies and job changes greatly impact participation in and the effectiveness of communities of practice. Therefore annual and systematic alignment checks should be conducted by communities of practice. In order to do this, community leaders and assistants should transmit business objectives to the community.

While aligning organizational goals and those of communities of practice is the first step on the road to success, many authors consider that the efficiency of a community depends on the existence of an atmosphere which promotes confidence, compromise, creativity, and innovation (Roberts, 2000). It is therefore essential to have a climate of organization open to the production and application of new ideas, initiative, collaboration, and the establishment of quality relationships that promote individuals to share their information beyond the formally established channels.

Specifically, informal as opposed to formal learning is emphasized and it is suggested that both the training and socialization processes will probably be ineffective if they are based on a formal routine, rather than on more informal and innovative experiences. It is difficult for communities of practice to be structured on a basis of decisions coming from the management, particularly taking into account the frequency with which a community can cross the boundaries of an organization, and therefore, be outside the confines of management decisions. Rather the opposite occurs: they emerge spontaneously around a reduced group of people that are interested in knowing and improving the way of doing things and bringing more people with similar interests together.

Their goals depend on the interest of their members in a specific subject and the learning that it implies. As a result, their members help each other without middlemen, tasks are delegated without scepticism, control processes are moderate and casual, and the individuals feel they can communicate their views or intuition through dialogue and cooperation. They do not yield to anyone but themselves and they do so in terms of satisfaction.

Although they are not structured responding to management decisions, the recognition and stimulus they receive can determine their level of productivity. Chin and Carroll (2000) offer some pragmatic advice in this context. They identify steps in which collaboration can be implemented by a community of practice, including group formation, the derivation of goals, objective, and hypotheses, the definition of task, their negotiation and allocation among the members, the identification of resources, detailed analysis, and discussion and dissemination of findings. Additionally, it is essential that the management be aware of the social position of the process of knowledge creation. This means

- Not impeding members of the organization to belong to communities of practice in the belief that because of this they will neglect their other work.
- Increasing the development of the members of the community.
- Helping to create leaders with wide perspectives, who assume risks and facilitate interaction among the members of the community.
- Providing places where their members can express themselves freely about the way to face problems and analyze solutions as a group.
- Negotiating the border between the community of practice and the formal organization; for example, community of practice teams and other organizational units.

Furthermore, organizations should be prepared to invest time and money in helping communities of practice to reach their full potential. This means intervening when communities run up against obstacles in their progress, such as IT systems that do not serve them or reward structures that discourage collaboration. In this respect, Wenger and Snyder (2000) point out that one way to strengthen communities of practice is to provide them with official sponsors and supports teams. Such sponsors or teams do not design the communities of practice or prescribe their activities or outcomes. Instead, they work with the internal community leaders to provide resources and coordination.

Finally, it is important to use nontraditional methods to asses the value of their contribution to the organization. The difficulty in assessing their contribution is that communities of practice are often hidden assets, appearing neither on an organization chart nor on a balance sheet (Lesser & Storck, 2001). Wenger and Snyder (2000) refer to this same idea saying that results generally appear in the work of teams and business units, not in communities themselves. As a result, it is often hard to determine if a great idea that surfaced during a community meeting would have bubbled away in a different setting.

Due to the difficulty in objectively establishing the value of the communities of practice, the use of more intangible indicators, more related to measurements of intellectual capital (Edvinson & Malone, 1997) or social capital (Naphiet & Ghosal, 1998) is required. Indirect approximations, such as the capacity of generating new knowledge for some people and how deeply integrated they feel in a community of practice can give a more exact idea although not accompanied by numbers.

CONCLUSION

In nature a simple parallelism to communities of practice can be found: The fact that trees standing alone grow slowly whereas, when they are grouped together, they compete for light and due to this competition, all grow. Communities of practice are emerging, following this parallelism, like a vehicle used by its members in the search for light (knowledge) and for its growth through exchange with others who are recognized as equals.

Given the great capacity that communities of practice have to increase available knowledge within the organization, it is no wonder the interest in their management. However, the nature of the willingness of its members makes it impossible to rigorously speak of managing communities from a board of directors that has no hierarchy over them. In order to take the highest advantage of some informal structures over which one has no control, a certain astuteness from management is required in order to keep the right distance, not overwhelming members with the weight of the formal organization nor leaving them completely alone. So, the management must understand what a community of practice is, how it works, and what kind of exchanges it can establish. Finally, it is also important for management to realize that they are nonformal sources of creation of knowledge, and therefore, their value is not easy to comprehend and even less to quantify.

KEY TERMS

Knowledge: It is defined (Oxford English Dictionary) variously as (i) facts, information, and skills acquired by a person through experience or education; the theoretical or practical understanding of a subject, (ii) what is known in a particular field or in total; facts and information, or (iii) awareness or familiarity gained by experience of a fact or situation.

Knowledge Management: KM comprises a range of practices used by organizations to identify, create, represent, and distribute knowledge for reuse, awareness, and learning. It has been an established discipline since 1995 with a body of university courses and both professional and academic journals dedicated to it.

Knowledge Transfer: In the fields of o and organizational learning, knowledge transfer is the practical problem of getting a packet of knowledge from one part of the organization to another (or all other) parts of the organization.

Organizational Learning: An area of knowledge within organizational theory that studies models and theories about the way an organization learns and adapts.

Situated Learning: A model of learning first proposed by Jean Lave and Etienne Wenger (1991). It suggests that all learning is contextual, embedded in a social and physical environment.

Social Organization: It can be defined in a narrow sense as any institution in a society that works to socialize the groups or people in it. Common examples include education, governments, families, economic systems, religions, and any people or groups that you have social interactions with. It is a major sphere of social life organized to meet some human needs.

Virtual Organization: An organization existing as a corporate, not-for-profit, educational, or otherwise productive entity that does not have a central geographical location and exists solely through telecommunication tools.

Chapter 1.6
Social Learning Aspects of Knowledge Management

INTRODUCTION

There are probably as many variations of knowledge management definitions as there are practitioners and researchers in the discipline. Complete consensus in such a group would be a surprising finding. This is because the two words are loaded with pre-existing meanings that do not always sit comfortably in juxtaposition, so what it means to "manage knowledge" is difficult to ascertain, and hence comes to mean different things to different people.

We do know however, that knowledge exists in the minds of individuals and is generated and shaped through interaction with others. In an organizational setting, knowledge management must, *at the very least*, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives. Put another way, knowledge management seeks to harness the power of individuals by supporting them with information technologies and other tools, with the broad aim of enhancing the *learning capability* of individuals, groups, and in turn, organizations (Ali, Warne, Bopping, Hart, & Pascoe, 2004). Social learning, in this context, is defined as learning occurring in or by a cultural cluster or organizational group or team and includes procedures for transmitting knowledge and practices across different work situations, settings, and time. However, the application of technology must be guided by the needs of the organization and its workers. As Davenport (2005, p.162) states, "While I don't question the importance of technology in organizations today, it's only one source of knowledge and learning for knowledge workers."

BACKGROUND

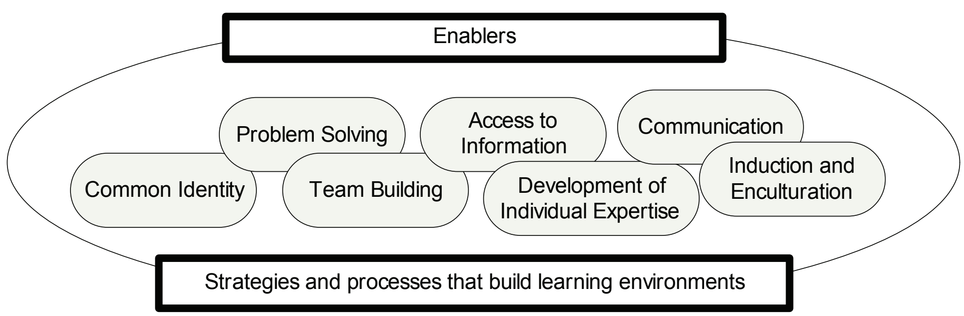
In this article, we examine both theoretical and practical socio-cultural aspects of knowledge management based on years of research by the authors in a large and diverse organization. The study involved numerous functional settings of the organization and the researchers used qualitative and quantitative methodology to gather data. Elements required to build an organizational culture that supports knowledge management are discussed. Unless otherwise specified, words in double quotes in the text are direct quotes from personnel in research settings.

ENABLERS OF SOCIAL LEARNING

The research team identified seven basic categories that constitute enabling processes and strategies to facilitate social learning: common identity, problem solving, team building, access to information, development of individual expertise, communication, and induction and enculturation (see Figure 1).

- **Common identity:** A common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organization unit. Based on our research, motivators impacting on *common identity* are: goal alignment, cultural identity, gendered identity, language, morale, and workplace design (spatial and physical design).
    - Doney et al. (1998) discuss the relationship between goal alignment and group cohesiveness, claiming that the extent of group cohesiveness relies on the extent to which a team's goals are clear and accepted and also on the degree to which all members adopt team behaviors.
    - The term cultural identity refers to member's sense of self in relation to the specific "tribe" and "tradition" to which they belong and how this distinctiveness applies in their workplace. Cultural identity is another important motivator for social learning because, like common identity, it impacts on the extent to which staff feel that they are part of the system or alienated from it.
    - Gendered identity relates specifically to one's sense of self, which is imbued with the social, cultural and historical constructions surrounding femininity and masculinity. Gender identity, because of its relationship with common identity, was also seen to impact on social learning (Agostino, 1998).
    - Language is another important factor fundamental to the overall social learning processes. By reflecting the

Figure 1. Constructs enabling social learning



social and political relationship between various members, language can impact on common identity. Language is also important in terms of creating a shared understanding among workers and their relationship to the wider organization. "Words are bullets. Never, never use imprecise language." Thus learning the specific work related language is of central importance to broader social learning development, and is an important outcome of the enculturation process.

    - Morale has been a significant focus in the overall study because the research team found evidence of low morale being coupled with higher levels of alienation towards senior management. Such alienation has obvious implications for the broader understanding of a common identity and thus for social learning.
    - Workplace design and proximity also threatens common identity when staff are not working in the same location. "[Building X] and us. We don't see them. There is not any spirit that we are belonging to one branch. I have more to do with [a specific area] than anything else and I've made some good contacts in there... who I sit around with."

- **Problem solving:** A core activity. It fosters social learning, because each problem represents an opportunity to generate knowledge. Motivators associated with this enabler are: networking, perceptions of the organization, systemic understanding, and time for inquiry and reflection.
    - An individual's personal and social networks are an important means of acquiring, propagating, and sharing knowledge. As Davenport and Prusack (1998) claim, when those who are in a position of "know-how" share their expertise, they contribute to problem solving. Personal networks were seen to function as channels supporting both "information pull" and "information push." Atkinson and Moffat (2005) state that sharing of information is based on trust developed through social interaction, shared values, and beliefs. A human is a node in such interactions and a link is a bond that people develop which is based on mutual trust. Therefore, a significant component of a person's information environment consists of the relationships he or she can tap into for various informational needs.
    - Individual and shared perceptions of the organization, and how they operate, provide an essential backdrop to problem solving within an organizational context. These perceptions may consist of deeply ingrained assumptions, generalizations, or even pictures or images that influence how people understand their organizational world and how they should act within it (Senge, 1992). The importance of these perceptions cannot be stressed enough, because they directly influence the construction of individuals' knowledge and understandings that they draw upon in their day-to-day-activities.
    - Effective problem solving often requires a systemic understanding of organizational and inter-organizational issues. Systemic understanding requires a holistic view of an organization and its inter-relationships, an understanding of the fabric of relationships and the likely effect of interrelated actions (Davenport, 2005; Senge, 1992).

- ◦ Inquiry and reflection together are a powerful means of enhancing social learning and knowledge creation. Inquiries, or questions, are triggered by problems that require solutions or explanation. Reflection allows time for examination, contemplation and, often, resolution of the inquiries. To use a common metaphor, it is perhaps the best means for distinguishing between the forests and the trees of everyday working life.

- **Team building:** Working together and understanding what each member is trying to do. Team building was seen to be essential for effective social learning and problem solving. As team-members got to know each other they become aware of each other's strengths and weaknesses, what they could or could not do, their expertise and experience. Motivators associated are: leadership, team-based morale, performance management, public recognition and reward systems, use of humour, and workplace design (Warne, Ali, & Pascoe, et al., 2003).
  - o In general, the caliber of leadership within the settings studied was to be admired. The leaders and managers were innovative and they motivated and developed their staff, mainly by demonstrating that staff are highly valued and by acknowledging expertise and knowledge regardless of their pay or position. Another team building issue that emerged was that people were appreciative of informal "drop ins" by senior managers inquiring how they were doing. This "roving management" was said to contribute to better cohesion of teams, to promote system thinking, to help to focus on overall goals, and to facilitate communication and feedback.
  - ◦ "Team spirit" and "team cohesiveness" are both important values within the work culture and work ethic, nonetheless, there was nothing uniform about this in the settings studied. Some teams did not see the significance of their particular tasks to the overall goals of the organization. However, good examples of teamwork and team spirit were also evident. There were instances where teamwork was well integrated into daily work and where people worked collaboratively. Such teams were goal oriented and were not only teams in structure but in spirit and were led by a leader who saw his/her role as serving team members rather than just having the position of a leader (Warne et al., 2003).
  - ◦ For many employees, the performance cycle is annual and the outcome of a performance report often determines the prospects of one's career progression. Some felt somewhat uneasy as their performance evaluation was due relatively early into their posting cycle. A well planned performance appraisal system should help to make equitable and unbiased decisions regarding staff selection, placement, development, and training (Wood, 1989). Researchers were told that there was often a lack of clear communication about performance expectations. Also, an annual performance appraisal appears to be too long to wait for recognition of good work and too late to correct a performance problem. Morgan (1989) and Wood (1989) explain that to maximize positive results, the appraisal process should be two ways, it should facilitate and coach staff in doing their jobs effectively, and it should be frequent and informal.
  - ◦ It was observed that humor was used for smoothing discussions that were

becoming heated and to stop the conflict from escalating whilst also enabling the conflicting subordinates to save face. At meetings, humor was used to assist in uniting people around common themes and to make criticism palatable.

  ◦ One way of and increasing team and individual morale is to publicly acknowledge outstanding work. Making employees feel appreciated, and saying, "Thank you, we know that you are a good employee, we value you and your work," is a big factor in motivation (Mitchell, 2000). Key informants stated that public recognition of good work was scarce and that a written or verbal word of praise, a pat on the back often means more, for example, than a pay raise—"praise is better than money" and praise is needed at all levels.
  ◦ Workplace design was seen to have impact on social learning. Staff located at small isolated outposts were at risk of feeling isolated and did not identify strongly with the parent organization. As stated earlier, outposted staff identified more with the workplace with which they were based than their Branch where they affiliated. This was further exacerbated by the fact that they often felt excluded by their colleagues.

- **Access to information:** The easy availability of corporate information in whatever format was observed to effect knowledge acquisition and generation of new knowledge and social learning. Motivators associated are: record keeping, networking, meetings, and information technology (IT) infrastructure.
  ◦ The researchers observed that general familiarity with records keeping procedures was quite poor. Some people have developed their own personal records keeping systems but there was little uniformity in these and no adherence to file naming conventions and standards. As some informants stated: "I believe that physical files in the … are no longer managed well because their management has been farmed out to outside bodies." or "I think we have problems with passing on information in the organization as a whole. We just don't do it very well." The issue of electronic records, particularly e-mail messages containing evidence of business transactions, posed problems not only in the setting studied but also in the ADO at large.
  ◦ Personal networks from previous postings as well as newly acquired contacts in the new environment play a vital role in knowledge construction and acquisition. New knowledge often begins with the individual and through conversations people discover what they know, what others know and in the process of sharing, new knowledge is created. Knowledge sharing depends on the quality of conversations, formal or informal, that people have. Sharing of information has a behavioural component and the emphasis is usually on one-to-one networking initiative and effort. It requires time and space (physical, cognitive and social) to develop the sense of safety and trust that is needed for information sharing. Webber (1993) aptly describes it "conversations—not rank, title, or the trappings of power—determine who is literally and figuratively 'in the loop' and who is not."
  ◦ Meetings are another means of accessing information and those that

were observed varied significantly in format and the protocols in place. At the tactical headquarters, meetings that were mission related provided excellent opportunities for learning. Strict protocols were observed at these briefings (e.g., allowing participants to discuss errors or problems encountered during missions without assigning blame or shame to individuals). There were few equivalent meetings at the strategic headquarters, other than some induction sessions and briefings and it appeared that learning how to do one's job was not given quite the same priority.

    - The researchers observed that information access due to failings in the IT infrastructure inhibited access to information within the strategic settings. Another issue that caused problems was the difficulty in finding information on the shared drive. Since there was no specific person responsible for maintaining the shared drive and for naming folders, it was left to the discretion of the document originator where information would be stored.

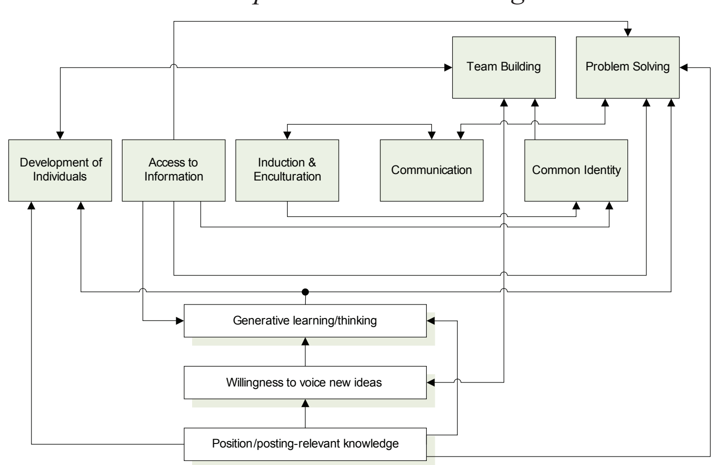
- **Development of individual expertise:** The acquisition and development of expertise was seen as an integral part of social learning. Motivators associated with this enabler are: career trajectories, professional currency, professional training, postings and promotion, and mentoring.
    - A career trajectory describes the positions, roles, and experience that individuals have accumulated, up to and including the position they currently hold. While not excluding personal experiences outside of a work or training context, a well designed career trajectory generally equips an individual with the skills, experience, maturity, and personal networks needed to successfully fill a particular posting.
    - The term professional currency has a somewhat different meaning within different environments. However, professional currency promotes social learning in the same way that appropriate career trajectories do so—by providing a foundation for the generation of new knowledge.
    - Appropriate professional training is a significant component of the development of individual expertise and, therefore, a fundamental for generating new knowledge. Training courses are important to furthering individuals' expertise, as well as for forming the personal networks that subsequently develop. However, in times of budgetary constraints, training money is often the first to go, with damaging consequences for the organization's ability to learn and manage their knowledge.
    - Mentoring is regarded as an effective method of assisting the development of individual expertise, especially for junior staff a degree of informal mentoring was seen to be built into elements of the training program in some of the settings studied. In terms of developing a career trajectory, the knowledge acquired through mentoring may also be important when individuals want to prepare themselves for specific roles in the future.
- **Communication:** Essential to effective learning within an organization and to effective social learning. Motivators associated with this enabler are: overall communication climate, formal and informal information flows, time for inquiry and reflection, use of humor, language, and workplace design.

- Supportive communication climates are being positively linked to open and free exchange of information and constructive conflict management. Characteristics of a supportive communication climate include a culture of sharing knowledge, treating each other with respect, and generally behaving in a cooperative manner. Research has established the link between supportive organizational communication climates and generative learning (Bokeno, 2000; Ruppel, 2000) and with higher levels of organizational commitment (Guzley, 1992).
- An important element of generative learning is for organizational members to be able to engage in dialogue, which is open and is based on inquiry and reflection. A supportive communication climate is a prerequisite for such dialogue and it requires learning how to recognize defensive patterns of interaction that undermine learning (Senge, 1992).
- The issue of workplace design and its impact on teams, network building, and on accessing information arose repeatedly during the study. Physical location and proximity to each other had the potential to promote the transfer of pertinent knowledge. The point was made that in addition to more quickly obtaining answers to questions about particular tasks, an open plan workplace enabled one to tap into pertinent knowledge by overhearing others' conversations. Hutchins (1996) uses the term "horizon of observation" to describe the area of the task environment, which can be seen, and is therefore available as a context for learning by team members.

• **Induction and enculturation:** Facilitates social learning by providing a foundation upon which an individual can become fully productive. Issues associated with this enabler are: timeliness and comprehensiveness of the process, buddy/mentoring system, handovers and information packages, and training.

- Good induction is more that just an introduction to new job and workmates; it is a way of helping people find their feet. Attitudes and expectations are shaped during the early days of new employment and work satisfaction is linked to well timed and conducted

Figure 2. Enabling processes and their impact on social learning



work orientation (Dunford, 1992; George & Cole, 1992). The interviews clearly indicated a relationship between meaningful and timely induction and subsequent job satisfaction. An interesting finding was that those who were not properly inducted or enculturated into the organization saw no need and responsibility to actually prepare any form of handover for anyone who may take over their position in the future.

- Although highly desirable, it was not always feasible to conduct an induction program at the beginning of a new posting cycle. In the interim, a "buddy" or "mentoring" system could fill in the gap. A "buddy" would be an experienced workmate who could be available to answer questions and assist the orientation of new members during the initial few weeks. Some interviewees said that having a buddy when they started was invaluable to settling into a new job and to effective learning.
- The researchers were repeatedly told that early training is an important part of effective induction and enculturation. It is an opportunity to learn the explicit knowledge that is taught as part of formal training. It is also an opportunity to be exposed to the attitude and cultural perceptions of colleagues and peers.

These factors enabling social learning identified from our data are by no means exhaustive, however, based on the available data the research team could see a relationship between these enablers and social and generative learning. Figure 2 depicts these relationships and their impact on social learning.

FUTURE TRENDS

Whether by design or necessity, humans tend to collaborate to achieve set goals. In fact, this sharing of information and knowledge, and the willingness to cooperate, are key elements for learning, innovation and advancement in general. The progress and proliferation of information technology greatly facilitate this process. However, this widespread application of information technology and emphasis on sophisticated networks for information sharing and social learning leads to a false assumption that once all networks are in place the information will be shared and freely disseminated. The subtle difference between "the network" and "to network" is the key. "The network" is a noun, the information technology, and can only be the enabler. "To network" is the verb, the human behaviour, the action, and the main focus. Therefore, the future trends in the area of social and organisational learning must look beyond the acquisition of technical enablers to individual and organizational behaviour (e.g., organizational structure, processes, and tactics) in order to shift emphasis from a technology-centric approach to a people-centric capability, ensuring that people will get the systems they need and want.

CONCLUSION

Organizations seeking to improve information sharing and knowledge generation need to develop a greater awareness of the processes and strategies of organizational learning. Organizational knowledge is distributed across functional groups and its generation and continual existence is dependant on the overall communication climate which is embedded in the organizational culture. This study indicates that information sharing and subsequent knowledge generation would be successful when interactive environments are cultivated before other (e.g., technology-based solutions are implemented). Therefore, the communication strategy in any organization must take into account the role played by informal and personal networks and trust in information sharing to optimise the process of transferring critical data to facilitate speedier decision-making. Technology should only be designed and applied after a thorough investigation of the work practices and work preferences of the people and teams in the organization.

KEY TERMS

Career Trajectory: Describes the positions, roles, and experience that individuals have accumulated, up to and including the position they currently hold.

Common Identity: A common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organizational unit.

Communication Climate: Extend to which there is an open and free exchange of information, transparency of decision-making, and how constructively conflict is managed.

Knowledge: An understanding gained through experience or learning: the sum, or a subset, of what has been perceived and discovered by an individual. Knowledge exists in the minds of individuals and is generated and shaped through interaction with others.

Knowledge Management: In an organizational setting, it must, *at the very least*, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives.

Social Learning: Learning occurring in or by a cultural cluster and includes procedures for transmitting knowledge and practices across different work situations/settings and time.

Systemic Understanding: A holistic view of an organization and its inter-relationships, an understanding of the fabric of relationships and the likely effect of interrelated actions.

Chapter 1.7
Agents and Social Interaction
Insights from Social Psychology

Joseph C. Bullington
Georgia Southern University, USA

ABSTRACT

Social interaction represents a powerful new locus of research in the quest to build more truly human-like artificial agents. The work in this area, as in the field of human computer interaction, generally, is becoming more interdisciplinary in nature. In this spirit, the present chapter will survey concepts and theory from social psychology, a field many researchers may be unfamiliar with. Dennett's notion of the intentional system will provide some initial grounding for the notion of social interaction, along with a brief discussion of conversational agents. The body of the chapter will then survey the areas of animal behavior and social psychology most relevant to human-agent interaction, concentrating on the areas of interpersonal relations and social perception. Within the area of social perception, the focus will be on the topics of emotion and attribution theory. Where relevant, research in the area of agent-human interaction will be discussed. The chapter will conclude with a brief survey of the use of agent-based modeling and simulation in social theory. The future looks very promising for researchers in this area; the complex problems involved in developing artificial agents who have mind-like attributes will require an interdisciplinary effort.

INTRODUCTION

As our technologies become more interactive in nature, the necessity of building in a social component has become more important than ever. The present chapter will review and discuss a variety of theories that have been used to guide academic research and development in the area of multi-agent interaction. Of particular interest are those models specifying an underlying theory of the character and development of social interaction, as well as those that have focused attention on the affective components of human-agent and agent-agent interaction.

As originally conceived (e.g., Maes, 1995), software agents were to carry out tasks on our behalf such as seeking out information that we might be interested in, or finding the best prices for products, or even carrying out negotiations on our behalf. The notion that we would have a relationship with an agent and how that relationship would unfold, and even how the agent could be designed with social capabilities in mind seemed somewhat far removed from the issues related to the design of an autonomous search agent.

In order to develop more life-like agents that are capable of interacting in a believable way with humans, it is necessary to imbue them with some of the same attributes that are thought to underlie human social interaction. Otherwise, the agents may be thought of by users as dumb or simply annoying (e.g., the Microsoft Office Paperclip). The development of simulations of an agent's interactions with humans (or with other agents) thus could be guided by some underlying theory of social interaction. If so, then which theories of human social interaction, particularly theories of mind and social cognition, could play a role in the development of multi-agent systems and in human-agent systems? The overall goal of this chapter is to introduce selected theory and research in the area of social psychology to others who may not be familiar with the concepts and theory in this field. Thus, though portions of the chapter will review instances where social psychological concepts have been applied to actual systems, the focus will be on surveying concepts and ideas, not on the practical application of such ideas to system development.

The chapter will begin with a look at the question of what guides our social interactions with others, whether they are human or artificial. Dennett's (1978, 1989) concept of the intentional stance will be examined in some detail, and will be used as a basis for understanding interaction at a basic level. The search for relevant concepts and research findings that could be applied to deepen our understanding of agent interaction will continue with a review of selected concepts from the ethological and animal behavior literatures, including the concepts of fixed action pattern, imprinting, and imitation.

The next section will include a brief review of theories and evidence from social psychology that are applicable to multi-agent systems research. Social psychology represents a rich source of theory and insights into the nature of social interaction in multi-agent systems, and the review will include the areas of social perception and impression formation, selected portions of the interpersonal relationship and social exchange literatures, as well as examples of research in the agent-human literature that have built on these underlying ideas. The aim here is not to provide a comprehensive review of these research areas, but to point out their relevance as we go forward with research in the field of agent interaction, particularly agent-human interaction.

Affective components have played a guiding role in research in the area of human-agent interaction, as exemplified in the work of Rosalind Picard and her group at MIT. Thus, Picard's work and its application to the area of social interaction will be discussed, along with that of Cynthia Breazeal and her efforts to build interactive robots.

The final section of the chapter will include a brief survey of the work in agent-based modeling, as well as a look into the future of this research. Of particular interest is the potential contribution this research can make to our overall understanding of social interaction. For example, can it provide confirming evidence for models of social behavior emerging from the human experimental social and developmental laboratories, as well as ethnographic and field research? Also, what types of interactive systems will emerge from this research and how will they change the way we use computing technology?

ISSUES, CHALLENGES, PROBLEMS

Social Interaction Between Agents, Both Human and Artificial

What is it that seems to guide our interactions with other agents? Whether these agents are people, animals, or machines? We will turn to a variety of disciplines for insight into this question, among them social psychology, philosophy and computer science.

Among philosophers, Dennett (1978) has used the term "intentional system" to describe "…a system whose behavior can be – at least sometimes – explained and predicted by relying on ascriptions to the system of beliefs and desires" (Dennett, 1978). He is careful to note that in using the terms 'beliefs' and 'desires,' he is not suggesting that the entity *has* beliefs and desires, only that we behave towards the entity *as if* it possessed such things. An entity is an intentional system only in the case where someone is seeking to explain and predict its behavior.

To further clarify these points, Dennett uses the example of someone seeking to predict the next move of a chess-playing computer. There are three 'stances' one can take in attempting to predict the computer's behavior. First, if one knows exactly how the computer is designed – including the hardware and software, then if the computer functions as it was intended, one can predict its behavior in response to any given move. This is referred to as the *design stance*. Second, one takes a *physical stance* if one knows the actual physical state of the entity at any moment in time. For instance, with a human chess opponent, this would require knowledge of (among other things) the firing patterns of all the neurons in the brain, or in the case of the chess playing computer, the physical state of all the electrical circuitry in the processor and all connected components. From this knowledge, one could predict the system's physical state in response to a particular move. Of course, because of the complexity of the chess-playing computer system (or a chess playing human), a person could never have the kind of detailed knowledge required by the design and physical stances. Therefore, one's best strategy for predicting the computer's next chess move is to assume that it will make the most *rational* move, given that its design is optimal and that it is not currently malfunctioning. This last strategy, assuming that one is dealing with a rational entity, whether animal, human or machine, is referred to as the *intentional stance.* The implication of this stance, according to Dennett, is that we ascribe to the system the possession of certain information (beliefs), and suppose it to be directed by certain goals (desires) (Though, it should be stressed again, that Dennett is not implying that the intentional system *has* beliefs and desires). When we take an intentional stance toward a person, an animal, or a machine, we are using a *theory of behavior* in order to explain or predict the behavior of the other entity, one involving the implied rationality of the entity.

Turning to our interactions with artificial agents, the question of how humans think about the technologies that they interact with on a daily basis was investigated in a series of studies by Reeves and Nass. Their research suggests that we tend to interact with computers as if they were people (Reeves and Nass, 1996). Using such methods as brainwave monitoring, home video, and questionnaires to measure peoples' responses to media in all its forms, they found that people tended to interact with computers and other media technology in a fundamentally social and natural way, and may not even have realized that they were doing so. For example, people tend to evaluate the performance of other people more favorably when the evaluation is given to the other person face to face, as opposed to giving the evaluation of the same performance to a third party. Reeves and Nass obtained the same finding when a computer's performance was being evaluated instead of another person. The theory they proposed to explain these findings suggests that for most of our history, humans only responded both socially and naturally to other humans (and perhaps animals), so no mechanism other than a human social response for dealing with artificial entities has ever developed.

Major Types of Interactive Systems

Conversational agents. The Turing test provides a model for human-machine interaction (Turing, 1950). Turing used a parlor game as an interaction model, designed originally as a response to the question of whether machines can think. The 'imitation' game involves two unseen people, a male and a female, along with a group of interrogators. The interrogators attempt to decide which person is the male, and which is the female based on written responses alone. The male tries to convince the interrogators that he is the female, while the female attempts to convince the interrogators that she is the female and that the other person is the male. In the revised version, a computer and a human take the place of the male and female, and the decision to be made is which is the human and which is the computer, based again on written responses to questions alone. The object of the machine is to try to cause the questioner to mistakenly conclude that the machine is the other person; the object of the other person is to try to help the questioner correctly identify the machine. Turing (1950) described his hopes for the test this way:

I believe that in about fifty years' time it will be possible to programme computers, with a storage capacity of about 10^9, to make them play the imitation game so well that an average interrogator will not have more than 70 percent chance of making the right identification after five minutes of questioning. … I believe that at the end of the century the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted. (Turing, 1950, p. 436).

Most observers believe that Turing would be disappointed at the performance of computers in this test today, judged by performance in the Loebner Prize Competition—an annual event in which computer programs are submitted to the Turing Test. Turing's test has nonetheless provided a kind of model for the development and evaluation of programs designed to provide an interactive component for their human users. Perhaps the best-known example of a conversational agent of the type suggested by Turing is Weizenbaum's ELIZA (Weizenbaum, 1966). The program was developed using the model (Weizenbaum suggested the term parody) of a non-directive psychotherapist. Rather than offer interpretations of a client's behavior, the non-directive therapist is trained to reflect the client's statements, in order to draw out their underlying emotional components (Rogers, 1951). A typical conversation would proceed as in the following; ELIZA's responses are capitalized (from Weizenbaum, 1966):

```
Men are all alike.
IN WHAT WAY?
They're always bugging us about
something or other.
CAN YOU THINK OF A SPECIFIC EX-
AMPLE?
Well, my boyfriend made me come
here.
YOUR BOYFRIEND MADE YOU COME
HERE
He says I'm depressed much of
the time.
I AM SORRY TO HEAR YOU ARE DE-
PRESSED
It's true. I am unhappy
DO YOU THINK COMING HERE WILL
HELP YOU NOT TO BE UNHAPPY
I need some help, that much
seems certain.
WHAT WOULD IT MEAN TO YOU IF YOU
GOT SOME HELP
Perhaps I could learn to get
along with my mother.
TELL ME MORE ABOUT YOUR FAMILY
My mother takes care of me.
WHO ELSE IN YOUR FAMILY TAKES
```

```
CARE OF YOU
My father.
YOUR FATHER
You are like my father in some
ways.
WHAT RESEMBLANCE DO YOU SEE
You are not very aggressive but
I think you don't want me to no-
tice that.
…and so on.
```

At the time, many people who interacted with ELIZA became quite quickly and emotionally involved with the program, in part motivating Weizenbaum to write *Computer Power and Human Reason: From Judgment to Calculation*, in which he explained the limitations of computers, and argued against the anthropomorphic views people had of the system he created (Weizenbaum, 1976). Web-based implementations of ELIZA can be found in several places, so one can experience the interaction for oneself.

Robots and interactive virtual graphic characters. With interactive conversational agents, as in the Turing test, the social context – social cues such as facial expressions and gestures, etc. - is taken away, so that the only information one has is the answer to a question displayed on a computer screen. The need to create software agents and robots that can interact with humans in a credible way has motivated more recent research, which has concentrated on building creature-like machines designed to provoke social responses on the part of humans (Bickmore & Picard, 2005; Breazeal, 2002a, 2003). These two types of agent-human systems will be discussed in more detail below, in the context of their use of social psychological theory.

The Place of Social Psychological Theory in the Development of Agent-Based Interaction

Social psychology can be defined as the scientific study of the way in which people's thoughts, feelings, and behaviors are influenced by the real or imagined presence of other people (Allport, 1985). This group of social scientists has had a great deal to say about human to human agent interaction, and their work could potentially make a contribution to the area of human to software/robot agent interaction. This review will not cover the whole of social psychology, as there are some areas of the field that would not provide as great a contribution as others at the present time. For example, there is a great deal of interest in the study of self-perception and self-understanding, including the mechanisms of self-awareness (Carver & Scheier, 1981; Duval & Wicklund, 1972). There are no claims on the part of any researcher in the field of robotics or software agents that these entities have any consciousness or awareness. In addition, although aggression and altruism are also important research areas within social psychology, they will also not be included in this review. We will instead concentrate on the social behavior of animals, the process of social perception, and social exchange theory and interpersonal relations. Following this section we will review work involving the use of social psychological theory in the development if interactive artificial agents.

Social Behavior in Animals

Behavior in lower species provide an interesting analog for understanding the behavior in artificial agents, whether software agents or robots. There has already been a great deal of work in the area of what has come to be called swarm intelligence (Bonabeau, et al., 1999). In this research, social insects, such as ants and bees, are viewed as collective problem solvers, where, although composed of simple interacting organisms, they are collectively able to solve complex problems. Their intelligence lies in the networks of interactions among individuals and between individuals and the environment. This analog has been translated into systems where software agents, acting according to simple rules in a virtual environment exhibit complex collective behavior, attempt to solve complex organizational problems (Bonabeau, 2002). This research has been largely concerned with the operation of population-level mechanisms.

Lower species also conduct social interactions at the individual level as well, and perhaps this level can provide some insights to researchers in the areas of robotics and other embodied (yet virtual) agents. Ethologists (Lorenz, Tinbergen, Hinde, and others) have studied animal social behavior both in the laboratory and the field for many years. Three major concepts are important for the purposes of the present chapter: *fixed action patterns, imprinting and imitation*.

A *fixed action pattern* is a response, thought to be innate, that occurs reliably in the presence of identifiable stimuli (called sign stimuli or releasing stimuli). These responses are distinguished from other types of behavior in that, unlike reflexes, they involve numerous muscles and parts of the body; and unlike purposive behavior, the responses are inflexible and run off in a mechanical way (Tinbergen, 1951). A classic example of a fixed action pattern is the aggressive response on the part of a male stickleback fish to the entry of another stickleback into his territory, caused by the sight of the threat posture of the encroaching stickleback. Tinbergen (1951) carried out numerous studies of this behavior and determined that the red belly in the proper orientation, even on an artificial model of a fish, was enough to trigger the response. Thus the red belly is a sign stimulus or releaser for the fixed action pattern of the aggressive response.

The remaining two concepts from ethology are part of the process of learning, particularly in young animals. Learning to distinguish your species from other, potentially harmful species is an important achievement. This can be accomplished in several ways. In some species it is attained during a very brief period in life called a *critical period.* During this early period, certain species of birds engage in a 'following-response' towards the mother. That is, they simply follow behind her because she possesses or exhibits a particular pattern of *releasers* that serves to trigger the behavior, much as the sign stimulus triggers the fixed action pattern. The releaser is composed of several attributes that the species has in common; for example an odor, shape or size, or, in the case of the greylag goose, the movement of the mother, that then triggers a response. Ethologists refer to this process as *imprinting* or the triggering of specific behaviors in the face of a pattern of releasers (Lorenz, 1961). In this case, imprinting has been explained as a primitive form of learning in which an individual finds out about the characteristics of their social group. In humans, the process of imprinting involves a strong emotional response to the mother that is referred to as *attachment.* This process is believed by some researchers to be irreversible, and important for the socialization of the child (Brown, 1965). A fictional portrayal of this process involving artificial agents was portrayed in the film "Artificial Intelligence," when the parents of the eternal child/robot "David" were given specific instructions on how to cause him to begin to perceive and behave toward the female human as "Mother." Though there is currently no actual analog for this process between humans and artificial creatures, Breazeal (2003), in developing Kismet, a sociable robot, used the idea of 'releasers' to encode and mediate the information from the robot's internal and external environments, and to generate an emotional response towards its human partner based on this information.

The final concept from ethology and the study of animal behavior that is relevant to work in agent interaction is *imitation,* which is also considered a primitive form of social learning. Though the topic remains controversial in ethology (Miklosi, 1999), there is a great deal of evidence for the role of imitation in human social learning and cognition in infants (Bandura, 1986). The evidence suggests that infants are able to model novel behaviors that they are physically capable of expressing. Meltzoff and Moore (1989) have demonstrated imitation of facial gestures in infants as young as 42 minutes.

In robotic applications such as household cleaning, building, and elderly care, which involve social interaction, robots will need to be able to coordinate their actions with their human partners. Thus, robots need to be able to recognize the actions of their human partners in order to understand the goals of the actions, and they will need to imitate their behavior as a method for learning new skills. Breazeal and Scassellati (2002) discuss the problems associated with building robots capable of imitation. Unlike studies of imitation in animal behavior or in infants, where the main goals most often are descriptive or involve the discovery of the mechanisms responsible for producing the behavior, in robotics the goal is to create or generate a behavior with minimal underlying capabilities. Two major issues in the development of robots that are capable of imitation that are currently far from being solved involve: (1) the perception of movement or "how does a robot know *what* to imitate, and (2) representing motor movements, or "how does a robot know *how* to imitate." Although there are differences in methods and goals, Breazeal and Scassellati nonetheless believe that animal research can contribute to work in interactive robotics and vice versa, and that greater understanding of robot imitation and social learning will contribute to our understanding of robot social cognition (Breazeal & Scassellati, 2002).

Interpersonal Behavior

Theories of interpersonal behavior are perhaps the most relevant for current work in artificial agent-human interaction. Social exchange theory forms the basis for later work in this area. The basic idea behind exchange theory is that humans are rational, utility maximizing creatures. Thus, we seek to maximize the social rewards a relationship with another person can provide. Given these assumptions, social exchange theory suggests that how we feel about our relationships is a function of the perception of the rewards we receive and the costs we incur, along with our feelings about what kind of relationship we deserve and the probability of obtaining a better one (Brehm, 1992; Kelley & Thibaut, 1978). When we find ourselves in a relationship with another person (or an artificial agent?) then, we evaluate the costs and benefits of that relationship to ourselves, and if the costs outweigh the benefits we seek to dissolve the relationship.

Even though there is empirical support for social exchange theory, some have criticized its view that people are simply out to get the most reward from a relationship at the least cost. Later versions of social exchange theory have incorporated the concept of equity in a relationship; in other words, we seek fairness in the amount of reward we offer the other person in a relationship and in the costs we incur. Thus, we want to be treated equally, and to the degree that the relationship is perceived as inequitable, we will seek to end it (Walster, Walster, & Berscheid, 1978; Berscheid & Reis, 1998).

Social exchange theory can help us understand what happens after a relationship begins, but what attracts us to other people to begin with? Here the major focus of the work has been on the examination of variables that determine attraction. Among the more important variables are (Berscheid & Reis, 1998):

- **Proximity:** We are more likely to develop relationships with the people who we are physically near.
- **Physical attractiveness:** Although we tend to pair up with those who are most similar to us in attractiveness.

- **Similarity:** We are more likely to be attracted to others who share our attitudes and values.

It is clear that applications that are meant to provide assistance to people, particularly the kind of live-in robotic assistants for the elderly that are envisioned, will be a part of a person's living space for extended periods of time. It thus becomes important to understand the process of developing a long-term relationship with an artificial agent. Research conducted by Bickmore and Picard (2005) is perhaps the best example of the use of concepts from social psychology to understand the interaction between humans and artificial agents. These researchers were interested in the development of long-term relationships with an artificial 'relational' agent. They developed an interactive embodied virtual character (Laura) that would interact with and help to motivate people as they engaged in a month-long exercise program. During the study, participants interacted with the agent on a daily basis over a 30-day period for at least a few minutes, in order to encourage the development of a basic level of relationship. While interaction took place via a kind of interactive chat, the animated character also used body language and facial expression to provide additional social cues. In a 'relational' condition, additional strategies were implemented in the design of the agent to encourage a relationship. For example, in a strategy involving *meta-relational communication,* the agent would periodically ask how things were going and would offer to make changes if needed. Periodically checking on the status of the relationship would then demonstrate concern and caring for the user (Bickmore & Picard, 2005). In a 'non-relationship' condition, these additional relationship-encouraging strategies were left off.

The results of the experiment suggested that even though there were few statistically significant differences between the experimental groups in their participation in the exercise program, the 'relational' group 'liked' the agent better, felt they had a 'good' relationship (approached statistical significance), showed an interest in continuing the relationship, and, when given the option of giving 'Laura' a sentimental farewell at the end of the program, chose to do this more often than the 'non-relational' group. In interviews conducted after the study, participants' impressions of the agent were very favorable; and they found interacting with 'Laura' very natural (Bickmore & Picard, 2005).

This study represents one of the first attempts to use concepts from the social psychological literature in the design of an artificial agent. Based on the finding of significant effects on relationship measures for the experimental condition in which these (and other) concepts were used, researchers and designers of such systems should begin to apply these techniques more widely. As we continue to explore the nature of the relationship between humans and artificial agents, perhaps the concepts from the social exchange literature might also be useful. Finally, as Bickmore and Picard suggest, agents that function in the role of 'helper' have a special obligation to develop a sense of trust in their human partners. Thus, going forward, research into the development of trust in these types of relationships will be particularly important.

Social Perception

This area of social psychology is concerned with how we form impressions of and make judgments about other people. For instance, what kinds of nonverbal cues are used in our attempts to understand another person's behavior? In addition, social perception concerns how we understand and attribute causes to another person's behavior.

Nonverbal communication. Impression formation will be important for the development of long-term relationships between humans and artificial agents. Part of our impression of another person is based, of course, on what they say to us, but an awful lot of information is derived from nonverbal channels. Work on nonverbal communication, and particularly the communication of emotion via facial expression has been an important focus for research in the area of social perception and impression formation (Ekman, 1965). Nonverbal communication refers to the way in which people communicate, intentionally or unintentionally, without words, including using facial expressions, tone of voice, and body position, among others. The most important of these, for the purposes of this chapter, is the use of facial expressions to communicate emotion. Charles Darwin (1872) is credited with beginning the work in this area with his contention that facial expressions served as a means of communicating information to others in the social group. For example, an expression of disgust may signal that the food I am eating doesn't taste very good; an angry expression may be followed by aggression, etc. Darwin believed that expressions for the so-called primary emotions (anger, happiness, surprise, fear, disgust, and sadness) were universal, that is, anyone, anywhere in the world should be capable of understanding and displaying these expressions. This view has received support, based on a great deal of cross-cultural research over a number of years conducted by Paul Ekman and his colleagues (e.g., Ekman & Friesen, 1975; Ekman, Friesen, & Ellsworth, 1982). Because of the importance of the face for communication of information about the internal state of the organism, designers of interactive systems, including robots, are taking these research findings to heart as they build new systems.

Emotion. In order to develop a complete understanding of how the mind works, most cognitive scientists and some artificial intelligence workers (e.g., Minsky, 2006) believe that it is necessary to understand emotion. In evolutionary terms, emotion may play a critical role in the allocation of cognitive and other resources to areas needed to solve environmental problems (Izard, 1977). Some theorists believe that negative emotions (anger, sadness, etc.) are a signal that some action needs to be taken to bring the organism back into a balanced state, while positive emotions (happiness) signal a more or less balanced, satisfactory state (Frijda, 1994; Plutchik, 1991). The emotion process unfolds as cognitive appraisal systems evaluate environmental conditions, and recruit resources (motor, respiratory, hormonal and other systems) to respond to the environmental appraisals. Facial expressions are also thought to perform a communicative function, giving others in the social group information on the internal state of the organism, providing input on how best to respond. The purpose of this brief explanation is not to provide the reader with a comprehensive understanding of emotion theory, but to emphasize its importance in the creation of interactive agents, and to provide context for the discussion of affective computing.

There are two threads of work in the area of human-agent interaction related to the topic of social perception with particular relevance to the expression and communication of emotion. One is Rosalind Picard's work on *affective computing* (Picard, 1997), which is concerned with the development of computing technologies that are capable of understanding and expressing emotion. Of course, whether computers *have* emotions, or whether they *truly* feel empathy for their human partners is beyond the scope of this research. The major technological difficulties involve developing systems that can understand and express emotion computationally.

Recognizing emotion. The ability on the part of an artificial agent to automatically recognize the emotion of a human agent will be critical to the development of interactive applications. Picard presents a scenario for such an application in this way:

Imagine you are seated with your computer tutor, and suppose that it not only reads your gestural input, musical timing and phrasing, but that it can also read your emotional state. In other words, it not only interprets your musical expression, *but also your facial expression, and perhaps other physical changes corresponding to your emotional feelings-maybe heart rate, breathing, blood pressure, muscular tightness, and posture… Given affect recognition, the computer tutor might gauge if it is maintaining your interest during the lesson, before you quit out of frustration and it is too late to try something different. "Am I holding your interest?" it would consider. In the affirmative, it might nudge you with more challenging exercises. If it detects you are frustrated…, then it might slow things down and proffer encouraging feedback. (Picard, 1997, p. 16)*

Recognizing emotion will require a variety of skills on the part of the system, each of which present technical challenges to the developers of such a system. Among these requirements are those involving vision and hearing for gathering information about facial expressions, gestures and vocal intonations, but in addition, once the sensory information has been gathered, an interpretation must be made based on knowledge about the situation and knowledge about emotion generation (Picard, 1997). Research suggests that computers are capable of recognizing videotaped actor portrayals of facial expressions of emotion with greater than chance accuracy (e.g., Cohen, et al., 2003), and in more complicated tests involving multimodal systems (Kapoor & Picard, 2005). In the latter study, the goal was to extract, process and interpret naturally occurring non-verbal behavior during natural learning situations, in order to provide personalized assistance to children engaged in learning tasks, a much greater challenge for the system. The researchers obtained data on facial features and head gestures, as well as data from a posture-sensing chair, which were then fed into feature extraction processes and the data classified as to whether interest was being expressed. The system achieved an overall accuracy rate of 86%, which was significantly better than using the individual sensory modalities alone. The challenge for this research area continues to be, as the Kapoor and Picard study suggests, being able to interpret multi-modal data in real time, in naturalistic settings, for ongoing emotional states involving constantly changing expressive states; and while an 86% accuracy rate is significantly better than chance, is it good enough for applications that seek to provide accurate and timely feedback to their human partners?

Expression of emotion. Picard (1997) has similarly developed criteria that need to be met in order for computers to be said to express emotion. These include *input,* in which the computer receives instructions about which emotion to express; *feedback*, which concerns the fact that, in humans, affective expressions can influence an ongoing affective state, as demonstrated in several laboratory experiments (Laird & Bresler, 1992). Other criteria proposed by Picard include *social display rules* or what are the relevant social norms that determine when, where, and how emotions are expressed; and the *output from the expressive process*, including changing facial expressions, posture or gait, or vocal signals. Each of these present enormously complicated technical challenges, let alone in combination, which is why, to date we have seen few examples of such systems. One exception to this is the work of Cynthia Breazeal, and her group's work on the development of socially engaging robots. She is also greatly interested in the development of emotion sensing and expressive systems for use in the service of humans.[1*]

The Sociable Machines Project at MIT is responsible for building Kismet, an expressive, anthropomorphic robot, capable of interacting in a social way with humans (Breazeal, 2003). In a nutshell (and greatly oversimplifying the entire process), the robot is capable of expressing emotions based on a complex system of sensors, drives (e.g., being over or under stimulated by an interacting human partner), and a perceptual system that keeps track of external and internal events. There is an emotion system comprised of an appraisal subsystem, which takes the results of the perceptual system and computes a value which it then hands to an emotion activation subsystem to make a decision about which emotion would be most appropriate, based on the value handed off from the appraisal subsystem. Finally, the motor system takes the result from the emotion system and generates the appropriate facial expression and posture. The robot is capable of conducting an ongoing interaction with a human partner in real time, in which the behavior of the human influences the emotional state of the robot and where the goal of the partner is to keep the robot's *drives* satisfied. This basically takes the form of keeping the robot awake and stimulated, but not overly stimulated, in which case the robot perceives threat and responds accordingly through appropriate facial expression and posture.

Breazeal and her colleagues also conducted a series of studies in which they examined the degree to which people categorized Kismet's facial expressions into one of seven categories of emotional expression. Whether they observed the expressions on a still photograph or saw Kismet model these expressions via videotape, the participants (which consisted of a group of 12 year old children and a group of adults) were able to correctly categorize the expressions significantly more often than by chance. Further, while "scolding" the robot during interactive sessions, the robot's sad face and body posture caused some participants to report that they felt 'terrible' or 'guilty,' perhaps evidence for the human partner experiencing a sense of empathy with the robot (Breazeal, 2003).

Taken as a whole, the work of Picard and Breazeal shows a great deal of promise for the development of systems that are capable of interacting with humans in a credible way. One example of a system that would have a great deal of practical value is a Furby-like creature that could serve as a companion for elderly people. Of course, such a system would have to be extremely easy to use as well as reliable; a person would need to be able to get it up and running easily, and it should not need a team of computer scientists and mechanical engineers to keep it running. Much more likely in the near future are learning technologies of the sort discussed above, combining multi-modal feedback from the learner to the system with the ability to tailor lessons to a learner on the fly based on this feedback. The acquisition of this feedback is a problem at present, requiring special headsets and, if physiological data is required, straps and sensors that provide ways of measuring processes like blood pressure and heart rate.

Attribution theory. Attribution theory is concerned with how we attribute cause to a person's behavior. People engage in this process as they attempt to understand the relationship between social situations and behavior, and predict future outcomes based on past occurrences of behavior. For instance, when we consider why a person stole another person's wallet, are we likely to place more weight on the person as causal agent, that is, to make a *dispositional* attribution? Or are we more likely to place greater weight on the environment, which would constitute a *situational* attribution? Such questions have intrigued social psychologists for years, beginning with Heider (1958), who developed most of the basic ideas and vocabulary. Once again, rather than attempt a comprehensive review of research and theory in this area, we will survey some of the major theoretical and empirical contributions, and then, because there has been no direct application of these ideas, we will speculate on their relevance to agent interaction.

Jones and Davis developed *correspondent inference theory* to understand the way in which we make internal (dispositional) attributions, or how we *infer* dispositions from *corresponding* behaviors (Jones, 1990; Jones & Davis, 1965). The theory is concerned with how we narrow down our choices for the dispositions that we think might have caused a particular behavior to occur. To do this, we look for what Jones and Davis call *non-common effects*, that is, effects or consequences of a particular behavior that could not be produced by another behavior or course of action. For example, suppose a friend decides to take a job at an investment bank in San Francisco. If we want to understand why this person chose this particular job we need some way of narrowing down our choices for an explanation. Correspondent inference theory suggests that we look for other choices our friend could have made, and examine the effects of the second choice. If the second choice produces effects that the first cannot, for instance, if we learn that our friend turned down a job working at a non-profit agency in rural Oklahoma, there would seem to be little overlap between the effects of the first choice and the second. In other words, there would be a large number of non-common effects. If this were the case, it would be more difficult for us to determine what caused the choice of jobs. If, on the other hand, we find out that our friend turned down a job at a consulting firm in San Francisco before accepting the job at the bank, we can narrow down the causal factors more easily, because there is more overlap between the effects. In this case there would be few non-common effects.

While correspondent inference theory focuses only on dispositional attributions, Harold Kelley's *covariation model* dealt with how people initially decide whether to make an internal (dispositional) or external (situational) attribution (Kelley, 1967). Kelley assumes that when we are in the process of forming judgments about another person, we gather information with which we can test hypotheses. We then look at the pieces of information that *covary* with other pieces, as if we are conducting a statistical test, and base our judgment on these pieces of information. Where does the information come from? There are three sources: first we call on our knowledge of or guess about the way a person has acted in similar situations (distinctiveness data), second, the way a person has acted in the same situation in the past (consistency data), and third, the way other people have acted in the same situation (consistency data). For example, in trying to decide why Jeff liked a particular movie, we consider how Jeff and others who have seen the film respond to it, and how they have responded to films like it in the past. If Jeff basically raves about all films of this type, or if others who have seen it are not enthusiastic, we are likely to attribute dispositional causes to Jeff's behavior. If Jeff rarely raves about films of this type or any other type, or if others also rave about it, we are inclined to make a situational attribution, that there was something about the film that caused his behavior. As with correspondent inference theory, there is a great deal of empirical support for Kelley's model (Ross & Nisbett, 1991).

Much of the research in social psychology tends to take place in a controlled laboratory environment, and while the theories discussed above have been confirmed in these types of settings, some interesting, somewhat contradictory findings have also emerged. Whenever you tend to find a character in a movie so compelling that you suspend disbelief and feel sadness at their misfortune for instance, you are making a mistake in judgment about this person. In reality, this person was an actor whose situation dictated that she behave in a certain way, yet we seem unable to view the person's behavior in an objective light. Though this may seem like an extreme example, results from laboratory experiments suggest that our judgment, in some cases is biased by our readiness to attribute the behavior of others to their dispositions. This tendency is referred to as the *fundamental attribution error.* In a classic experiment on this concept, groups of college students were asked to read an essay written by a fellow student that either supported or opposed the rule of Fidel Castro in Cuba. Half the participants were told that the writer had freely chosen their position before writing the paper, while the other half were told that the students had been assigned the topic beforehand. The participants were then asked to what degree the writer actually supported the position she wrote about. Logically, the participants should have concluded that being assigned the topic would not indicate actual support for the position; instead, the participants concluded that the authors actually supported their positions, whether they had freely chosen the topic or not (Jones & Harris, 1967). Thus, in general we tend to underestimate the role of the situation when making attributions about another's behavior, however, when judging the causes of our own behavior, we tend to be biased in the other direction, towards seeing situational components as the major cause. This is referred to by social psychologists as the *actor/observer bias* (Ross & Nisbett, 1991).

It is unclear just how the findings of attribution theory will be applied to the design of agent-human interactions. Breazeal (2003) has suggested that one of the next steps in the evolution of socially interactive robots like Kismet is that they be capable of acquiring mental models of other people. Scassellati (2000) has taken an important first step in this direction by examining the processes involved in shared attention. Going beyond this level, should designers build in the same reasoning biases that humans have, like the fundamental attribution error, into the systems they build? This would presumably cause the system to make the same errors in judgment as a human. Would these errors make the system seem more human? Or would it cause a human observer to feel more negatively towards the system ("Stupid robot!"), and thus be less likely to trust it? After all, aren't computers supposed to be logical? Or would we view the system as more unfeeling if it did not occasionally make mistakes? The answer would seem to be that it depends on the purpose for which the system was constructed. For a conversational system or one designed as a companion it would seem better to have the system appear as human-like as possible. In the interpersonal attraction literature this is known as the *similarity* effect; the more similar we are, the more I may like you (Berscheid & Reis, 1998). On the other hand, for a system designed for use in dangerous environments with a human partner, biased reasoning processes when it comes to making judgments about other people or the environment could be dangerous, and so should not be built in. In short, the ability to reason about the interpersonal environment would seem to be of some importance in the design of interactive systems if what we are interested in is the construction of artificial minds.

Agent-Based Modeling and Social Psychological Theory

There are two distinct strands in the agent literature that have utilized social psychological theory. One strand in this effort has used theory and research findings to develop new technologies, so their primary purpose has been on the engineering side. We have talked at great length in this chapter about this research. Representative of this approach is the work of Bickmore and Picard (2005), discussed above, and their use of the literature on human interpersonal relationships in the development of a software agent. Also representative of the engineering approach is the work of Breazeal and her colleagues, who have utilized work on the display and communication of emotion to develop socially engaging robots, and Rosalind Picard, who has pioneered the work on machine detection of affective states in human partners.

The second strand in the agent literature, which will only be briefly described here, uses agent-based modeling methods in the study of social psychological processes. In this research, the focus has been on the emergence of patterns relevant to social phenomena from the interaction of a group of autonomous software agents, programmed with a few simple rules. The approach has been referred to as *generative* in that, a phenomenon is explained by postulating underlying mechanisms that, through their interaction, generate the phenomenon. The phenomenon is said to emerge as a result of the interaction of the underlying mechanisms (Epstein, 1999; Smith & Conrey, 2007).

The use of simulation to develop and test theories in the social sciences has a long history

(Abelson, 1963). In contrast to the generative approach to theory building discussed above, these programs embody a particular theory of social and/or cognitive process. Robert Abelson (1963) was one of the first social psychologists to develop computer simulations of social cognition. One of his first efforts was the development of a program that simulated Heider's Balance Theory (Heider, 1958), which suggests that if a person holds contradictory thoughts, the person must rationalize the contradiction, or change one of the thoughts in order to bring the process into balance. For example, the statement "my simulation produced silly results" contains a thought that is positively valued in the person's belief system (my simulation) and a thought that is negatively valued (silly results). According to Heider, holding these contradictory thoughts causes discomfort until the person is able to somehow balance the values by somehow rationalizing the negatively valued thought. Abelson's program took statements that were out of balance and attempted to bring the statement into balance so that it would fit into a pre-determined simulation of a belief system.

One of the first social scientists to use a generative approach was Thomas Schelling (1978). He explored the question of whether segregation can arise from a group of agents who do not explicitly desire segregation. His program used the simple rule that if the population with your 'color' fell below a certain percentage in your neighborhood, move to an empty space on a virtual grid. The pattern that emerged upon running the simulation to completion was that the populations appeared completely segregated. Thus, the motive to not be in a minority in one's neighborhood, not a desire to be segregated appeared to cause this pattern.

Following Schelling, Robert Axelrod, a political scientist at the University of Michigan designed a series of computer tournaments, which would have the effect of evaluating strategies for winning an iterated Prisoner's Dilemma. However, he also used these results to try to answer the 'generative' question: can cooperation *emerge* from the interactions of rational self-interested individuals (Axelrod, 1984). Axelrod has continued to generate interesting research on these questions, which have some applicability to real world issues such as conflict resolution (Axelrod, 1997).

The agents in Axelrod's research represent entities stripped of everything psychological except self-interest; thus, these agents provide social scientists with tremendous control over extraneous variables like emotion, feelings of empathy, or other relationship-oriented variables that human beings possess. They represent the process of social exchange at its most fundamental level. Thus game theory is often used in this type of research because it contains simplifying assumptions about social behavior (basically that we are rational, self-interested creatures) that are appropriate for modeling the interaction between two or more human agents or between computational agents.

For those seeking more information about the generative approach in social science, Smith & Conrey (2007) have written an excellent article in which they provide a justification for the use of an agent-based approach to the development and testing of theory in social psychology. They also provide a review of the use of the generative approach in social psychology and the social sciences in general, and a comprehensive bibliography which should serve as a guide for the interested reader.

CONCLUSION

We have reviewed theories and research in social psychology that may be of interest to researchers and those engaged in the design of interactive technologies. Beginning with a detour into the philosophical literature and a summary of Dennett's concept of the intentional system, the chapter subsequently examined the Turing test, as well as conversational systems that utilize written verbal means of communication only, such as

ELIZA. The contribution of social psychological (including animal social behavior) concepts was then surveyed, as well as the application of these concepts to research in agent-human interaction. We reviewed selected theories in interpersonal relations, along with their application to an understanding of long-term relations between humans and artificial agents in the work of Bickmore and Picard. The survey also included concepts from social perception, with special attention to the use of emotion as a method of communicating the state of an organism, along with applications from the work of Picard and Breazeal to artificial agents. Attribution theory, the study of how we draw conclusions about the causes of an agent's behavior - are they inside the agent (personality) or outside (environment)? – was discussed, and though there have been no direct applications of this particular set of theories to agent-human interaction to date, if agents are to seem life-like, should they be subject to the same attribution biases as a human? A different strand of research, in which artificial agents are used to simulate social processes was then examined. This area has received renewed interest from social scientists, in part because of the computational power of modern personal computing platforms, and the availability of simulation software. Smith and Conrey (2007) have surveyed the major contributions to the literature and argued for the use of agent-based modeling in the development and testing of theory in social psychology. Finally, though the issues of whether artificial agents are truly intelligent, or are really capable of having feelings, or attaining consciousness, though important issues, may never have a final resolution. Philosophers and scientists will continue to debate these questions, but until we have a better grasp on what it means for a *human* to be conscious, or intelligent, or have emotions, it is premature to speculate about how these processes manifest themselves in an artificial being.

It is hoped that the present chapter inspires researchers and designers concerned with researching and developing interactive technologies to investigate the literature in the field of social psychology more closely. In a review such as this, one can only scratch the surface of the concepts and issues in this field, knowing that most of the ideas that have inspired researchers for many years cannot be given the space that they deserve. The field of human-computer interaction encompasses many researchers from many different backgrounds, who have come together to solve some of the most complex problems in computer science, engineering, and psychology. It behooves researchers from these areas to learn as much as they can from each other (and from fields like ethology and animal behavior, anthropology, and linguistics), because it is only as a truly interdisciplinary field that these problems can be solved. The applications resulting from this collaboration: live-in companions who can provide a psychological dimension to their interaction, workers who are able to learn new skills from their human counterparts, tutors who are genuinely able to enrich the learning experience for both children and adults, can be a great benefit to humans.

FUTURE RESEARCH DIRECTIONS

The future for the topic of this chapter, the contribution of social psychological theory to understanding and developing systems that engage in social interactions, looks very bright. The history of research efforts along these lines lies mainly in two unrelated bodies of work; first, there is the research that has sought to develop and test social theory using agent simulation (Abelson, 1965; Axelrod, 1984, 1997; Axtell & Epstein, 1999). These efforts represent a viable alternative and a complement to the current use of laboratory, ethnographic, and survey methods, characterized by Smith and Conrey (2007) as *Variable Based Modeling* as opposed to *Agent Based Modeling*. One of the advantages of such an approach for social scientists is that they are not limited in the scope of their research. That is, one is not constrained to conduct analyses at the level of the 'individual' actor, as most social psychological research is. One can create individual agents that act as nodes in a connectionist cognitive network, or agents that simulate the social networks within a large organization; the choice is up to the ingenuity of the researcher.

For researchers and designers of interactive systems the challenges include incorporating mechanisms whereby the agents are able to learn from their human partners. The interaction between human and artificial agent is most often represented as a parent-infant form of relationship. Thus, the development of systems that are capable of some form of imitation, which is thought to be one of the more primitive forms of social learning, is an important goal of this area of research and development. In addition, the ability of an agent to begin to take an intentional stance toward their human partners, in other words, to begin to reason about the behavior of their partners, as discussed in the section on attribution theory, would be a significant milestone towards the development of artificial agents who are able to reason in a social way.

Chapter 1.8
Cyber-Identities and Social Life in Cyberspace

Eleni Berki
University of Tampere, Finland

Mikko Jäkälä
University of Jyväskylä, Finland

ABSTRACT

Information and communication technology gradually transform virtual communities to active meeting places for sharing information and for supporting human actions, feelings and needs. In this chapter the authors examine the conceptual definition of virtual community as found in the traditional cyberliterature and extend it to accommodate latest cybertrends. Similar to the ways that previous social and mass media dissolved social boundaries related to time and space, cyber-communities and social software seem to also dissolve the boundaries of identity. This, in turn, questions the trust, privacy and confidentiality of interaction. The authors present a way of classifying and viewing self-presentation regarding cyber-identity management in virtual communities. It is based on the characteristics that cyber-surfers prefer to attribute to themselves and accordingly present themselves to others. In so doing, the authors coin the terms for five distinct phenomena, namely nonymity, anonymity, eponymity, pseudonymity and polynymity. They subsequently compare and contrast these terms, summarising information from their investigation, and outlining emerging questions and issues for a future research agenda.

DOI: 10.4018/978-1-60566-208-4.ch003

INTRODUCTION

Cyberspace and virtual communities are often described by features such as structure, setting or formation. From the view point of the user more important than the features are the social qualities. One of the important social features is the sense of community. Sense of community is often described as a set of subjective experiences of belonging, mutual respect, and commitment that can be gained only through participation (McMillan & Chavis, 1986). It is not just the space but the people with their collective experiences. Furthermore, human empowerment in designing for sociability and usability for socially acceptable information and communication technology has become a research and development issue of increasing importance (Preece, 2000; Earnshaw et al., 2001; Berki et al., 2003). Online communities cannot merely be built, only facilitated in order to provide platforms for people to come and form a community of their choice. This emphasises the human factor within design and research of cyberspaces.

Cyberspace does not have physical borders but social life within cyberspace does have expression boundaries as well as norms and rules for behaviour. These boundaries for social actions and behaviour are either inherited by the structure of a certain e-space or different social software, i.e. discussion forums and work spaces, or imposed by the designers and users of e-spaces. In order to succeed, online communities, e-spaces and other electronic congregations need regular users. Cyberspace does not exist without electronic inhabitants; otherwise it is a deserted cyber place. Recent studies show that the degree of success and functionality of virtual communities is incorporated and built through trustworthy group interaction (Werry & Mowbray, 2001). The rise of social software technologies and online social networks impose new challenges for law, security and trust, identity and interaction (Kollock, 1999; Kimppa, 2007; Berki et al., 2007). The challenges go sometimes so far as to raise questions related to democracy and citizens' degree of participation in private or public virtual communities (Wilhelm, 2000). The existence of cyberplaces also challenges the definition of membership since within digital worlds inclusivity and exclusivity have totally new semantics or terms of definitions with different applications and tools to facilitate membership management.

Boundless digital spaces also challenge the ways of participation. Entering cyberspace concerns issues of identity and identification. The possibility to participate in online communities anonymously may ease the entrance to digital worlds. Some participants, however, may dislike anonymous people and they, instead, gravitate towards digitally eponymous people welcoming them in an electronically-mediated social environment. To some extent identity, both in real life and cyber life, can be seen as composed of similar qualities. Notwithstanding, questions of security, safety and trustworthiness are often associated with cyberpartcipants and their identities. In real life, however, identities are not that often questioned, authenticated or even doubted.

Understanding cyberspace requires exploring the meaning of individual and group (collective) identities, in particular how they are built and how they affect interaction and participation (Renninger & Shumar, 2002; Georgiadou et al., 2004). Arguably, the identity shared by the cyber-societies participants should be empowering to facilitate participation and support communication. An overpowering group identity might block communication and create difficulties in promoting innovative ways of thinking and functioning. A shared, cohesive identity, used by eponymous or anonymous people facilitates the development of mutual trust among the participants and balances communication within a group. On the other hand, a pseudonym or plenty of names may decrease certainty and control in interaction but still increase the willingness to communicate. Technology-mediated-communication is often seen as faceless and task-oriented. However, it seems that communication in cyberspace may speed up initial interaction as well as self-disclosure, which, in turn, may facilitate interpersonal connections and building of relationships (Walther, 1994; Walther and Burgoon, 1992). Without doubt, anonymity, pseudonymity and eponymity affect trustworthiness, credibility and security of e-transactions and e-interactions (Jäkälä & Berki, 2004).

There is a multiplicity of people in e-spaces: e-learners, visitors of different chat rooms, participants of electronic interest groups, and members of support groups and e-communities, all with different needs and different aims (see e.g. Werry & Mowbray, 2001; Jäkälä & Mikkola, 2001; Renninger & Shumar, 2002). In cyberspace, group and community formation as well as identity building, testing and maintenance comprise the social, cultural and psychological aspects of behaviour with communication technologies (Jäkälä & Berki, 2004). Social behaviour online aims at facilitating a trustful communication environment providing acceptable and credible interaction (see Li et al, 2007).

In this chapter, the authors identify and discuss rules that govern interaction in cyberspace. Furthermore, the traditional definition of virtual community (see Rheingold, 1993) is scrutinised and extended. The authors aim at describing and distinguishing different types of identity that are presented or represented in the cyberspace, and associate their research findings to the cyber surfer's identity formation in the context of various virtual communities or e-spaces. Configuring the transformation of individual and collective identity to online identity, the chapter, simultaneously, provides a classification on the pitfalls and certain expectations from five different types of cyber-identity, namely *eponymity*, *nonymity, anonymity, pseudonymity* and *polynymity*. The authors coin these five terms here for the first time in order to describe five different phenomena in cyber communication that are associated with five different types of cyber-identity. These, though being common phenomena in everyday life on the screen (see e.g. Turkle, 1997, Papadimitriou, 2003), have remained undefined and unclassified while their positive or negative consequences influence online communication but remain largely unnoticed. There is a need to investigate these phenomena especially since online presence compromises the privacy of the interaction. An improved understanding of the relations between online identity building, online identity types and e-activities could contribute to the design of e-spaces, where people's activation and participation increase. For instance, this new information might lead towards the design of e-learning communities that could increase learners' participation in the e-learning process. Similarly this new knowledge could contribute to open new ways for social inclusion by overcoming biases and digital divides.

Internet is a relatively new means for interaction, where identity and identity formation have recently been paid attention especially from the technical point of view, e. g. authentication, privacy and identity theft. Other scientific domains such as communication and social psychology (see e.g. Bosma et al., 1994; Wallace, 1999; Wood & Smith, 2001) have paid more attention to these concepts. The main investigation approach is examining the recent research findings in the combined domains of cyberspace and identity. In the examination, theories and principles from other scientific domains are combined and utilised for the online identities comprehension. In the discussion and comparison the chapter also draws knowledge from personal experiences in e-learning, e-instruction and cyberspace usage through years of action research in the domain of cyber education, cyber communication and cyber culture.

CONCEPTUALIZING VIRTUALITY AND COMMUNITY

Originating from the Internet and expanding rapidly due to advances of Information and Communication Technology (ICT), virtual communities (VCs) nowadays pervade the public and private life. Within this context, the role of ICT as a facilitator for human interaction becomes gradually a resource of special significance and research study (Wallace, 1999; Earnshaw et al., 2001; Renninger & Shumar, 2002). Recent studies (Earnshaw et al., 2001; Kisielniki, 2002; Werry & Mowbray, 2001) concentrate on the commercial exploitation of leisure and the use of Internet as a means for controlling personal and collective identity (Wallace, 1999; Jäkälä & Berki, 2004). An equally important number of current research scholars concentrate on the growth of and the benefits from online support for a number of needs and every day activities (Jäkälä & Mikkola, 2001; Berki & Cobb-Payton, 2005).

Being part of a community or group fulfils one of the basic human needs, that of belonging (see e.g. Maslow 1987). In our era the use of ICT to build different interest-based and self-identified communities evidently stresses that communities do not necessarily need to interact face-to-face. The development of the Internet resulted in the increase of online communities since ICT enabled geographically dispersed groups to communicate with the aid of different technological solutions. According to Rheinghold (1993, 5), *"virtual communities are social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace."* Starting from short message exchanges and advancing to more demanding forms of e-discussion and e-interaction, humans express their sympathy, empathy, concern and demonstrate their needs to communicate and ability to support other humans. (Preece, 2000.)

Research-wise, the scientific domain of research in virtual communities includes themes that have recently raised the interest of sociologists, psychologists, anthropologists, computer scientists, communication scholars and information technology professionals. Many opinions have been exchanged in an attempt to coin a successful definition. However, there is not yet a single accepted definition, except agreement to a few certain elements that should exist in VCs. *"Nearly everybody agrees on certain elements. One of these is inclusivity"* (Werry & Mowbray, 2001), meaning that everybody should be able to participate. Thus, it is challenging to re-define the term online community. One of the very important reasons is that similar or different definitions have been coined and co-exist in an attempt to define e-group, e-environment, e-space, digital space, virtual environment, virtual space, online community, cyberspace, cyberplace, cybercommunity, to name just a few. These terms are often used interchangeably but there might be variations in their use, based on the context.

Internet as such is a large online community. However, quite often the term online community refers to a particular web-based subgroup within the Internet. Furthermore these online communities have labels such as special interest groups, support groups and other. Above all the authors suggest that online communities are technology-supported web-based *contexts* that provide *contact* for individuals and groups, upon specific *content*. Online social aggregations, such as families, groups of friends, distance mode learners, players of online games, and members of political discussion forums are gathered to socialize, discuss, exchange their thoughts, or seek support for their emotional needs. The content of these online communities ranges from entertainment and leisure, e-learning and education or edutainment, to political agenda setting, e-governance, e-democracy and e-health matters.

Inevitably, the Internet has been one way to build communities and promote relationships between individuals and within groups. Wood and Smith (2001) state that the essence of virtual community is more than just a group of people communicating online. Community is based on the feeling of belonging. According to Jones (1997) there are qualities that characterize online communities: i) a minimum level of interactivity among the participants; ii) a variety of communicators for conversation and contribution; iii) a common public space that identifies virtual communities from cyberspace with cyberplace; and iv) a minimum level of sustained membership that maintain and develop the community. These characteristics stress the human factor of online communities and communication.

Inhabitants of virtual worlds and communities might create an alternative identity for themselves that they use exclusively online, or several identities to be used during different online forums or simultaneously within one forum. Some or all of these *identities-on-line* may be complemented with embodiment of the user's image, picture, photo or live video. There are various applications of shared work spaces that equip task-oriented groups such as tele-working teams and virtual organizations. Even when using solely text-based technologies, it is possible to perceive interpretations of personal characteristics and relationships between the communicators. The strength of these interpretations probably varies between individuals. This affects both the notion of telepresence as well as immersion.

Virtual communities are not simply a diminishment or enlargement of personal life. When the real life communities are threatened, virtual communities may provide a shelter needed. In many cases, these communities are based on relationships and feelings. They replicate common and communal features of real life, or, if needed, they may create an environment that is beyond the limits of real life. As observed in real life communities, personal relations whose main objective is sociability, informed by loyalty and authenticity, become as much as part of the social situations of modernity as the encompassing institutions of time-space distanciation (Giddens, 1990). But can they offer commitment or merely a pseudo-community, where commitment could only be virtual? (see e.g. Wilbur, 2001).

Access to cyberspace does not necessarily imply inclusion in any virtual community. Similarly, participation in cyberspace does not automatically imply inclusion in virtual communities. There are different levels of authorisation while permissions are granted after identification and authentication take place. Membership in a certain virtual community does not guarantee access to other exclusive virtual communities; there are always boundaries to cross. However, the feelings of belonging and self-awareness are strongly bound to our group memberships (see e. g. Tajfel, 1982). When privacy is needed the only place to find it might be an exclusive virtual community that identifies and to some degree authenticates its users to guarantee their privacy. This is largely facilitated with the interaction tools that are available and with the cyber-surfers' choice of the cyber-identity that want (or not) others to perceive. Social software may or may not facilitate inclusion and privacy.

TRANSFORMING IDENTITY TO CYBER-IDENTITY

Even though the word 'identity' is often used in diverse scientific domains, it is also considered as an unclear word to be used as a scientific term. It also refers to an increasing number of concepts from personality traits to authenticating computer networks (Camp, 2004). However, the concept of identity has a long history – as long as human beings have been using different types of masks (both material and abstract) to cover their faces and identity (see, Wiszniewski & Coyne, 2002). There are different definitions for identity depending on the context of its use. Identity is often defined as the combination of essential qualities, which characterize and differentiate a person from others. The concept of identity describes the continuum between sameness and differentiation. A person can objectively be identified by physical characteristics: name, date of birth, biographical description; as well as objectively assessed by cognitive and psychological characteristics: Intelligent Quotient, attitudes or personal traits. Subjective identity, then, refers to the person's mental presentation of these objective identifiers and an awareness of being distinct from the others. (Bosma et al, 1994.). Depending on the time and context, a distinctive identity can be seen as a way to be separated from uniformity; albeit in some cases, it may be seen as social stigma or spoiled identity, as described by Goffman (1986).

People use different sides of their personality and different roles in various situations: e.g. communicating with colleagues, family members, friends, acquaintances or strangers. Identity includes individual's considerations of 'who am I?', 'how do I want to be perceived by others?', and 'how am I actually perceived by others?' Others perceive identity of a certain person as a set of identifiers that distinguish this person from other persons. The meaning of identity in its social context is often viewed in social psychology in relation to the person's or group's inclusion and exclusion from the society, and affects the personal or group considerations about self and groupness, respectively. The transition from the concept of identity in its traditional context to the meaning of identity in a post-modern sense is attempted below, considering the semantics of individual and collective identity as viewed in the post-technological era.

Management of self-presentation takes place when people enter e-spaces. By picking up the username, nickname or alias and selecting or creating personal information that they want to share with others, they simultaneously decide how they wish to be perceived by the other members of the community they are entering. This also emphasizes the relationship between community and identity (Jäkälä & Berki, 2004). The reflection of/on one's identity needs the others, and cyberspace communities help their members to identify and being identified both on the level of personal and collective identities. Real life and virtual communities offer guidelines for becoming 'one of us', distinguishing simultaneously their members from others, outsiders of the community. From the viewpoint of social technology, technology does not only provide structures and tools for online communities. In addition to that, technology provides tools for social construction of reality and the outcomes depend on how these tools are being used. Same technology can be used to gain access to community membership and e-space with shared ideas and interaction or space to manifest individuality to all passerby or selected audience. Technology can also be used to block interaction and increase protection. Technology can be the gatekeeper between different users or groups of users. One way of using social technology is to self-manage identity - either personal identity or shared identity of a certain group. In the following paragraphs we will describe and discuss different possibilities for e-identity.

The next five sections refer to, classify and analyse five distinct phenomena that are observed in online communication. We name them: eponymity, nonymity, anonymity, pseudonymity and polynymity. Different context, contact and content of online interaction require different self-presentation rules, and the following types of identity offer opportunities and borders to human participation, inclusion and exclusion from virtual communities.

Eponymity

Eponymity is the state of being identified and recognised by name (eponym) and other distinctive individual features. Being eponymous implies having a set of known, distinctive characteristics, such as name, title and affiliation, used for identification, and to some degree for authentication.

One way of participating in cyber-activities is by being eponymous, when the identity of the communicator is then apparent. Interacting eponymously has often been considered as the way to grant authorization in technology-based communications. Eponymity does not challenge the protection of privacy and declares the responsibility and credibility of the activities. The online group and role formation that is based on *real* identities range from the very traditional roles of educators and learners in virtual learning environments (Putz & Arnold, 2001) to modern research and development collaboration teams for promoting innovation. New cyber-activities that include eponymous interaction are minority groups in society, who seek for re-inventing their roots by creating their own cultural and national identity (Bakker, 1999; Nocera, 1998). For some ethnic minorities or socially suppressed groups, eponymity in cyberspace serves as a step to openness and further recognition (Berki & Cobb-Payton, 2005).

Eponymity may be associated with official communication. For example, in teaching, guidance and customer services real face needs to be seen instead of artificial replica. Being able to transfer the notion of familiarity from virtual world to real world -and vice versa- may also increase trustworthiness. But could artificial and virtual identity be more believable, credible and attractive than the real one?

Nonymity

Nonymity, or rather nonappearance, is the state of not being identified by any name nor any other distinctive individual features. Being at the state of nonymity implies not having a set of known, distinctive characteristics, such as name, title and affiliation, used for identification and/or authentication. Actually, nonymity refers to identity that avoids detection consciously or unconsciously. Nonymity is a stealth mode of identity. Nobody knows whether a person exists when is not apparent while participating. Out of sight, out of mind. No technological means could possibly determine the appearance.

Nonymity is silent, non-observable and no public identity. It is even a non-communicative and non-interactive with other participants, state of identity, where participation and sharing is unidirectional, based on the choice and control of the nonymous person. No-one is aware of the online presence, sometimes not even of the actions of a person with no identity. For instance, these actions might be malicious in case of stealing others' identities to use them later or gathering useful information for malfunctions. A nonymous person could also benefit in an e-learning virtual community or in an instruction and learning forum, by accessing confidential examination and assessment in online forms of exams. On the other hand, nonymity could also offer protection and safety for the real person behind, in situations where real life communities, persons or identities are threatened.

A nonymous person can hardly ever be distinguished or identified. He or she is a silent participant, whose online silence is different from the silence of the users of other types of identity because no-one else knows or is aware of this silent participation.

Anonymity

Anonymity is the state of not being known by any name. Anonymity is defined as freedom from identification and implies lack of distinctiveness. An unnamed person is someone, who is unacknowledged as the doer of something because of a lack of distinctive features. Sometimes anonymity can be seen as a negative identity. For example within discussion forums the anonymous participant may lurk others - follow their actions without own participation. Online communities have often built-in tools that make other participants visible by adding a feature of awareness of the situation in the online environment. Therefore, other e-participants are aware of the online presence of anonymous persons even without their direct participation, while in the case of nonymous persons are not. Anonymous participants are not necessarily silent, like the nonymous persons. Their participation in a forum, however, can or cannot be identified, while they can be visible or not. Anonymity has been implicated, among other, in research on social facilitation and crowd behaviour. Yet its conceptual status and the processes by which anonymity achieves its effects are still far from clear (Lea et al. 2001).

One way of entering cyberplaces is by strategically choosing anonymity that is the state at which the identity of the communicator is not apparent. Interacting anonymously has often been considered as a questionable identity in technology-mediated communication; it challenges the protection of privacy as well as the responsibility and credibility of the activities (Li et al. 2007). On the other hand, anonymity may facilitate citizens' rights, democratization of processes, consensus participation, and in some cases it may encourage interaction and provide support (Jäkälä & Berki, 2004). While it might be easier to discuss delicate issues anonymously, there might also be doubts about the trustworthiness of other communicators and about security and safety of shared interaction and information. It should also be easier to break up anonymous interaction than interaction with a known other.

Pseudonymity

Pseudonymity is the state of being identified by a pseudonym, that is by a name, which is not somebody's real, correct name. Furthermore, being pseudonymous in virtual communities means bearing a set of false distinctive characteristics, such as name and title that are used for identification and to some degree for interaction of the person concerned. Even though pseudonymity is often addressed with suspicion, it is not always used to mislead others as frequently believed. Sometimes eponymity can be too challenging or the option of anonymity is not available. Sometimes pseudonymity evolves to eponymity, since many cyberspacers are recognised or traced by their nicks or aliases which may lay there to be addressed as their eponyms.

Pseudonymity can offer safety needed when entering virtual communities that otherwise might stay unvisited. For some people, the only option to join a virtual group is by pseudonymity, which provides possibilities to veil under false name or nickname. Pseudonymity offers possibilities to decide on the type of personal information that a person wants to provide, whether real or artificial. While eponymity could be as a desirable property for functioning, and a requirement for inclusivity in reality and in a technological sense (see e.g. Berki & Cobb-Payton, 2005), it is the pseudonymity and its misuse that has raised many questions regarding abuse of language and misbehaviour of humans on the net (see Wallace, 1999).

Pseudonymity could, for instance, enhance self-presentation management for online students and online courses instructors in order to facilitate e-participation, overcome digital divide and increase social inclusion.

Polynymity

Polynymity is the property of having and presenting oneself with many different names. Thus, it is also associated to the state of being identified by several pseudonyms. Having multiple names as identifiers in cyberspace's communities, means possessing and using a mix of real or artificial distinctive names and characteristics, which are presented in interaction with different persons or groups. While communicating with the aid of technology, the management of self-presentation has totally new expression tools. People can have multiple simultaneous roles, each of which is actualised within certain communities (see Papadimitriou, 2003). These roles can totally differ from each other. One person can also participate in the same event with several parallel identities (Turkle, 1997). Nowadays this seems to be the most often used identity in cyberspace. However, that might also be the main reason why some people do not consider virtual communities as a space for *real* interaction.

In case of polynymity, online communication is sometimes seen as loaded with mistrust, since the source of communication cannot always be verified. Sometimes, online participants choose polynymity for fun, but in some cases the user does not have the possibility for choice. At some cases the community guides the community members to polynymity. For example, academic scholars participate in electronic learning environments with their students by using an eponym, while they participate in chat rooms or tutor support groups using a pseudonym; and anonymously evaluate eponymously written but anonymously presented paper proposals for a conference.

Table 1. Identity types and interaction prerequisites

Identity type / interaction prerequisites	Eponymity	Nonymity	Anonymity	Pseudonymity	Polynymity
Awareness	yes	no	yes	yes	yes
Visibility	yes	no	limited	yes	yes
Identification	yes	no	limited	limited	limited
Approachability	yes	no	limited	limited	limited
Authentication	limited	no	no	no	limited

THE EMPHASIS FROM CYBERSPACE TO CYBERPLACE

The previous subsections provided a taxonomy of the most frequent types of e-identity formation as phenomena observed in cyberspace and partially described in cyber literature in a limited fashion. Furthermore, the authors provided meaningful names considering the semantics and pragmatics of these cyber-identity types. The five distinct types of identity discussed here, namely eponymity, nonymity, anonymity, pseudonymity and polynymity are subsequently compared and contrasted providing a tabular representation of their features regarding their interaction prerequisites in e-spaces. The following table summarises the information presented above regarding online awareness, visibility, identification, approachability and authentication.

Table 1 itself is a broad summary of the information currently gathered, analysed and classified by the authors. While it depicts significant knowledge on cyber-identities, it is by no means an exhaustive source of what are the advantages and disadvantages of every type of identity or what are the pitfalls and limitations of each one in online communication. It rather comprises issues that set a future research agenda for the technologist, communicator scholar and for the cyber culture scepticism followers. The entries of the table underline the need to get more information about the potential importance of cyberspace to political liberties and established human rights and the ways virtuality is likely to change our experience of the society and e-society in a comparative way. Technological means in the form of social software for achieving this transformation should also be viewed critically since there might be potential pitfalls when mixing technology and human relationships for the sake of communication (or non-communication).

During the last ten years the cyberspace has turned into a populated cyberplace. Before it had merely been an abstract space to present and publish context. Nowadays, it is increasingly becoming a common public place where the virtual communities' users themselves are empowered to produce the content for other users. Cyberspace has been established as an everyday medium for communication, where sociability is increased with the enrichment of personal expression (e.g. applications of social media). It is, thus, important to know which forms of identity might or not facilitate approachability, visibility and authentication (see Table 1).

The number of e-groups in which people participate seems to go on increasing, since pursue of effectiveness is achieved by encouraging people to form different groups, teams and communities. Participation in virtual communities shows a range of diverse interests, different roles and different work tasks. Leisure time and hobbies are more often also net-based which increases the use of different e-spaces also after and during working hours.

One significant aspect of online communication is management of identity. In general, identity formation and self-presentation become significant when there is a desire to regulate the functions and functionality of the virtual community. Apart from regulation, self-expression and self-presentation issues are connected to ease of access to the e-space where all are linked to the content that is provided within a particular context. Table 1 presents a non-definite list of cyber-identity types, which, again, should not be viewed as final and isolated forms of self-expression and presentation. In fact, the entries of table 1, especially those attributed to pseudonymity and polynymity, indicate that identity in cyberspace is not and sometimes cannot be a constant attribute of someone's online presence. It rather is a fluid concept, which evolves during time, enriched or simplified according to the communication needs of the cyber surfer. A significant issue of the future research agenda is the observation of identity changes and the study of the conditions and events that trigger these changes.

SUMMARY AND FUTURE RESEARCH

Online communities can be divided into *permanent* infrastructures, which co-exist with the physical community or can perform as *temporary* virtual environments in order to support the timely functions of real life within a virtual space (Jäkälä & Berki, 2004). For instance, permanent cyber-communities could be perceived as free public networks, public access media and advisory boards, educational collaborations, independent or private media and internet cafes. Cyber-communities of temporary online nature could be the web-based support provided for conferences and symposia, technology centres, governmental and organisational programs. The latter can be online, supporting by social software, especially when in need to support community activism and research initiatives, or merely for completing a work task. Due to the evolution of technology, the emphasis can not be on the technology as such but on the use of it to support social actions and behaviour online.

The development of the virtual life increased the demands for trust in interpersonal communication. Building, testing and maintaining identity might lead to pretensions and precautions. When referring to nonymity or pseudonymity nontrustable interaction comes to mind, while anonymity and eponymity are associated to domination but also liberation. Liberation and simultaneously deception are terms that are inevitably linked to polynymity, as well as self-expression and creativity. Likewise, the demands for anonymity, eponymity and pseudonymity in different virtual groups have to be approached from the point of view, that best-fitted technological solutions are best-fitted for humans, too. Technology should cater for ethical competition, privacy and transparency in marketing, security in e-sales, individual and intellectual freedom of expression.

The expansion of virtual communities indicated many emerging themes that have not yet been attributed as research objects to a well-formed discipline with a sound scientific and theoretical background. They are, though, promising research areas because onlineness is explored as the possibility for wider participation. Virtuality opens boundaries for new forms of communication and sociability. The concept of identity as a trust-based interaction in online worlds can be realized by considering the power and suitability of technology to create identity assets such as security, integrity and safety for the adequate provision of trust. At the same time, there is a need to combine the principles and capabilities of other disciplines in order to establish cohesive understanding of real people in virtual communities. Real people both in reality and virtuality have different roles and identities. Cyberspace does not demand more out of those, only makes them more visible.

KEY TERMS AND DEFINITIONS

Anonymity: Anonymity is the state of not being known by any name. Anonymity is defined as freedom from identification and implies lack of distinctiveness. An unnamed person is someone, who is unacknowledged as the doer of something because of a lack of distinctive features.

Eponymity: Eponymity is the state of being identified and recognised by name (eponym) and other distinctive individual features. Being eponymous implies having a set of known, distinctive characteristics, such as name, title and affiliation, used for identification, and to some degree for authentication.

Nonymity: Nonymity, or rather non-appearance, is the state of not being identified by any name nor any other distinctive individual features. Being at the state of nonymity implies not having a set of known, distinctive characteristics, such as name, title and affiliation, used for identification and/or authentication. Actually, nonymity refers to identity that avoids detection consciously or unconsciously.

Polynymity: Polynymity is the property of having and presenting oneself with many different names. Thus, it is also associated to the state of being identified by several pseudonyms. Having multiple names as identifiers in cyberspace's communities, means possessing and using a mix of real or artificial distinctive names and characteristics, which are presented in interaction with different persons or groups.

Pseudonymity: Pseudonymity is the state of being identified by a pseudonym, that is by a name, which is not somebody's real, correct name. Furthermore, being pseudonymous in virtual communities means bearing a set of false distinctive characteristics, such as name and title that are used for identification and to some degree for interaction of the person concerned.

Chapter 1.9
Establishing the Credibility of Social Web Applications

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

In recent years, there has been a steady shift in the *nature* of Web applications. The vehicle of this transition of Web applications is *us*, the people. The ability to post photographs or videos, exchange music snippets with peers, and annotate a piece of information, are but a few exemplars of this phenomenon. Indeed, the pseudonym Web 2.0 (O'Reilly, 2005) has been used to describe the apparent "socialization" of the Web.

In spite of the significant prospects offered by human-centric Web applications, the mere fact that virtually *anyone* can set up such applications claiming to sell products and services or upload/post unscrutinized information on a topic as being "definitive," raises the issues of credibility from a consumers' viewpoint. Therefore, establishing credibility is essential for an organization's reputation and for building consumers' trust.

The rest of the article is organized as follows. We first provide the background necessary for later discussion. This is followed by the introduction of a framework within which different types of credibility in the context of human-centric Web applications can be systematically addressed and thereby improved. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

In this section, we present the fundamental concepts underlying credibility and present the motivation and related work for addressing credibility within the context of Web applications.

Basic Concepts of Credibility of Web Applications

For the purposes of this article, we will consider credibility to be synonymous to (and therefore interchangeable with) believability (Fogg & Tseng, 1999).

The concept of credibility can be classified based upon the types of user interactions with a Web application. A user could consider a Web application to be credible based upon direct interaction with the application (*active credibility*), or consider it to be credible in absence of any direct interaction but based on certain pre-determined notions (*passive credibility*). There can be two types of *active credibility*, namely *surface credibility*, which describes how much the user believes the Web application based on simple inspection, and *experienced credibility*, which describes how much the user believes the Web application based on first-hand experience in the past. There can be two types of *passive credibility*, namely *presumed credibility*, which describes how much the user believes the Web application because of general assumptions that the user holds, and *reputed credibility*, which describes how much the user believes the Web application because of a reference from a third party.

Related Work on Credibility of Web Applications

The issue of the credibility of Web applications has garnered attention in recent years from diverse viewpoints and this has lead to theoretical (Fogg, 2003; Metzger, 2005) and empirical (Consumer Reports WebWatch, 2005) studies pertaining to the credibility of both commercial and non-commercial Web applications.

There have been some partial efforts in addressing the credibility of Web applications. A set of guidelines for improving the credibility of Web applications have been presented (Fogg, 2003). However, these guidelines are stated in such a fashion that they can be open to broad interpretation, do not always present the relationships among them, and are stated at such a high-level that they may not always be practical or may be difficult to realize by a novice user.

A general framework for addressing the credibility of Web applications has been proposed previously (Kamthan, 2007; Kamthan, 2008). This article presents an adaptation as well as a modest extension of these works.

A SYSTEMATIC APPROACH TOWARDS THE CREDIBILITY OF WEB APPLICATIONS

In this section, we consider approaches for understanding and improving active and passive credibility.

Stakeholders and Credibility of Web Applications

We identify two broad classes of stakeholders with respect to their *roles* in relationship to a Web application: a *producer* (such as the provider or an engineer) is the one who owns, finances, develops, deploys, or maintains the Web application, and a *consumer* (such as a novice or expert user) is the one who uses the Web application for some purpose.

We then assert that credibility is a *perceived* quality attribute with respect to the stakeholders of a Web application. Indeed, we view credibility as a *contract* between a producer and a consumer. This contract can have ethical, legal, and/or moral implications.

Addressing Active Credibility of Web Applications

We consider a Web application to be an interactive information system and adopt semiotics (Shanks, 1999; Stamper, 1992) as the theoretical basis for communication of information. The active credibility of Web applications is viewed as a qualitative aspect and is addressed indirectly from the perspective of semiotics (Table 1).

We now discuss each of the components of Table 1 in detail.

Identification of Semiotic Levels

The first column of Table 1 addresses semiotic levels. We are particularly interested in the communicative properties of the representations of a Web application, which in semiotics we can view on six interrelated levels: physical, empirical, syntactic, semantic, pragmatic, and social.

We focus only on the quality concerns at the last two levels: at the *pragmatic level* the interest is in the utility of the representations to its stakeholders, while at the *social level* the interest is in the manifestations of social interaction among stakeholders with respect to the representations.

Decomposition of Semiotic Levels and Assignment of Quality Attributes

The second column of Table 1 draws the relationship between semiotic levels and corresponding quality attributes.

Since each semiotic level is rather high to be tackled directly, we decompose it further into quality attributes that are widely-known and relevant. Not all attributes corresponding to a semiotic level are on the same echelon, and therefore they are placed at different tiers. We contend that the quality attributes included are necessary but make no claim of their sufficiency. Also, the quality attributes are not necessarily mutually exclusive, and this dependency can be either favorable or unfavorable (Wiegers, 2003). We note that some of the quality attributes are classical and relevant in a desktop environment but they get amplified, and in certain cases exacerbated, in a networked environment.

Specifically, credibility belongs to the social level and depends on the layers beneath it. The quality attributes aesthetics (presentation), legality, privacy, security, and transparency (of the producer) also at the social level depend upon the quality attributes accessibility and usability at the pragmatic level, which in turn depend upon the quality attributes comprehensibility, interoperability, performance, readability, reliability, and robustness also at the pragmatic level.

We discuss only the entries in the social level in some detail. The sensitivity part of visual perception is strongly related to aesthetics as it is close to human senses. The artistic expression plays an important role in making a Web application "attractive" to its customers beyond simply the functionality it provides. It is critical that the Web application be legal (for example, is legal in the jurisdiction it operates and all components it makes use of are legal); takes steps to respect user's privacy (for example, does not abuse or share user-supplied information without permission); takes steps to secure itself (for example, in situations where financial transactions are made). The provider must take all steps to be transparent with respect to the user (for example, not include misleading information such as the features of products or services offered, clearly label promotional content, make available their contact information including physical address,

Table 1. A semiotic framework for active credibility of Web applications

<table>
<tr><th>Semiotic Level</th><th>Quality Attributes</th><th colspan="2">Means for Assurance and Evaluation</th><th>Decision Support</th></tr>
<tr><td rowspan="2">Social</td><td>Credibility</td><td rowspan="4">Process-Oriented: Inspections, Testing

<tr><td rowspan="2">Pragmatic</td><td>Accessibility, Usability</td></tr>
<tr><td>Comprehensibility, Interoperability, Performance, Readability, Reliability, Robustness</td></tr>
</table>

policies regarding returning/exchanging products, and so on).

Next, we separate the semiotic quality attributes and the means for addressing those.

Means for Active Credibility Assurance and Evaluation

The third column of Table 1 lists the means for assuring and evaluating active credibility. We note that the mapping between the aforementioned pragmatic and social quality attributes and the means for addressing them is many-to-many.

We now briefly discuss two product-oriented means, namely training and guidance for assuring the active credibility of a Web application.

Training

Often, the courses related to the Web offered at institutions tend to focus primarily on the manipulations of the "popular" (and moving target) client- and/or server-side technologies-of-the-day. The result is that the students tend to learn more about "technology hacks" rather than the fundamentals of analysis and design necessary towards a *systematic* approach to the large-scale development of Web applications.

Apart from an exposure to a comprehensive technical background in Web engineering (Mendes & Mosley, 2006), the toolbox of a prospective professional Web engineer should include several other aspects: means of precisely identifying user classes, user preferences, and their needs; understanding of quality attributes specific to the domain of the Web application and their social manifestations; appropriate use of standards for both the process and the product; ability of journalistic writing, including the ability of balancing information with other types of media (related to marketing such as advertisements); training in informed and balanced decision making in order to analyze the trade-offs and decide amongst different design approaches, or between the use of early and established technologies; basic knowledge of issues related to legal issues such as those related to intellectual property rights (IPR) and licensing; and basic knowledge of financial issues (such as those related to merchant accounts and payment systems) in the lieu of support for commercial transactions.

Guidance

We consider guidelines and patterns as two "bodies of knowledge" based on past experience and expertise that can serve as aids for structured guidance.

The guidelines encourage the use of conventions and good practice. They could serve as a checklist with respect to which an application could be heuristically and, to certain extent, automatically evaluated. There are guidelines available for addressing accessibility (Chisholm, Vanderheiden, & Jacobs, 1999) and usability (Nielsen, 2000) of Web applications. However, guidelines suffer from certain limitations: they may seem rather general at times, often do not discuss trade-offs as a consequence of their application or relationships among them, and tend to assume a certain level of knowledge of the domain and therefore are more suitable for an expert than for a novice.

A pattern provides a conceptually reusable and proven solution to a recurring problem in a given context. It has been pointed out (Friedman, 2005) that identifying patterns for the design of Web applications could be useful towards improving the credibility of these applications. Indeed, patterns for Web applications have begun to appear (Van Duyne, Landay, & Hong, 2003), and a judicious use of patterns can tackle many of the pragmatic and social quality attributes in Table 1. However, there are certain caveats in the adoption of patterns: there is an evident cost involved in adaptation of patterns to new contexts; since the mapping between patterns and quality attributes is many-to-many, their selection may not be trivial; and there is always a distinct possibility that for a given problem, there simply may not be any suitable pattern available.

We next briefly discuss two process-oriented means, namely inspections and testing for evaluating the active credibility of a Web application.

Inspections

Inspections are a rigorous form of auditing based upon peer review that, when practiced well, can help evaluating some of the quality attributes at both pragmatic and social levels in Web applications. These are aesthetics, comprehensibility, legality, privacy, readability, and transparency. Inspections could, for example, assess if the presentation of information appears "professional", determine "sufficiency" of contact information, or decide what information is/is not considered "promotional."

Since inspections is a means for *static* verification, it can evaluate in rather limited form (if at all) the quality attributes that by necessity require some form of "dynamism" or real-world use. These include accessibility, interoperability, performance, reliability, robustness, security, and usability.

In spite of the usefulness of inspections in early defect detection, adoption can depend on the level of organizational process maturity, their effectiveness lies strongly on the reading technique deployed, and entail an initial cost overhead of training each participant in the structured review process followed by the logistics of checklists, forms, and reports involved.

Testing

Testing is a means for *dynamic* verification and is usually supported by most Web application development processes. The attributes of accessibility, interoperability, performance, reliability, robustness, security, and usability can to a large extent be tested (semi-)automatically using tools or with the help of actual users.

However, not all quality attributes at either pragmatic or social levels in a Web application can be tested automatically. For example, it is not possible to completely test a Web application for aesthetics, comprehensibility, legality, privacy, readability, or transparency (like producer's intent) using tools; human inspection would be necessary for checking and determining the level of support of these quality attributes. Thus, inspections and testing do not replace but *complement* each other.

Tools

There are various tools that can help improve quality concerns at technical and social levels, manually, semi-automatically, or automatically. For example, they can help us detect security breaches, inform us of absence of privacy metadata, report violations of accessibility guidelines, or suggest image sizes favorable to the performance on the Web.

However, state-of-the-art tools can be expensive, although this situation is changing with the rise of open source software (OSS). They also may not always be applicable.

Decision Support

The last column of Table 1 acknowledges that the activities of assurance and/or evaluation must be realizable in practice.

The providers of Web applications take into account organizational constraints of time and resources (personnel, infrastructure, budget, and so on) and external forces (market value, competitors, and so on), which compels them to make quality related decisions that, apart from being sensitive to credibility, must also be feasible. For example, an a priori guarantee that a Web application will be credible to *all* users at *all* times in situations that they can find themselves in, is simply impractical.

The feasibility analysis is evidently related to decision making and could be a part of the overall Web application project planning activity. Further discussion of this aspect is beyond the scope of this article.

Addressing Passive Credibility of Web Applications

In this section, we briefly look into the case of passive credibility, specifically reputed credibility.

Like in the real-world contexts, Web applications could be audited for quality in general and credibility in particular. Indeed, WebTrust and TRUSTe are two relevant initiatives in the direction of addressing reputed credibility.

We acknowledge that the perceptions related to presumed credibility may be one of the most difficult to tackle. There are no absolute guarantees but the following could be helpful for presumed credibility assurance of a Web application: personalizing the application to user context, making organizational policies explicit, and appropriately labeling the nature of content as per the requirements of the Internet Content Rating Association (ICRA).

Scope of Credibility of Web Applications

We note that credibility is not a "universal" concern. The credibility of a Web application is a concern to a user if there is an associated cost (say, in terms of lost time, effort, or money) that is outright unacceptable to the user.

That the credibility of a Web application is a concern may also depend on the purpose of the interaction and the role played by the user. For example, credibility may be a lesser concern to a user if (s)he is casually browsing a gossip column on a movie artist than if (s)he is filling out an annual tax return form.

We also note that credibility is *not* a quality attribute that is absolute with respect to users or with respect to the Web application itself. We contend that for a Web application to be labeled as non-credible there must exist at least a part of it that is labeled non-credible based on the aforementioned classification by at least one user at some point in time. For example, a user may question the credibility of information on a specific product displayed on a specific "Web page" within a Web application.

FUTURE TRENDS

The work presented in this article can be extended in a few different directions, which we now briefly discuss.

It is known that, when applied judiciously, standards can contribute towards quality improvement. Indeed, credibility has recently been a topic of interest in standards for Web applications such as the IEEE Standard 2001-2002. However, awareness and broad use of these standards among engineers is yet to be seen.

Due to the unique nature of Web applications, any initiative towards addressing the credibility of Web applications should take place within the auspices of a development process that is that is sufficiently *agile*. This would require that the current agile methodologies for the development of Web applications evolve to provide support for credibility in general and for pragmatic and social quality attributes discussed in this article in particular.

The semantic Web has recently emerged as an extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning (Hendler, Lassila, & Berners-Lee, 2001). At the highest level of this infrastructure is the issue of trust. For example, ontologies are central to the semantic Web and their development and subsequent use is based on mutual trust among the stakeholders. For the sustainability of the Web architecture, it is critical that the social Web and the semantic Web co-exist and evolve harmoniously. However, the "human" aspects of the semantic Web remain largely unaddressed. A natural extension of the discussion on credibility of the preceding section could be within the context of semantic Web applications.

CONCLUSION

By shifting from a collective of computers towards a community of people, the Web is becoming a symbiotic means of contribution, participation, and collaboration. The consumer concerns of credibility and the extent to which they are addressed will remain a key determinant towards the success of this paradigm.

Although there have been many advances towards enabling the technological infrastructure of the Web in the past decade, there is much to be done in addressing the social challenges, including user perceptions and expectations.

In conclusion, if credibility is important to an organization, it needs to be considered as a *first-class* concern, rather than an afterthought, from inception to conclusion of a Web application development process. Addressing the credibility in a systematic and feasible manner is one step in that direction.

KEY TERMS

Credibility Engineering: The discipline of ensuring that a system will be perceived as credible by its stakeholders, and doing so throughout the life cycle of the system.

Delivery Context: A set of attributes that characterizes the capabilities of the access mechanism, the preferences of the user, and other aspects of the context into which a resource is to be delivered.

Quality: The totality of features and characteristics of a product or a service that bear on its ability to satisfy stated or implied needs.

Quality Model: A set of characteristics and the relationships between them that provide the basis for specifying quality requirements and evaluating quality of an entity.

Semantic Web: An extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning.

Semiotics: The field of study of signs and the communicative properties of their representations.

Web Application: A specific to a domain Web site that behaves more like an interactive software system rather than a catalog: it will in general require programmatic ability on the server-side and may integrate/deploy additional software for some purpose (such as dynamic delivery of resources).

Web Engineering: A discipline concerned with the establishment and use of sound scientific, engineering and management principles and systematic approaches to the successful development, deployment, and maintenance of high-quality Web applications.

Chapter 1.10
The Evolution and Influence of Social Presence Theory on Online Learning

Patrick R. Lowenthal
University of Colorado, Denver, USA

ABSTRACT

The theory of social presence is perhaps the most popular construct used to describe and understand how people socially interact in online learning environments. However, despite its intuitive appeal, researchers and practitioners alike often define and conceptualize this popular construct differently. In fact, it is often hard to distinguish between whether someone is talking about social interaction, immediacy, intimacy, emotion, and/or connectedness when they talk about social presence. Therefore, this chapter outlines the evolution of the construct of social presence in an effort to understand better its relationship to online learning.

INTRODUCTION

People are social creatures (Brown & Duguid, 2002; Read & Miller, 1995). They learn and work in groups (Read & Miller, 1995). The Internet evolved out of an effort to connect computers and information and therefore people. Since its early days, the Internet has grown exponentially (Madden, 2006). However, unlike the early days when only scientists used it, people use the Internet today in a variety of different ways, including communicating with friends, family, and co-workers. In addition to connecting with current friends and family, people also use the Internet to form new relationships (Madden & Lenhart, 2006). As a result, some researchers have begun to describe the Internet as a social medium (Baym, Zhang, & Lin, 2004; Walther & Parks, 2002).

However, just as the Internet can bring people together and be described as "social," it can separate people and be described as isolating and impersonal (Kraut, et al., 1998; Morahan-Martin & Schumacher, 2003; Nie, 2001). Some researchers have reported cases of Internet addiction and dependence (Hiltz & Turoff, 1993), and others (Nie & Erbring, 2002) have found that the more time that people spend on the Internet, the less time they spend with people in face-to-face social situations. Further, van Dijk (2006) determined that the Internet invites certain types of people to withdraw into the computer. Whether the Internet is a social medium, therefore,

DOI: 10.4018/978-1-60566-830-7.ch010

remains a heated debate in many ways (Kraut et al., 1998; Nie, Hillygus, & Erbring, 2002). As states like Michigan begin to require high school students to take online courses to graduate (Watson, 2006), and online enrollments at the college level continue to grow (Allen & Seaman, 2006), the sociability—or isolation—of the Internet remains a nationwide concern.

The theory of social presence is perhaps the most popular construct used to describe and understand how people socially interact in online learning environments. However, despite its intuitive appeal, researchers and practitioners alike often define and conceptualize this popular construct differently. In fact, it is often hard to distinguish between whether someone is talking about social interaction, immediacy, intimacy, emotion, and/or connectedness when they talk about social presence. Therefore, the focus of this chapter is on outlining the evolution of the construct of social presence in an effort to understand better its relationship to online learning.

BACKGROUND

In the late 1980s and early 1990s, researchers began to study the effects of computer-mediated communication (CMC). Some concluded that CMC was inherently antisocial and impersonal (Walther, 1996; Walther, Anderson, & Park, 1994). While Hiltz & Turoff (1993) acknowledged that interpersonal relationships might be fostered through CMC, early research suggested—and convinced others—that CMC was better at task-oriented communication (Walther & Parks, 2002). These early CMC researchers turned to social presence theory to make sense of their findings.

Social Presence Theory

Short, Williams, and Christie (1976) originally developed the theory of social presence to explain the effect telecommunications media can have on communication. They defined social presence as the degree of salience (i.e., quality or state of being there) between two communicators using a communication medium. They posited that communication media differ in their degree of social presence and that these differences play an important role in how people interact (p. 65). They conceptualized social presence primarily as a quality of a communication medium that can determine the way people interact and communicate. From their perspective, people perceive some media as having a higher degree of social presence (e.g., video) and other media as having a lower degree of social presence (e.g., audio). More importantly, they believed that a medium with a high degree of social presence is seen as being sociable, warm, and personal, whereas a medium with a low degree of social presence is seen as less personal. CMC researchers later used this to theory to explain that CMC was inherently impersonal because nonverbal and relational cues—common in face-to-face communication—are filtered out of CMC (Walther & Parks, 2002).

The Role of Context and Setting

Early researchers, though, studied CMC primarily in organizational or business settings; that is, early on, they conducted very little research on CMC in educational settings. Educational settings—specifically classroom settings—have different dynamics that researchers consider when studying CMC because no such thing as a typical CMC message exists (Herring, 2007). Much of the meaning and significance of CMC depends on its surrounding discourse (Herring, 2007), and the surrounding discourse in educational settings—specifically online educational settings—is very different from that in business settings (Gee, 2007).

Education is a social practice (Lafey, Lin, & Lin, 2006; Shea, Frederickson, Pickett, & Swan, 2001); consequently, any formal learning environment must be able to support the social practice and process of learning (Shea et al., 2001). Earlier on though, people criticized online education because they believed that the absence of social cues would interfere with teaching and learning (Berge & Collins, 1995). Despite this criticism, online education continues to grow as access to the Internet increases; in fact, enrollments in online education continue to grow each year (Allen & Seaman, 2006; Tallent-Runnels et al., 2006).

However, despite occasional reports of loneliness and isolation (Grubb & Hines, 2000; Robinson, 2000), proponents and practitioners of online education argue that online education and CMC can support the social practice of learning. Even though nonverbal and relational cues are filtered out, these researchers have argued that CMC can still be very social and interpersonal (Gunawardena, 1995; Gunawardena & Zittle, 1997) and at times even hyperpersonal (Walther, 1996). Further, as researchers (Gunawardena, 1995; Tu, 2000) began examining the sociability of online education, these new researchers began to question the degree to which the attributes of a communication medium—in this case the cues filtered out of CMC systems—determine how people socially interact and are perceived as "being there" when communicating online (Danchak, Walther, & Swan, 2001; Gunawardena, 1995; Gunawardena & Zittle, 1997; Richardson & Swan, 2003; Tu, 2000).

The Evolution of Social Presence Theory

As a result, these researchers began questioning and further developing the theory of social presence developed by Short et al. (1976). They argued, based on their experience and research, that participants in online discussions, using text alone, are able to project their personalities into online discussions and create social presence (Swan, 2003; Swan & Shih, 2005). They found that online learners are able to present themselves as being "real" as well as "connect" with others when communicating in online learning environments by doing such things as using emoticons, telling stories, and even using humor (Rourke et al., 2001; Swan, 2003). Thus, a user's personal perceptions of social presence and the behaviors used to make up for the cues that are filtered out matter just as much, if not more, than a medium's supposed capabilities. This new line of research sparked a renewed interest in the sociability of online learning, social presence, and CMC as evidenced in the increased amount of literature focused on social presence.

Social presence is now a central concept in online learning. For instance, social presence has been listed as a key component in theoretical frameworks for learning networks (Benbunan-Fich, Hiltz, & Harasim, 2005) and distance education (Vrasidas & Glass, 2002). Researchers have shown—in varying degrees—a relationship between social presence and student satisfaction (Gunawardena, 1995; Gunawardena & Zittle, 1997; Richardson & Swan, 2003), social presence and the development of a community of learners (Rourke, Anderson, Garrison, & Archer, 2001; Rovai, 2002), and social presence and perceived learning (Richardson & Swan, 2003). Just as earlier researchers of CMC (Kiesler, 1986; Kiesler, Siegel, McGuire, 1984) used social presence theory to explain why CMC was inherently impersonal, later researchers (Gunawardena, 1995; Tu, 2000) reconceptualized social presence theory—focusing less on the medium and more on people—to explain how CMC in online learning environments can be very personal and social.

SOCIAL PRESENCE AND ONLINE LEARNING

Social presence theory has a complex history. To understand better how this complex history has evolved over the years, it is important to look at influential and related research on social presence, competing theories of social presence, and finally some ways that contemporary researchers define, operationalize, and study social presence.

Influential and Related Research on Social Presence

Short et al. were members of the Communications Studies Group (CSG) at the University College in London. The CSG consisted of roughly 30 researchers conducting experiments in the 1970s on communication media (Pye & Williams, 1977). Interestingly, *The Social Psychology of Telecommunications* appears to be the only joint publication of Short et al. Despite this, each of them conducted a number of studies on the effects of communication media during the 1970s (e.g., Short, 1974; Christie & Holloway, 1975; Christie & Kingan, 1977; Williams, 1975; Williams, 1977; Wilson & Williams, 1977).[1] Their research focused on comparing people's attitudes toward different communication media (e.g., face-to-face, audio, video). The following paragraphs will briefly summarize a few key findings from this early research that later influenced the development of and people's understandings of social presence theory.

The majority of their early research focused on the assumed importance of the visual channel of communication. Short (1974), Christie (1974), and Williams (1975) initially found that communication media were strengthened by the addition of a visual channel. Christie (1974) reported from one study that,

> *visual media were ... more useful for complex group discussions, private conversations and non-private dyadic conversations. Thus, the presence of visual channel appears to be perceived as an important advantage of a communications medium. (p. 367)*

However, as more research was conducted (e.g., Christie & Kingan, 1977; Williams, 1975), it became apparent that the value of a visual channel was more situational than originally thought. For instance, research began to show that the importance of a communication medium depended largely on the task at hand. In fact, according to Christie (1974), "it is clearly misleading to conceptualize different media as lying along a single dimension of acceptability or usefulness. Their perceived usefulness varies according to the application considered" (p. 368). People might want a less intimate or immediate communication medium for certain tasks (Williams, 1975). For instance, Williams (1975) suggested "that with tasks of very high intimacy—perhaps very embarrassing, personal or conflictual ones—the least immediate medium, the telephone, would lead to more favorable evaluations than either or the more immediate media" (p. 128). Further, Williams (1978a) showed that tasks that are low on interpersonal involvement and cooperative in nature can easily be accomplished by audio or video conferencing; however, tasks that are higher on interpersonal involvement "are sensitive to the substitution of telecommunications for face-to-face interaction" (p. 127).

For the most part, these early communication researchers were not concerned with the role the visual channel of communication had on educational or instructional tasks. Williams (1978a) though argued that "tele-education seems especially promising since educational activities are primarily for cooperative problem-solving and the transmission of information—activities which have been shown to be almost unaffected by the medium of communication used" (p. 129). Williams (1978a) intelligently pointed out though in the very same article that our knowledge about the role of mediated communication is far from complete—as was our understanding of how people learned in the late 1970s.

Their later research, among other things, showed that while visual cues are helpful, they are not necessary for people to communicate effectively (Christie & Kingan, 1977, p. 272). Also, contrary to previous theories, Williams (1978b) found that physical presence may be even more important for people communicating than visual communication (p. 101). Results like these began to call for a more complex explanation for the role of visual cues in the communication process, which Williams (1978b) thought might be found in social presence theory.

Competing Theories of Social Presence

The theory of social presence developed by Short et al. (1976) was only one of a number of theories used to explain the influence communication media have on communication. Three popular competing theories of social presence—especially during the 1980s—were *Cuelessness Theory* developed by Rutter (1984, 1987), *Media Richness Theory* developed by Daft & Lengel (1984, 1986; Daft, Lengel, & Trevino, 1987), and *Social Information Processing Theory* developed by Walther (1996; Walther & Parks, 2002). The first two theories (like Social Present theory) have been described as deficit models because they focus on the cues that are filtered out while idealizing face-to-face communication as the gold standard of communication (Thurlow, Lengel, & Tomic, 2004). Each of these competing theories will be addressed briefly in the following sections in an effort to illustrate the zeitgeist of the 1980s and early 1990s—a time that led to the reconceptualization of Short et al.'s theory of social presence.

Cuelessness. Working from a similar theoretical framework as Short et al. (1976), Rutter (1984, 1987; Rutter, Pennington, Dewey, & Swain, 1984; Kemp & Rutter, 1986) developed the cuelessness model. Rutter was concerned with the over-emphasis placed on the importance of eye- contact when two people communicate. As a result, he and his colleagues (1984) set forth to challenge the intimacy model developed by Argyle and Dean (1965) and later Argyle and Cook (1976). They argued that previous research had focused too much on looking and eye-gaze and not enough on the mutual gazing back and forth. Like Williams before, Rutter et al. (1986) found that what matters when communicating is visual access to the entire person rather than simply access to another's eyes. Rutter et al. argued that it was the combined social cues—from vision and other senses—that mattered more than simply eye-contact.

The cuelessness model essentially claims that the fewer the number of social cues, the greater the psychological distance between two communicators (Rutter et al., 1984). Further, Rutter and his colleagues argued that the greater the psychological distance between two people the more likely communication will be task oriented and depersonalized (Kemp & Rutter, 1986; Rutter, 1984; Rutter et al., 1986). In fact, Rutter (1989) and colleagues found that the number of social cues—that is, both visual and physical presence cues—decreased when people used a closed-circuit television (i.e., visual cues), versus a curtain and wooden screen (i.e., no visual cues), versus audio (i.e., neither visual or physical cues) to communicate with each other.

Media Richness. Another competing theory that emerged during the 1980s is the theory of media richness. Daft and Lengel (1984, 1986) developed the theory of media richness. Whereas Rutter and colleagues were aware of the work of Short et al., Daft and Lengel never explicitly acknowledge the work of Short et al. (1976). Daft and Lengel (1984) were focused primarily on information processing behaviors in organizations. More specifically, they were interested in a concept they called information richness

Richness is defined as the potential information-carrying capacity of data. If the communication of an item of data, such as a wink, provides substantial new understanding, it would be considered rich. If the datum provides little understanding, it would be low in richness. (p. 196)

They posited that communication media can determine the richness of information (Daft & Lengel, 1986). They argued that face-to-face communication has the highest richness whereas numeric communication (e.g., spread sheet with numbers) has the lowest. According to Daft and Lengel (1986), a "medium's capacity for immediate feedback, the number of cues and channels utilized, personalization, and language variety" (p. 560) all influence its degree of information richness.

Social Information Processing. The last of the three competing models is the social information processing model developed by Walther (1992, 1994, 1996). Walther developed his model in response to the previous "deficit" theories. Whereas previous researchers were interested in media effects across various communication media, Walther focused primarily on CMC. He criticized previous research, like that addressed earlier in this chapter, for a number of reasons. First, the majority of the early research was conducted in experimental settings that failed to mirror how people communicate with different media in the real world (1992). Second, these early studies and researchers assumed that the absence of visual cues led to an absence of sociability. Third, they assumed that task-oriented communication lacked relational and social communication. And fourth, they failed to acknowledge that just as cues are filtered out, other cues are filtered into CMC and therefore CMC has some affordances that face-to-face communication does not (Walther, 1996; Walther & Parks, 2002).

Walther (1992) argued that human's social nature is the same in CMC and face-to-face environments. Given enough time, he believed that people will finds ways to compensate for any cues that are filtered out in CMC. The social information processing model essentially posits that given enough time, CMC can be very personal and even hyperpersonal (Walther, 1992, 1996). Previous research tended to put time restrictions that Walther believes diminished the possibility of interpersonal and relational communication. Walther also found that previous interaction between communicators influenced how people communicated online. Further, Walther (1994) found that the possibility of future interaction influenced the degree to which people socially interacted online. Finally, he found that the way users used emoticons also influenced interpersonal communication online. In summation, Walther's social information processing model argued that "given the same investment of time and commitment, relational quality in CMC will be the same as face-to-face communication" (Thurlow, Lengel, & Tomic, 2004, p. 249)

These competing theories, as illustrated in Figure 1, help illustrate the way that thinking about a medium's effect on communication—especially interpersonal and social communication—changed over time. Research on social presence and online learning, that began with the work of Gunawardena (1995; Gunawardena & Zittle, 1997)—which I consider the third phase of social presence research (see Table 1)—was influenced by this previous research and theories, especially that of Walther. Rather than conceptualizing social presence as Short et al. (1976) did, Gunawardena and those that followed her (most notably is Garrison, Anderson, and Archer, 1999) began reconceptualizing social presence theory—moving away from a technological deterministic conceptualization of mediated communication.

Defining Social Presence

Given the evolution of social presence theory, it is probably not surprising that there is not a clear, agreed upon, definition of social presence (Rettie, 2003; Tu, 2002b). In fact, nearly everyone who writes about social presence seems to define it just a little differently. To complicate matters, related terms such as presence, copresence, and telepresence are used to describe similar things (and sometimes even the same thing) as social presence.

Figure 1. Timeline of competing theories of social presence

Presence is a key theoretical construct used in a variety of disciplines besides communication and online learning—most notably virtual reality (see Biocca, 1997). In fact, Lombard and Ditton (1997) identified six interrelated (and cross-disciplinary) but distinct ways people understand "presence": (a) presence as social richness, (b) presence as realism, (c) presence as transportation, (d) presence as immersion, (e) presence as social actor within medium, and (f) presence as medium as social actor. They even attempted to create one *all* encompassing definition of presence. According to Lombard and Ditto, the following definition takes into consideration all six ways presence is understood; presence is "the perceptual illusion of nonmediation" (presence explicated section). To date, though, Lombard and Ditto's all encompassing definition has not received wide spread adoption—especially by researchers of online learning. Lombard and Ditton, though, were not alone; Biocca, Harms, and Burgoon (2003) also recognized the different ways researchers across different fields defined presence. They also created an all-encompassing definition of social presence; they defined social presence as simply the "'sense of being with another'" (p. 456) whether that other is human or artificial.

Despite attempts by Lombard and Ditto (1997) and Biocca et al. (2003) to develop some conceptual clarity about presence in general or social presence in particular, researchers of social presence and CMC in educational environments continue to redefine and categorize social presence (Picciano, 2002). For Gunawardena (1995),

Table 1. Phases of social presence research

Phase	Period	Key Figures	Focus of Research
Phase 1	1970s	Short et al.	Focused on Telecommunications
Phase 2	1980s-early1990s	Rutter Daft & Lengel Kiesler Walther	Focused on CMC
Phase 3	Early/mid 1990s-Present	Gunawardena Rourke et al. Tu Swan	Focused on Online Learning

social presence was "the degree to which a person is perceived as a 'real person' in mediated communication" (p. 151). Garrison et al. (2000), on the other hand, defined social presence "as the ability of participants in a community of inquiry to project themselves socially and emotionally, as 'real' people (i.e., their full personality), through the medium of communication being used" (p. 94). Tu and McIsaac (2002) defined social presence as "the degree of feeling, perception, and reaction of being connected by CMC to another intellectual entity through a text-based encounter" (p. 140). Finally, for Picciano (2002), social presence in an online course "refers to a student's sense of being in and belonging in a course and the ability to interact with other students and an instructor" (p. 22).

Definitions of social presence, at least for researchers of social presence and online learning, tend to fall on a continuum. At one end of the continuum, researchers tend to conceptualize social presence as the degree to which a person is perceived as being "real" and being "there." These definitions tend to focus on whether someone is able to project him or herself as being "real" in an online environment and whether others perceived this person as being there and being real. In fact, Williams (1978a) defined social presence in this way when he defined social presence as "the feeling of contact obtained…" across various communication media (p. 127). At the other end of the continuum, researchers tend to go beyond whether someone is perceived as being "present"—that is, simply "there" or "real"—but focus on whether there is an interpersonal emotional connection between communicators. It is important to note, though, that on this end of the continuum, there tends to be an assumption that the interpersonal and emotional connection that communicators establish when there is social presence is a positive connection (Wise, Chang, Duffy, & Del Valle, 2004). Finally, like most continuums, the majority of researchers find themselves somewhere in the middle—placing a little bit of emphasis on an emotional connection—rather than on the ends of the continuums.

Operationalizing and Measuring Social Presence

The differences in how researchers define social presence might seem minor but they end up having significant consequences on how people conceptualize social presence. For instance, Garrison et al. focused on students (or instructors) ability to project themselves as "real" whereas Picciano focused more on student's sense of belonging to a community. Issues of definition are important because the way researchers define social presence influences how they measure social presence and the conclusions they draw.

After all the theorizing, researchers need to be able to identify, measure, and test their theories about social presence. As researchers of CMC and online learning began to reconceptualize social presence, rather than use the techniques developed and utilized by past researchers—perhaps in part because of Walther's critique of these techniques—they began to look for new ways to study social presence. Gunawardena and Zittle (1997), Rourke et al. (2001), and Tu (2002b) have each been very influential in developing ways to study social presence. But just like in the mid-1970s—when researchers either studied social presence by observing user behavior or examining users attitudes (Christie, 1974)—researchers in this third wave of social presence research have tended to either focus on user's attitudes or behaviors online. For instance, Gunawardena and Zittle as well as Tu focused primarily on studying user's attitudes whereas Rourke et al. focused on studying user's behaviors. Regardless of their focus, these researchers have heavily influenced most of the studies on social presence and CMC. Therefore, in the following paragraphs, I briefly summarize how each of these researchers studied social presence.

Social Presence Scale. Gunawardena (1995; Gunawardena & Zittle, 1997) conducted some of the earliest studies on social presence and CMC in an education setting. In her first article, Gunawardena (1995) had student's rank 17 bi-polar scales on a 5-point likert-type scale (from negative to positive). For instance, she asked students whether CMC was more socialable or unsocialable or more warm or cold. The bi-polar scales she used appear to focus on user's perceptions of the medium more than the degree to which others are perceived as "real" or "there." In a later more influential article, Gunawardena and Zittle (1997) reported on additional data collected with an instrument called the Social Presence Scale. The Social Presence Scale was similar to the previous scale used by Gunawardena, but instead of responding to bi-polar scales (which were similar to the semantic differential technique used by Short et al.), students were asked to rank 14 questions on a scale of 1 to 5. For instance, one question asked students to rank, on a scale of 1 to 5, to what degree they agree or disagree that, CMC is an excellent medium for social interaction. The Social Presence Scale was tested for internal consistency (Alpha = .88); Gunawardena and Zittle concluded that it investigated the construct of social presence more directly than the previous scale.

Social Presence Indicators. Unlike Gunawardena and Zittle who measured social presence through a self-report questionnaire, Rourke et al. (2001) sought to measure social presence through analyzing online discussions. Rourke et al. identified three different categories of social presence: affective responses, interactive responses, and cohesive responses. They then developed twelve indicators that researchers could use to analyze transcripts of CMC (primarily through content analysis). For instance, the indicators of affective responses are the expression of emotions, use of humor, and self-disclosure. Rourke et al. developed these categories and indicators based on their previous work (Garrison, Anderson, & Archer, 1999; Rourke, Anderson, Garrison, & Archer, 2001), other literature in the field, and finally their experience reading online transcripts.

Rourke et al. tested and measured the "efficacy and reliability" of their categories and indicators by using them with participants in two graduate education online courses. Other than latent variables (e.g., expression of emotion and use of humor), they had high interrater reliability. However, Rourke et al. cautioned readers about generalizing their results because their main purpose was to "develop and test the efficacy of a tool for analyzing the social presence component of educational computer conferences" (Discussion section) rather than to draw conclusions specifically about the samples in question. They also acknowledged that they were still unclear whether all 12 indicators should be weighted equally—which later researchers have questioned (Hughes, Ventura, and Dando (2007)—as well as whether or not there is an optimal level of social presence. In fact, Garrison mentioned in a round table presentation at the 2008 annual meeting of the American Educational Research Association (AERA) that these indicators might need to be revisited to ensure that they do not need to be revised (Arbaugh, et al., 2008).

Social Presence and Privacy Questionnaire. Tu (2002b) criticized early research on social presence that used the same semantic differential technique as Short et al. (1976) (e.g., Gunawardena, 1995). Tu argued that this technique is not an adequate measure one's perception of social presence when it comes to CMC. He also argued that the Social Presence Scale developed by Gunawardena and Zittle (1997) failed to take into consideration different variables cited in the research (e.g., recipients, topics, privacy, task, social relationships, communication styles). As a result, Tu (2002b) developed The Social Presence and Privacy Questionnaire (SPPQ).[2] Tu developed the SPQQ by using parts of Steinfield's (1986, as cited in Tu, 2002b) CMC attitude instrument and Witmer's (1997, as cited in Tu, 2002b) perceived privacy instrument.

Tu tested the content validity and the construct validity of his instrument. Five factors emerged from the factor analysis: social context, online communication, interactivity, system privacy, and feelings of privacy; these five factors accounted for 82.33% of the variance with Cronbach's alpha values ranging from .74 to .85. While Tu acknowledged that online privacy had a weak correlation and therefore might need to be removed as a dimension of social presence, he continued to use online privacy as a dimension of social presence in later studies (Tu & Corry, 2004; Tu & McIsaac, 2002). Despite the strengths of his survey, Tu and McIsaac (2002) later determined as the result of a mixed method study, using the SPPQ and a dramaturgy participant observation qualitative approach, that there are "more variables that contribute to social presence" than previously thought. Therefore, Tu and McIsaac concluded that social presence was more complicated than past research suggested. Specifically, they found that the social context played a larger role than previously thought.

These three examples are evidence that there is still little agreement on how to measure social presence (Lin, 2004; Stein & Wanstreet, 2003). Just as Tu criticizes how Gunawardena measured social presence, others have criticized and modified Tu's work (Henninger & Viswanathan, 2004). Also, while social presence has been presented as a perceptual construct, Hostetter and Busch (2006) point out that relying solely on questionnaires (i.e., self-report data) can cause problems because "respondents may be providing socially desirable answers" (p. 9). Further, Kramer, Oh, and Fussell (2006) point out that self-report data "are retroactive and insensitive to changes in presence over the course of an interaction [or semester]" (p. 1). But at the same time, even the scale created by Rourke et al. (2001a) has been modified by Swan (2003) and later by Hughes, Ventura, and Dando (2007); moreover, Hughes et al. also questioned the usefulness of "reducing social presence to an overall number" (p. 27) as Rourke et al. did.

Researchers need "a multifaceted presence instrument, one that examines presence more than single items and addresses the construct more by evaluating specific behaviors rather than a global effect" (Russo & Benson, 2005, p. 60). However, it is likely that any multifaceted instrument would be influenced by the work of Gunawardena and Zittle (1997), Rouret et al. (2001), and/or Tu (2002b) because most researchers continue to use (or adapt) the instruments created by these researchers. Therefore, any study of social presence should at least acknowledge how its methodology has been influenced by these early pioneers.

FUTURE TRENDS

Despite failing to meet initial estimates of growth (Shank & Sitze, 2004), enrollments in online courses and programs continue to grow dramatically each year (Allen & Seaman, 2006; Tallent-Runnels et al., 2006). This growth, coupled with the people's concerns with the Internet, will nearly ensure that researchers, policy makers, and practitioners will continue to debate the sociability of the Internet and the role that online learning should play in our future (Wray, Lowenthal, Bates, & Stevens, 2008). The third wave of research on social presence will likely give birth to a fourth wave of research on social presence. During the fourth wave, it is likely that researchers will begin to employ multiple and mixed method approaches (e.g., like the work of Swan and Shih, 2005) of studying social presence that focus on, among other things, the socially situated and contextual nature of social presence. Further, researchers and practitioners alike will have to consider a new host of things related to social presence with the continued blurring of boundaries between classroom and fully online courses as well as between course bound communication tools (e.g., discussion forums) and non-course bound tools (e.g., Facebook and Twitter) (Dunlap & Lowenthal, 2009; Lowenthal, 2009a; Lowenthal & Dunlap, 2007;).

CONCLUSION

Despite initial concerns about the sociability of the Internet, researchers of social presence and CMC have demonstrated that indeed online learners can project themselves online and be perceived as being there and being real (Lowenthal, 2009b). However, given the history and evolution of social presence theory, coupled with the multitude of ways that researchers define and operationalize social presence, researchers as well as practitioners must begin to question what we know and do not know about social presence. Regardless of one's perspective, one thing is clear, researchers need to continue to study social presence using multiple and mixed methods as well as how it manifests and changes in different contexts.

Chapter 1.11
Social Presence

Patrick R. Lowenthal
Regis University, USA

INTRODUCTION

Learning is a social process (Harasim, 2002; Swan & Shea, 2005; Tu, 2000). Discourse plays a key role in the social process of learning (Harasim, 2002). Therefore, it is extremely important that we understand how students and teachers socially interact in online courses where asynchronous computer-mediated communication (CMC) is the major form of discourse. Theories of social presence help explain how students and teachers interact and learn online.

BACKGROUND

Short, Williams, and Christie (1976) are credited with developing the initial theory of social presence. Short et al. developed their theory of social presence to explain the effects a communication medium can have on the way people communicate. Working from previous research in psychology and communication (i.e., Argyle and Dean's concept of intimacy and Wiener and Mehrabian's concept of immediacy), Short et al. defined social presence as the degree of salience (i.e., quality or state of being there) between two communicators using a communication medium. They conceptualized social presence as a critical attribute of a communication medium that can determine the way people interact and communicate. Further, they posited that people perceive some communication media as having a higher degree of social presence (e.g., video) than other communication media (e.g., audio).

In the late 1980s and early 1990s, as the popularity of CMC grew, communication researchers began to apply the theory of social presence developed by Short et al. to CMC. Many of these early researchers came to the conclusion that CMC was antisocial and impersonal because social context cues were filtered out (see Walther, 1992).

In the mid 1990s, researchers with experience using CMC for educational purposes began to question whether the attributes of a communication medium determined its social presence (Garrison, Anderson, & Archer, 2000; Gunawardena, 1995; Gunawardena & Zittle, 1997; Swan, 2003b; Walther, 1996). They argued that a user's personal

DOI: 10.4018/978-1-60566-198-5.ch280

perceptions of presence mattered more than the medium's capabilities. They also illustrated that contrary to previous research, CMC can be very social and personal (Gunawardena, 1995; Gunawardena & Zittle, 1997) and even hyperpersonal (Walther, 1996).

MAIN FOCUS: SOCIAL PRESENCE

Definitions of Social Presence

There is not a clear, agreed upon, definition of social presence (Rettie, 2003; Tu, 2002). Instead, researchers continue to redefine it (Picciano, 2002). For instance, Gunawardena (1995) defined social presence as the degree to which people are *perceived* as "real" in CMC. Garrison et al. (2000), on the other hand, defined social presence as the ability of students "to *project* themselves socially and emotionally, as 'real' people" (p. 94). Tu and McIsaac (2002) defined social presence as "the degree of feeling, perception, and reaction of being connected by CMC" to another person (p. 140). Finally, Picciano (2002) defined social presence as student's perceptions of being in and belonging in an online course. Nearly everyone who writes about social presence continues to define it just a little differently; therefore making it very difficult for both researchers and practitioners to come to any firm conclusions about the nature of social presence.

Measuring Social Presence

Just as social presence is difficult to define, it is even harder to measure. There is little agreement on how to measure social presence (Hughes, Ventura, & Dando, 2007; Lin, 2004; Stein & Wanstreet, 2003). In fact, very few researchers have operationalized social presence into observable and measurable parts. The surveys and coding schemes developed by Gunawardena (1995; Gunawardena & Zittle, 1997), Rourke et al. (2001), and Tu (2002b) have influenced the majority of research on social presence (e.g., Baskin & Henderson, 2005; Hostetter & Busch, 2006; Hughes, Ventura, & Dando, 2007; Lin, 2004; Lomicka & Lord, 2007; Na Ubon & Kimble, 2004; Richardson & Swan, 2003; So, 2005; So & Brush, 2007; Stacey, 2002; Swan, 2002, 2003a; Swan & Shih, 2005; Wise, Chang, Duffy, & Del Valle, 2004).

Gunawardena (1995; Gunawardena & Zittle, 1997) and Tu (2002) created surveys to measure social presence based on past literature in the field. Whereas Gunawardena (1995; Gunawardena & Zittle, 1997) and Tu (2002) focused primarily on surveying and interviewing students about their *perceptions* of CMC and social presence, Rourke et al. (2001) focused on identifying observable behaviors used by students to project themselves as "real" people. More specifically, Rourke et al. identified three categories and twelve indicators of social presence from their previous work, other literature in the field, and experience reading online transcripts (see Anderson, Rourke, Garrison, & Archer, 2001; Garrison, Anderson, & Archer, 2001; Rourke, Anderson, Garrison, & Archer, 2001); the categories and indicators of social presence are listed in Table 1.

Table 1. Categories and Indicators of Social Presence

Categories	Indicators
Affective	Expression of emotions Use of humor Self-Disclosure
Interactive	Continuing a thread Quoting from other messages Referring explicitly to other messages Asking questions Complimenting, expressing appreciation, expressing agreement
Cohesive	Vocatives Addresses or refers to the group using inclusive pronouns Phatics / Salutations

Note. Adapted from Rourke et al. (2001).

Tu and McIsaac (2002) later argued though—as the result of a mixed methods study they conducted—that social presence is more complicated than previously thought. As a result, they identified additional dimensions and variables of social presence (see Table 2).

Because of differences like these, Russo and Benson (2005) argue that there is a need for a multi-method approach and instrument to measure social presence. However, most researchers seem content to use (or adapt) the instruments and coding schemes created by Gunawardena and Zittle (1997), Rourke et al. (2001), or Tu (2002).

Effects of Social Presence

Despite the differences in definitions and methodology, researchers of social presence have come to similar conclusions about the nature of social presence in online learning environments. The following section highlights a few of the main findings.

Researchers have found a relationship between social presence and student satisfaction in online learning environments (Gunawardena, 1995; Gunawardena & Zittle, 1997; Hostetter & Busch, 2006; Richardson & Swan, 2003; Russo & Benson, 2005; Swan & Shih, 2005).

For instance, Richardson and Swan (2003) found that students who were identified as having high social presence online were highly satisfied with their instructor; further, Richardson and Swan found a link between student satisfaction with their instructor and perceived learning. While Russo and Benson (2005), like Richardson and Swan, found a relationship between student satisfaction with learning and instructor presence, they interestingly found a stronger relationship between student satisfaction and the perceived presence of other students. Therefore, suggesting that it is just as important for instructors and students to establish and maintain social presence in online learning environments.

Social presence has also been found to influence online interaction. Learner-to-learner interaction is motivating and stimulating for students (Moore & Kearsley, 2005) as well critical in learning (Richardson & Swan, 2003). Social presence is directly related to learner-to-learner interaction (Tu, 2000). That is, students need to interact with their peers to be perceived as being “there” and being “real.” Tu & McIsaac (2002)

Table 2. Dimensions and Variables of Social Presence

I. Social Context	II. Online Communication	III. Interactivity	IV. Privacy
Familiarity with recipients	Keyboarding and accuracy skills	Timely Response	Formats of CMC
Assertive / acquiescent	Use of emoticons and paralanguage	Communication Styles	Access and Location
Informal/formal relationship	Characteristics of real-time discussion	Length of Messages	Patterns of CMC
Trust relationships	Characteristics of discussion boards	Formal/Informal	
Social relationships (love and information)	Language skills (reading, writing)	Type of tasks (planning, creativity, social tasks)	
Psychological attitude toward technology		Size of Groups	
Access and location		Communication strategies	
User’s characeristics			

Note. From Tu and McIsaac (2002).

conducted a mixed methods study in which they found that social presence influences online interaction. However, they also found out that the quantity or frequency of participation online did not necessarily result in high social presence; rather, it is the quality of interactions online that make the difference.

Finally, researchers have investigated the relationship between social presence and student learning. Picciano (2002) found a strong relationship between "students' perceptions of their interaction … and their perceptions of the quality and quantity of their learning" (p.28). Focusing more on perceived learning, Richardson and Swan (2003) found a relationship between student satisfaction with their instructor and perceived learning. Finally, Russo and Benson (2005) found a statistically significant relationship between student perceptions of their own presence and the points they earned in a class. Research on social presence and online learning, though, is based on an assumption that social presence enhances learning. Therefore, despite these positive results, there is a need for additional research on the relationship between social presence and student learning (Swan & Shea, 2005).

Establishing and Maintaining Social Presence

Every member of an online learning community is responsible for establishing and maintaining social presence. However, an online instructor has some additional responsibility to help establish and maintain social presence in a course (Anderson, Rourke, Garrison, & Archer, 2001; Gunawardena, 1995); this added responsibility is often understood as teaching presence.

Garrison, Anderson, and Archer (2000) were the first to coin the term teaching presence as one of the three elements of their community of inquiry framework. They defined teaching presence as "the design, facilitation, and direction of cognitive and social process for the purpose of realizing personally meaningful and educationally worthwhile learning outcomes" (Anderson, Rourke, Garrison, & Archer, 2001, p. 5).

Regardless of whether researchers of social presence fully adopt the community of inquiry framework (Garrison et al.) or the concept of teaching presence, most researchers seem to agree that it is the instructor's responsibility to create a space for social interaction and an opportunity for a learning community to form (Gunawardena, 1995; Stacey, 2002). Given the important role that both students and instructors play in developing and maintaining social presence, Aragon (2003) identified a number of strategies used to establish and maintain social presence (see Table 3). Aragon (2003) differentiated between course design strategies (e.g., limiting class size), instructor strategies (e.g., providing frequent feedback), and participant strategies (e.g., sharing personal stories). A number of the strategies identified for instructors and participants (i.e., online learners) are the same (e.g., contributing to the discussion boards, using humor, using emoticons). Therefore, instructors can model for student's effective ways to establish and maintain social presence in online learning environments—which can ultimately increase student satisfaction, learner-to-learner interaction, and possibly even student learning.

FUTURE TRENDS

The Internet is a social medium (Baym, Zhang, & Lin, 2004; Walther & Parks, 2002); it can bring people together but at the same time separate them (Morahan-Martin & Schumacher, 2003). Education is a social practice (Lafey, Lin, & Lin, 2006; Shea, Frederickson, Pickett, Pelz, & Swan, 2001); therefore, online learning environments must be able to support the social practice and process of learning (Shea et al., 2001). The construct of social presence, and research on social presence, help explain how the social practice and process of learning takes place online. Therefore, as

Table 3. Strategies to Establish and Maintain Social Presence

Course Design:	Instructors:	Participants:
• Develop welcome messages • Include student profiles • Incorporate audio • Limit class size • Structure collaborative learning activities	• Contribute to discussion boards • Promptly answer e-mail • Provide frequent feedback • Strike up a conversation • Share personal stories and experiences • Use humor • Use emoticons • Address students by name • Allow students options for addressing the instructor	• Contribute to discussion boards • Promptly answer e-mail • Strike up a conversation • Share personal stories and experiences • Use humor • Use emoticons • Use appropriate titles

Note. Adapted from Aragon (2003)

enrollments in online learning continue to grow each year, the construct of social presence will become even more important. As CMC continues to change and evolve with the development of new ways to communicate online (e.g., Twitter), practitioners will continue to find new ways to adapt how they communicate in order to project themselves as being "real" and to connect emotionally and socially with others.

CONCLUSION

Social presence is a complex construct initially developed to explain the effect a communication medium can have on how people communicate. Over time, though, research on social presence and CMC has shown that personal perceptions of social presence and adaptations people make with how they communicate matter more than the objective qualities of a communication medium. Further, research has shown that learner's perceptions of social presence are related to their satisfaction with the course, the instructor, and at times their learning.

KEY TERMS AND DEFINITIONS

Computer-Mediated Communication: Asynchronous (e.g., email or threaded discussions) or synchronous communication (e.g., chatting) conducted via a computer.

Immediacy: Psychological distance between communicators.

Interaction: The combined or reciprocal action of two or more people or objects that have an effect on each other; in online learning environments, interaction is often understood as learner to content, learner to instructor (and instructor to learner), learner to learner, and learner to interface interactions.

Intimacy: A communication concept that explains how people will adjust their behavior—whether online or face-to-face—to maintain a sense of equilibrium.

Online Learning Community: Broadly defined as a group of people with shared interests who come together online to collaboratively learn together.

Social Presence: The degree to which a person is perceived as being real and being there in mediated communication.

Teaching Presence: The design, facilitation, and direction of cognitive and social process for educational purposes.

Chapter 1.12
Reconceptualising Information Literacy for the Web 2.0 Environment?

Sharon Markless
King's College, London, UK

David Streatfield
Information Management Associates, UK

ABSTRACT

This chapter questions whether the shift from the Web as a vehicle for storing and transmitting information to the new Web as a series of social networking environments, requires significant changes in how students interact with information when they are studying within a formal learning environment. It explores the origins and growth of the idea of information skills development, the translation of this work into frameworks and sequential models and the adaptation of these models to take account of changes in information storage and transmission brought about by the Internet. The chapter then examines the changing contexts and changes in learning being brought about by the Web 2.0 environment and questions whether adjustment of existing information literacy models is a sufficient response to deal with these changes. We conclude that although Web 2.0 developments are not fundamentally undermining the nature of teaching and learning they do provide important possibilities for more effective information literacy development work. A non-sequential framework is offered as a contribution to supporting HE students when seeking to obtain, store and exploit information simultaneously in the informal social world of Web 2.0 and in their formal academic discipline.

THE RISE OF INFORMATION SKILLS

In the early 1980s a spate of books appeared in the UK containing a new term in the title: 'information skills'. This term was the brainchild of a working party concerned about school pupils' competence in *"using libraries, exploring references and making notes"* (Marland, 1981, p7) and arose out of the Schools Council's desire to explore what a curriculum for a changing world might comprise. The working party report asserted that *"Individuals today have an increasing need to be able to find things out…never before have our lives depended so much on our ability to handle information successfully"* (Marland, 1981, p9). Narrow concerns about library skills and user education were replaced by a focus on students' problems in finding and using information to tackle assignments and conduct their research within a formal learning environment. This intervention was due to the interest in these skills by educationalists, who, working alongside librarians, ensured wider adoption for information skills and a clearer place for the concept within the learning process.

However, despite this development and the appearance of a number of books exploring the place of information skills in learning (see, for example, Markless and Lincoln, 1986, and Wray, 1985) the concept of information skills was far more widely accepted by librarians than by teachers. This resulted in heavy emphasis on competence in resource use and on finding information.

Models of Information Skills

From the outset writers wanted to show the need for students to develop these 'new' information skills. The issue was presented as one of skills deficit and consequently led to a plethora of information skills frameworks and models, spelling out what students should be able to do. (Many of these models were later 'rounded up' and described by Loertscher and Woolls, 2002.) Model constructors conceived the requisite process as tying together distinct elements of information-related behaviour into a logical, sequential process which could then be taught (e.g. Marland, 1981; Brake, in Markless and Lincoln 1986).

An important retrospective review of these models and frameworks (Eisenberg and Brown, 1992) concluded that

"while each author may explain this process with different terms … all seem to agree on the overall scope and the general breakdown of the process … it appears that the various process models are more alike than different and it may be possible and desirable to begin speaking about a common process approach to library and information skills instruction." (p. 7)

The approach to information skills as a 'common process' to be applied to library research and information handling unfortunately tended to result in a disregard for the context of learning. Skills were perceived as generic; the sequential process outlined in the models was to be adopted at all ages and across different subjects. The process formed a 'curriculum' to be taught to students and applied by them whenever necessary. This view was hardly challenged in the early world of information skills although research on information behaviour in context and on critical thinking skills was calling into question the whole notion of easy transfer, which is also a well-established assumption in mainstream education (Perkins and Salomon, 1992).

Perhaps the most influential of these generic information skills models was advanced as the Big6. This model was created by Eisenberg and Berkowitz (1990); it was widely disseminated in book form and continues to be heavily promoted in the USA and internationally through their website and through an extensive programme of workshops. We will use this Big6 framework as the basis of our critique for the remainder of this chapter because it is one of the frameworks most widely used in USA and UK schools to support information skills teaching and because its authors were amongst the first to integrate ICT into information skills in a distinct and transparent manner.

The Big Six Skills™ Approach

The main elements of this model are outlined below:

1. Task Definition: (determine the purpose and need for information)

Define the problem
Define the information requirements of the problem

2. Information Seeking Strategies: (examining alternative approaches to acquiring the appropriate information to meet needs)

Determine the range of possible resources
Evaluate the different possible resources to determine priorities

3. Location and Access: (locating information sources and information within sources)

Locate sources (intellectually and physically)
Finding information within resources

4. Use of Information: (using a source to gain information)

Engage (e.g. read, hear, view) the information in a source
Extract information from a source

5. Synthesis: (integrating information drawn from a range of sources)

Organize information from multiple sources
Present information

6. Evaluation: (making judgements based on a set of criteria)

Judge the product (effectiveness)
Judge the information problem-solving process (efficiency)
Eisenberg and Berkowitz (1990)

It is not surprising that when the concept of information skills was new, and people sought to understand its scope, frameworks such as the Big6 were widely adopted. They provided a foundation on which to build learning activities and assessment. Would such frameworks survive intact into the 'information age' of ICT?

The Shift to Information Literacy: A Broader View?

With the advent of Worldwide Web and the extensive accompanying investment in ICT in educational institutions of all kinds, concerns about students' ability to find and use information grew exponentially and a new vocabulary began to emerge in formal education - that of information literacy. The notion of information literacy developed in the USA in the 1980s in response to a move towards more active learning in universities and the concomitant need to move away from terms implying passive instruction (Martin, 2006). Use of the term expanded considerably in the 1990s (Bawden, 2001) and has gained some worldwide influence, leading to a declaration by UNESCO (2003) stressing the global importance of information literacy within the information society. A parallel growth in the UK has seen the term widely adopted in academic libraries and national educational bodies (but with most school libraries until now still preferring to focus on information skills - Streatfield and Markless, 2007).

Did the new term signify any fundamental change in thinking or signal a new characterisation of the skills or processes previously called information skills? National Information Literacy Standards in Australia (CAUL, 2001) and the USA

(ACRL, 2000) echoed much of what was in the earlier process models, as did the information literacy model proposed in the UK by the Society of College, National and University Libraries (1999). Despite the fact that 'literacy' is a problematic and contested concept (it has been variously described as encompassing notions of functional competence and skills, of sets of wider cognitive abilities, and as part of a contextualised approach to learning in its social and economic context - Bowden, 2001), information literacy was usually reduced in presentation to a series of skills, procedures and technicalities. This inhibited approach attracted some criticism for being too mechanistic and some writers moved towards a conceptualization that includes attitudes, underpinning knowledge and meta-cognitive abilities (Kuhlthau, 1988; Bruce, 1997). Although Kuhlthau recognised the importance of student attitudes and emotions in her information process model, these elements have not been integrated into other process models - although the commentaries accompanying these models usually refer in some way to motivation and attitudes.

Information Skills and the Internet

In this phase of its development, the Internet was viewed primarily as a new information storage and delivery system for which existing information skills frameworks could simply be expanded or adapted to take account of the growth in access to information via the Internet. Eisenberg and Johnson (1996) exemplified this view when they explicitly integrated ICT into the Big6 Skills model, saying that

Students need to be able to use computers flexibly, creatively and purposefully… (they) should be able to use the computer as part of the process of accomplishing their task. (p. 2)

During the 1990s, the creators of the Big6 confidently extended the model to include student use of ICT when solving learning problems. They claimed that various computer and information technology skills were integral parts of the Big6 Skills. This claim was sustained as their model continued to be implemented in schools across the USA and the UK (Eisenberg and Berkowitz, 2000). Adherents of this and other process models confidently asserted that the basic principles of information seeking and use, derived from years of watching and helping students to interact with print-based information, remained unchallenged.

We have chosen to exemplify current process models by citing the Big6 when looking at whether the concept of information literacy needs to be repackaged or reconceptualised because:

- the model crystallizes the general process approach favoured until now and serves as an adequate exemplar of the model-driven approach
- it serves our purpose because it was the only model advanced until recently that systematically encompasses the ICT dimension
- It is still currently being used and promoted in that form.

The Big6 framework is useful for this purpose because it is a systematic and widely adopted model. Our comments should not be construed as an attack on this particular framework.

Examining the Process Models

What are the assumptions underpinning the Big6 and similar models and what are their main characteristics?

- A sequential view of the process of student research, conceived as a series of logical steps

- Use of prescriptive language to convey an 'ideal approach' to information-seeking and use (e.g. "After students determine their priorities for information-seeking they must locate information from a variety of sources"; "once the information problem has been formulated, the student must consider all possible information sources and develop a plan for searching"). This approach is commonplace in this period, despite the warning offered a decade earlier by Tabberer and Altman (1986) about the danger of idealising study behaviour and promoting 'the right way to …' They stressed that success came by diverse routes and as a result of different choices made in different situations. They warned that students did not always gain much by being confronted with 'the ideal' because there is a range of influences that prevent adoption of 'best behaviour'.
- The process models were designed to support information skills teaching (i.e. to provide a 'curriculum' for the teachers and a pathway to be followed by students when doing their research).
- A particular and limited conception of information-related behaviour is represented in these models, with much emphasis on information seeking, location and access. Use of information is reduced to determining relevance and extracting pertinent items of information (by taking notes or resorting to cut and paste). The words knowledge, understanding and making sense of, seldom occur in these models, nor does the idea of creating one's own viewpoint. The apparent assumptions are that this shortcoming will be addressed in the subject teaching or that the acts of extracting and organising relevant information will themselves stimulate the construction of meaning. What happens instead is frequently cut and paste activity leading to more or less unintentional plagiarism. In these models, synthesis is not about transforming information to encapsulate new knowledge
- Overall they present ways to support teaching ("innovative instructional methods") designed to provide a framework to guide teachers or librarians when preparing appropriate activities or tasks for their students.

These models reflected the main uses conceived for the Web in this period as a vehicle for storing and transmitting information.

Information Literacy and Web 2.0: Changing the Context, Changing the Learning?

The 'orthodoxy' of information skills within formal learning environments, as enshrined in the Big6 Model, is being increasingly challenged. Recent research into information literacy is moving away from technological processes and skills-based models, recognising the complexities inherent in finding and using information. A more experiential perspective that recognises the contextual and affective elements of information literacy is emerging (Williams and Wavell, 2007). Two complementary developments have influenced this shift in focus: greater interest amongst information literacy researchers and practitioners in the processes of learning (especially theory about variation in learning and constructivist approaches); and an electronic environment that is increasingly being shaped by its users.

Have traditional views of information literacy really been rendered obsolete? Does learning through Web 2.0 require different skills and abilities? Are a new range of cognitive and metacognitive strategies needed to learn effectively within the Web 2.0 environment? Or, does the Web 2.0 environment provide tools that enable teachers to engage students more effectively in well-established learning processes than could be achieved hitherto?

In our view, learning is not fundamentally different within Web 2.0, nor does the 'new' social software change the basic processes of learning. Where Web 2.0 has made a difference is in making it easier to engage with some aspects of learning that were previously difficult to address (for example, real collaboration and groupwork, peer critique, hearing students' authentic voices and construction of new knowledge). None of these important aspects of effective learning are new: all can be found in the education literature of the 20th Century, from Dewey to Ausubel, and from Vygotsky to Marton. However, despite their importance, few of these elements have found their way into information literacy models or practice.

When the Worldwide Web was primarily a vehicle for storing and delivering information it was easy to portray information literacy as an ordered sequence of skills to be ***transmitted*** to students, whilst ignoring other approaches to learning. Web 2.0 effortlessly undermines this approach with its disregard for authority, hierarchy and order and its focus on the voice of the individual and on ever changing constructed groups. Any contemporary approach to information literacy must consider how to engage more effectively with learners, by understanding these multiple aspects of how they can learn.

Before we examine in a little more detail some of these key elements of learning and their relationship to information literacy and social software, we need to note two other factors that may influence this relationship: the reluctance of individuals and institutions to change; and the ways in which the 'Google generation' of 'digital natives' may interact with information and learn in new and different ways. What are the key elements of learning as they relate to information literacy and social software? Some at least of these key elements are:

1. Reluctance to change (institutions and teachers)

Faced with the unfamiliar challenge of a new world of social networking, some education institutions have tended to react in a predictably conservative way by blocking access to elements such as Face book and Second Life. As a result of such embargos, as well as a reluctance by teachers to engage with this new world, students are frequently operating in different electronic environments during formal learning from those in their out of hours experience (especially in schools). This makes teaching of information literacy more problematic.

To somewhat over-dramatize the dilemmas created: as a teacher, how can you fully engage with students in helping them to exploit information if you don't have easy access to what may constitute their major sources of information? Or, from a student perspective, why should you bother to engage with all this 'information literacy stuff' if your perception is that all you have to do to get the information and help that you need, is to resort to your social networks? When you are away from the institution, if you can effortlessly manipulate multi-media information to build your own web pages, why jump through what might be seen as sterile and irrelevant information literacy hoops when you are in formal learning mode? Again, as the world of Web 2.0 becomes increasingly sophisticated, the version of ICT encountered in formal learning is likely to appear ever more limited and pedestrian.

2. Digital natives and others

" Future students in higher education belong to a generation that has grown up with a PC mouse in their hands, a TV remote control, a mobile phone, an i-pod, a PDA and other electronic devices for communication and entertainment … computer games, the Internet, MSN, wikis and blogs being an integral part of their lives" (Veen, 2007, p.1).

Prensky has labelled these young people 'digital natives' and has asserted that they now exhibit different characteristics from their forbears (the digital immigrants) due to the extent of their exposure to technology in all its forms.(Prensky, 2001). He claims that changes in activity during development may result in different neural wiring via processes of 'neuro-plasticity'; a view recently echoed by Martin Westwell of the Institute for the Future of the Mind (2007). Both advocates assert that current students have much better visual skills, do better at visual-spacial tests, are able to deal with lots of information at once, and can process this information and make decisions quickly. On the other hand, this generation of students may have shorter attention spans, be easily distracted, may not maintain focus well when interrupted and may have less ability to reflect on topics than the previous generation. Veen (2007) adds to this list of differences, talking about non-linear learning behaviour; clicking and zapping to deal with information overload; using exploratory approaches to new situations; and becoming experienced at problem solving at a young age. "We now have a new generation with a very different blend of cognitive skills than its predecessors – the digital natives." (Prensky, 2001)

As a result of Web 2.0 developments, we can also anticipate that 'digital natives' may have different social skills.. This is because the Internet is increasingly used for socialisation rather than just information-seeking, with even those seeking information often doing so via peer groups. Westwell claims that more people use Second Life and Facebook than use Google. Whether or not we believe all these claims, Oblinger and Oblinger (2005) have forecast that the next generation of students entering higher education will be digitally literate, highly Internet-familiar, connected via networked media, used to immediate responses, and preferring experiential learning. This generation will be highly social: they will prefer to work in teams and will crave interactivity in image-rich environments as distinct from text-intensive environments.

Where does this leave traditional information literacy, with its focus on using libraries and finding primary sources, its reliance on laborious sequential steps and its scant reference to collaboration or to multi-media resources? If Westwood and others are correct, their picture of our 'new' students implies that not only have they gained from their early digital experiences but they have also lost in terms of opportunities for reflection and 'slow-learning'. This picture of gains and losses calls into question the widespread claims that elements of Web 2.0 (wikis etc.) automatically help to develop meta-cognitive skills. However, it is also interesting to note that traditional information literacy frameworks do not emphasise reflection and its role throughout learning.

Web 2.0, Information Literacy and Formal Learning

Where do all these changes leave information literacy? How might traditional models of information literacy need to be altered to accommodate the experience and expectations of students within formal education? Where does Web 2.0 fit in?

- The sequential view of skills deployment is now being questioned. Learning tasks make a range of different demands on students, which call into question the notion of applying the same series of steps to meet all these demands. Observations of pupils from 5-18 in schools and students in further education colleges show that they seldom follow the prescribed sequence (Streatfield and Markless, 1994; Moore, 1997; Markless and Streatfield, 2000). Formal studies of information-seeking behaviour in universities again challenge this premise (Foster, 2006). To be fair, most of the process models that are set out in steps are accompanied by some form of caveat recognising or even advising that it is not necessary to follow the prescribed sequence. However, there is usually little help offered on how to use the model in a non-sequential way, with the result that the framework tends to be taught as a sequence. The desire to inflict sequences on students is remarkably resilient in the world of information literacy. Even writers who are responding to the Web 2.0 environment tend to present a sequence of processes to be learned in order to become 'information fluent' (e.g. the five-stage process of Jukes (2007): asking questions; accessing data; analysing and authenticating information; applying it to real-life problems; assessing product and process). This approach takes no account of the influence of context on any sequence, the influence of learners' cognitive styles, or the need to make sense of any information and transform it into knowledge.

In addition, a core characteristic of Web 2.0 tools is that they transfer power, ownership and authority to the participants. This inevitably gives people license to design their own routes through learning tasks in any way that suits them. Finding information is less likely to involve systematic information seeking than, for example, interest groups, peer web pages or social bookmarking.

These observations lead to the key question - can the Big6 or any similar information literacy model be adapted to take account of how students actually find and use information, especially in the Web 2.0 environment?

- Although the importance of learning as construction is recognised within the rhetoric of information skills pedagogy and "Information literacy is often seen as the school library version of constructivism" (Moore, 2005 p.3), much of the observed planning and practice[1] suggests heavy reliance on transmission, learner practice, and feedback, all heavily structured into manageable segments and strongly 'teacher' controlled (that is, the classic behaviourist approach). Early voices such as Kuhlthau's (1993), which present information-seeking as a process of seeking meaning, were at first largely ignored in practice. In recent years there have been intensified efforts to ensure that people who are teaching information literacy adopt constructivist approaches (e.g. Todd, 2001). Limberg (2007) asserts that to learn is not to receive knowledge and information, but is about changing the relationship between a person and the world. She claims that information-seeking is too often focussed on teaching technical procedures and on fact-finding rather than on students formulating authentic questions and constructing their own positions. The concept of authenticity is central to Limberg's ideas on information literacy. Contrived questions and tasks, designed solely to meet externally imposed assessment and with no other consequences for the student, will not engage and motivate students. Without a real and personal interest, students will be satisfied with the superficial answer, the first 'hit', or 'good enough' information. There is no incentive to go beyond using technical skills to collect facts.

Again, the latest outputs from the USA-based Center for International Scholarship in School Libraries (Kuhlthau and others, 2007) focus on the concept of 'guided inquiry' as the basis for teaching and learning of information skills. The main characteristics of guided inquiry are:

- active engagement by students in the learning process
- students building on what they already know
- high levels of reflection
- a recognition of the importance of social interaction and of students' different ways of learning (Kuhlthau and Todd 2007)

All these are recognisable characteristics of learning as construction (see, for example, Papert and Harel, 1991). There is little doubt that constructivist approaches are particularly suited to Web 2.0 tools. In this environment, students can construct artefacts such as video presentations, blog entries and wiki pages both individually and collaboratively. Teachers can join in with collaborative editing and can scaffold students' work. It seems likely that the constructivist approach to teaching and learning so well supported by Web 2.0 tools may finally lead to information literacy teaching becoming more attuned to how students learn.

If constructivist principles are used to inform and guide information literacy work, students will be required to develop a repertoire of strategies that are conspicuously absent from most information literacy models. This will involve:

- reflection: the ability to reflect constructively and to use that reflection in planning for their own development
- evaluation of the processes undertaken as well as of the products of their study
- making sense (deep understanding) of the information that they obtain, linked to the ability to transform the information to reflect their own emerging views

We do not think that these aspects of learning can simply be grafted onto existing frameworks or inserted after any particular element of a linear, sequential model. They are part of an iterative process of learning not well represented in existing information literacy frameworks.

The Importance of Context

The importance of context in relation to information behaviour is well established (e.g. Streatfield and Wilson, 1980; Dervin, 1992; Ingwersen and Jarvelin, 2005). Context in information-related behaviour is recognised as multi-dimensional: with different facets reflecting features of the task; characteristics of the learner; and features of the system. Louise Limberg observed in a conference presentation that "Influential studies have abandoned the idea of information literacy as a set of generic skills applied anywhere. Information literacy is not generic but should be seen as social practice …" (Limberg, 2007). Looking at secondary schools, Williams and Wavell (2007) warned that if we are trying to to develop pupils' information literacy we cannot ignore content in favour of technicalities and procedures - if we do so, we will get trivial learning outcomes. Nevertheless, as we have already noted, information literacy advocates have persisted in offering generic skills development frameworks that take little no account of context.

How can the importance of context be reflected in an information literacy framework? We believe that a different type of framework is needed; one that moves away from offering a list of abilities to be taught or applied in an unvarying sequence, irrespective of context.

Alongside the challenge of producing an appropriate information literacy framework we face another problem: how can we teach information literacy in ways that respect the influence of context? Current views on skills development (e.g. Luke, 2006; Williams and Wavell, 2006) assert that if students are to develop their information-related skills through assignments there is a need for:

- Authentic tasks that are recognised as relevant by the students (tasks that have

meaning to students on a personal or academic level; not contrived to allow them to practice particular skills)
- Immersion in authentic contexts (realistic environments, current information drawn from the real world, engagement with real world problems and concerns)
- High quality tasks related to current academic work (e.g. asking students to conduct critical evaluation of sources to construct a position for an essay, rather than offering general guidance on evaluating information)
- Learning embedded in the relationships, values and discourse of the learning community (inherently social)
- Timely teacher interventions in order to move learners on at transition points in their work

Web 2.0 can once again be a powerful support for increasing authenticity and enabling the deployment of information literacy strategies in a variety of meaningful contexts. The possibility of a public platform for their work may help students to take more seriously the underlying information literacy processes involved in producing that work.

Student Reflection

If we are to take context into account when deciding on information literacy strategies, this immediately introduces the concept of variation. Bowden and Marton (1998) argued that not only do students need to experience variation in order to learn, but they must also explore variation by comparing and analysing their experiences. To do this, students need to:

- actively engage in discussion and reflection about finding and using information in order to uncover variation in their conceptions
- confront variation in their own experience and in the experience of others. (Based on Bruce, 2007, pp. 51-52)

Since at least the 1970s, reflection has been seen as a mainstay of learning and this concept has found its way into many models of learning (e.g. Kolb, 1975; Schon, 1983).

Reflection is a particularly important element in developing the processes underpinning learning and is therefore potentially important in any systematic approach to information literacy. Reflection is taken for granted in most models of information literacy or placed at the very end of the process. This approach in not likely to enable the development of the meta-cognitive strategies necessary to perform problem-solving with information. It is likely to be difficult to integrate reflection into existing information literacy frameworks in any meaningful way (see the discussion about constructivism above). The possibilities for learning provided by Web 2.0 may provide a way forward. For example, peer critique and the collaborative production of artefacts may automatically stimulate reflection. If not, engagement in these processes should provide opportunities for a more formal emphasis on reflection as part of information literacy teaching.

Collaborative Learning

Collaborative learning has long been seen as a desirable process: for example, groupwork is a key element of training courses for teachers in all sectors. Web 2.0 tools have turned many students into sophisticated social networkers via YouTube, Facebook, blogs and discussion boards (Ipsos MORI, 2007). The same tools can also be used to facilitate collaboration in formal learning settings, whether the focus is on creating specific interest groups, building learning communities or enabling the collaborative production and editing of artefacts.

Collaborative learning requires many skills of communication and interaction, but does it make fundamentally different information literacy demands on learners than those made when individually finding and using information? There is little in recent research to indicate that this is the case (Williams and Wavell, 2007; Kuhlthau, 2007). The influence of context (subject, learner characteristics and teacher expectations) is not just about whether students are working individually or in groups to find and use information. At the same time, Web 2.0 can be seen as working counter to collaboration through increased personalisation of learning paths. Overall, this aspect of Web 2.0 raises important issues in the wider context of approaches to learning by providing increased scope for a variety of activities. It may offer valuable avenues for the teaching of information literacy but does not seem to fundamentally affect the information handling skills required.

Learners' Expectations of Information

Web 2.0 inevitably raises questions of ownership and authority of information. It is an environment in the course of creation by its participants. These participants individually and collaboratively generate content in a form, format and structure that best suits their own needs and preferences. This process works well when the primary focus is on participation in social networks or developing personal interests. However, it can create major difficulties when the same processes are applied in formal learning. Keen (2007) claims that we are diving headlong into an age of mass mediocrity because of the absence of gatekeeper expertise and the increase in user-created content. This view is echoed by Gorman in his Britannica Blog (2007) which identifies an erosion of traditional respect for authenticity and expertise in a world in which everyone is an expert "ignorant of the knowledge they will never acquire and the rich world of learning that search engines cannot currently deliver to them."

Most students should be able to operate both in the social world of web 2.0 and in more formal learning environments (even before we take account of the growing presence of academic interests and institutions on Web 2.0). However, to operate effectively in formal learning environments, student autonomy may have to give way to recognised academic authority. Students' preferred use of Wikipedia and social bookmarking, alongside their facility in creating new 'knowledge' through remixing text, image and audio, or through the collaborative creation and editing of web pages may come into conflict with the necessity to conform to academic norms of using externally-validated information. Students will not be able to simply replicate their social/leisure on-line behaviour when engaging in formal academic tasks. Information literacy should help in this arena: traditional information literacy models do focus on evaluating sources of information, on considering authority and credibility. Such an emphasis should raise students' awareness of the problems associated with following their own preferences and concentrating on their own perspectives. A new balance may need to be drawn between encouraging students to use the range of pathways to information that are open to them in Web 2.0 and ensuring that they have the ability to choose the most appropriate for academic study.

However, do we also need to respond more positively to students' expectations of information? Should the information literacy field legitimise elements of students' preferred information-related behaviour? For example, should we ensure that information literacy frameworks encompass such concepts as 'good enough' information, trial and error, and peer 'expertise' rather than focusing primarily on a set of competencies that appear to be designed to turn all learners into systematic researchers, regardless of the task context?

Does Finding Information Really Matter Any More?

One question likely to worry traditional information literacy proponents is whether there will be a continuing need for skills in information seeking, given an information world in which search engines are become increasingly sophisticated and in which Web 2.0 offers a range of enticing alternatives to systematic searching. According to Carol Kuhlthau (2007) what is important in the 21st century is the ability to use information for problem-solving ***not*** "the technology of finding."

Is a New Model of Information Literacy Needed to Meet the Challenge of Web 2.0?

We are not convinced that the Web 2.0 environment on its own necessitates the development of new sets of abilities for finding and using information. It does, however, move learning into new directions (e.g. increased collaboration, more authentic tasks, peer critique, non-linear aaproaches to information). In doing so, learning with Web 2.0 tools should put increasing pressure on proponents of information literacy to move in the direction of well recognised learning principles and practices. In particular, information literacy can be enhanced in a formal learning environment by exploiting some possibilities offered through Web 2.0 tools:

- Enhanced group work and shared tasks
- Cooperative creation of multi-media artefacts
- Collaborative editing and critiquing
- Searching for information (e.g. using social bookmarking and folksonomies)
- Organising information in new ways (e.g. using tagging)
- Increasing authenticity of work by presenting ideas to others in a more public space and using a wider range of media
- Providing 'just-in-time' scaffolding to support students
- Facilitating student reflection using records of individual and group processes and providing virtual contemplative spaces

None of these aspirations are new to formal education but some have been difficult to achieve hitherto without the benefits of advances in Web 2.0.

If the information literacy community is prepared to design materials, activities and support mechanisms based on the opportunities offered by Web 2.0, can they adapt existing information literacy frameworks to scaffold their work? Is a framework needed at all to enable information literacy development in formal education settings?

Any model or framework will be flawed because it cannot fully take account of the influence of context on information use or the problems inherent in producing any generic view of information literacy. However, whilst doing research and development work in many further and higher education institutions and schools, we have found that staff and students want to put some sort of framework in place. They want a public statement that clarifies what is encompassed by information literacy; a guide to support curriculum planning; and something that students can refer to when doing research and tackling academic tasks.

The following framework (Markless and Streatfield, 2007) was originally designed to address problems being encountered by the University of Hertfordshire. The University was trying to develop an institution-wide approach to supporting students when finding and using information in an electronic environment. At first it was thought that an existing framework could be used or adapted to meet the needs of staff and students. However, consideration of the issues explored in this chapter made the shortcomings of such an approach apparent. We concluded that many of the traditional information literacy models had been built on a series of assumptions about learning and information behaviour that were problematic and that the increasing use of Web 2.0 threw these assumptions into stark relief. We therefore needed to offer a different solution that is more in keeping with the changing learning environment.

The solution offered is essentially a framework to support student choice in learning rather than information literacy teaching. The framework is designed to enable students to get help where and from whom they need it rather than to usher them through a regimented programme of information skills development. Some of the individual elements of the framework hark back to those designed in the 1980s and 90s. The skills and strategies included are not all new, although we have moved away from a heavy emphasis on systematic searching. In addition this framework is designed to be approached and used differently from traditional frameworks such as the Big6. The drivers behind our approach are student choice and reflection to support effective learning rather than laying out a sequence of steps to be taught.

During three key stages (which do tend towards the sequential) students ***choose*** which strategy to adopt at different points in their research. Help and guidance is available for each of the key elements. Importantly, if one avenue fails students can go back to the big picture and choose another route; they are not trapped in a sequence that they are expected to follow. The framework is designed for students to construct their own problem-solving approaches to finding and using information, either individually or collaboratively. The impact of context on learning should lead students to make different choices about which strategies to employ and which skills to draw on depending upon the nature of the task they are addressing and the wider social context in which they are operating. The framework is designed to take advantage of technological developments that allow individuals to make choices, navigate between options and then save their search paths for future reflection.

Figure 1.

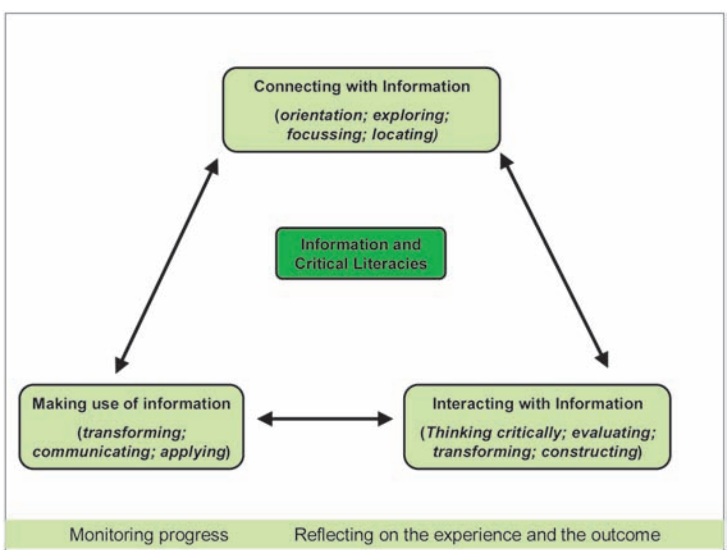

Figure 2.

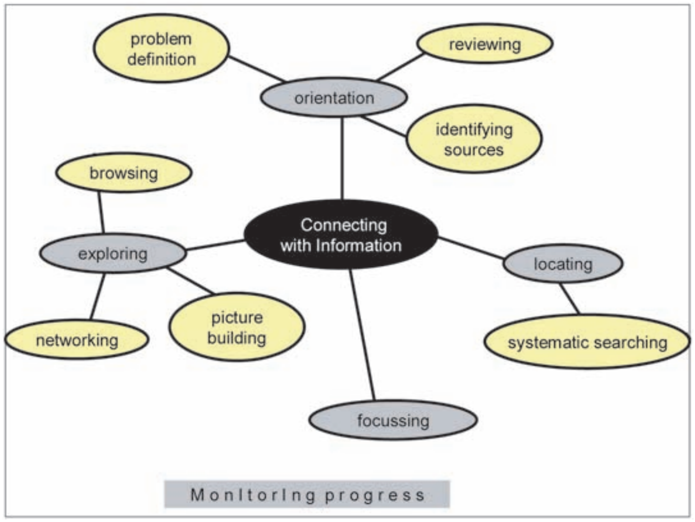

The framework that we designed drew on two research-based published models, a non-linear model of information-seeking behaviour[2] devised by Allen Foster (2004; 2006) and a model of information and critical literacies offered by Ross Todd (2001). Foster worked with academics to show the fallacies inherent in the assumption that researchers looked for information using a fixed sequence of steps. Todd's overview of information literacy emphasised transformation and construction of knowledge because he wanted to encourage students to stop interpreting research tasks or assignments merely as processes of collecting information. Instead they are encouraged to think in terms of forming their own perspectives, creating new insights and presenting their own authentic voices.

Figure 3.

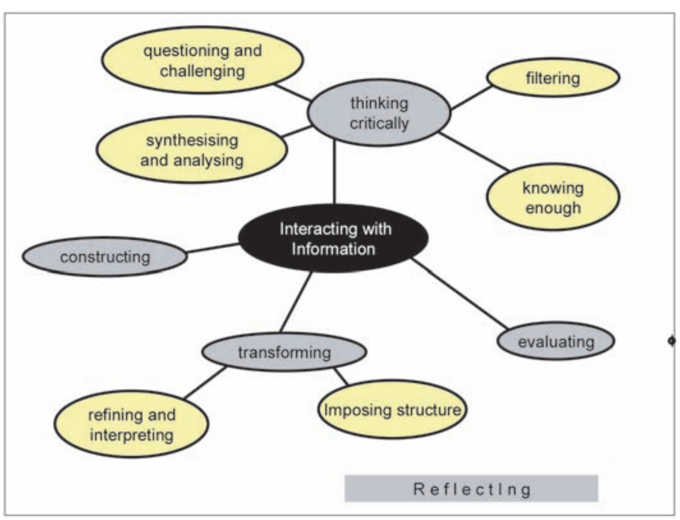

Figure 4.

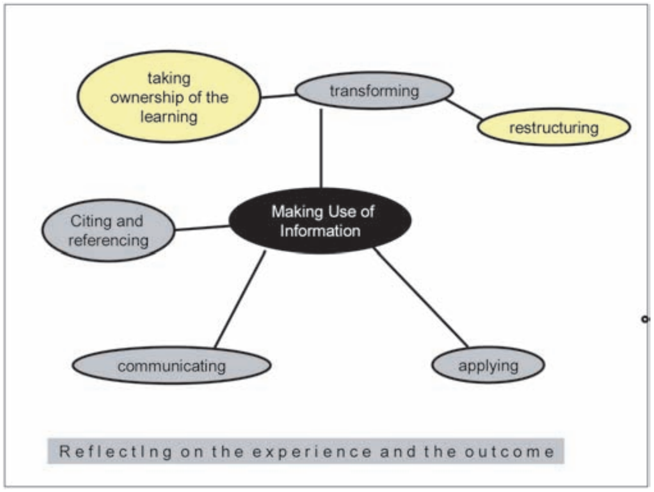

Our new framework builds on these ideas as well as addressing some of the concerns discussed earlier in this chapter. It is presented below as a series of figures.

Figure 1 provides students with an overview of what is involved with finding and using information. It was important to avoid the trap of presenting information literacy as a series of steps (anything between 5 and 12 stages in many traditional frameworks. The Big6 actually contains 12 steps as there are two stages in each of the 6 main elements of the framework.) Students can choose to engage in any one of the 3 main elements depending on the nature of the academic task they are tackling.

Figures 2, 3 and 4 are what the students see when they click on the relevant box in figure one. There is no set path through any of these figures; if the student is at the beginning of a project they may look at figure two and decide that the best place to begin is with networking. If they click on networking they will get some ideas about who they might contact and how they might work with peers. Equally, a student might decide to begin with problem definition. Again, this element is populated with activities, ideas and advice about how to analyse a problem. Whatever path a student or group of students decides to take through this framework they are offered on-line support at the point of need. They are also encouraged to save their path so that they can see how they worked through a particular assignment - the choices they made. Students compare their chosen paths with those of their peers and consider which have been most effective. They can also review their approaches across a number of different tasks to see whether and how they have adapted their approach to the context. Encouraging reflection on the process of learning was an important element in our design of a non-sequential framework.

Where our framework is being used, each element is being populated with material designed by both academic staff and librarians. The framework itself has stimulated some useful collaborative work between staff interested in specific elements most relevant to their discipline. Their aim is to provide support for students who want to use a particular information skill or strategy in the course of their academic work without dictating a path through that work.

This framework is very much a work in progress. It is being tested at universities in the UK and Spain and is currently being translated into

Arabic. The real test for this framework will be if students do not see it as a straightjacket, constraining their normal interactions with information, but find it useful no matter what the information environment in which they are working.

Conclusion

The traditional information skills models (such as the Big6) that grew out of early interest in enhancing the use of libraries and text-based resources tended to be based on a simplistic view of learning and information behaviour. These models served a purpose in introducing students to the formal world of academic information and, as such, continued to be of use when responding to the arrival of the Internet in its original conception as an information storage and transmission vehicle. However, the shift in focus towards ever greater information access through the Internet combined with greater attention to teaching and learning of information literacy based on constructivist education principles, has led to the traditional information skills approaches being increasingly questioned.

The changes being brought about by the advent of Web 2.0 have served both to provide a further challenge to traditional approaches to information literacy and potential solutions to some of the inherent problems in traditional approaches. The value of teacher-led, text-focussed, sequential models must now be in question because they are based on very un-web 2.0 propositions. Instead, the social networking possibilities offered by Web 2.0 provide fresh opportunities for supporting social learning, including peer information seeking, evaluation, critique of strategies and capturing of processes when helping students to engage with information literacy development. Accordingly, a new framework is tentatively offered here as an alternative to the Big6 and similar models, with the intention of allowing students to construct and revisit their own paths to information discovery, organisation, sense-making and exploitation in the evolving world of Web 2.0.

key terms

KEY TERMS AND DEFINITIONS

Constructivist Learning: Learning as an individual or social act of construction, leading to sense-making and the building of meaning.

Information Literacy: A set of abilities for seeking and using information in purposeful ways related to task, situation and context. (Limberg, 2007)

Information Skills: The sets of skills and competencies required to find and use information, usually in a formal education context.

ENDNOTES

1. This observation is based on our experience over twenty years of observing information skills/ literacy lessons and examining lesson plans.
2. Although Foster describes his model as non-linear, it may be more helpful to regard it as a non-sequential model

This work was previously published in Handbook of Research on Social Software and Developing Community Ontologies, edited by S. Hatzipanagos; S. Warburton, pp. 493-511, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 1.13
Social Networking

INTRODUCTION

It is in man's nature to form communities, and it is also in his nature to communicate. Psychologists hold that man is moved by instincts, desires which can only find full satisfaction in a community and by communication. Social networking (or network theory) is not an exact science and may reasonably be termed a social catalyst in discovering the method in which problems are solved; organisations are run to the degree in which individuals succeed in achieving goals (Freeman, 2004). In the network theory, social relationships are discussed in terms of *nodes* and *ties*: the former individual actors, the latter, relationships within networks frequently described diagrammatically where the *node* is a point, and the *ties*, lines of social connectivity (Scott, 2000).

Such social network diagrams can be used to measure the social capital of individual nodes/actors: a measurement, or determination of the usefulness of the network to the actors individually, as it is that measurement of usefulness to the individual which not only assesses the social capital of actors, but which by extension may shape and expose the very nature of the network as an entity. Loose connections (weak ties) reflect the greater possibility of openness in the network (Granovetter, 2003). This, in turn, is more likely to bring new ideas, new opportunities, and greater scope for innovation than close networks with many redundant ties. It is clear that "the friendly network" composed of friends already have common knowledge, common interests, and common opportunities. Better

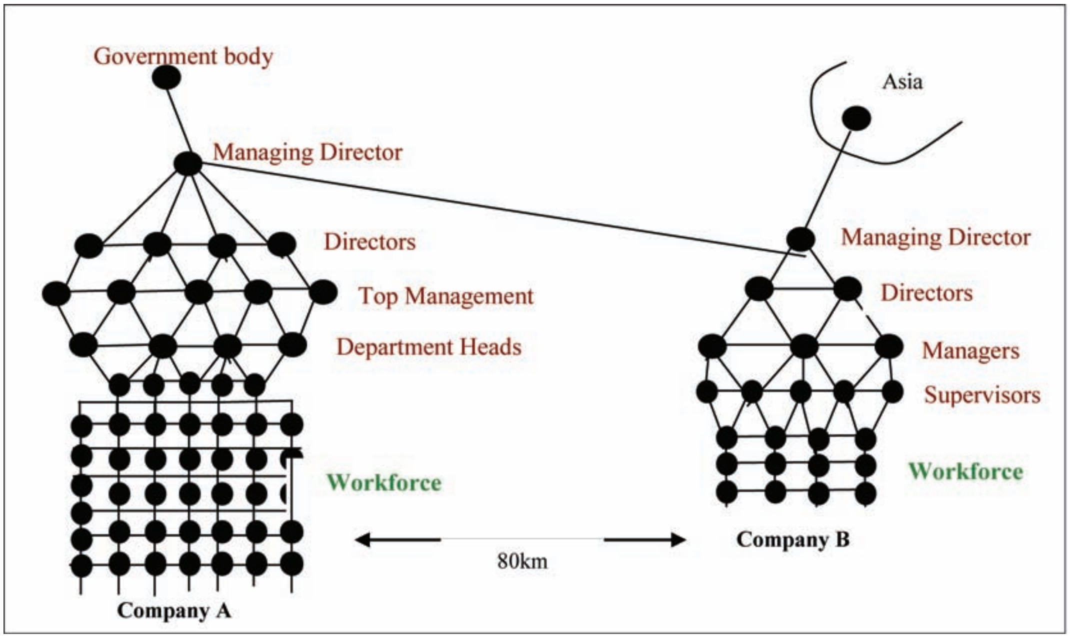
Figure 1. Social networking



still, it has access to wider social geographies. Again, the group with links to many networks has potentially greater access to other social arenas and a more extensive field of information, and thus the individuals, have links to a diversity of networks, as opposed to those within a single network, and can exercise more power and exact more influence by acting as brokers between their own and other networks not directly linked. This "polylinkage," or "filling social holes," places greater emphasis on the qualities or attributes of individuals. The ability of individuals to influence their success depends largely on the nature and structure of their network. Figure 1 illustrates a social network. Company A is a large fashion design house, a national company.

Company B imports and packs material for A's use, but so far, A has little interest in a take over bid because of continuing government financial enhancements and certain tax concessions. A has, thus far, also ignored the lure of outsourcing to Asia, where it could control material at the point of manufacture. Company B imports most of the material A requires, and supplies A at a mark up sufficient to meet all the transport costs. B is in "comfortable survival," for as a condition of title to financial enhancements in an area of high unemployment. This interaction when examined within the social network characterizes, not only interdependence that exists between the companies, but the *in-group* factor, and however "shocking" a statutory body for justifiable reasons, supports the "cosy" arrangement (Wellman & Berkowitz, 1988). That arrangement, in a very real sense, runs contrary to Sociometry, which attempts to quantify social relationships and which Granovetter explained in finding that, "Power within organisations" comes from an individual's power within a network rather than the post or the title he or she holds (Granovetter, 1990). In the relatively simple example of companies A and B, the power of each company is totally dependant on government legislation, which was arrived at as the result of a debate in the House and a vote in parliament. Self evidently, the individual within networks A and B have little to do with the present state of

Figure 2. Matrix of group relationships

	Ryan	Tara	Paul	Geraldine
Ryan	---	1	0	1
Tara	1	---	1	0
Paul	0	1	---	0
Geraldine	1	0	0	---

business. B depends on A and A on the legislation derived from a free vote in parliament.

However, in a strike or work to rule situation, it is the individual who holds the power. Granovetter, in the final analysis, appears to be correct, if and only if the cosy status quo continues. It is a basic law of Physics that, "Every action has an equal an opposite reaction," and that law appears, so far, to hold true in Social Networking. There are, however, those who would claim that Social Networking or Network Theory is all theory, yet not really theoretical on account of too much methodology (Scott, 2000). The core problem with this stems from an apparent inability to test hypothesis in a mathematical way, that is, using statistics as the data by its very nature negates the random sampling, which statistics demands. Here, even the computer and its resources do not appear as being capable of handling larger and larger databases, where networks expand. We present examples of social networking which integrate sociology and psychology within everyday life. In particular, we use examples relating to an organisation's internal structure, but this can also be extended further to university classes as well as the politics associated with any group in relation to sports teams and then with work and sport aside another example given to address this essay topic is the rise of social networking Web sites such as *bebo.com*. As an overview there will always be the so called in-groups and out-groups, and so there will be the inevitable group politics associated with the individuals involved. Social networking was first created in 1954 by "J.A. Barnes" (Barnes, 1954) where he talks about social circles relating to casual acquaintances or friends and these connections are important as they have a direct impact upon productivity and individual motivation. Here, we concentrate on social networking in relation to analysis. The examples presented show how groups behave and how group politics affects everyone involved, whether it be working in a job or studying at university (Alexander & Danowski, 1990).

SOCIAL NETWORKING

The amount of information needed to describe even the smallest of social networks can be quite big. Tools from mathematics are used to help all of the tasks of social network methods (Newman, 2003). To help with the manipulation of network data and the calculation of indexes describing networks, matrices are very useful for recording information. An example of a simple matrix is shown in Figure 2.

The above matrix shows the structure of a close friendship in a group of four people: Ryan, Tara, Paul and Geraldine. It describes a pattern of liking ties with a point-to-point matrix where the rows represent choices by each actor. We put a "1" if a person likes another, and a "0" if they don't. One reason for using mathematical and graphical techniques in social network analysis is to represent the descriptions of networks compactly and more efficiently. This also enables us to use computers to store and manipulate the information quickly and more accurately than we can by hand. The smaller, tighter networks are not as useful to their members as networks with lots of loose connections (weak ties) to individuals outside the main network. This is because networks with weak ties are more likely to introduce new ideas and opportunities to their members than closed networks. For example, people who do things only with each other already share the same knowledge and opportunities, whereas people with connections outside of each other are more likely to have access to a wider range of information. It is a lot more beneficial for individual success to have connections to a variety of networks rather than many connections with that of one network. Another advantage of having connections to a variety of networks is the use of filling social holes. This is when individuals can bridge two networks that are not directly linked to exercise influence or act as brokers within their social networks. Social network analysis (also known as network theory) has become a key technique in modern subjects such as:

- **Sociology:** The study of society and human social action, and includes the examination of the origins, institutions, organisation, and development of human life.
- **Anthropology:** The study of humanity. It is concerned with all humans at all times and with all dimensions of humanity.
- **Social psychology:** The study of how individuals perceive, influence, and relate to others. The study of how our thought and self-awareness is social in origin.
- **Organisational studies:** Organisational behaviour, a distinct field of academic study which exams organisation through using the methods of economics, sociology, political science, anthropology, and psychology.

Social networks operate on many levels and play an important role in solving problems and how organisations are run, and it helps individuals succeed in achieving their targets and goals. In Social Network Theory, the attributes of individuals are less important than their relationships and ties with other points within the network (Newman, 2004). This approach both has its advantages and disadvantages. The advantage of this approach is that it is useful for explaining many real-world phenomena. The disadvantage, however, of this approach is that it leaves less room for individual agency, and the ability for individuals to influence their success because so much of it rests within the structure of the network. Social networks are also used to examine how companies interact with each other, as well as between individual employees at different companies. These networks provide ways for companies to: gather information, reduce competition, and cooperate with rival companies for their mutual benefit in setting prices and policies. Social networking can refer to a category of Internet applications to help connect friends, business partners, or other individuals together using a variety of tools. These applications are known as online social networks and are becoming increasingly popular (Watts, 2004). Online social networks are a special network service. It is social software specifically focusing on the building and verifying of social networks for whatever purpose. Social networks play a major role in hiring, in business success for firms, and in job performance. Social network theory in the social sciences began with the urbanisation studies of the "Manchester School." A genuine social network is limited to about 150 members (Cross & Parker, 2004). This is sometimes known as the Dunbar number, which measures the cognitive limit to the number of individuals with whom any one person can maintain stable relationships. It is theorised in evolutionary psychology that the number may be some kind of limit of average human ability to recognize members and track emotional facts about all members of a group. The need to track "free riders" is important, as larger groups tend to more freely allow cheats and liars to succeed. Free Riders are points who use more than their fair share of resources, or shoulder less than a fair share of the costs of its production. To connect two random people anywhere in the world through a chain of social acquaintances is generally short. This idea gave rise to the famous phrase six degrees of separation, which is a theory that anyone on earth can be connected to any other person through a chain of acquaintances that has no more than four intermediaries. Research has shown that about five to seven degrees of separation are sufficient for connecting any two people through the Internet (Hill & Dunbar, 2002).

In 1995, the first social networking Web site was set up called *Classmates.com*. It was not until 2001 that Web sites using the Circle of Friends social networks started appearing, and the popularity of these is still growing today. The most recent social networking site is *bebo.com*. It currently has over 20 million members world-wide and is a free service. Through *Bebo.com* you can search for friends, browse member homepages, learn more about people you see every day, write and draw on other people's white boards, join "Clubs," see events and parties on the calendar, keep in contact with friends at other schools and colleges, share photos privately or publicly, create quizzes about yourself, and blog. These social networks start out by an initial set of founders sending out a message inviting members of their own personal networks to join the site. The new members then repeat this process, growing the total number of members and links in the network. These sites then offer different features like viewable profiles, chat, and so forth. Social connections can also be used for business connections. Blended networking is an approach to social networking that combines both off-line elements (face-to-face events) and online elements. Social computing is the use of social software, which is based on creating or recreating social conversations and social contexts online through the use of software and technology. An example of social computing is the use of e-mail for maintaining social relationships (Carrington, Scott, & Wasserman, 2005). There are some indices for social network analysis, which are as follows:

- **Betweeness:** Measures the extent to which a particular point lies "between" the various other points in the graph. It is the most complex of the measures of point centrality to calculate. It is the number of people who a person is connected to indirectly through their direct links.
- **Closeness:** The shortest distances between each individual and every other person in the network. The people who have the shortest paths have the best visibility into what is happening in the network.
- **Degree:** The amount of ties to other points in the network. It measures network activity for a node by using the concept of degrees.
- **Eigenvector centrality:** Measures the importance of a node in the network. It assigns relative scores to all nodes in the network.
- **Clustering coefficient:** Measures the likelihood that two associates of a node are associates themselves. Clustering coefficient graphs measure to determine if a graph is a small-world network (a class of random graphs where most nodes are also neighbours of one another) or not.
- **Cohesion:** Measures how well the lines of source code within a module work together to provide a specific piece of functionality. It is expressed as either higher cohesion or low cohesion. The advantages of high cohesion are robustness, reliability, reusability, and understandability. The disadvantages of low cohesion are difficult to maintain, difficult to test, difficult to reuse, and difficult to understand.
- **Density:** Individual-level density is the degree a respondents' ties know one another. Network/global-level density is the number of ties in a network to the amount possible.
- **Integration:** Measures of group dispersion or how network links focus on specific nodes.

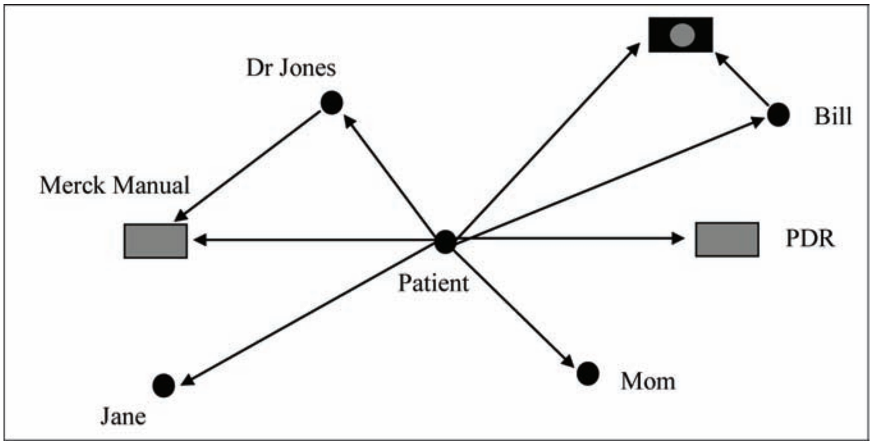
- **Radiality:** The degree in which a person's network reaches out into the network and provides new information and influence.
- **Reach:** The manner which any member of a network can reach other members of the network.
- **Structural equivalence:** The extent to which nodes have a common set of linkages to other nodes in the system. The nodes do not need to have any linkages with each other to be structurally equivalent.
- **Structural hole:** These can be filled by connecting one or more links to link together other nodes. Structural Hole is linking to ideas of social capital, for example, if you link two people who are not linked you can control their communication.

A social pyramid is a model of social relationships. Social intimacy is based on what layer of the pyramid you are on. The person with the least amount of social intimacy is placed at the foundation of the pyramid and the individual at the top of the pyramid has the highest amount of social intimacy. So on each successive layer going down, the individual has less and less intimacy. For example, a random person you interact with on the street is at the base of the pyramid, but your next of kin would be very close to the top. The philosophy of Social pyramids holds that the energy a person puts into the base of the pyramid is magnified at the top. For example, if a person gives positive energy to the people with whom they are at the base of their pyramid, it will be reflected in their personal life. Vice versa, the same can be said for the negative energy. Another type of social network is a sexual network, which is defined by the sexual relationships within a set of individuals. They can be formally studied using the mathematics of graph theory (Valente, 1996). Epidemiological studies (scientific study of factors affecting the health and illness of individuals and populations) have researched into sexual networks, and have discovered that the statistical properties of sexual networks are crucial to the spread of sexually-transmitted diseases (STDs). Social contract is a political theory that explains the basis and purpose of the state and of human rights. Within a society, all its members are assumed to agree to the terms and conditions of the social contract by their choice to stay within the society without violating the contract. The social safety net is a term used to describe a collection of services provided by the state (e.g., welfare, homeless shelters, etc.). They help prevent anyone from falling into poverty beyond a certain level. An example of how the safety net works would be a single mother unable to work. She will receive benefits to the support the child so the child will have a better chance at becoming a successful member of society. Mathematical sociology is the usage of mathematics to draw up social theories. In sociology, the connection between mathematics and sociology is limited to problems of data analysis. In mathematical sociology, the phrase "constructing a mathematical sociology" is used. This means making relevant assumptions about some mathematical objects and providing practical evaluations for ideas. It can also mean detecting properties of the model and comparing these with the relevant practical data.

NETWORK ANALYSIS

There are two kinds of Social networking analyses offering two kinds of network data. These are Ego network analysis and complete network analysis. Ego network analysis questions respondents in the form of social survey, wherein each is asked about people they interact with and relationships within and between them (see Figure 3). Clearly, random sampling would be used, that is, from a large population, and thus Ego network analysis looks at and assesses the quality of each respondent's network (size, income, age, etc). This type of network analysis lends itself to random sampling, where statistics can be used to test the hypothesis.

Figure 3. Ego network



Complete network analysis deals with a set of respondents, for example, all employees in a given company, and the relationships between them such as friendships and socialising (see Figure 4). The majority of research in Social network analysis is into complete networks, where centrality by way of subgroup examination is central and the only valid one.

Social networking involves the linked measurement of relationships between people and the product of their intellectual effort—knowledge/information. That knowledge must be seen as a "surrogate" who reflects the information released from the minds and made available for retrieval, or simply viewing as the circumstances require. This is truer than in our relationship with the computer, as an electro mechanical device which affords access to and retrieval of desired information. The computer and its operator may correctly be deemed a single node, one part active and capable of directing, the other, the computer, capable of obedience. Obedience in this context is its capacity to respond to the primary nodes' will, for example, read the work of others, study the nature and function of organisations, or to analyse a computer network and its topology. In the simplest of terms, the operator uses the computer to access particular information, or to contact a person or persons in order to gain information: a reciprocal operation (Carley & Newell, 1994).

People are used to find content, and content is used to find people, which is a reciprocal relationship, as illustrated in Figure 5.

Figure 4. Complete network

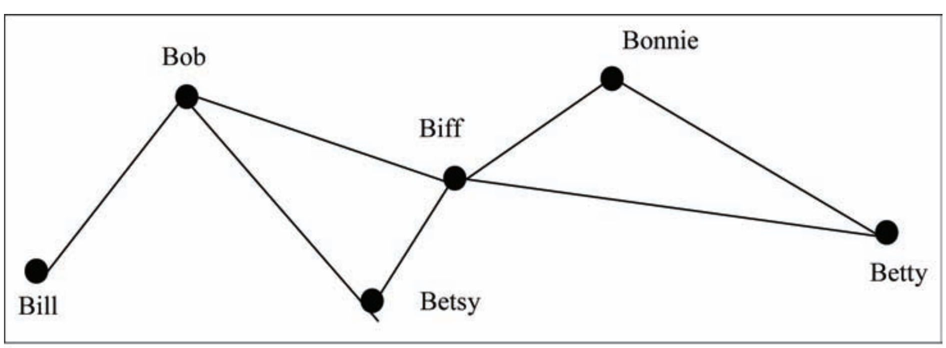


Figure 5. Relationship between people and content

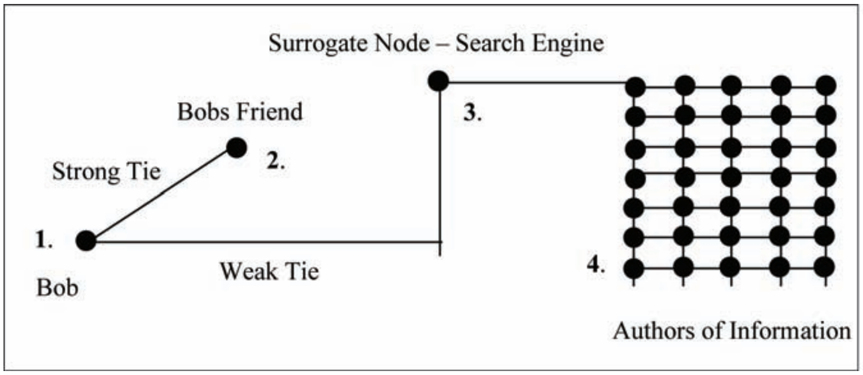


a. Bob (1.) asks his friend (2.) for information (strong tie but limited in information).
b. (2.) directs (1.) to search engine (3.) (again, a strong tie).
c. The information found here has been provided by others, the authors (4.) of the information (weak ties with unlimited information).

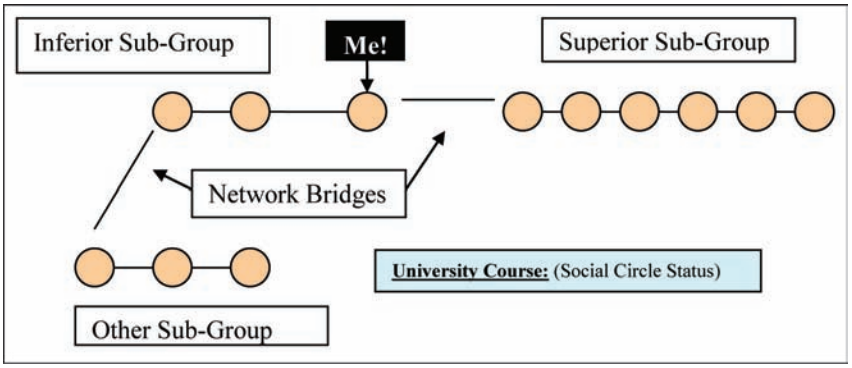
This situation reinforces network theory in that weak ties provide most information and strong ties provide limited information. Often the industrial application of social networking depends on "feedback" via hierarchical route and occasionally by way of random surveys. There have been instances when large corporations have altered policy, or procedures, or created innovations gathered from the minds of employees without those persons contribution being acknowledged. Such surveys have often produced new ideas to boast profits, or form the basic idea for a new product, capable of being produced more cheaply. So far, the computer/node links to information has been used as a simple social network example. There are, however, within computing in general and as a specialism, specific social networks where data is processed into a format useful to people and feeding "the information society," groups of people who both generate and depend on information (Wasserman, 1994). The single node/sole user consists of the combination of an animate and an inanimate node: the former the user, the latter the computer. At their interface exists almost infinite access to information and presuming the link with the ISP, the potential to become part of the network of networks, the Internet. If the operators, the animate node goes "online," and are consciously or unconsciously engaging in the social anthropology of their own environment, their own social network, and that of the "global village." In the context of networking, the node/operator has the choice of selecting strong ties with family and friends, but these limit diversity and the exploration of weak ties to the ever expanding realm of information. This node/operator, perhaps unwittingly, may enter the new world of "face to face" experiences of varied interaction (social computing), and while such social networking tends to recruit members from members, it is probable that the operator node will cooperate and enlarge the social site by inviting others from within a social network. These "introduction services" and similar social connections may be organised to include business connections. The attraction of these social sites lies in features offered, such as automatic address book updates, viewable updates, displayed feedback, and their introduction services with the potential to expand from sparse to dense social networks. It is a logical assertion that social networks are prerequisite to the creation of valuable economics and computer linked communities, and because it is in our nature to socialise, maybe its time we demonstrated this in the systems we design, for the success or failure of societies may well depend on the patterns of those social networking systems. Perhaps a good point at which to begin would be to fully study, and having fully learned, try to achieve that level of social networking which already exists in nature's lower orders: ants, dolphins, and whales (all "wireless" of course).

SOCIAL NETWORKING EXAMPLES

Social networking analysis, according to *Wikipedia.com,* is defined as "The mapping and measuring of relationships and flows between people, groups, organisations, animals, computers or other information/knowledge processing entities." This in effect means that it relates to any network of people who are known as nodes. These nodes are connected to others via associations or connections. These nodes or people connections have seven status types, which are as follows:

- **Degree centrality:** Social networking nodes relate to the degree concept. This is the number of node or people connections. This in English means the number of people that one individual knows within, say, a company or classroom or sports club. These connections can be significant and hence the following phrase of – "Having friends in higher places."
- **Betweeness centrality:** This terminology relates to the node/ individual with a bridge role between two or more subgroups. Hence, there is communication flow between the subgroups through the runner, so to speak, and this has its advantages and disadvantages.
- **Closeness centrality:** Individuals with this label in the network are in a good position as they are in the loop in relation to information flow through a network. These people know individuals and subgroup's both high and low, and because of there closeness with everyone involved they get to see what is actually going on. (Hence Manager and Supervisor team).
- **Network centralisation:** This refers to the location of certain nodes within the network and relates to the network structure or hierarchy/chain of command and shows who reports to whom.
- **Network reach:** The reach here refers to the direct and indirect connection or contacts between different networks or social circles. For instance, in the case of two networks, these are linked via the individual or nodes using direct and indirect links either directly between two individuals or subgroups linked through bridge nodes across the network.
- **Peripheral players:** These people are simply the dark horses within the network. Although these nodes are not directly connected to others, they still play a significant role in which a company would not exist without them. The classic example is a supplier of resources needed to create the overall product. The supplier works external to the organisation, but they are still valued by the company, as both must coexist to enable customer satisfaction through a high quality product being manufactured.
- **Boundary spanners:** These individuals are the key connectors to other subgroups and so these people integrate many people together and allow information transfer to flow better through more people within the network. These people are in a good position because their social circles are large, which enables them to swap ideas, and this information can be channelled effectively into quality goods and services.

Figure 6. University social network



Social Networking Example

Figure 6 illustrates a model (based on a real-life experience by one of the article authors) of a university course where there are many subgroups, including the inferior subgroup and the superior subgroup, along with another subgroup that was indirectly connected to the inferior Subgroup.

- **Degree centrality:** The total number of connections within the "Inferior Subgroup" is 3, which is the same as the "Other Subgroup" that had a total of 3 connections also. But the "Superior Subgroup" has the most connections, with a total of 6.
- **Betweeness centrality:** There are 2 nodes that act as "Bridge Individuals" and they have the role as connectors of Subgroups. Hence, the "Superior Subgroup" was connected to the "Inferior Subgroup" through me, while the "Other Subgroup" was linked to the "Inferior Subgroup" through other nodes or "Bridge Individuals."
- **Closeness centrality:** Although 2/3 of the subgroups appeared to be stable from the outside in, the "Inferior Subgroup" that consisted of a trio had barriers because 2/3 members were already friends and so they are known as "Clicks," and therefore have a closer association compared to someone whose association with them is merely as a social acquaintance. These, however, are the "Bridge Individuals" that connect subgroups together so information flow can pass throughout the entire network of people.
- **Network centralisation:** There is no chain of command structure as such, but in relation to class hierarchy the Superior Subgroup" has the most numbers in there alliance, and so they monopolise the entire network because there is strength or power in numbers. Hence, they are positioned at the top end of the network, while the other subgroups are inferior and so lower down because it is the "Superior Subgroup" that has the best information flow between its larger alliance, and so they hold the most power within the network.
- **Network reach:** The "Superior Subgroup" is connected to the "Inferior Subgroup" through the nodes that act as "Bridge Individuals." Also, the "Other Subgroup" is connected to the "Inferior Subgroup" through the "Bridge Individuals," and so it is these bridge nodes that allow for Network Reach as they connect up the different Subgroups and enable information to be passed through the network.
- **Peripheral players:** There are none in this social network because "Peripheral Players" refers to suppliers whose network is external to a company, although if any

Sub-Group individual had connections with computer students higher up in the university, they could use these contacts to there advantage by seeking help from advanced students and this information flow could benefit any Subgroup, but this is beyond the scope of this article.

- **Boundary Spanners:** This basically relates to nodes that connect other Subgroups together to allow the passing of information between the networks, and hence the class network diagram has four Boundary Spanners or the two pairs of "Bridge Individuals."

Here, we see that initially the number of students was large enough to fill a lecture theater. However, as the course progressed, more and more students left, and as the numbers decreased, the social circles became more evident. Therefore, in subsequent years, the competition was even fiercer because the numbers were so small that every subgroup knew who each other was. With the smokescreen gone, the social politics were more serious, for the numbers were whittled down to the elite, those who really wanted to be there. Now that there were subgroups formed by individual students, these groups would have their own status between the in-group. For example, when it comes to a group assignment, if the numbers are inadequate, then any individual may take the initiative to find someone to make up the numbers, but this is not always in the control of the group, for the lecturer may intervene to make up the numbers for an assignment, and if new subgroups are not formed, then existing groups are added, and these groups expand via the new individual who joins the subgroup, but the status battle continues. Thus, the ability for the group to gel as a whole may determine the outcome of the group assignment, for personality clashes may affect the team to work together as a whole, and so the big question is whether or not any new members get along with the established subgroup or not. The level of success or failure may go down to the balance of power within the group, and the best way to explain this is by the common phrase of the word "Cliques," for if members in a group are friends, then they are likely to stick together, and if they are in the majority they can control group activity to there own favor at the cost of minority individuals.

CONCLUSION

Social networks are social structures made up of nodes and ties. They indicate the relationships between individuals or organisations and how they are connected through social familiarities. They are very useful for visualising patterns. The use of mathematical and graphical techniques in social network analysis is important to represent the descriptions of networks compactly and more efficiently. They operate on many levels and play an important role in solving problems and on how organisations are run, and they help individuals succeed in achieving their targets and goals. In today's society, social networks allow two people in different locations to interact with each other socially (e.g., chat, viewable photos, etc.) over a network. They are also very important for the social safety net because this is helping the society with the likes of the homeless or unemployed. Group politics relate to "In-Groups" and "Out-Groups," as each competes with each other. Social Networking is all around us and so there is always going to be friends and casual acquaintances, both within the subgroups and outside it. These status types link all subgroups together, as well as the internal structure of a group. Hence, there are direct and indirect connections to link everyone together within a work place, classroom, and sports club to online social circle Web sites like *Bebo.com*. Both these status types affect productivity, and so individual competition aside, success is determined by how well everyone involved can work toward a common goal.

KEY TERMS AND DEFINITIONS

Betweeness: Measures the extent to which a particular point lies “between” the various other points in the graph. It is the most complex of the measures of point centrality to calculate. It is the number of people who a person is connected to indirectly through their direct links.

Closeness: The shortest distance between each individual and every other person in the network. The people who have the shortest paths have the best visibility into what is happening in the network.

Degree: The amount of ties to other points in the network. It measures network activity for a node by using the concept of degrees.

Cohesion: Cohesion measures how well the lines of source code within a module work together to provide a specific piece of functionality. It is expressed as either higher cohesion or low cohesion. The advantages of high cohesion are robustness, reliability, reusability, and understandability. The disadvantages of low cohesion are difficult to maintain, difficult to test, difficult to reuse, and difficult to understand.

Network Density: Individual-level density is the degree a respondent's ties know one another. Network/global-level density is the number of ties in a network to the amount possible.

Network Integration: This measures a group dispersion or how network links focus on a specific nodes.

Network Shape: The shape of the social network helps determine a network's usefulness to its individuals. Smaller, tighter networks can be less useful to their members than networks with lots of loose connections to individuals outside the main network.

Radiality: The degree in which a person's network reaches out into the network and provides new information and influence.

Reach: The manner which any member of a network can reach other members of the network.

Social Network: A network is a social structure made of nodes, which are generally individuals or organizations. It indicates the ways in which they are connected through various social familiarities, ranging from casual acquaintance to close familial bonds. The maximum size of social networks tends to be around 150 people and the average size around 124. Social network theory views social relationships in terms of *nodes* and *ties*. Nodes are the individual actors within the networks, and ties are the relationships between the actors..

Structural Equivalence: The extent to which nodes have a common set of linkages to other nodes in the system. The nodes do not need to have any linkages with each other to be structurally equivalent.

Structural Hole: These can be filled by connecting one or more links to link together other nodes. Structural Hole is linking to ideas of social capital, for example, if you link two people who are not linked, you can control their communication.

ABSTRACT

A social network represents a set of social entities that interact through relationships like friendship, co-working, or information exchange. Social Network Analysis studies the patterns of relationships among social entities and can be used to understand and improve group processes. The arrival of new communication tools and networking platforms, especially the Web 2.0 Social Networking Services, opened new opportunities to explore the power of social networks inside and outside organizations. This chapter surveys the basic concepts of social networks methods, approaches, tools, and services. In particular, this chapter analyzes state-of-the-art social networks, explaining how useful Social Network Analysis can be in different contexts and how social networks can be represented, extracted, and analyzed in information systems.

INTRODUCTION

The notion of a social network and the methods of social network analysis (SNA) have attracted considerable interest and curiosity from the social and behavioral science communities in recent decades (Wasserman and Faust 1994). Social Network Analysis (SNA) has been used as a powerful tool in organizations to understand the connections and influences both inside and outside the organization as well as how these connections affect the performance of core processes.

A social network is generally defined as a set(s) of actors and the relationship(s) defined among them. Actors, also defined as social entities, can be individual or collective social units that are connected by links. Links constituting a social network may be directed or undirected, but they can be categorized as confirmed or unconfirmed based on the confirmation of the relationship by both actors (Cross and Parker 2004). The relationships between actors can be also classified based on cardinality: a dyad is a linkage or relationship between two actors and a triad involves a triple of actors and associated ties.

In structural terms, there are different kinds of social networks: one-mode networks study just a single set of actors, whereas two-mode networks focus on sets of actors and one set of events. Dyadic networks and affiliation networks are examples of two-mode networks (Wasserman and Faust 1994). An ego-centered network is an example of a one-mode network and consists of a local actor (termed ego), a set of alters who have ties to ego, and measurements of the ties among these alters (Wasserman and Faust 1994). Subsets or subgroups can be identified and studied separately in the network. A clique designates a subset of a network in which the actors are more closely tied to one another than they are to other members of the network (Jamali and Abolhassani 2006).

Both social actors and links may have additional attributes that express additional information about them. Such attributes include the relationship role played by the entity (Masolo, Vieu et al. 2004), more information about the entity, or the relationship between nodes.

The introduction of computational methods opened new opportunities for the use of social networks by allowing the analysis of larger datasets. This analysis facilitates the addition of social networks as well as their automatic extraction from existing information repositories.

Web 2.0 popularized the concept of the semantic web. Several social communities permitting users to connect and share information and knowledge with their friends or the whole community appeared.

This chapter presents the tools and methods for correctly extracting a social network and representing it in a form that can be later analyzed. After that, different software tools for performing SNA are analyzed. With regard to the organizational context, the Web 2.0 social networking services phenomenon is developed. Several examples of known worldwide platforms are presented and compared, and we show how organizations are using these tools to improve connections and knowledge sharing inside organizations. We discuss also our vision about what the future can bring to this field with the integration of different platforms and methodologies. Finally, we present SNARE (Social Networking Analysis and Reengineering Environment), a system we are currently developing that proposes to integrate Organization Network Analysis and Social Networking Services with different approaches and techniques. We conclude with our vision of the major concerns in these topics and how they are related to the general topic of the book.

BACKGROUND

Social Network Analysis represents a method for achieving analytical results about almost any group interaction in which social entities are present. This section introduces SNA and its most common measures and explains its use in the organizational context.

Social Network Analysis

The roots of SNA techniques were affected by three main influences beginning in 1930s. The most notable influence was Jacob Moreno, who investigated how an individual's group relationships affected his own actions and development. Moreno was credited of devising a sociogram as a way to depict such social relationships (Fredericks and Durland 2005). Most of the concepts and techniques were introduced in the 1950s by work done in the fields of sociology, anthropology, mathematics, networks, and graph theory. Even, if it was not always considered a theoretical field, the arrival of computer methods and the automatic analysis of large quantities of data gave SNA new importance. Since then, it has been the subject of studies and applications from widely diverse fields of study (Borgatti and Foster 2003).

In the 1990s, network theories emerged in virtually every traditional area of organizational scholarship (e.g. leadership, power, turnover, job satisfaction, job performance, entrepreneurship, stakeholder relations, knowledge utilization, innovation, and profit maximization) (Borgatti and Foster 2003).

SNA is now used wherever a social network is present, and its study can be interesting for understanding and improving any group process. Recent projects applied the same methods in the following totally different social network contexts:

- Economy (the analysis of economic relationships between countries (Krempel and Plümper 2002))
- Health (the analysis of social networks in epidemiology studies (Chen, Tseng et al. 2007; Rubeis, Wylie et al. 2007))
- Politics (the analysis of the political relationships in a congress (Fowler 2006))
- Academic research (the analysis the research network on a continent (Besussi 2006))
- Leisure and sport (the analysis of all the actions performed among all players on a football team during a game (Bundio and Conde 2004))
- Organization improvement (the identification of tacit knowledge in enterprises (ZHU, SHAO et al. 2007))
- Marketing (the analysis of customer preferences for buying certain items (Kappe 2006))
- Fight against crime and terrorism (Tsvetovat and Carley 2005).

Social Network Analysis is also the focus of associations (INSNA, INSNAE), conferences (SUNBELT), and journals (JOSS, Social Networks and Redes).

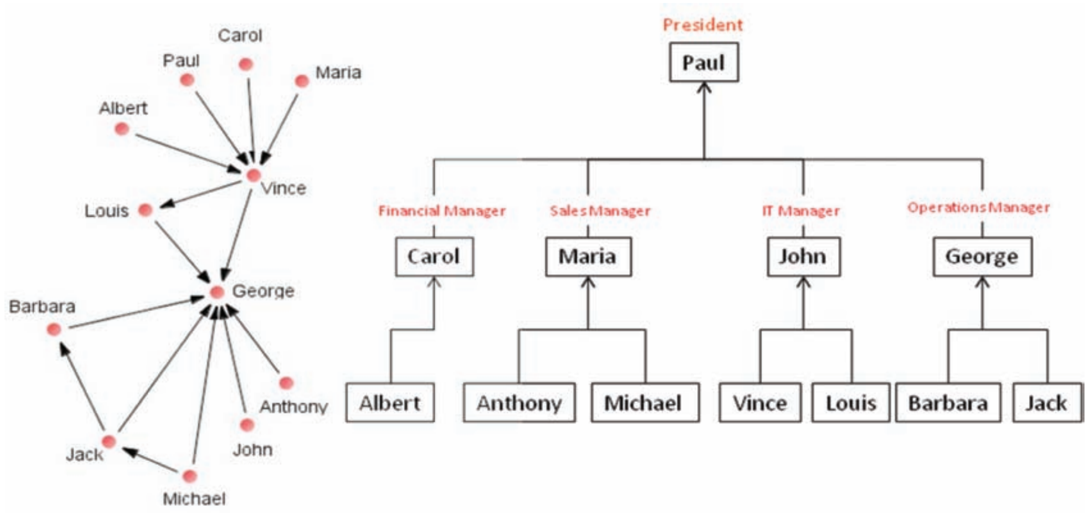
SNA Measures

To perform SNA, it is necessary to define measures that can be compared between actors or networks. Measures in SNA can be distinguished as those that evaluate the entire network and those that evaluate only a specific node (Wasserman and Faust 1994).

At the individual level, the most frequently analyzed measure is *centrality*. This measure evaluates an actor's position in the network and can be interpreted as the prominence of an actor in the social group. It can be measured using: (1) *nodal degree* (number of nodes adjacent to a node, with ties from it, or with ties to it), (2) *betweeness* (the number of times a person lies along the shortest path between two others), and (3) *closeness* (how far a person is from all others in the network). Other important concepts are the *geodesic distance* (the shortest distance between one node and another in the graph) and the *structural equivalence* (the extent to which an actor shares the same set of links with another).

At the network level, it is important to understand how the network is structured. *Clustering* measures the ease of partitioning the graph into a finite number of subsets: a higher clustering coefficient indicates greater separation between the groups in a network. *Centralization* is directly connected with the notion of central nodes: a more centralized network indicates that most of the ties are dispersed around one or a few nodes. *Path Length* is defined as the average of the distance between all pairs of nodes. *Cohesion* measures the percentage of actors directly connected to each other by cohesive ties. Directly linked with this concept are the members who would disconnect the group if they were removed. These kinds of nodes are called *cutpoints*. Ties that disconnect parts of the graph when removed are called *bridges.*

Figure 1. Example of differences between an organizational chart and real relations (adapted from Cross and Parker, 2004)



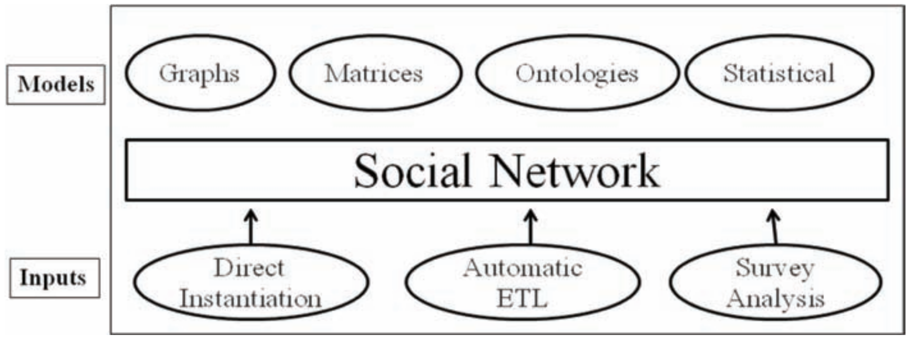
Organizational Network Analysis

The need for more agile, flexible, dynamic, and polyvalent organizations and employees in locations where organizational change is a daily routine, and the rise of new ways of working, collaborating and interacting has caused Social Network Analysis to become a "must-have" tool for analyzing communities and groups. Management consultants use this methodology with business clients and refer to it as Organizational Network Analysis (ONA). As Rob Cross states in his book, real organizations are typically different from those expressed in organizational charts (Cross and Parker 2004). A company's hierarchy topology is represented in Figure 1 along with the relationships extracted by internal questionnaires. Looking to the sociogram, we can understand that actors in lower hierarchical positions can have great importance inside the organization due to their knowledge, role, or personal relationships with other peers.

Factors like gender, age, ethnicity, and education can drive people to communicate primarily with peers who do not have relationships with them in the organizational chart or are not connected to their organizational role. The same reasons, when introduced into department and project separation, can produce a lack of communication, lack of awareness of resources, and lack of collaboration between actors within a company. Conversely, the excess of importance of an actor can bottleneck the entire organization. SNA is a powerful managerial tool because it makes visible the patterns of relationships within and across strategically important networks (Cross and Parker 2004).

Social network analysis can be used in an organization to better understand the social capital (connections within and between the network) (Borgatti and Foster 2003), support partnerships and alliances (Cross and Parker 2004), measure the degree of embeddedness of the actors as well as actors' importance in the network, support knowledge management policies, identify who really knows what in the company (Helms and Buijsrogge 2005), integrate networks across core processes, promote innovation, integrate new members or organizational changes, support the development of informal communities of practice,

Figure 2. Different approaches for capturing and representing a social network



improve leadership effectiveness, replicate high performance throughout an organization, and understand and improve the disconnects between groups in the organization or between groups and the outside world (Cross and Parker 2004).

TOOLS AND SERVICES

Several software packages that support Social Networks Communities or perform SNA are available. The packages can range from complete software to analyze and visualize social networks to systems that permit the design and execution of surveys and then use the data obtained to perform a full network analysis. Other systems allow the automatic discovery of network information via mining a data repository or communications gateway. As depictured in Figure 2, this section surveys approaches and formats for representing Social Networks as well as approaches, tools, and services supporting Social Network Analysis.

Representations

Most common forms of representing and analyzing social networks work through (1) descriptive methods (e.g. text or graphs), (2) analysis procedures based on matrix operations presented in data files with proper formats or ontological representations, and (3) statistical models based on probability distributions. One reason for the use of mathematical and graphical techniques in SNA is their ability to represent the descriptions of networks compactly and systematically (Jamali and Abolhassani 2006).

Graphs

Graph theory provides a vocabulary that can be used to label social structural properties: points called nodes are used to represent actors, and lines or arrows connecting the points are used to represent links. A graph is called directed when its edges have a direction, and it is called undirected when they do not. Visual representation of graphs can be used to center in the screen the most connected actors in the network, isolate in the periphery the less connected, and alter the actor and tie sizes in order to represent more or less importance in the network. It thus offers a powerful tool for uncovering patterns in the network (Cross and Parker 2004).

Matrices

Matrices contain the same information as graphs but are more suitable for calculation in the analysis. The adjacency list is the primary matrix used in SNA and is usually referred as the sociomatrix. Actors occupy the first line and first column of a matrix composed of as many rows and columns as there are actors in the dataset, and cells have a positive value when relations are present.

Ontologies

Conceiving ontologies (explicit specifications of the conceptualization of a domain) as engineering artifacts permits their objectification, separation from their original social context of creation, transferation across the domain (Mika 2005), and export to other sources. GraphML (Brandes, Eiglsperger et al. 2002) is a language for modeling graphs that can be adapted to represent social networks. FOAF (Miller and Brickley 2000) is a machine-readable ontology describing people, their activities, and their relationships to other people and objects. hCard (Çelik and Suda 2004) is a format for publishing contact details of people, companies, organizations, and places that is used to import and export data in social networking websites. DyNetML is a universal data interchange format that enables the exchange of rich social network data and improves the compatibility of analysis and visualization tools (Tsvetovat and Carley 2003; Diesner and Carley 2005).

Statistical Models

Statistics models enthusiasts argue that it is most fruitful to consider models where network evolution is represented as the result of many (usually unobserved) small changes made at discrete times occurring between consecutively observed networks (Carrington, Scott et al. 2005). That kind of model describes the evolution of local structure, global connectivity, search ability, and highly skewed degree distributions as mathematical formulae that can be predicted and analyzed. Recently, there has been a growing interest in exponential random graph models (ERGMs) (Robins, Pattison et al. 2007) that describe a general probability distribution of graphs on *n* nodes and consider the possible ties among nodes of a network as random variables.

Social Networks Tools

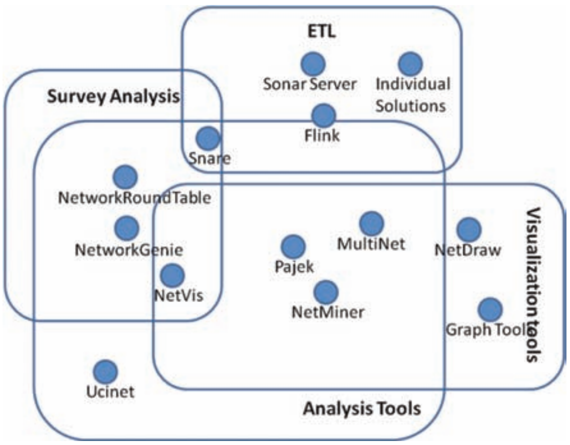
The common way to extract a social network is by instantiating it directly through SNA software packages. However, it is also possible to automatically extract Social Networks from information gateways or through automatic survey analysis. Figure 4 represents the most important tools organized by their main scope of application. Most of the software packages analyzed share common features to extract, analyze, and visualize social networks.

Visualization and Analysis Software

Ucinet (Borgatti 2002) is probably the best-known and most frequently used software package for the analysis of social network data (Wasserman and Faust 1994). It is a commercial product developed by Steve Borgatti's team, but an evaluation version is available for 30 days. Ucinet uses datasets as collections of matrices, can import data in various formats, and has a spreadsheet editor to permit data manipulation. Ucinet works as a graphical application and is distributed with a user manual and reference guide for social network analysis. It contains a large number of network analysis methods, such as analysis procedures for computing centrality degree, ego network analysis, and the detection of subgroups and structural holes in both the entire and parts of the network. It includes statistical procedures and can handle two-mode network transformations and analysis. Ucinet does not contain graphic procedures or visualization techniques, but it can export directly to NetDraw (developed by the same team and included in its package) or other formats. (See Figure 3)

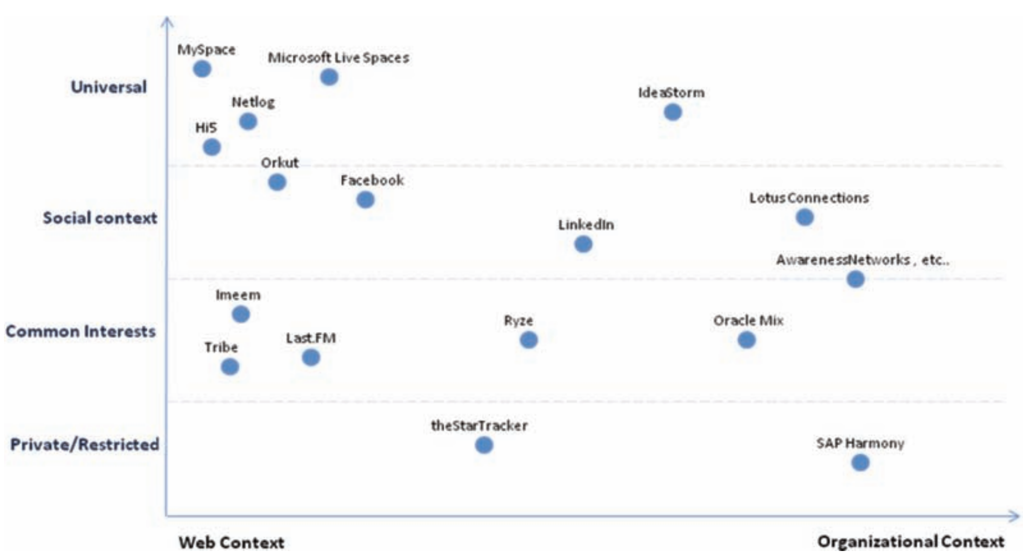
Pajek is a free software developed by the University of Ljubljana and is designed to handle large data sets (Batagelj and Mrvar 2008). It is distributed with a reference manual containing a list of commands and operations, but there is also a textbook about SNA theory, applications, and the use of Pajek in network analysis (Nooy, Mrvar

Figure 3. Main scope of Social Network Software



et al. 2005). Data can be entered directly into the program by 1) importing ASCII network data from network files, 2) importing data with other formats (e.g. UCINET), or 3) opening a Pajek project file (.paj) that combines all the data structures supported in one file. Pajek permits the manipulation of all of its structures (e.g. of the transposition of networks, change of directionality in graphs, or extraction of networks). Advanced visualization techniques are present in Pajek: network drawing is based on the principle that distances between nodes should reveal the structural pattern of the network. Pajek uses spring-embedding algorithms that seek a configuration of the bodies with locally minimal energy; they seek a position for each body such that the sum of the forces on each body is zero (Eades, Battista et al. 1999). The algorithms from Kamada-Kawai (Kamada and Kawai 1988) and Freuchterman-Reingold (Fruchterman and Reingold 1991) are good examples of this kind of technique. Graph images can be exported to traditional image formats. In Pajek, descriptive methods are also present and include: the computation of degrees, depths, and cores; centrality (closeness, betweeness); the detection of components, paths, structural holes, and some binary operations in twomode networks (Carrington, Scott et al. 2005). Unlike Ucinet, Pajek has no direct procedures for detecting cliques due to the difficulty of this procedure for large networks. However, it contains a p-cliques procedure that partitions the network nodes into clusters such that the nodes within one cluster have at least a proportion of p neighbors inside the cluster. Some statistical procedures are also available, and Pajek can invoke directly statistical software.

Figure 4. Social networking services scope



Netminer is a commercial product developed by Cyram and contains analysis and visualization techniques (Cyram 2007). NetMiner has an innovative data model composed of a dataset of various unit data designed to represent almost every feature of network data. NetMiner has the easiest and simplest user interface of all of the software in this category, and almost all of its results are presented both textually and graphically. Constructing new datasets out of nodes and links on a visualized network map for subgroup analysis can be easily achieved by mouse-dragging on the network map without time-consuming main menu navigation. Network-drawing can be based on spring-embedding algorithms, multidimensional scaling, analysis procedures (e.g. centrality), and simple procedures (circle, random). Built-in standard statistical procedures and charts are also integrated in NetMiner.

Survey Analysis Platforms

The problem present for software introduced in the last section is that this software requires the analyst to insert data gathered through other means (e.g. interviews, surveys, or observation) into specific formats. Other kinds of tools, including initial surveys to infer relationships in a network, have appeared to aid SNA.

Netvis is a web-based tool distributed as an open-source program to analyze and visualize social networks using data from comma-separated value files (csv) and surveys (Cummings 2008). The software permits the registration of actors present in the network, and then it allows users to define a survey and use the data received from the answers to perform a social network analysis. Although the software itself has standard procedures to analyze and visualize networks, it can also export data to most common formats.

A team at University of Virginia's McIntire School of Commerce headed by Research Director Rob Cross developed an application called Network Round Table. Most of the content and documentation is not public and is only available to clients who subscribe by paying an annual fee; however its features, steps, and procedures are available on the website. Based on an organizational perspective, the software permits an analyst to register or import all of the actors into the system, join them into teams or groups, and assign them roles. After that, the analyst can create a survey with questions to infer all of the social relationships in the network as well as their strength or frequency. The software is powerful enough to direct specific questions and answers to specific actors or groups, and questions can be open-ended, rating scale type, multiple-choice, order importance choice, or nested in groups. The analyst can explain how each question is important and what he wants to infer from the analysis of the answers. After the survey's activation, the users registered receive an email directing them to visit a web address and properly complete the survey. The analyst can check the status of the survey; when he gets a satisfactory amount of answers, he can close it. After closing the survey, an individual action plan is available to all actors with the analysis of their own answers. The analyst can view and analyze the results of the complete network. There are options available to export the data to the most common formats, but simple direct analyses are also present in the software. The analyst can also view, edit, annotate, or delete individual answers and filter them by parameters. The team states that the personal network feedback enables by itself each actor to assess his connectivity within the network and improve it by planning changes. The feedback is delivered either on paper that can be analyzed in group meetings or in an online action plan that allows actors to annotate and plan actions to increase connectivity.

Network genie is an online application developed by Tanglewood Research for designing and managing social network projects. It includes the design of surveys and survey questions, the management of social network projects, the collection of social network survey data, and the import/export of data to SNA software.

The main objective of this kind of software is to gather information from surveys and automatically export data to the most common software applications for SNA.

Platforms to Social Networks Extraction, Transformation and Load

More recently, the use of electronic data extraction became popular in the study of social networks. While traditional survey or interview methods are limited by the size of networks and the number of measurements (time-points), gathering electronic data enables large scale, longitudinal studies of networks (Mika, Elfring et al. 2006). Automatic detection of relationships is possible from various sources of information, such as e-mail archives, schedule data, and web citation information (Matsuo, Mori et al. 2006). What this kind of systems proposes is to 1) gather information from a large collection of data, 2) identify and disambiguate social entities, and 3) understand both the links between them as well as their strength, periodicity, and probability.

The SONAR platform developed by Trampoline Systems proposes to plug into a corporate network and connect to existing systems like email servers, contact databases, and document archives to extract and analyze data to build a map of social networks, information flow, expertise, and individual interests throughout the enterprise (TrampolyneSystems 2008). The platform consists of several functional modules that can be combined as required by each customer; all information is available to managers, and personal data is available to users.

Flink, the best semantic web application at the semantic Web Challenge of 2004 in ISWC2004, was developed by Peter Mika's team and supports the complete process of data collection, storage, and visualization of social networks based on heterogeneous sources of electronic data (Mika, Elfring et al. 2006).

Data comprising social networks tend to be heterogeneous, multirelational, and semi-structured (Han and Kamber 2006). Link mining is an emergent field of research with contributions from many areas that can help in social network mining. It can be used to classify entities based on their links, predict the type or even the existence of links and their evolution, and detect subgroups and properties common to some group (Han and Kamber 2006). Polyphonet (Matsuo, Mori et al. 2006) is a social network mining system that has been used at four academic conferences in Japan to infer the relationships between authors, reviewers, and participants. It is a good example of the use of link mining, because it uses web search engines to understand and measure the connections between people via balanced coefficient that define relationships.

SOCIAL NETWORKING SERVICES

Although the Web itself is an example of a social network and the formation of communities is one of its most important achievements, the Web 2.0 boom brought the possibility of group information sharing to users via the spread of wikis, forums, blogs, and social networking communities. Although these websites feature much of the same content that appears on personal Web pages, they provide a central point of access and bring structure in the process of personal information sharing and online socialization (Jamali and Abolhassani 2006). People can register or be invited to these websites. After uploading information about themselves, they can upload photos, join groups of people, and connect to other friends or people with similar interests. People become organized in networks or groups and can see each other's profiles, relationships, and actions in the network. Most of these websites allow people to upload and tag photos, share files, post in blogs, and interact in other ways with their peers. (See Figure 4)

Community-Wide Services

According to web statistics (HitWise.com), Myspace is still the dominant social networking service and has more than 200 million users registered (Alexa.com 2008). It is also the sixth most popular website in the world. Founded in 1999, MySpace offers to its users features like profile customization, comments, and the ability to post videos and music and participate in groups and bulletins. Apart from these functions, MySpace offers users an instant message service, a classified ads system, news, and a video sharing system.

Founded in February 2004, Facebook.com was initially open only to college students; today, it has more than 70 million active users and 55,000 networks. The website permits people to register and join a university, workplace, or village network, upload information and photos, tag photos, organize and join events in the network, and exchange messages and other content with friends' networks. Facebook's Platform API enables anyone to build complete applications that users can join and use with their profiles and friends network, opening new opportunities for development of new concepts using the social network. To date, 12000 applications have been built on Facebook platform. Other facts about Facebook are impressive: the number of active users doubles every 6 months; more than half of the active users return daily; people spend an average of 20 minutes on the site daily. (See Table 1)

Friendster.com, with almost 50 million registered users, is a very important website in Asia and has recently developed a public API as Facebook that permits the growth of the community. In Europe, Netlog.com has more than 32 million registered users and Hi5.com has 50 million users.

Big enterprises are also already in this market: Microsoft has Live Spaces, Google has Orkut.com, and Yahoo has Yahoo 360º .

Specific networks oriented to people with similar interests (e.g. Tribe.net, iMeem, Last.fm), people who want to find old friends (e.g. classmates.com, graduates.com), people who want to share photos with friends (Flickr.com), or people who want to join in charity projects (SixDegree.org) also exist.

According to Hitwise.com, 6.5 percent of all Internet traffic in February 2007 in the world was generated by this kind of social networking website. According to Nielsen/NetRatings (another web statistics website), social networking sites are the reality television of the Internet. In Portugal, the most frequently used social networking website is Hi5; this was the most frequently visited website in Portugal in 2007 according to Alexa.

Even if few social networks currently charge money for membership, the fact that these kinds of communities are constantly renewed by their members and organized in networks by interests, location, or situation means that these websites can sell specific ads to specific groups. This is quite appealing for investors and can extend the context of these communities even further in the future. There is also a tendency to define a standard way to exchange data between these services. Google OpenSocial (Google 2008) provides a common set of APIs for social applications across multiple

Table 1. Most popular social networking services

	Users (Millions)	Notes
Myspace	200	Oldest and most famous SNS. Sixth most visited website in the world.
Facebook	70	Has the most rapid current growth. The number of users doubles every six months.
Friendster	50	Used particularly in Asia.
Hi5	50	Most visited website in Portugal in 2007.
Netlog	32	Used particularly in Europe.

websites and is supported by some social networking websites. It is composed of three APIs that permit programmers to access core functions and social network information like profiles, friends' information, and activities.

Some concerns are being raised due to the success of these communities. These include concerns about users giving out too much personal information, lack of privacy, and fake content and profiles. Information posted on sites like MySpace, Hi5, and Facebook has been used by the police to prosecute users.

Social networking services can be also used in a more oriented professional context. LinkedIn is a website where people can post their professional experience as well as share and connect with others with the same interests, professional background, or company. Ryze is designed to link business professionals, particularly new entrepreneurs. The site claims to have over 250,000 members in 200 countries, with over 1,000 external organizations hosting subnetworks on the site. The Portuguese website theStarTracker allow its members to join communities of Portuguese people working abroad and understand what they are doing.

It is not easy to explain why different services have different popularities in different countries and cultures. Each service is mainly used by a certain type of community or culture. ValleyWag published in 2007 a world map of social networks according to their use in different countries. Even though MySpace is still the global leader, different websites are more popular SNSs in different regions.

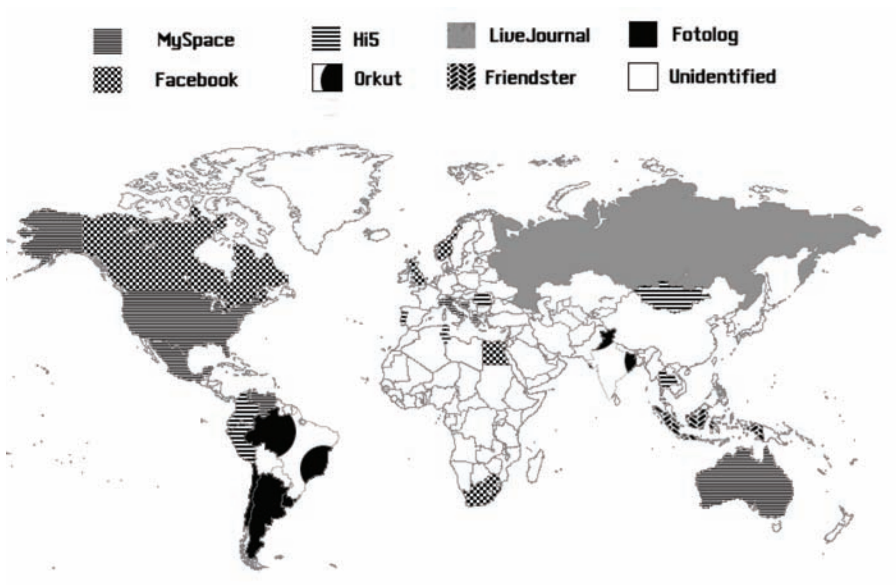
Organization-Wide Services

Big companies have begun to understand the power behind this kind of system for sharing knowledge, experience, and practices inside and outside their companies. In November 2007, a team in Oracle launched Oracle Mix (Oracle 2007). Oracle Mix is a social network for oracle developers, partners, employees, and customers that allows them to share the best practices, experiences, and ideas. Dell also developed a similar system called IdeaStorm (Dell 2007), which is used by customers to share ideas with the company and receive feedback from the community. Sap developed an internal system called Harmony that is already being used by SAP Labs users behind the firewall. IBM went further, introducing in July 2007 the Lotus Connections Suite. This software suite permits a company's employees and partners to register profiles, share ideas, experiences, activities, and resources about company products as well as what they are doing in the company, and create new communities. IBM uses this suite inside the company as the company yellow pages. Even SharePoint 2007, a collaboration suite from Microsoft, already has some business social networking capabilities like user profiles, people search facilities, and tools like wikis and blogs; it is expected to be expanded by a social networking driver. Other firms like AwarenessNetworks and HiveLive are also developing this kind of social networking applications for enterprises. (See Figure 5)

FUTURE TRENDS

The integration of social network-based platforms is already a reality, and their use should prove effective to organizations that adopt them. Platforms that gather social communities, social network analysis, and knowledge management features would be an amazing information broker inside the organization. They would offer a powerful directory in which knowledge and expertise is easy to find, and they would centralize information and reduce the distance between departments and groups inside the organization. Additionally, these platforms would also be a powerful decision tool to help managers understand the real connections and daily activities developed by their employees. By joining the best of these two worlds, organizations would gain a real notion of what is going on

Figure 5. The world map of social networks (Adapted from Valleywag, http://valleywag.gawker.com/tech/notag/the-world-map-of-social-networks-273201.php, published June 27th, 2007 © Gawker Media 2007. All rights reserved. Used with permission.)



inside and outside their walls; employees would have access to a new tool to increase their productivity and provide precious information that would be covered in other ways.

However, copying or adapting existing social networking services is not sufficient. These kind of joined platforms that can be referred to as Social Networking Services for Enterprises (SNES) have different requirements than normal social networking systems do. They need to be used in an organizational context, and they should be used to increase productivity. They should be extremely secure, and privacy should be a major concern. Users should be able to feel secure and in total control of the information they share.

Organizations already have their own information systems, and SNES should plug into them to make sure that information is automatically and constantly retrieved. This represents a huge challenge because of the heterogeneity of tools, servers, technologies, and software present inside organizations. SNES should plug into mail servers, workflow applications, client relation management systems, phone logs, or other information systems that employees or customers use to communicate or work.

Systems should adapt to an organization's characteristics and workflow processes to provide increased value to employees and departments instead of creating unnecessary entropy inside an organization's walls. Employees should recognize a system's value before they begin using that system. These systems should contain important information even without the contribution of organizational actors. However, actor contribution is fundamental for success, so different modules should be present in order to promote strong connections among actors. These modules could include bulletin boards, profile pages, groups and communities of practice, messaging, the ability to find people based on their interests, departments, or related work, easy content sharing using wikis or blogs, and other popular Web 2.0 tools.

Following these concerns, we are currently working on the SNARE project (Barão and Silva 2008) to design and develop a suite of software tools to be used in organizations to analyze and capture social networks. The SNARE system provides social network features in information systems not originally designed for this effect. SNARE is also able to capture existing social networks by analyzing answers to surveys and inferring relationships and properties. These questions focus mainly on how people trust, rely, and work in the organization; they can thus be useful for analyzing the way people understand each other in the organization.

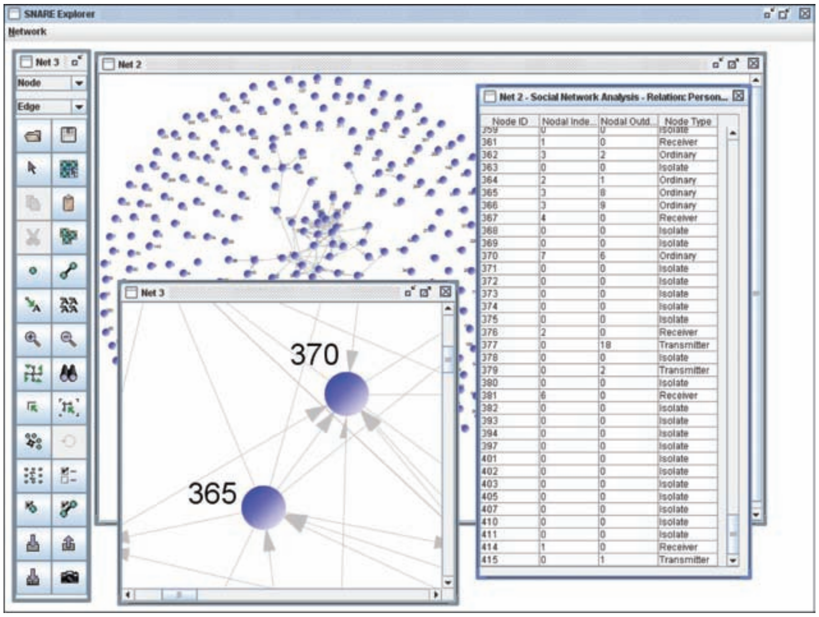
SNARE architecture is composed of a core application in which other applications can connect through web services. WebSNARE is a web application designed to help managers and consultants construct social communities, define social entities (persons, groups, and external entities), define the type of relationships and their instances, and enrich relationships and social entities with customized properties. Managers can also define surveys to apply to the network in order to infer relationships from the answers given. Every social entity can have a unique system login, so users can update their personal data or answers to surveys after seeing after their personal results. In addition to these functions, SNARE can be used like the usual Social Networking Systems: social entities can connect to each other and define what they do together. Each user is able to search in the organization by some context or name and retrieve the content required. Users can also organize and join groups (e.g. groups based on interest or communities of practice inside the organization). Users are able to publish and retrieve content in their profiles or network pages.

In addition to the ability to promote networking and knowledge sharing inside the organization, SNARE can also perform Social Network Analysis on relationships defined by users or extracted from surveys. Managers can identify bottlenecks inside organizations or specific groups, highlight social entities with specific properties, and use SNA measures to analyze different domains or enterprises processes. SnareExplorer is a stand-alone application that is used to visualize and analyze social networks and can import and export data directly to SNARE.

SNARE ETL Services provide a technical interface-to-Desktop ETL Tool. This desktop application defines and controls ETL actions and has a required interface for executing SNARE Service methods. The aim of this component is to extract relevant social network data through ETL mechanisms. This tool allows users to specify transformations through a graphical user interface. Data transformation can involve the following: (1) smoothing, which works to remove noise from data, (2) aggregation, which involves summary operations applied to the data and is typically used in constructing a data cube for the analysis of data at multiple granularities, (3) generalization of the data, where low-level data are replaced by higher-level concepts through the use of concept hierarchies, (4) normalization, where attribute data are scaled so as to fall within a small specified range, and (5) attribute construction, where new attributes are constructed and added from the given set of attributes to help the mining process (Han and Kamber 2006). This module can be used to plug SNARE into different existing systems and constantly update data that can be analyzed. Future work will be done in this field, and different modules will be developed in order to achieve integration with common systems. (See Figure 6)

SNARE is already being applied in some projects and tested in different contexts and with different goals. The SNARE model is able to represent relationships in almost any context and enrich them by populating relationships and entities with customized properties. The ability to join entities and relationships with temporal or contextual similarity is a powerful advantage and will be fundamental for achieving the richest analysis. It will better support reengineering in organizational contexts while it promotes networking and information sharing inside organizations.

Figure 6. Snare Snapshot



CONCLUSION

Social Networks are not a new or recent concept. However, Web 2.0 evidence suggests that they now constitute an emergent field of study. The way people connect and work in enterprises brought a new drive SNA and changed its main goals. Using traditional concepts, studies conducted in many subjects and areas uncovered interesting aspects. Now, the challenge is to create systems that are able to represent, extract, and analyze social networks in the context of enterprise information systems.

There is not a perfect way to take a snapshot of social relationships, and all methods present some problems and limitations. Surveys can be manipulated by who is answering. Direct observation does not permit understanding of all relationships present in a group, and the most important relationships cannot be extracted from information gateways like email servers. The combined application of these techniques can, however, provide the best approach to represent and analyze a social network.

Social Networking Services are also a key player in this field. They began as just a new way of connecting people but are already being used in organizations. Companies who use them understand that injecting trust into the equation lowers the barrier to entry and sharing ideas. Employees and customers find these systems useful and fun to use, and that permits a new way to connect inside and outside the company. The future will show what benefits social networking tools and services provide when they care connected with HR (Human Resources) systems, ERP (Enterprise Resource Planning), CRM (Customer Relationship Management) software packages, and different SNA tools.

KEYS TERMS AND DEFINITIONS

Organizational Network Analysis: Organizational Network Analysis (ONA) involves the use of Social Network Analysis in organizational contexts in order to help managers to better understand the relationships present inside and outside the organization. It can be used in an organization to better understand the social capital, support partnerships and alliances (Cross and Parker

2004), measure the degree of embeddedness of the actors and define their importance in the network, support knowledge management policy and reveal who really knows what in the company, integrate networks across core processes, promote innovation, integrate new members or organizational changes, support the development of informal communities of practice, improve leadership effectiveness, replicate high performance throughout an organization, and understand and improve both the disconnects between groups in the organization as well as connections to the outside world.

Social Network: A social network is generally defined as a set(s) of actors and the relation(s) defined for them. Actors, also defined as social entities, can be individual or collective social units that are connected by links. Links constituting a social network may be directed, undirected, or mixed. Social Networks can be analyzed using defined measures, and their results can be compared with those from similar networks. Each actor's position and connections can also be individually analyzed and compared with those of other actors in order to understand their relative importance in the network and highlight network bottlenecks and cutpoints as well as isolated and equivalent actors.

Social Network Analysis Measures: Measures in SNA are the metrics through which networks and social actors can be evaluated and compared. SNA measures can be distinguished into those evaluate the entire network and those that evaluate only a specific node. At the individual level, the most frequently analyzed measure is *centrality;* this can be measured using *nodal degree*, *betweeness*, and *closeness.* At the network level, is important to understand how the network is structured; it is therefore important to measure network *cohesion*, *centralization*, *and clustering* and identify important nodes like *cutpoints*.

Social Network Tools: Social Network Tools are software tools that can be used to represent, visualize, and analyze social networks. These tools can usually read and write in common formats and use matrices to compute social networks and graphs called sociograms to represent them. Other platforms have other important characteristics like the ability to convert answers from internal surveys to social network data or extract social network information from existing systems using ETL techniques. Some graph software or general network analysis software can also be used to identify key aspects in social networks.

Social Network ETL: Social Network Extraction, Transform, and Load designates the set of techniques used to map existing information system data into social network models. Entities present in the systems should be normalized and resolved, and the selected interactions between them are transformed into relationships. After extraction and transformation, data can be loaded in the usual SNA tools. Good examples of social network ETL use arise from community boards, server communication logs, knowledge repositories, and wikis.

Social Networking Services: Social Networking Services (SNS) are websites where people can register their personal profiles and connect with others to share information based on interest, upload photos, or join groups. This kind of website is a popular Web 2.0 phenomenon; millions of people are currently registered, and SNS websites are some of the most visited websites on the internet. SNS represent a new way to connect to collaborators, and they permit the sharing of information and breaking of common barriers. Although concerns regarding privacy issues arise, restricting information to only those users people trust circumvents the problems of sharing it with no restrictions in the network.

Social Networking Services for Enterprises: Social Networking Services for Enterprises are internal information systems used by organizations to increase connections and information sharing among their collaborators. These systems share the same features as social networking services but are used to low barriers inside organizations.

They are intended to promote productivity by increasing information sharing. Usually, they are platforms that try to join features of Social Networking Services and knowledge repositories with Social Network Analysis. They give the managers and consultants the ability to access existing organization networks and hidden relationships and make decisions for reorganization based on what is really happening in the organization.

Chapter 1.15

Educational and Social Benefits of Social Network Sites:

Applications to Human Services Education and Practice

Christine Greenhow
University of Minnesota, USA

Beth Robelia
University of Minnesota, USA

ABSTRACT

Online social network sites present opportunities for human service educators, practitioners, and clients. Human services education students can collaborate through multimedia networks, sharing ideas and experiences. Human services professionals can leverage online networks to problem solve, socialize and develop common resources, and clients can use such networks to engage in self-reflection and get support from those facing similar challenges. This chapter offers an introduction to online social network sites, summarizing their features, uses, demographics, and trends, and presents emerging research on their social and educational potential. An accompanying case study reveals how young adults might use online social network sites to further personal and educational goals. The chapter concludes with a discussion of how such sites might be employed by human services education students, practitioners and clients.

OPENING VIGNETTE

It is seven o'clock in the evening. Emilio has just finished dinner with his family and retreats to his bedroom to check in on the other social network in his life. Like the majority of U.S. online teens who are daily users of a social network site, logging twenty minutes to an hour or more, Emilio goes to MySpace.com and signs in. Once within his profile page — his entry point to this online international community — he notices that several things have changed among his "friends" in just the few hours since he last communicated with them. Looking at his list of "updates" he notices that Julia has joined the network. Alex has written in his blog about the challenges of college life. Jade has finished her midterm and thinks she did okay. Whitney has become a supporter of the Democratic president-elect, Barack Obama, and Jose has added four new photos of his new dorm room. Emilio accepts Julia as a friend so she can see his complete online profile. He comments, "Congratulations!" on Jade's update. He visits Alex's page to leave a comment about his blog entry on college life. He visits Whitney's profile to see what other people have said about her support for the U.S. president. He visits his own home page to read comments friends have left him about a video he created for a school project about sports casting, his career interest. Earlier, he had posted an unfinished essay for sociology in his blog so that friends could give feedback on what he had written. Using the instant messaging feature within the MySpace network, Emilio messages another classmate who appears to be online and asks for advice on a social work assignment. He stays logged into the MySpace system while he works on his homework, waiting for friends to respond to his requests and comments. Soon messages began to appear. One friend instant messages some feedback on the sociology essay. Another friend compliments him on the finished video, and another gives him advice on the psychology assignment. At nine o'clock, Emilio changes his MySpace mood setting to "tired" and signs out of the network. His work is finished. He looks forward to following up with his friends on the night's events when he meets them tomorrow, online or off.

INTRODUCTION

This opening vignette describes some of the many ways young people participate in online social network sites (SNSs). Emilio (a psuedonym) was a shy, soft-spoken eighteen year old who had a few close friends at university. Within MySpace (www.myspace.com), however, Emilio had a large network of friends, acquaintances, and contacts from within and outside his local community. His MySpace profile contained videos and photos he had created and posted to share. Often portrayed in the media as dangerous or distracting (Hass, 2006; Rowan, 2007), many young people are actually making important, positive connections through their use of online social network sites. They find emotional support, get help with school work, relax, socialize and flourish in using this outlet for their creativity.

The purpose of this chapter is to explore the social and educational benefits of online social network sites and the implications of social network site affordances for human services education and practice. The unique features of today's social network sites will be discussed in relation to other forms of virtual communities. The chapter will present theoretical foundations, application of social network site features to education and ways in which the competencies users demonstrate in social network sites can have educational benefits and enhance learners' experience. Moreover, a case study of one students' use of an online social network will be provided for tertiary social work students who seek to consider the potential application of this information communication technology for human services education and practice. This case study may also be useful for researchers in the field of information communication technology and human computer interaction in various disciplines who seek to describe and illuminate online social networking practices.

BACKGROUND

Adherents of social networking – including 70% of today's 15- to 34-year-olds– utilize their preferred social networking sites at all hours of the day and night to fulfill a roster of needs as diverse as the users themselves (February 2007, U.S. ComScore data, ages 15-34 at all locations).

Social Network Sites: A Unique Form of ICT

Since their introduction in the late 1990's, and rising to mainstream prominence with MySpace and LinkedIn in 2003, online social network sites have attracted millions of users. In the United States, a majority of online teens have created a personal profile on a social network site like MySpace or Facebook and visit their social network site daily or several times a day, devoting an average of 9 hours a week to the network (Lenhart & Madden, 2007; National School Boards Association, 2007).

According to boyd & Ellison (2007) an online social network site is a 'web-based service that allows individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system' (p. 1). What distinguishes social network sites from other forms of virtual communities is that they allow users to articulate and make visible their social networks, similar to allowing others to view your address book and interact with it online. In this way your connections potentially become the connections of your "friends." Boyd & Ellison (2007) suggest that these "friending" behaviors through social network sites can result in more and different types of connections between individuals that would not otherwise be made (Haythornthwaite, 2005). In addition to individuals, SNSs may include profiles of bands, companies, events, non-profit organizations or political parties (Childnet International, 2007). Other terms such as "online social networking site," "networked social media" and just "social network" have been used to describe these Web 2.0 technologies. For our purposes, we will use the term online social network site (SNS) according to boyd and Ellison's (2007) definition.

A growing body of survey research suggests that youth's participation in online social network sites may cross gender, ethnicity, and income boundaries as teens once disconnected from the Internet (e.g., low-income African-American, Latino and other low-income students) now largely have access (College Access Marketing, 2008; Lenhart, Arafeh, Smith & Macgill, 2008). For instance, in our surveys with 600 urban high school students from low-income families in the upper Midwestern United States (i.e., median family income at or below US$25,000), we found that over 80% go online regularly from home and 77% have a profile on an online social network site. The majority use MySpace (65%) with Facebook (37%) being the second most popular site, and many students belong to more than one network (Greenhow, Walker & Kim, 2008).

Use of Social Networking Sites for Social and Educational Purposes

Social Networking Sites can serve a range of purposes, including helping users maintain existing friendships or forge new relationships based on shared professional interests, political views, a common language or shared racial, sexual, religious, or cultural identities. In studying U.S. Internet trends, Lenhart and Madden (2007) found that 91% of SNS users employed these sites to maintain relationships with existing friends with whom they frequently socialize, and 82%, to maintain connections to others with whom they do not socialize; 72% used these sites to make social plans.

Such relationship building can be accomplished through a range of SNS features that accommodate data-sharing in various forms (e.g., video, audio, text, photo, hyperlinks, etc.) and user-generated content. For instance, most sites allow users to share personal profiles, write comments, upload files, and select applications, although the extent to which sites incorporate new information and communication tools, such as mobile connectivity, blogging, and photo/video-sharing varies. Many SNSs offer condensed versions of their services for customers who want access via mobile handheld devices such as cell phones, which have become nearly ubiquitous among youth and adults of all ages (Lenhart, Madden, Macgill & Smith, 2007).

Some of the most common activities young people engage in are creating online profiles, visiting others profiles and leaving messages, viewing digital content, authoring content and sharing content created by a third party (Childnet International, 2007). Indeed, students engaged in SNSs are more likely to be content creators: posting or remixing digital images or video, creating or commenting in blogs, or maintaining a website (Lenhart & Madden, 2007). Interestingly, a recent survey involving over 2,000 nine- to 17-year old students, parents and school district leaders in the U.S., reported that much of students' online sharing in SNSs involves frequent exchange of private and public messages and comments, with education being a common topic of conversation —e.g., 60% of students surveyed reported using their SNS to talk about education topics and 50%, to talk specifically about schoolwork) (National School Boards Association, 2007). Outside of the United States, the Digizen Project of Childnet International is examining how SNSs can benefit young people in the United Kingdom and around the world. The Digizen site (http://www.digizen.org/) offers a framework for evaluating the appropriateness of SNSs for formal or informal learning. A downloadable evaluation chart considers a site's age restrictions, the presence of advertisements, collaboration tools, security options and data management restrictions. The site also outlines considerations for educators trying to integrate such sites, including privacy issues, cyberbullying prevention and legal issues.

Demographics of SNS Use

Typically thought of as a youth phenomenon, the demographics of SNS users are increasingly diverse. Today there are hundreds of online social network sites, the two most popular being MySpace and Facebook with about 115 million users each worldwide (Stone, 2008). Launched in 2004, MySpace generated more page views than Google or Yahoo and has broad appeal across all age ranges (Compete, 2008). More than half of MySpace users in the U.S. are under 35 years of age (77%), with young people 12 -17 years (29%), 18-34 years (44%) and the over 35 demographic representing a smaller (23%) but still significant proportion of users (Quantcast, 2008). About 300,000 new people sign up for MySpace every day. Its users span more than 20 international territories, including the United States, United Kingdom, Australia, Japan, France, Germany, Mexico, and Canada. In the U.S. one in four Americans is on MySpace and in the UK, it is as common to have a MySpace profile as it is to own a dog. Moreover, MySpace has a large presence within the entertainment industry. It maintains a dominant position as a media-sharing site (i.e., uploading music, videos, scanned artwork, photography, etc.), giving users the opportunity to interact with brands, bands, artists, actors, and other creative professionals as well as to self-express. Analysts expect to see more television and video networks integrate and work with MySpace (Owyang, 2008).

By comparison, Facebook also appeals to a broader demographic than simply teenagers. People ages 18-24 (34%) and 35-54 years of age (33%), constitute Facebook's two largest groups of users. Originally created to foster social networking among U.S. college students, Facebook is still a dominant presence on college campuses; however, more than half of Facebook users are outside of college, and its fastest growing demographic is 25 years of age and older (Owyang, 2008). Facebook has also expanded internationally, with the most active users residing in the U.S., Canada, the UK and Australia. Facebook's orientation overlaps with MySpace in that it maintains regional, profession-related, and school-related networks; however, Facebook is perhaps more strongly affiliated with collegiate and work-related networks than is MySpace and maintains 85 percent market share of 4-year U.S. universities.

Moreover, Facebook emphasizes its niche as a platform for independently generated applications. According to the company's analysts, 24,000 applications have been built on the Facebook platform and an estimated 140 new applications are added per day allowing users to increasingly customize the functionality of their network (See for more information: http://www.facebook.com/press/info.php?statistics). *Socialyze,* for instance, is an application Facebook users can add to their profiles (and invite friends to add) which enables them to analyze data, statistics and trends generated by their "friends" within the Facebook system. The application can be used as a game to get to know people better and strengthen social connections. Users can test their social knowledge and compete against friends to earn points and "climb the social ladder." *Books iRead* is a Facebook application that may be useful for educational or professional uses. It lets one share ratings of books and showcase a virtual bookshelf. Users can see what their colleagues or students are reading and read reviews of what others have read. Users can join a virtual bookclub, get book recommendations or meet new people who share the same reading interests. Facebook *translator* applications allow real-time translation of messages between users who speak different languages. The *Where I've Been* application allows users to post an interactive world map on their profile, showing those who visit their site, where they have been, lived and want to go. Visitors to a user's *Where I've Been* map can click on a country or city to get more information.

No overview of online social network sites would be complete without emphasizing the increasing proliferation and diversity of this emerging information and communications technology. A quick Google search reveals millions of hits for "online social network sites." Wikipedia lists over 130 on its list of "notable, well-known" sites (http://en.wikipedia.org/wiki/List_of_social_networking_websites) and reviews abound, such as this one from Top Ten Reviews (http://social-networking-websites-review.toptenreviews.com/), which strive to characterize and distinguish one site from another. Sites like Hi5.com, Friendster.com, Orkut and Bebo.com rank just below MySpace and Facebook in size and international presence (ComScore, 2008a). Bebo is especially popular in the U.K., Ireland and New Zealand while Orkut is popular in Brazil, Paraguay and India, and Cyworld is the site of choice among many young South Koreans (Wikipedia, 2008).

Furthermore, a growing number of SNSs are designed specifically to support education. EducatorCentral (http://www.takingitglobal.org/tiged/ec/) within TakingITGlobal (www.takingitglobal.org) supports teaching and learning (Childnet International, 2007). Ning (www.ning.com) is an increasingly popular SNS that allows people, schools, and companies, to build and design their own social Web sites tailored to their students, clients, friends, and employees. Within Ning.com there are a few SNSs that specifically address human services professionals. These include Social Work 2.0 (http://www.socialwork20.com/) and Social Work Advocates (http://socialworkadvocates.ning.com), which is a community of social workers who are passionate about advocating for vulnerable and oppressed populations. Other sites are just beginning such as Social and Human Services (http://sociallyhuman.ning.com) and Social Work Grad Students (http://socialworkgradstudents.ning.com/). In the UK, a relatively new SNS offered by the social work magazine *Community Care* (http://www.communitycare.co.uk/carespace/) features high quality podcasts of research seminars and educational products, which can be subscribed to within iTunes (http://www.iriss.ac.uk/audio). In addition, this SNS features an open access repository of human services related content called the Learning Exchange (http://www.iriss.ac.uk/openlx/).

There are also numerous networks for specific human services client populations. For instance, people addicted to alcohol and other drugs can identify treatment options and get peer support within SoberCircle (http://www.sobercircle.com/). Sobercircle blogs and chats offer a place for clients in recovery to voice their struggles with addiction and seek support from others. Separate forums for social service professionals allow those who counsel people recovering from addiction to connect and share ideas. PatientsLikeMe (http://www.patientslikeme.com/) allows people dealing with certain life altering neurological conditions such as multiple sclerosis or Parkinson's disease to share their experiences, find similar patients, and learn from the latest research. People with mood disorders (e.g., depression, bipolar disorder) are also supported within the site. The philosophy of open sharing within PatientsLikeMe allows people to discuss their treatment histories anonymously so others can benefit from information about successful approaches. Although we have been focusing on SNSs used primarily by teens and adults, there are also sites, such as ClubPenguin (http://www.clubpenguin.com/) and Imbee (http://imbee.com/) that are designed for and used by younger children, ages 8-14. These sites have stricter privacy controls and require a parent's email to sign up.

Finally, there is significant diversity in the SNS user population. A person's gender, race and ethnicity, and parental educational background, for instance, are all associated with SNS use. According to the Pew Internet and American Life studies in the United States, older girls ages 15-17 are more likely to have created an online profile on a social network site (70%), while only 57% of online boys have done so (Lenhart et al., 2007). Hargittai (2007), in studying college students' differential adoption of online social network sites, found differences in the percentage of racial and ethnic groups that used four popular SNSs (Facebook, MySpace, Xanga and Friendster). Hispanics favored MySpace over Facebook and other sites. Students of Asian background favored Friendster and Xanga. Both African Americans and Caucasian students used MySpace and Facebook more than the other two sites in the study. Using parental education as a measure of family income, Hargattai (2007) also found that students with parents who had less than a high school diploma were significantly more likely to be on MySpace than Facebook. Students whose parents had a college degree where significantly more likely to use Facebook. However, it is important to note that this study was completed before Facebook opened its membership to everyone. Previously only those with a college email could use Facebook. Next we turn to the theoretical foundations underlying this chapter.

THEORETICAL FOUNDATIONS

Not surprisingly, given that people's use of online social network sites is a relatively recent phenomenon, much of the published research on the use of SNSs is still emerging. The handful of studies that exist stem mostly from communications, information science, anthropology, sociology, economics, political science, cultural studies, and computer science and are both conceptual and empirical in nature (boyd & Ellison, 2007). Very few studies explore the link between social network site use and education. For instance, Hewitt and Forte (2006) examined how college age students feel about having their professors on Facebook, and Mazer, Murphy & Simonds (2007) investigated how faculty presence on Facebook impacts student-educator relationships, but these studies do not deal directly with *students'* experiences in using online social network sites and how

SNS use may impact their *educational* experience, which is the focus of this chapter.

The theoretical foundations for this research stem from education, communication and sociology, specifically interpersonal ties theories from communication and sociology, constructivist frameworks for how people learn, and twenty-first century skills frameworks in education.

Meeting Interpersonal needs Online

Despite troubling public accounts of Internet-mediated communication as socially isolating and necessarily inferior to other modes of communication (Thurlow, 2006), a number of studies have argued that, in fact, communication via the Internet can help users develop, maintain, and extend social relationships, leading to a broader network of support when faced with important life decisions (Ellison, Steinfield, & Lampe, 2007; Kraut et al., 2002; Wellman, Haase, Witte, Hampton, 2001). Such findings are important for human services education if we consider that interventions which increase students' connections to their peers and community resources can lead to greater persistence and success in university programs (Zhao & Kuh, 2004; Tinto, 1998).

In examining interpersonal interactions within the context of a SNS and how SNSs may be supporting interpersonal needs, it is important to consider: the technological affordances of the environment; how users employ (or not) these and for what communicative purposes; and the conditions surrounding these interactions (e.g., computer and Internet access/context, frequency and duration of social network site use, nature of the relationship between SNS participants). This examination of the potential of social network sites to fulfill interpersonal needs, as illustrated in the case study that follows, is informed by recent studies on how social networks are created, maintained and negotiated through media (Donath & boyd, 2004; Gross & Acquisiti, 2005; Ellison, Steinfield & Lampe, 2007; Herring, 2004; Wellman, Salaff, Dimitrova, Garton, Gulia, Haythornwaite, 1996).

Supporting Constructivist Pedagogy and How People Learn

Social Networking Sites are uniquely positioned to mesh with theories of adult pedagogy which stress that adults expect their experience and connections will be incorporated into their learning. Younger and older adults are entering university education classes with the expectation that they will be able to contribute to the discussion, giving feedback as well as receiving it. Students expect to critique each others' ideas and projects as well as contribute to class discussions blending their ideas and experiences with others to create learning. This atmosphere of constructivism is different from that of classrooms where students submit assignments to one person (their instructor) and receive feedback from that person. Multiple evaluations by peers, instructors, and others are quickly becoming the norm in the networked classroom. In synthesizing over a decade of educational and cognitive neuroscience research on how people learn, Bransford, Brown and Cocking (1999) developed guidelines for effective teaching that emphasizes learning with understanding. Effective instructors, they argue, help structure a complete learning environment that encompasses three focal points-- learner, knowledge and assessment--within a larger community or society (p. 120-130). High technology-using environments, such as those embodied by social network sites, may be conducive to both developing learning and innovative pedagogy because they typically feature "learners" informally sharing thoughts, emotions, and skills within a networked community where production, distribution, feedback and reciprocity are valued. Moreover, in developing and displaying a "public" profile and engaging in collaborative acts of production with others in the system, users may be demonstrating the kinds of knowledge construction and problem-solving activities frequently sought in twenty-first century instructional reform efforts.

Although there are various forms of educational constructivism, generally, constructivism is a theory of learning that views the nature of "knowledge" as created or formulated by the learner actively engaged in the process of making meaning (Fulton, 1999). Learners make or "construct" new meaning by taking what they already know and applying what is being learned to new situations. "Knowledge," rather than inherently meaningful, becomes meaningful through the learner's interpretation and application of what he or she knows in a community where knowledge is shared. Experience and individual differences, therefore, are important and respected, and situations that have direct relevance to the learner or applicability to life are those that provide the best opportunities for learning. In the constructivist model, the learner's background, expertise, and beliefs all affect the learning or knowledge that is assembled (Brown & Duguid, 2000). When applied to pedagogy, the constructivist view of learning supports a learner-centered instructional environment where learning and teaching are "facilitated" by the instructors rather than "transmitted" as in a traditional lecture-oriented teacher-centered classroom. Online social network site features may support such environments by enabling users to profile their individual differences and commonalities, communicate interests, ideas, and experiences in multimedia forms, negotiate learning goals, aggregate the wisdom of the group to co-construct solutions, and solicit and get feedback from multiple audiences.

21st Century Skills Frameworks

Ultimately, at all levels of education, from undergraduate to graduate programs, we want our students and clients to be trained in and proficient at using emerging digital tools and social media to ultimately enhance their career-related decision-making and performance. Therefore, this chapter considers how students, in using SNSs, are practicing the kinds of "21st century skills" that are increasingly emphasized in educational and workplace settings, but perhaps especially important in human services occupations. These include *creative thinking*: the ability to construct knowledge and develop innovative products and processes; *communication and collaboration*: the ability to communicate in multiple media and to work collaboratively to support individual learning or the learning of others; *research and information fluency*: the ability to locate, organize, evaluate and process data from a number of sources and present the results; and *problem-solving*: the ability to define problems and manage activities toward a range of solutions (International Society for Technology in Education, 2007; Partnership for 21st century Skills, 2008). Moreover, today's instructors are expected to develop and model these competencies as well as to facilitate their development in students (International Society for Technology in Education, 2008).

CASE STUDY CONTEXT

Drawing on these frameworks above, we undertook an exploratory qualitative study in the spring of 2008 to examine whether and how urban youth from low-income families in the upper Midwestern United States used the online social network site, MySpace.com, as part of their everyday lives and whether and how their MySpace use demonstrated educational and social benefits. This investigation is part of a larger three-year effort to profile these students' Internet technology access, use, and capacity. A total of 1200 students (17- and 18-years of age) were given paper surveys in the winter of 2007 (number of respondents=850) and again in the winter of 2008 (number of respondents=600). They were asked a series of questions about their location, frequency, duration, type of computer and Internet use, and their purpose for using various Web-based technologies. Focus groups were also conducted to triangulate survey data. Students who participated in this research were from thirteen urban high schools (56% female) and were all participating in an after-school program, Admission Possible, aimed at improving college access for low-income students. These students were from families whose incomes were at or below the county median income (at or below $25,000) (Greenhow, Walker, & Kim, 2008).

To investigate students' use of online social network sites, specifically, we conducted follow-up in-depth interviews, talk-alouds, and content analysis of MySpace profiles with a randomly selected sub-group of eleven students (all frequent MySpace users). The case study that follows draws from this larger research effort.

THE CASE OF THERESA SOMMERS

[You learn] different things about different people. . . . you get afforded different opportunities from the social network like with the [political] caucus invitation. I wouldn't have been able to go there; I wouldn't have known how to get there otherwise. (Theresa, age 21)

Theresa Sommers grinned as she talked about getting to know different sides to her "friends" within MySpace.com. She talked excitedly about friending the Democratic nominee for United States president, Barak Obama, and the opportunities to get involved in the 2008 presidential election that had come her way through her online social network. A young woman from a Chinese-American family, Theresa spoke animatedly of her plans to attend a university next year. In just a few short weeks, she would graduate from her large urban high school and transition to the next phase of her life.

Technology Background & Context for SNS Use

We met Theresa in the spring of 2008 when we interviewed MySpace-using teens in order to begin to understand whether and how online social networks might be utilized to support educational and social goals. Theresa was 18 years old and from a low-income family living in a Midwestern city. Like many of the students in our study, Theresa had access to high speed Internet at home. However, unlike others, she had her own laptop and did not have to share time on the Internet with siblings or parents. Theresa was a relatively experienced SNS user, having used MySpace for three years and Facebook.com for 1.5 years. Thus, she maintained two SNS accounts: her MySpace account, for its connections to high school friends, musicians, artists, politicians, and entertainment or school-related groups and her Facebook account as part of her journey toward college access and enrollment. In fact, she used Facebook to "network" with students currently enrolled in colleges she was considering, and she believed these online interactions had factored into her college decision. Theresa used her MySpace several times per week for about one hour, which was slightly less than the majority of students we interviewed who visited daily or every other day. However, her time on SNSs also varied depending on her workload and purposes; she used her SNSs most intensely in the time leading up to submitting her college application, wanting not only to network with current college students but to keep her contacts updated on her college search process.

Patterns and Purpose for SNS Use

As Theresa sat down in front of MySpace, she talked us through her most common activities and strategies when logging in. Like many online teens who prefer communicating through the multiple channels offered by SNSs rather than through older technologies such as email (Lenhart et al., 2007), Theresa used MySpace to make and maintain connections to friends, acquaintances, and potential "friends" within the system. Keeping up with "mail" communications within her MySpace account was, therefore, a top priority. Typically, she sorted through and responded to incoming messages and checked that older messages had been answered or deleted. Next, she moved on to review "friend requests," that is, other people within the MySpace system who wanted to be part of her "friend" network. She accepted the request of an old friend from middle school who had since moved away and that of an acquaintance who had graduated from her high school last year. She denied the request from a "random band" because she did not like the music playing on the band's MySpace page. Next, she skimmed the latest updates among her friends list (e.g., updated profile information, new connections among members, new photos posted to an online photo album, new blog entries on college life). Clicking on the most interesting updates, or on updates from those she had not visited in a while, took her to their individual profile pages. There she "commented people," posting her feedback to a friend's blog or picture or posting a message to a friend's page so that he knew she had stopped by. In travelling to the MySpace pages of people in her network, Theresa could also see who was connected to whom and decide who among her "friends' friends" she would like to get to know. Clicking on the photo of a person outside her network, instantly brought her to that contact's limited profile with the option to "add to friends." Clicking on this option would generate a "friend request" and send it to that person, asking him or her to accept Theresa as a new "friend, thereby, allowing her access to his or her complete profile and online address book.

Theresa also used her network to find multimedia resources and information. For instance, she was looking for a new photograph of herself for her profile homepage. She remarked that she had not changed her profile picture for some time yet valued the dynamic and continually updating nature of the MySpace world. Browsing for photos within her friends' online photo albums, where she had been tagged, enabled her to identify potentially useful images. She mentioned another incident where she had needed resources for a class project. Sending a bulletin or group message to the many friends in her network, she claimed, provided an easy way to gather valuable resources. When time allowed, she wrote poetry in her blog and composed updates on her college application process for those younger friends in her network she hoped to motivate and inspire.

When asked why she used SNSs such as MySpace, she explained how her purposes had shifted from purely social ones to more complex social and education-related purposes. Introduced to MySpace as a sophomore, she had logged in daily, spending an hour or more crafting an online persona through her profile page, searching for "cool" background layouts and changing the colors, design, music, and overall "look and feel" of her page. In many ways, she felt that she was participating in an online popularity contest to see who could have the most interesting-looking profile, the most number of "friends," and the most heavily visited site. As she eventually integrated MySpace into her everyday life, with its competing priorities and time constraints, her purpose for using the site became more authentic and personally meaningful. As a high school senior about to enroll in college, Theresa now says she uses MySpace primarily to strengthen and maintain relationships with people she has met online and offline, to obtain emotional support from her peers, to solicit help with school assignments, to report on school/college-related progress and accomplishments, and to express her creativity.

In this next section, we will discuss how these stated goals were manifested in Theresa's case, highlighting observed social and educational benefits of her participation in the MySpace network.

Developing Relationships & Meeting Interpersonal Needs

The young people in our study, like Theresa, used the capabilities of the online social network MySpace.com to develop and maintain various types of relationships. Contrary to the popular perception that SNS users falsify their identities making truthful relationships difficult, Theresa's profile illustrated her attempts to craft and present an authentic self within the online space. She posted an actual photograph of herself, listed her hometown and country, displayed a username that related to her first name only, truthfully reported her relationship status as single, provided her actual age and encouraged her "friends" to exchange messages with her: "Facebook or text me," now that she was entering college. However, she also took steps to protect her full identity from unwanted viewers, setting her MySpace profile to "private" and allowing only those within her approved network to see her full profile and contacts. Moreover, like the other students we interviewed, Theresa, talked about the advantages of freely expressing her thoughts, opinions, fears, and emotions through the multimedia channels SNSs afford but also noted her hesitancy to reveal too much personal information, such as her full name, address, and contact information, which could subject her to unwanted fraud or abuse.

Walking the line between self-expression and anonymity, Theresa's profile revealed that she used various MySpace features to maintain interpersonal connections with people she saw everyday as well as with those she rarely saw or had never met. Features such as the address book, asynchronous message system, online chat, bulletins, friend requests, event alerts, and automatically generated, aggregated lists of friend "updates" or "status and mood" reports allowed her to keep abreast of the lives of people in her network and grow it. In her view, MySpace was a virtual "hang out" where one could relax around other people (e.g., close friends, distant friends, acquaintances, people she had never met) and keep the "line of communication open" without frequent and costly time and emotional investment:

I think it's a good way to keep in touch with people you may not have time to call or meet or even text them…it's kind of a "kick-back"…it's just kind of a way to relax and hang out and not necessarily having to worry about talking directly to a person but just kind of like keeping that line of communication open.

However, Theresa also noted that a core group of "friends" in her MySpace network were actually people she talked to and physically hung out with regularly. She felt that her connections to those people, especially, deepened with her use of MySpace because she was able to "see more sides to them" than she would have otherwise as they could now express themselves in audio, video, graphical, and text media. For instance, friends she never knew had political interests or artistic abilities were displaying these sides of themselves in MySpace. Friends who were not usually emotional in person were revealing emotions through emoticons, descriptive status updates, or online writing.

Maintaining this range of social connections from which to draw—e.g.,"strong ties" as among family members and close friends and "weak ties" as among acquaintances, distant friends and potential contacts (Granovetter, 1973)— makes SNSs potentially advantageous to young people who are able to activate connections appropriate to their purposes when they need them. For instance, one "friend" in Theresa's network, a former classmate now at a distant university, activated his network to build an audience for his budding radio career. Using the "bulletin" feature in MySpace, he posted the following message titled "New Information," which asked his contacts to check out a new radio show:

I have a radio show entitled "Know it Al!" (a pseudonym for the real title). The information for that is on facebook. Also, if you search for "Know it Al!"on facebook there is a fan site that you can join and become a fan. Through that site I will be sending people updates and everything. So there are two things going on.... The radio show is on Thursdays from 2:30-3:30 and you can stream it online at [name of URL] . All you have to do is hit listen and even if you have a slow internet connection you can still get it. Trust me...

Theresa also used MySpace to initiate connections for career-building and inquiry purposes. For example, she was interested in photography as a potential career. Through MySpace she was able to view the work of professional photographers and exchange comments and questions with them about the field, including the kinds of training and skills that are needed. MySpace allows its users to join public forums and search within the network for people with particular skills like "professional photographers." Because it is a media-rich environment that lets users post their own content without requiring sophisticated technical expertise, experienced and novice artists can scan and upload or link to their work, asking others for advice and feedback. Such intergenerational and cross-disciplinary exchange might rarely happen in the "real world" but in the virtual world of SNSs, with its low costs to self-promotion and sharing, such interconnections are prevalent.

Similarly, Theresa used MySpace to become a resource for younger students, making visible her college search and application process. Posting personal updates where others could view them allowed her to model the process for students like her who were just beginning to think about choosing and applying to schools:

And I would even get questions [online] from different organizations I work with, like students in them, and they'll ask me like what's the process like? and what schools are you picking from? and they seem like they're really into it because that's what they're looking forward to, and so I think I did it a lot more for them [posted that information on MySpace] than for my peers here in school that I work with. (129-133)

Mentoring younger students, something Theresa may not have had the time, inclination or opportunity to do face-to-face, was facilitated through this networked information space. As this example suggests, social digital technologies available on the Web, such as SNSs, may prove particularly useful in helping us address educational inequities. For instance, it is well known that students from low-income families do not graduate from high school, enroll in postsecondary education, or obtain undergraduate and graduate degrees at the same rate as their peers from more affluent families. Often these students lack the social and cultural capital available to students from college-educated and affluent families. Technologies, such as online social network sites, may help "level the playing field" by providing such students with rich, affordable access to supportive peers and adults from similar backgrounds who have succeeded.

Moreover, in providing a range of creative and communication tools without the physical social cues that can discourage self-expression face-to-face, SNSs offer young people an interactive outlet for their emotions, reflections, and experience. For instance, when writing in her MySpace blog, Theresa wrote about topics that were personally meaningful and emotional, "It's kind of me venting." She wrote for herself as well as for an audience, straddling the line between confession and meditation:

I know my friends will go on and read it. For the most part, I'm really up front with them, but then for some things that are kind of hard to say to people… with those things, they read it, and then they take it in their own way and they have time to digest it and then, react to it, like they [have] *a little section where they can leave a comment (178-184).*

Below, Theresa recalled how she was prompted to respond to a friend in need through MySpace, speculating that she probably would not have done so otherwise:

Like somebody will write me and tell me, "I'm going through this." And I wrote a poem for a friend because she and her boyfriend broke up, and that's just probably one thing I wouldn't have done [written the poem] if she hadn't written me about it on MySpace" (475 -478).

As these examples illustrate, SNSs facilitate semi-public sharing, as opposed to writing in a private journal, emailing, or posting in a public online community; feedback and encouragement from other members are aggregated, archived, and can be viewed over time within a sanctioned social circle. Such collective thoughts can provide a powerful source of support, motivation, and recognition for a job well done, even building on and extending relationships in the physical world. For example, in Theresa's case, one of her senior projects was to give a final in-class performance related to an issue she cared about. She felt that many of her peers gave fine performances and wanted to tell them so. Her strategy was to recognize her peers semi-publicly within MySpace: "I like to post it so that everybody can see it [my positive comments to a person]. Of course, you'll tell them face to face but I like to put it on MySpace just so everyone can know they did a good job. (591-596)"

In addition to cultivating and maintaining close and distant interpersonal connections for a range of purposes, young people may be using SNSs to demonstrate the 21st century competencies that educators value, including creativity, communication in multiple media, collaboration to support one's own or the learning of others, problem-solving, and research and information fluency. Examples from Theresa's case illustrate how some of these competencies may be demonstrated.

Demonstrating 21st Century Competencies

Recent survey reports and preliminary descriptive research suggest that today's young people are using participatory media such as SNSs to practice and develop creative processes and innovative content (Lenhart et al., 2008; Lenhart et al., 2007; Perkel, 2008; Hull & Nelson, 2008; Coiro, Knobel, Lankshear & Leu, 2008). Copy/paste literacy practices where youth manipulate and "remix" code in the production of a MySpace profile are giving new meaning to our notions of "reading" and "writing" online (Perkel, 2008). Youth's digital stories, multi-medial compositions produced by layering text, music, and images, are engendering new, respected writing genres (Hull & Nelson, 2005). These are just some examples of how young people may be developing creative capacities and technical proficiency within SNSs which have implications for formal education. Theresa, for example, posted original photographs within her MySpace profile as a means of personal expression. She credits MySpace with motivating her to share this work with a wider audience:

I always liked to take photographs, and I had a bag full of like 15 disposable cameras that had not been developed. So MySpace got me to develop them and put them on MySpace. . . . I develop more pictures; I make more of an effort to get what I'm doing out to people just because it's an open space for people to observe.

In fact, she marveled at the positive effect SNSs had on her ability to represent herself, "I think [SNSs] have changed my communication skills in some ways because I don't necessarily have a problem [now] speaking my mind." We also saw evidence of this in the range of artifacts students posted within MySpace (e.g., videos they had created, photographs, graphically interesting backgrounds, music, song lyrics, links to other artifacts).

In addition to sharing photographs, Theresa shared her creative and school-related writing. Prior to joining MySpace, she felt others rarely read her work, but MySpace helped motivate such efforts by giving her multiple audiences for which to perform. The audience for her school writing was generally classmates while the audience for her creative writing and photography was a diverse group of people, such as artists she had come into contact with through MySpace and believed she would not have known otherwise. Theresa's sense was that people young and old enjoyed sharing their creativity in SNSs: "I know people that dance and sing and they have little videos on their profiles and I know some other poets and people who like to write and rap and do art and paint and take photographs and everything."

The interconnections and creative capabilities evident in SNSs like MySpace offer learners initiation into a Web-based "participatory culture" (Jenkins, 2006) with low barriers to artistic expression and civic engagement, strong support for creating and sharing one's digital productions, a sense of social connections to each another (or at least caring what other people think about what one has created), and a belief that contributions matter. Participatory culture is manifested as: *affiliations* such as "groups" or "forums" centered around people's background, interests, connections, and media; *creative self- or collective expressions* (e.g., video-making, mash-ups), and *circulations* (e.g., podcasting, blogging) (Jenkins, 2006, p. 1). Such opportunities potentially enrich learning by making it more personally meaningful, collaborative, and socially relevant.

Moreover, the self-assertiveness and confidence developed by "speaking my mind" to a select audience, often for purely social reasons, may encourage youth to turn to those networks for help in solving important problems or decisions. As 21^{st} century educators, we value critical thinking, reflective decision-making, and collaboration and seek to develop these competencies in today's learners to prepare them for tomorrow. In MySpace networks, youth may be developing their ability to solicit advice and feedback from others they trust in order to manage projects and explore solutions. This was evident in Theresa's case where she and her peers in a school program posted excerpts of their essays within MySpace so that the group could collaboratively determine how the essay should be structured. Theresa commented: "Everybody's always working on projects like this at the same time and so, we'll [post in MySpace]: 'How long did you take on your essay?' or 'How'd you begin in there? How'd you write it?' So then sometimes we'll share that and everybody kind of does it, at least in our SLC [small learning community]."

Beyond creative thinking, multimedia communication, and collaborative problem-solving skills, we as educators also want our students to develop research and information fluency for the 21^{st} century. It is not enough to consult one source, such as a family member or book; in today's constantly shifting, global economy, learners need to be skilled in consulting multiple sources of information and people and synthesizing disparate bits of data, often in teams, to make well-informed, strategic decisions. Past research on students' online inquiry processes has documented students' difficulties in finding quality information online and discerning the truth or reliability of information they find (Kuiper, Volman & Terwel, 2005). "Social navigation" (Jonassen, 2000) within SNSs—as when a group of users with common interests help each other navigate the Web's complexities by sharing URLs, personal contacts, and aggregated resources —may help learners develop more nuanced research strategies and greater information fluency. The young people we interviewed told us they "tapped the network" to gather information on various topics, and this was evidenced in MySpace bulletin posts from individuals seeking information or responding to requests. In Theresa's case, she supplemented the information she found about different colleges from promotional materials, college Websites, college guides, and people in her local network with first-hand personal accounts from actual college students she had identified and contacted through Facebook:

It kind of was, like, I had a laundry list of schools I wanted to apply to. And so, I kind of narrowed it down based on my conversations on Facebook because the students on there, they feel more comfortable telling me what they think of the school . . . So they can kind of just share their honest interpretations and some schools, I got such great feedback and others, it's was just like, well, I know not to go there. (291-296)

Learning how to quickly mine different types of information from a diverse but bounded universe of social and professional contacts, as Theresa did, may help learners develop research and information fluency more effectively than relying on a single authority (e.g., the instructor) or peer group for guidance. Indeed, the new social Web is generating a particular brand of social network sites dedicated to making the Web more navigable and semantically organized. Social bookmarking and tagging sites (e.g., http://delicious.com/) allow their members to develop folksonomies. Folksonomies are collections of resources on varying topics such as educational research, cooking, video games, computer software, research on health conditions, tennis and other special interests. Anyone with a special interest can start tagging sites that relate to a topic and add them to an existing folksonomy or start one of their own. For instance, Citeulike.org is a site specifically oriented towards scholarly resources where groups can post articles related to the topic they are researching and other scholars can post articles to the same topic. These social bookmarks can be private, shared only among members of a particular social network (e.g., American Association of Internet Researchers) or they can be publicly available for anyone to use and contribute.

DISCUSSION AND RECOMMENDATIONS

The case of Theresa Sommers, and that of students like her who use online social networks for interpersonal relationships, school-related processes, college and career inquiry, leisure pursuits, community service, and 21st century skills development, offers several insights for human services education and practice.

SNSs in Human Services Education

First, in human services education, online social network sites might be integrated as a component in flexible learning and human service delivery within graduate school education, complementing the core practicum and other integrated learning components of university programs. Instructors seeking to implement learner-centered constructivist teaching strategies may benefit from layering an online social networking component over traditional in-class, online or hybrid course structures. For instance, it is well established that large enrollment classes and online or hybrid (partially online) courses which have high levels of peer-to-peer and instructor-student interactivity also tend to have higher student retention, satisfaction, and course completion. However, typical course management systems used to support or deliver such courses, such as Blackboard (http://www.blackboard.com/us/index.bbb), are designed more for content delivery controlled by a central administrator (instructor) than they are for ongoing, multi-channel communication, multimedia-sharing, and networking among course members. In addition, incorporating peer-to-peer interaction and group-building activities is time-intensive, costly, and usually not feasible where curriculum demands and staffing shortages favor direct instruction.

Supplementing human services courses with anytime/anywhere, freely available online social networking services may help work around these barriers, providing all course members with a cheap solution to help them monitor, learn from, and co-construct the group's experience. For example, *Social Work 2.0* (http://www.socialwork20.com/) is an intergenerational SNS of current undergrad and graduate students, social work professionals (1-20 years in the field), non-profit leaders, researchers and others. Within this network, each member has an individual online profile page where he or she can list location, professional status, degree-granting institution, and areas of social work/interests. Online forums within this SNS such as "Speak" and "(ME)Career" reveal a wealth of career and job-seeking resources, experiences, and advice for social work students and early career professionals. In addition, each Social Work 2.0 member can share reflections in his or her blog, generate discussion questions, share resources, request contacts, invite new members, etc. When an online profile is changed, as when someone writes a new blog entry or uploads a video or shares a question, the change appears prominently on the community home page so all members can track each others' activities. For instructors who seek to foster reflective practitioners, group cohesion, and a supportive and caring community for their students, SNS environments may help facilitate this by motivating students' self-expression, public sharing, support and commentary as we saw in Theresa's case.

Moreover, information and communication tools such as SNSs offer a dynamically updating method of pooling users' collective wisdom, interests, and contacts. As Theresa's case suggests, when initiated into an online community where multi-media sharing is not only valued but promoted, students may be developing important habits, preferences and skills that prepare them for the human service education workplace of the future. Theresa tapped her network to promote her creativity, solve problems, make life-altering decisions, augment her knowledge base, and pull others with varying levels and types of expertise into her network. Initiating students into these ways of thinking and using social digital technologies may help them develop the interpersonal skills and creative practices that are essential to cultivating an effective professional network of colleagues, service providers, and clients in the human services field. As future human services professionals, graduate students must develop proficiencies in: helping others obtain information and services, keeping and monitoring updated records, communicating clearly in varied formats to multiple audiences, collecting input/ideas/information from clients, establishing trust, and leading or facilitating team activities. Employing a customized SNS for similar tasks within a guided learning environment, such as a university course, may help students develop these proficiencies as part of their core practicum or work-integrated learning experience. However, SNSs may be most powerful as educational tools when the community students join goes beyond the limited experience base of a particular course or university program to encompass and expose students to the broader institutional, social, cultural, and political perspectives of a national or international network in their field.

SNSs as Tools for Human Services Practitioners

Second, human services practitioners might leverage SNSs to reflect on their work, tap peer-reviewed online continuing education, develop 21st century work practices, and grow their personal and professional networks, thereby improving their ability to develop, implement and maintain a comprehensive service plan. Similar to integrating these tools into human services education, practitioners in the field might utilize SNSs as outlets for personal reflection and creative expression. Keeping an online semi-private journal with SNS blogging tools, for instance, may motivate practitioners not only to vent and get support from friends or troubleshoot with colleagues but reflect on their practices over time. Within the Social Work Advocates and Community Care SNSs introduced earlier, human services practitioners use a range of online communication tools to reflect on their stance toward particular issues, to strategize how to advocate successfully, and to educate themselves (e.g., uploading educational videos, reports, relevant URLs, anecdotal evidence, etc.). SNSs that interface well with multi-functional handheld devices such as "smart" phones may be especially beneficial to travelling practitioners who need continuous, multi-channel, on-the-job access to their professional network. In addition, using SNSs to foster ongoing exchanges between students entering the field, current graduates, and experienced practitioners may do much to keep human services education programs relevant, to facilitate effective job placements, and to keep professionals current on research and evidence-based best practices.

Furthermore, Web-based SNSs, or some future version of them, may eventually help human service professionals engage in transformative inter-agency data-sharing, case planning and service coordination, which current proprietary knowledge managements systems and bureaucracies prevent (O'Looney, 2005). Various sectors, not just human services, are inquiring into how to harness emerging social technologies for organization- and job-changing impact. For instance, businesses are looking into how to tap their employees "social connections, institutional memories and special skills – knowledge that large, geographically dispersed companies often have a difficult time obtaining" by using social networking software to connect a company's employees into a single private Web forum (Stone, 2008, p. C2; Gratton, 2007). News media are increasingly tapping viewer participation in the form of online comments and testimonials, independently produced videos, and citizen journalist blog entries to enhance the accuracy, power and spread of centrally produced stories (e.g., CNN's documentary *Black in America*).[1,2] And apparent in the U.S. 2008 presidential election campaign is a new style of "Netroots" politics: "open-sourced and inclusive, multi-racial and multicultural" where potential voters don't just consume campaign propaganda but help shape and distribute it via online meet-ups, blogs, videos and Internet social networks (Sheehy, 2008, p. 79) Small scale proof-of-concept projects between human services units may help move us closer to understanding how the field can similarly benefit from the range of affordances SNSs allow.

SNSs as Tools for Serving Clients

Third, practitioners may also consider identifying SNSs that fit the needs of particular clients and recommending how clients might use them to obtain support, learn healthy behaviors, mitigate stress, express their passions or career interests, and other potential uses as appropriate to an overall personal development plan. In Theresa's case, MySpace was a place to work out everyday personal, school, and career-related issues and identify or process emotions by blogging, writing poetry or finding a song that matched her mood. In SoberCircle, introduced earlier, clients can find support from others who understand how difficult recovery can be when struggling with emotional and relationship issues. Family and friends of those in recovery can also obtain support on SoberCircle. Clients and/or their families can explore treatment options as well as find a human services worker. Within PatientsLikeMe, members can find information on the latest treatments from those who are using them. Information is available on neurological disorders including: Multiple Sclerosis (MS), Amyotrophic Lateral Sclerosis(ALS), Parkinson's, Progressive Muscular Atrophy (PMA) and Devic's Neuromyelitis

Optica as well as other conditions. PatientsLikeMe also offers specific resources for people with mood disorders such as depression, anxiety, bipolar disorder, obsessive-complusive disorder (OCD) and post-traumatic stress disorder (PTSD). The site supports clients with immune conditions HIV/AIDS. Patients can volunteer to be in research studies or read about cutting edge treatments under development. The site is searchable by location, age, disease, treatment, or symptoms, making it easy for members to connect with each other and find relevant information. Privacy protections prevent using real names (patients use screen names) or contact information. Members have the option of posting photographs or diagrams with their condition, gender and age. Multiple communication channels encourage open sharing about new treatments, uncommon symptoms or overcoming everyday problems, and site features address a range of learning styles

In addition to potentially developing clients' basic technological competence, confidence, and 21st century skills, which are prerequisites for many jobs and education options, facilitating their use of social digital technologies, such as online social network sites, may provide them with a rich, multimedia toolkit through which to express their talents, interests and aspirations. Early research is beginning to discern how digital story creations, for example, serve social functions, especially for traditionally underserved, disengaged students (Hull & Nelson, 2005). Displaying different sides of oneself in a supportive peer-to-peer network may help forge beneficial social relationships around common interests and/or help human services professionals, if linked in to such profiles, better understand their clients' needs.

Gustavsson and MacEachron (2008), in examining the role of the Internet in foster care, suggest that where youth experience multiple placements and risk losing an accurate biography of their childhoods, email accounts that function as an electronic diary may be one solution. We suggest that agencies and human services professionals might better serve such young people by not only helping them develop a secure digital repository —providing "a portable life biography and sense of self over time" —but also a portable, dynamic network of people and resources they take with them independent of place and time. An online support network can be available when a social services professional is not. Since many of these networked communities are international, members are online chatting and blogging at all hours of the day dealing with a variety of issues. Clients are likely to find someone who can empathize and offer support when other resources may be unavailable. In these ways, SNSs may complement or extend a client's overall treatment plan.

FUTURE TRENDS

As human service professionals utilize social networking technologies to forge individualized, constructivist learning experiences, work practices, and technology-integrated service or treatment approaches, new research opportunities will develop and best practices, evolve. People, both young and old, who understand how to use these online social networks for self expression, community-building and professional development, may have a decided advantage over those who do not. According to a survey by the U.S. National Association of Colleges and Employers published in March 2008, employers will not only use online social network sites to check profiles of potential hires, over 50% will use sites like Facebook (www.facebook.com) and LinkedIn (www.linkedin.com) to "network" with candidates. Recruiters and recruits in entertainment, business, higher education and other industries are beginning to capitalize on these social digital technologies to find new talent, make professional connections and promote their accomplishments (Rosenbloom, 2007). Moreover, technology executives predict an increasing proliferation of SNSs as online social networking moves away from restricting users to walled-off membership in a few sites toward a more open and flexible sharing between numerous niche communities (Stone, 2007; Helft & Stone, 2007). Thus, participation in such networks may increasingly become part of the educational and career development process for people of all ages, in all fields.

CONCLUSION

This chapter introduced the reader to online social network sites, summarizing their features, uses, demographics, and trends, and presenting emerging research on their social and educational potential through the case study of one young woman in transition. Exploring SNSs through a case study illustrated how they can be used to support young people's social and emotional development as they provide spaces to express emotions, deepen friendships and demonstrate creativity. The young woman in the case study developed 21st century skills working in the multimedia environment of her MySpace profile. She also utilized her connections for academic ends, getting help with homework as well as giving advice to younger students about the college application process. Other young people can use SNS's to similar advantage.

Social networking sites specifically for human service professionals and their clients were also discussed. Several sites where professionals can share resources, mentor others and find career information were listed. This chapter also listed SNSs that support clients such as SoberCircle and PatientsLikeMe. We also emphasized how private networks can be constructed to facilitate work with clients without exposing private information online. Finally, in our discussion and recommendations, we suggested how human services educators, students, professionals, and clients might take advantage of such information and communication technologies to advance their own development and the state of the field. Through a greater accumulation of research and practice we look forward to building on the conversation started here.

Chapter 1.16
Teens and Social Networking Services: An Overview

Maryann Mori
Evansville Vanderburgh Public Library, USA

ABSTRACT

This chapter provides an overview of the ways teens interact with social networking services. It acknowledges that teens are active users of social networking sites, and the implications of this usage affect and/or cross social, moral, educational and political lines. By reviewing current trends and statistics from various authors and sources, this chapter provides background information to understanding the growth and importance of online social networking among the Internet generation. Topics include demographics, ramifications on social behavior, adults' concerns, policies designed to restrict teens' Internet access, educational benefits and future directions of teens' use of social networking services. Realizing the importance and influence of online social networks among teens should provide readers with a better understanding of how these sites can not only be used for educational and marketing purposes, but also be integrated within work environments.

DOI: 10.4018/978-1-60566-104-9.ch009

INTRODUCTION

Adults may refer to the online sites as social networking services or sites, online social networks, interactive Web applications, or variations on a theme of Web 2.0. But as adults create titles and descriptions for these sites, "teens are speeding ahead, making it up as they go, including the language and the tools and their uses. To them, these sites are just another tool for socializing" (Magid & Collier, 2007, p. 2). Teens generally refrain from using any of the adult variations of titles and simply refer to the services and sites by function or commercial site name. By reviewing current trends, uses, effects and concerns of teens' use of social networking services, this chapter provides background information about the continued growth and importance of online social networking among teens.

In order to increase awareness and understanding of the various implications of social networking as they influence teens, this chapter will attempt to do the following:

- Review the way the Internet in general and social networking services specifically have influenced teen generations;
- Examine teens' online behavior and their use of social networking services;
- Discuss why social networking sites are so attractive to teens;
- Consider the ways social networking affects teens' interaction in online and real-life social situations;
- Address the concerns of parents, other adults and media reports of online dangers;
- Review information about various legislations and policies designed to restrict minors' use of social networks;
- Present successful and creative uses of social networking among teens;
- Show that social networking services are a major part of teens' lives and a viable aspect that will continue to increase in usage among teens and impact their adult lives.

While the exact age of teens varies among sources, the term usually describes students in middle school and high school. The American Library Association's division of Young Adult Library Services Association (YALSA) defines *teens* as students ages 12-18 (American Library Association [ALA]:Young Adult Library Services Association [YALSA], n.d.). It is the definition generally used for purposes of this chapter.

When Donald Tapscott wrote his book *Growing Up Digital: The Rise of the Net Generation* in 1998, he referred to teens as the Net generation (also Net Gen or N-Gen). Teens born after the rise of computer technology have been given an assortment of generational titles including the Internet generation, Generation M (for Media) (CBS, 2005), Gen Y and MySpace generation. The Pew Research Center for the People and the Press calls these teens "Generation Next" (2007). The assortment and interchangeability of titles seem appropriate for a generation that is used to constant change in technology. For purposes of this chapter either Net Generation or Next generation (or variances of those two titles) will be used to describe the generation. The titles describe a generation used to multi-tasking and instant information (Tapscott, 1998). This generation is willing to compromise privacy (Kelsey, 2007) in exchange for accessing the world 24/7 via the Internet. They are more literate in visual concepts than previous generations (D. Oblinger & J. Oblinger, 2005), yet equally comfortable with text that amply appears on the screens of computers, cell phones and video games. They are a generation that is inclusive and social (D. Oblinger & J. Oblinger, 2005), as well as interactive and investigative (Tapscott, 1998). Specifically, they are a generation born around 1980—after Generation X which comprises individuals born from 1966-1980 (Pew Research Center, 2007). Tapscott refers to the Net generation as those people "born between 1977 and 1996 inclusive" and declares that "internationally the Net Generation is huge, numbering over two billion people" (Tapscott & Williams, 2006, p. 46). Next generation teens are creative, and they have found an outlet for their creativity by using social networking services to express themselves, and to evaluate each other and their world.

INFLUENCES OF THE INTERNET AND SOCIAL NETWORKING SERVICES ON TEENS

Anastasia Goodstein (2007) wrote in her book *Totally Wired: What Teens and Tweens are**Really**Doing Online,* that while teen trends may have changed, the basic struggles of adolescent development have not changed much from previous generations. Goodstein believes these wired teens, like their predecessors, are still "trying out different identities, learning responsibility, being impulsive and idealistic, feeling invincible, dealing with physical changes, distancing from parents, and creating meaningful relationships with friends" (2007, p.2). One thing that does denote a change for the Net generation, however, is the fact that this generation is "the first cohort to grow up fully wired and technologically fluent" (Hempel & Lehman, 2005, p. 88), and that fact has had an obvious effect on teens.

Professors Diana G. Oblinger (2005) and James L. Oblinger (2005), editors of *Educating the Net Generation*, identify five characteristic differences in the way Next Gen students analyze and absorb information. Oblinger and Oblinger credit all of these characteristics directly to technology's influence on the generation. Among these differences are students' ability to understand more visual communication, to easily navigate between the virtual and physical worlds, to learn through self-discovery, to quickly retarget their attention (similar to multi-tasking), and to respond quickly and anticipate equally fast responses (D. Oblinger & J. Oblinger, 2005). Social networking services feature capabilities that cater to these types of characteristics by including ample visual stimulation through photographs, videos, virtual environments and vlogs; allowing students to have real-life types of communication, relationships and experiences in a virtual setting; giving teens the opportunity to explore topics, express their ideas and learn for themselves; and enabling instant messaging and rapid posting of constantly-changing information. Another observation by Oblinger and Oblinger is the desire for socialization by Net generation learners, who prefer activities that encourage "social interaction" (2005, p. 2.6). In many online situations, this social interaction becomes mass collaboration or what Tapscott calls "peer production" (2006, p.11). Additionally, these teens have an "openness to diversity, differences, and sharing;" "are at ease meeting strangers on the Net;" are "emotionally open," and have "developed a mechanism of inclusiveness that does not necessarily involve personally knowing someone admitted to their group" (D. Oblinger & J. Oblinger, 2005, p 2.6).

USE OF THE INTERNET AND SOCIAL NETWORKING SERVICES AMONG TEENS

According to 2007 reports by the Pew Internet & American Life Project, 93% of American teens use the Internet (Lenhart & Madden, 2007b, p.3), and "more than half (55%) of all online American youths ages 12-17 use online social networking sites" (Lenhart & Madden, 2007a, p.1). Berkeley doctoral candidate Danah Boyd believes the latter figure is low. Boyd, who has become the oft-quoted and recognized leader in social networking research, particularly as it pertains to teens, says that in her experience with teens, 70-80% of them have an online profile (2007b, Methodological notes, para. 4). Boyd acknowledges that not all the teens she interviews are active on their profile accounts or may not have created the profiles themselves (rather, allowing friends to create profiles for them). She believes 50% indicates the percentage of teens who are active (as opposed to inactive) users of social networking services (2007b, Methodological notes, para. 4).

Globally, the number of people accessing the Internet and (often) social networking sites is increasing. In July 2007, comScore, which calls itself "a global leader in measuring the digital world" (Lipsman, 2007c), released global statistics regarding the use of social networking sites among Internet users over the age of fifteen. According to comScore's executive vice president of international markets, "social networking has really taken off globally" (Lipsman, 2007c). Observing an increase in the daily visits to social networking sites, comScore says "it would appear that social networking is not a fad but rather an activity that is being woven into the very fabric of the global Internet" (Lipsman, 2007c). In the United Kingdom, people aged15-25 are "25% more likely to be online than the general population" (Lipsman, 2007b). In Australia, nearly half of all children ages 6-17 are online daily (Woodhead, 2007). Australian teens ages 15-17 go online daily, often to access social networking sites (Woodhead, 2007). Canada boasts "the world's ninth-largest Internet population" with 80% of the population visiting social networking sites (Canada online overview, 2007). As of May 2007, Japan's Mixi, the nation's largest social networking service, had eight million registered users (McNicol, 2007). Half a million teens are part of Mixi's registered users (Katayama, 2006). CyWorld has 18 million Korean users (Schonfeld, 2006) with 90% of Korean teens and twenty-somethings having an account (Ihlwan, 2005). Orkut, Google's social networking site, has made major inroads in Latin America, particularly in Brazil (Kharif, 2007). 12.4 million unique users from Latin America visited Orkut in August 2007, twice the amount of visitors from that same region to MySpace and Facebook combined (Kharif, 2007).

Lenhart and Madden's study analyzes American teens' online behavior by demographics and shows that younger teens with online profiles are fairly divided between the genders until they get older (2007a, p.3). A larger gender division occurs when age becomes a factor. Seventy percent of online girls ages 15-17 have created a profile, while 57% of online boys this age have done likewise (Lenhart & Madden, 2007a, p.3).

An earlier Pew Internet report (Lenhart, Madden, & Hitlin, 2005) indicates a major increase in Internet use as teens advance in grade levels. These figures denote general online use and not necessarily use of social networking sites. While 60% of 6th grade students were shown to be online, by 7th grade the number rose to 82%, and by grade eleven 94% of teens indicated being online (Lenhart et al., 2005, p.1). Age is also a factor in the frequency of Internet use. American teens between the ages of 15-17 frequent the Internet more than younger students, with 59% of those older teens going online at least once a day (Lenhart et al., 2005, p.2).

The amount of time teens spend online continues to increase. Nielsen/NetRatings from October, 2006 showed the amount of time American teens spend online increased 27% within a three-year time period (Bausch & Han, 2006). The survey shows that American teens spent an average of nearly 27 hours per month online (Bausch & Han, 2006). A study with variances from the aforementioned comparison indicates the hours European visitors over age 15 spend on social networking sites and rates the United Kingdom with the highest time spent at an average of 5.8 hours per month, followed by Germany at 3.1 hours per month (Gavin, 2007). "Heavy users" in the U.K. spend an average of 22 hours on social networking sites (Gavin, 2007). According to Lenhart and Madden (2007b), daily use of the Internet by American teens has risen from 42% in a study conducted in 2000 up to 61% in a similar study conducted in 2006 (p.3). Teens are spending much of their online time visiting social networking sites. "[Forty-eight percent] of teens visit social networking Web sites daily or more often; 26% visit once a day, 22% visit several times a day" (Lenhart & Madden, 2007a, p.2).

Sites that are especially popular among this age group tend to be those that are social networking in nature (Lipsman, 2007b). Bob Ivins, executive vice president and managing director of comScore Europe, says the high Internet usage among younger people shows that the Internet is "integral" to this generation (Lipsman, 2007b). "Younger people use the Web for communications, content, community and commerce more than other age segments," says Ivins (Lipsman, 2007b). So many young Australians are using the Internet that statistics among youth ages 6-17 have now plateaued at 92% (Woodhead, 2007). Commenting on American students' use of social networking sites, Ken Cassar, chief analyst for Nielsen/Net Ratings says, "The Internet is as much a part of children's lives as TV, school and books. We can expect the time kids spend online to increase along with expanded offerings on the Web and the growing network of their friends and family who use the Web frequently" (Bausch & Han, 2006).

One of the ways teens use social networking services is by creating and maintaining a personal profile page on a site such as MySpace, Facebook, Orkut, Bebo or one of many other such commercial sites. These profiles usually include photographs, comments, surveys, likes and dislikes, and personal interests. Video clips, songs, and decorations often complement the profile. Online profiles may be compared to interactive scrapbooks or photo albums. Since keeping their profile pages interesting is an important aspect for teens, it is possible that many teens are spending their online time posting new information to their profile. The Nielsen/NetRatings survey shows that American teens' favorite Internet sites are those which offer tools or assistance in developing content or layouts for online profiles (Bausch & Han, 2006). However, according to Lenhart and Madden, the overwhelming reason American teens cite for visiting their social networking sites so often is to "stay in touch with friends" (2007a, p.2).

Social networking sites are often compared to the malls, soda shops and other assorted hangouts that appealed to previous generations of teens. "Social networking sites have become the virtual commons where teens go to hang out with their friends" (Rapacki, 2007, p.29). In a *People* magazine article about MySpace, psychologist David Walsh said "Kids have always congregated with other kids. Two generations ago, it was at the corner candy store. Now, in this high-tech age, MySpace is the candy store on steroids" (Hewitt et al. 2006, pp. 116, 118). Teens do many of the same things online that previous generations did in school hallways, friends' rooms, locker rooms or local hangouts. They talk, laugh, gossip, share and flirt with each other. Just how many teens are on which sites is difficult to determine, primarily because the numbers keep increasing so rapidly, and as Boyd recently observed, "one of the biggest problems with studying youth culture is that it's a moving target, constantly shifting based on a variety of social and cultural forces" (2007b, Methodological notes, para. 3). Couple that moving target with rapidly evolving aspects of technology, and statistics often become difficult to track. In December 2005, *BusinessWeek* named three popular social networking sites and showed that the number of users ages 12 to 24 accounted for 45% of all users on MySpace, 50% of all users on Xanga, and 57% of all users on Facebook (Hempel & Lehman, pp.90, 92, 94). The January 2007 Pew Internet report also shows that MySpace, Facebook and Xanga are popular sites among American teens (Lenhart & Madden, 2007a, p.4).

ComScore released statistics on July 31, 2007, revealing the "expansion of social networking across the globe" among various users ages fifteen and over (Lipsman, 2007c). The study lists seven sites, all of which experienced significant growth from the previous year ranging from a 56% increase for Hi5 to 774% for Tagged (Lipsman, 2007c). ComScore notes that "specific social networks have a tendency to skew in popularity in different regions" (Lipsman, 2007c). MySpace and Facebook are the top contenders in North America, Bebo's audience appeal is in Europe, Orkut's following is in Latin America, and Asia-Pacific regions prefer Friendster (Lipsman, 2007c). Hi5 and Tagged are identified as having "more balance in their respective visitor bases, drawing at least 8% from each of the five worldwide regions" (Lipsman, 2007c).

Boyd (2007) offers an interpretation of teens' preferences for specific sites as those preferences fall within social issues. On her blog, Boyd discusses recent trends of high school students transferring their online profiles to Facebook from MySpace, a change she believes reflects socio-economic factors rather than age or gender (2007b). Boyd calls this exodus a "fragmentation" (2007b, para. 1) rather than a shift, and her essay has been summarized as suggesting "MySpace users tilt toward the lower middle classes" (Atal, 2007). Although Boyd admits the essay she posted on her blog is not academic in nature, she writes that she has recently seen a clear division in the kinds of students using MySpace versus Facebook. Facebook, which was previously open only to college students, opened its membership in 2005 to include high school students. Boyd acknowledges that students who are from families where education is emphasized are the ones now using Facebook (2007b). She believes MySpace is the preferred social networking site for teens whose parents did not go to college, and who themselves will be expected to get a job rather than pursue higher education after high school (2007b). Boyd divides the two groups of teen users, those on Facebook versus those on MySpace, as hegemonic and sub-altern, respectively (2007b). She admits that the terms are not completely adequate for her descriptions but adds, "Sub-altern teens who go to more mixed-class schools see Facebook as 'what the good kids do' or 'what the preps do.' … [T]he hegemonic teens see MySpace as 'where the bad kids go'" (2007b, Socio-economic divisions, para. 9). Boyd summarizes her observations by saying that this "division around MySpace and Facebook is just another way in which technology is mirroring societal values" (2007b, Thoughts and meta thoughts, para. 2). Additional research is necessary regarding this division.

BusinessWeek notes that many of the same online users are utilizing both MySpace and Facebook and quotes comScore as reporting "a 64% overlap" of those people who use both sites (Atal, 2007). *BusinessWeek* does not indicate the ages of the people in their findings.

THE ATTRACTION OF SOCIAL NETWORKING TO TEENS

Regardless of which teen is using which social networking site, just what is the appeal of these sites to teens? Social networking sites are the commons or hangout for Next generation teens. Because this hangout is in a virtual world, it not only means that it is open any time, but also that it is, more often than not, clear of parental control. Parents are often not as tech-savvy as their online children and therefore do not always frequent the same online social networks as their teens. Candice M. Kelsey (2007), author of *Generation MySpace: Helping Your Teen Survive Online Adolescence*, compares MySpace to a kind of virtual "clubhouse" for teens—a clubhouse with access through the "doors" of every computer, PDA and some cell phones (2007, p. 2). Kelsey adds that MySpace is a "parent-free zone" where teens "can pretend to be anything or anyone they want" (2007, p. 2), both of which are additional appeal factors to teens. The same descriptions can be said of most social networking sites frequented by teens.

Boyd agrees that the absence of parental or adult authority is part of the appeal of social networking sites among teens. As quoted in Kelsey's book, Boyd says "MySpace is the product of youth creating space of their own. Teens are looking for a release from the control of their usually unstable homes. …It is a control issue at heart" (Kelsey, 2007, p. 13). Boyd also says that technology (namely social networking) is helping teens cope with their often stressful and fragmented lives by providing places to socialize and develop a sense of "community" with other teens (2007b, Thoughts and meta thoughts, para. 7).

Tapscott rightly predicted that the Internet would soon become a place that would "carry audio and full-motion, full-color video" and that "anyone…with a video camera and PC will soon be able to broadcast to the world" (1998, p. 50). He declared that "tens of millions of N-Geners around the world are taking over the steering wheel" (p. 26) of the media and added that this generation was unique in that it was the first group to take "control of critical elements of a communications revolution" (p. 26). Again, the issue of control becomes a factor when reviewing reasons social networking sites appeal to teens. Teens grabbed hold of the steering wheel, and as Magid and Collier declare in a subtitle, "Teens Are in the Driver's Seat" (2007, p. 172). Instead of being just spectators to information, stories, events and news (as previous generations had to be with television and print sources), teens are now content creators and contributors through the concepts and capabilities of social networking sites.

With little parental involvement or control, teens are very open in their online postings and express an attitude of independence—aspects which, for many adults, open issues of Internet ethics. Teens' postings often include "raw content" (Hewitt et al., 2006, p. 119) such as crude language and risqué photographs or videos, in addition to discussions of sex, alcohol and drugs (Simon & Majewski, 2007). As Tapscott (1998) noted, independence and openness, as well as free expression are some of Net generation's characteristics, although past generations of teens have also freely shared dirty pictures and discussed taboo topics among themselves when parents or caregivers were absent. Part of the way teens develop independence is by exploring their identities as they mature, and social networking sites can contribute to this self-identity process by allowing teens to experiment with different representations or identities of themselves online. Tapscott addressed the topic of "vanity" (p. 113) in his book although he believed the opportunity for teens to post personal information online was a way for students to develop their self-esteem.

Some adults believe teens' social networking use goes beyond building self-esteem and use the word *narcissism* to assess teens' love affair with social networking. Psychologist Michael Brody boldly declares "digital technology is associated with self absorption, narcissism and isolation" (2006, p. 8). Boyd acknowledges teens' desires for fame, something akin to "peer validation" (2007a, para. 7) and admits that technology such as social networking allows for free distribution for teens and other "fame-seeking narcissists" to post themselves online "in the hopes of being seen and being validated" (2007a, para. 7). Boyd's comments echo Lenhart and Madden who show that a major attraction of social networks for teens is the feedback and sense of belonging to a group that they receive from the sites (2007b, p. 13). To some teens, having their image and ideas noticed by others on the Internet is the equivalent of fame.

When *University Business* wrote an article about social networking services (Sickler, 2007), research was conducted with college students about their use of Facebook and MySpace. Although slightly older than teenagers, these college students' comments echo many teens' views of social networking sites:

- "It is way too much fun to think that people are looking at me and paying attention to me in their free time"
- "It reminds me that I have friends"
- "I also like that it is an excellent way to get people to stare at pictures of me and basically worship me by writing things on my Facebook wall" (Sickler, 2007).

While Boyd does not believe social networking sites cause narcissism, she does believe sites such as MySpace serve as "a platform for people to seek attention" (2007a, para. 15). Mike Riera, author of several parenting books, says," I think the very nature of being a teen is very narcissistic. They're so in love with themselves that they think everyone else will love what they have to say, too" (Goodstein, 2007, p. 34).

SOCIAL NETWORKING SERVICES AND TEEN SOCIAL BEHAVIOR

Having their say on blogs is yet another way teens are socializing and promoting themselves online. According to Forrester Research, blogging—including publishing a blog—is "booming" among North American youth ages 13 to 17 (Charron & Florentino, 2006). Blogs, which may be compared to online diaries, allow teens to express themselves in an environment free from parents, to explore their own identities, to form virtual relationships, and to locate people with common interests (Goodstein, 2007, pp. 30-32). An interesting aspect of online socializing is the way anonymity affects teens' interaction with each other. Teens online find that they are not judged by physical characteristics such as race, clothing styles or age as they might be in real life (Goodstein, 2007, p. 66; Lenhart & Madden, 2007b, p. iii). Goodstein references a *San Jose Mercury News* article that discusses teens at a particular high school who socialize virtually with classmates they would never socialize with in person. "For some teens, the friends they meet on blogs remain online friends who don't interact at all offline, even if they pass each other in the hallways" (Goodstein, 2007, p. 32).

The New York Times published an article about the rise in popularity of self-portraits, especially among teens (Williams, 2006). Williams' article refers to the generation as one "raised on a mantra of self-esteem" who now is comfortable with taking pictures of themselves and posting them online for anyone to see. Williams quotes a developmental psychologist as saying young adults have an idea known as "the imaginary audience"—that is, "the idea that adolescents think people are more interested in them than they actually are" (2006). Although the concept may not be new, today's teens seem "more comfortable with public self-exposure" (Williams, 2006).

Unfortunately, many teens are willing to do or post anything to gain exposure online, which causes actions that raise additional concerns about Internet ethics. According to a *USA Today* report, some children identified in Internet child pornography are actually photographs of older teens who have taken provocative photos of themselves and posted them online (Sher, 2007). Kelsey's research indicates this phenomenon is common and growing among American teens, especially girls. Kelsey writes, "girls are ferociously searching for boys' attention, and MySpace is the ideal platform for achieving this goal. The sexier the photos, the taglines, and the screen names are, the more male MySpace friends a girl will earn" (2007, p. 144). In a random search of high school students' profiles, a professor at Fresno State found photographs of sexual poses on 59% of the sites (Kelsey, 2007, p. 148). Detective James McLaughlin of the Keene, New Hampshire police department says, "I don't think a week goes by where we don't see two to three adolescents post nude photos of themselves" (Hewitt et al, 2006, p. 120).

A *Washington Post* article indicates peer pressure as one of the growing reasons teens exaggerate their online postings (Bahrampour, Aratani, & Stockwell, 2006). However, sometimes students are tricked into posting provocative photographs of themselves. Older men create fake profiles and disguise themselves as teen boys who then identify "lonely" girls (based upon information contained in the girls' profiles) and become a "boyfriend" to the girl (Sher, 2007). With a little coaxing, such at-risk young females end up being seduced online and convinced to send the so-called boyfriend a sexually graphic picture, a process sometimes called "sexual grooming." The United States Justice Department refers to these kinds of solicitations as "cyber enticement" (Sher, 2007). Emily Vacher is an FBI undercover agent who says this type of online behavior is "a trend, and it's scary" (Sher, 2007).

There are other forms of misrepresentation that take place on social networking sites. For example, MySpace has a minimum age requirement of fourteen to join, yet "the most common example of misrepresentation [online] is teens under age fourteen lying about their age to beat the minimum age requirement for using the service" writes teen services librarian Sean Rapacki (2007, p. 30). As already noted, teens can post profiles that reveal anything they want, including a totally different personality from what they display in real life. Kelsey describes her shock at viewing a social networking profile of one of her students—a student she described as polite, conservative and quiet. The student's MySpace page, however, reflected "an angry young woman in full gang attire" with numerous references to sex, derogatory slang, and assorted images and phrases that were completely contradictory to the image the student portrayed on a daily basis at school (Kelsey, 2007, p. xxii). Lenhart and Madden (2007b) show that over half (56%) of online American teens have posted some false information to their online profiles (p. 23). However, only 8% of online teens have created mostly or entirely fake profiles (Lenhart & Madden, 2007b, p. 23). Boys are more likely than girls to post false information to their profiles (Lenhart & Madden, 2007b, p. 24). When Kelsey asked a psychotherapist about which representation of a student is real—the online or real-life version—the psychotherapist responded that neither version correctly identifies a student since teens are still developing their identities (Kelsey, 2007, pp. 158-159).

Teens often falsify information on their social networking profiles in an attempt to get the most visits to a page, or to collect the most *friends* on their profiles (Kelsey, 2007). The concept of meeting people and collecting friends online describes *friending*, a word used to describe the development of online relationships. Boyd writes that friending is "a key component of social network sites" (2006, abstract). "Friending" writes Kelsey, "is a newly coined verb direct from the MySpace lexicon, short for befriending. It simply means *the act of accepting or being accepted by a new contact with the mutual intent of labeling one another 'friend'* [*sic*]" (Kelsey, 2007, p. 81). "Friending supports pre-existing social norms, yet because the architecture of social network sites is fundamentally different than the architecture of unmediated social spaces, these sites introduce an environment that is quite unlike that with which we are accustomed" (Boyd, 2006, abstract). Just as past generations had cliques, and teens' social statuses were dependent upon their circle of friends, so do today's teens rely upon the circle of online friends with whom they keep company to establish their status. The difference, however, is that friends in the online world are often really strangers, a fact that raises concerns about online behavior and relationships.

Visitors to an online profile can ask for a "friend request" or to be "added" to the teen's profile page. Being included on another teen's profile (especially if that other teen is deemed socially cool) can elevate an individual to wider and often higher social circles. Likewise, a teen whose profile has numerous friends is showing that he or she is popular and worthy of having even more friends. Not only does the teen accumulate a higher number on his or her profile listing of friends, but that teen is then added to the profile page of the persons whom the teen accepts as friends. Since profile pages often list the number of friends the profiler has, friending thus becomes a numbers game as well as a vicious popularity competition. "As people navigate Profiles [*sic*], they build an image of who people are through their Friends [*sic*]" (Boyd, 2006, Friending as context creation, para. 2). Kelsey calls the friending process a "commodities-trading style of relating" where teens judge each other "merely by how many other people like him or her" (2007, p. 86). "Listing your buddies and your friends is a way of establishing yourself, of feeling connected and feeling like you're accepted" says adolescent psychologist Susan Lipkins (Kelsey, 2007, p. 83).

In addition to collecting numerous online friends (often numbering in the thousands), teens are also ranking those online relationships. MySpace initiated the concept of a *Top 8* friends list. Instead of listing friends in the order of the date of their acceptance to a profiler's page, the profilers themselves can put friends in a pecking order, so to speak. "By implementing a 'Top 8' feature, MySpace changed the social dynamics around the ordering of Friends [*sic*]" (Boyd, 2006, But am I, para. 2). Teens often admit that they do not really know many of the so-called friends on their lists, and they realize the damaging consequences of *friends lists*, especially among younger teens who may not be strong enough mentally or emotionally to understand why they may not be part of a Top 8 list. "MySpace is a psychological warfare" says one teen (Boyd, 2006, But am I, para. 4). Dr. Lipkins says "friending is not just a pastime, it's also an indication of social success or failure" (Kornblum, 2006). Teens can add, rearrange, and even delete friends with little more effort than clicking a computer key. "If someone seems interesting or you want to get to know them better, what's the loss in Friending [*sic*] them? As far as most participants are concerned, Friendship [*sic*] doesn't mean anything really, so why not?" (Boyd, 2006, To friend or not, para. 9). Quoted in a *USA Today* article, Michael Bugeja, author of *Interpersonal Divide: The Search for Community in a Technological Age,* makes the following distinction between the superficial online friending list and the real-life list of friendships: "Friending really appeals to the ego, where friendships appeal to the conscience" (Kornblum, 2006).

BusinessWeek's cover story titled "The MySpace Generation" (Hempel & Lehman, 2005) notes that social networks are "creating new forms of social behavior that blur the distinctions between online and real-world interactions" (p. 89) and "today's young generation largely ignores the difference" (p. 89). Even some teens are beginning to worry about their generation's attitudes regarding friendship. "All those friendships aren't real" says one 17-year-old student (Kornblum, 2006). Another teen says, "MySpace cuts out real communication between people.… Since the communication is so meaningless, it makes relationships meaningless" (Kelsey, 2007, p. 85). Dr. Larry D. Rosen, professor at California State University, has spent over two decades examining what he calls "the psychology of technology" (Rosen, 2006, p. 1). In a 2006 study, Rosen researched pairs of teens and parents and found that teens had "about 200 friends" on their MySpace accounts with 75 of those friends being deemed "close friends," in spite of the fact that teens had never met them (p. 2).

ADULTS' CONCERNS

The amount of time teens spend online concerns some adults who wonder about the possibility of teens becoming addicted to computer use. Psychologists seem divided on the issue of Internet addiction, and the topic is still deemed relatively new in the field of psychology, although Dr. David Greenfield, a clinical psychologist in Connecticut, believes the concept is "getting more and more recognition" (Klimkiewicz, 2007). Concerns about teens' "Internet gaming addiction" has led the Chinese government to initiate a nationwide program to "promote civilized Internet use" and limit the amount of time students under age eighteen spend online gaming (M. Lee, 2007). The discussion of online or Internet addiction has been debated for only ten years, and the American Psychiatric Association has not yet recognized the description as a disorder (Klimkiewicz, 2007). However, a Stanford University study shows that "one in eight Americans exhibited at least one sign of problematic Internet use" (Klimkiewicz, 2007). Psychiatrists who disagree with the diagnosis of Internet addiction believe that people who spend large amounts of time online are often suffering from other problems such as depression or anxiety (Klimkiewicz, 2007). Dr. John Grohol, a psychiatrist who oversees PsychCentral.com, believes that previous generations have had similar experience of abuses of new communication modes and says, "When you introduce a new technology into society, it takes a generation or two before it becomes well integrated" (Klimkiewicz, 2007). Rosen's study reveals that 20% believe "MySpace has negatively affected school, job, family and friends" (2006, p. 3) and that depression and Internet addiction were attributed to more time spent on MySpace in spite of the fact that more online friends were a benefit of time spent there (p. 3).

Kelsey devotes an entire chapter in her book to the subject of teen addiction to MySpace. She observes that many of the effects from frequent

MySpace use are similar to those of other compulsive behaviors or addictions, and she readily admits that she believes teens have become Internet addicted to MySpace (2007, p. 17). Kelsey writes that an addiction can be described as "an uncontrollable compulsion to repeat a behavior regardless of its negative consequences" (2007, p. 16). She quotes teens who admit that MySpace is "ruining" their lives, is "unhealthy," and "addicting" (2007, p. 16), yet those same teens will say they are unwilling to give up their MySpace profiles. One user of Japan's Mixi comments, "It's fun getting replies and comments to your diaries. Pretty soon, you get addicted" (Katayama, 2006). Dr. Michael Brody, professor of American Studies at the University of Maryland and CEO of the Psychiatric Center in Washington, D.C., says, "The words 'addicting' and 'obsessive' seem to describe much of the teen involvement in these electronic activities" (2006, p. 8). Kelsey's book includes the narrative of Rob Alderman, a graduate student who struggled to give up his MySpace profile. While Kelsey acknowledges that Alderman is beyond the teen years, his struggle is still the same as that of many teens she has interviewed. Alderman tells of his staying awake late at night in order to be part of a social network, of typing so often that the letters faded from his keyboard, and of spending more time with his online friends than his real-life friends (Kelsey, 2007, p. 23). "You can be who you want, when you want, with whom you want. In fact, it's so perfect and so addictive that it's easy to spend all of our time there, pouring ourselves into our own little MySpace kingdoms," says Alderman (Kelsey, 2007, p. 23). Alderman compares his online interactions to "worshipping at the MySpace altar" (Kelsey, 2007, p. 23).

A 2005 study by the Stanford Institute for the Quantitative Study of Society, as reported in *The Standford Daily*, revealed results of "social isolation" among those individuals with high Internet usage (Hanson, 2005). "[T]ime spent on the Internet is time taken away from other activities. Every minute spent on the computer is a minute taken away from face-to-face relationships with family and friends" (Hanson, 2005). Authors of the study reported that "each hour spent on the Internet reduces face-to-face time by 23.5 minutes" (Hanson, 2005).

Lenhart et al. (2005), however, found different results in their studies of online teens. They found that teens between the ages of 12-17 actually spend more physical time rather than online time with their friends (Lenhart et al., 2005, p. 30). On average, teens spend "10.3 hours a week with friends doing social activities outside of school and about 7.8 hours talking with friends via technology like the telephone, email, IM or text messaging" (p. 30). Additionally, 83% of teens participate in at least one group activity such as a school club or youth organization (Lenhart et al., 2005, p. 12). The author of this chapter has observed groups of teens in a public library setting who use computers to access social networking sites. Often these teens are interacting online with people sitting at a neighboring computer, or several of the teens will congregate around one computer and view aspects of a social networking site together, making comments to each other in the process. Thus, while the teens may individually be on the Internet, they are simultaneously interacting with real-life friends and not isolating themselves from real-life socialization. As previously stated, researchers and psychologists are still divided on the issue of Internet addiction and its ramifications on real-life social interactions. Additional research is needed, especially where these topics concern adolescents. Whether or not a formal acknowledgement of online or Internet addiction disorder is made, "teens are affected by this electronic culture and in turn, are effecting further changes in it" (Brody, 2006, p. 8).

In addition to their concerns about addiction, many adults (especially parents) fear that young people are making themselves too vulnerable to contact from online predators. Headlines and assorted media reports of such predators help feed adults' fears. Police warn there are predators who purposely search social networking sites in order to find their next victim, and finding that next victim is not hard for these predators to do according to Detective Frank Dannahey, an officer with the Rocky Hill, Connecticut Police Department. Dannahey provided written testimony before the Committee on Energy and Commerce Subcommittee on Oversight and Investigations, United States House of Representatives, about his findings as an online undercover detective. Early in 2006, Dannahey went undercover as a teen and created a MySpace account. He called himself "Matt" and claimed to be nineteen years old. Dannahey testified, "I have seen technology change in a direction that both benefits and assists online predators in carrying out their criminal activity. With the majority of America's teens online, the pool of potential online victims is vast" (2006, para. 1). He highlights the following results of his undercover social networking scenario: Teens as young as 14 and 15 years old willingly allowed Matt (presumably an adult) as a friend on their private profiles; many teens allowed Matt as a friend with no questions asked; teens voluntarily shared personal information; teens posted inappropriate and provocative photos of themselves on their profiles; teens routinely discussed their social activities and included dates, times and locations of such activities, as well as phone numbers to contact them; online surveys that include detailed personal information about the teen were common aspects of teen profiles (2006).

Dannahey summarizes his findings by observing that "teens are very trusting of people they meet online and are very willing to share their personal thoughts and information with virtual strangers" (2006, para. 6). He adds that bulletins, which often post real-time information, and the aforementioned surveys are key components whereby predators can glean pertinent information to learn details about a teen's daily routine, personal interests, and contact information. Dannahey's undercover assignment was developed in conjunction with a Dateline NBC broadcast and in reaction to the sexual assaults of seven teenage girls within a one-month time period in Middletown, Connecticut—assaults that were all the result of MySpace encounters (Dannahey, 2006).

Although many teens seem to realize (at least to some extent) the fact that their social networking profiles can be public information, they are not overly concerned about this fact. One sixteen-year-old says, "We're willing to give up some of our privacy to connect with people easier. The realization that people can find you online isn't that threatening to this generation" (Kelsey, 2007, p. 272). In spite of being comfortable sharing personal information online, teens are becoming more cautious with what they post to their online profiles. Lenhart and Madden indicate that 66% of American teens' online social networking profiles have limited access (2007a, p. 5). Fifty-nine percent of teens limit their profiles to viewing only by their friends, and the actual percentage of teens who post ample personal information to a public access profile is only 3% (Lenhart & Madden, 2007a, p. 5). However, as Detective Dannahey's undercover profile revealed, teens sometimes accept friend requests from people who are adults and total strangers, often without question or thought. Teens may also fail to realize that although they may be careful in setting their own page to private, their personal information can end up on someone else's page, and that second person may not have private settings. Lenhart and Madden (2007b) note that "many, but not all, teens are aware of the risks of putting information online in a public and durable environment. Many, but certainly not all, teens make reasonable, informed choices about what to share in what context" (p. 30). Lenhart and Madden further observe that "the warnings and concern coming from parents and educators are not falling on deaf ears" (2007b, p. 36).

Some of those warnings have come from news reports which abound with details of adult sexual predators who pretended to be teens online and lured unsuspecting, vulnerable young people to personal meetings where the teens were subsequently assaulted. ABC News and Good Morning America aired a report titled "All Children Vulnerable to Online Predators" and included the following quote as a byline in its online version: "Authorities Say 1 in 5 Children Has Been Approached By Online Predators" (Muir, 2006). The report included the story of a teen who had been swept into the online world of self-promoted sex sites by an online predator. "My experience is not as isolated as you might hope," said the teen, who added that "there are hundreds of kids in the United States alone who are right now wrapped up in this horror" (Muir, 2006).

Stories such as the one published and aired by ABC News focus on extreme incidents and often utilize the numbers reported in the Youth Internet Safety Survey (YISS) (Wolak, Mitchel & Finkelhor, 2006), a national survey conducted in the United States by the Crimes Against Children Research Center. Two such surveys were conducted. YISS-1 statistics were gathered from August 1999 to February 2000, while YISS-2 surveys were conducted from March to June 2005 (Wolak et al., 2006, p. 1). The ABC News "1 in 5" quote about children being approached by online predators stems from YISS-1. YISS-2, the more recent survey, shows a decrease in this number with 1 in 7 youth receiving "unwanted sexual solicitations" (Wolak et al., 2006, p. 1). An interesting discovery of the YISS-2 study is the additional information noted about the "1 in 7" sexual solicitation. YISS-2 shows that "43% of all solicitations and 44% of aggressive solicitations" were made by individuals under the age of eighteen (Wolak et al., 2006, p. 17). In other words, in many cases it is teens themselves who are making the solicitations of each other. Additionally, 14% of solicitations came from people the teen knew in person prior to receiving the solicitation (Wolak et al., 2006, p. 17). In 2000, a Pew Internet report showed that 60% of teens had received online contact from a stranger (Lenhart & Madden, 2007b, p. 34). A 2006 study shows the number dropped to 32% of teens who have been contacted online by a complete stranger, and of those teens, 65% of them say they ignored or deleted such contacts (Lenhart & Madden, 2007b, p. 34). Additionally, only 7% of online teens say they have been contacted by a stranger to the point of "feeling scared or uncomfortable" (Lenhart & Madden, 2007b, p. 35). According to the National School Boards Association, only .08% of students between the ages of nine to seventeen have met someone in person (without parental consent) after an online introduction (NSBA, 2007).

Teens often face a more immediate threat than predators on social networking sites—bullies. "Cyberbullying" is defined as "willful and repeated harm inflicted through the medium of electronic text" (Patchin & Hinduja, 2007). Cyberbullying can include a variety of tactics, such as sending nasty or threatening messages, posting untrue or exaggerated stories about the victim, impersonating the victim, or intentionally excluding someone from an online group. "Cyber-bullying is nothing short of social terror by technology" (Kelsey, 2007, p. 108) and is "the most common 'risk' for middle-school-age social networkers" (Magid & Collier, 2007, pp. 114, 115). A comparison of the two YISS surveys (Wolak et al., 2006) show that online harassment increased 50% by youth ages 10 to 17 (p. 10). The YISS-2 survey also notes that the number of students who say they have harassed or embarrassed someone else online has increased to 9%—up from YISS-1's 1% statistics (Wolak et al., 2006, p. 11). "The Internet is apparently being used more and more for the bullying and harassment widespread among many youth peer groups" (Wolak et al., p. 11). Half of teens surveyed at Ireland's Young Scientists' Exhibition said they had "experienced or witnessed" cyberbullying, with 10% saying it had happened "lots of times" (Cullen, 2007). An Associated Press story about online bullying indicates that Internet bullying, which allows harassment and insults to be sent to victims anonymously "can be more damaging to victims than traditional bullying like fistfights and classroom taunts" (Norton, 2007).

The New York Times published an article titled "Teenagers Misbehaving, for All Online to Watch" (Norton, 2007) which discusses teens' seeming obsession with posting online pictures or videos of violent behavior, including the abuse and beating of other teens—an extreme form of cyberbullying. While adolescent bullying is nothing new, it has "taken on a new dimension as online cinema verite. Instead of being whispered about among friends and then fading away, such rites of ridiculousness are now routinely captured on video and posted on the Internet for worldwide perusal, and posterity" (Kilgannon, 2007). The article included comments by Nancy E. Willard, author of *Cyberbulling and Cyberthreats,* who observes that teens may not realize the seriousness of posting themselves (or others) committing crimes such as vandalism and abuse, "but a lot of teens have this idea that life is a game and it's all just entertainment" (Kilgannon, 2007).

LEGISLATION AND RESTRICTIONS

In an effort to combat cyberbullying, predators, and pornography, the United States Congress introduced legislation in 2006 known as the Deleting Online Predators Act (Fitzpatrick) or DOPA, as it was more commonly abbreviated. The bill targeted schools and libraries in an attempt to establish Internet policy that would "protect minors from commercial social networking Web sites and chat rooms" (Fitzpatrick, 2006). DOPA passed the House in July, 2006 but later died in Senate (American Library Association [ALA], 2007). At the beginning of 2007, Senator Ted Stevens of Arkansas introduced S. 49, the "Protecting Children in the 21st Century Act" which is also known as the Deleting Online Predators Act of 2007. S.49 includes three components or titles. It is the second title that most affects teens. Title II mimics DOPA but targets schools and libraries by requiring them to enforce Internet safety policies that prohibit cyberbullying and to prohibit access to commercial social networking sites and chat rooms without parental consent and/or educational purposes (Stevens, 2007). As of July, 2007, this bill had been referred to the Senate's Committee on Commerce, Science, and Transportation (GovTrack). Not trusting another defeat in Congress, at least six states have initiated their own versions of DOPA—bills designed to place more restrictions on social networking among minors (Medina, 2007).

Other countries are equally concerned about Internet predators and are developing ways to establish some sort of Internet policy or protection plan for children online. Australia's federal governmental program, NetAlert, has a taskforce created to "examine the potential use of networking sites by pedophiles to groom children for sexual abuse and exploitation" (Wilson, 2007). The Council of Europe, which comprises 46 countries (including the United States), is hoping to pass a treaty that "seeks to protect children by criminalizing online behavior like 'sexual grooming'" (Carvajal, 2007). Germany already has a public service commercial that has become a "cult classic" on YouTube—one that is designed to warn children about "potential hazards" they may face online (Carvajal, 2007). The European Schoolnet hosts "Safer Internet Day" which involves schools in countries throughout Europe, as well as Australia, the United States and Canada (Richardson, 2007). The annual event has developed a "worldwide blogathon" which allows hundreds of schools throughout the world "to create internet safety awareness material" (Richardson, 2007). The Korean National Assembly is seeking ways to prevent "cyberviolence" (Katayama, 2006). In the United States, several states are seeking legislation to establish an age verification system (Medina, 2007). Such a system could require minors to prove they are old enough to meet minimum age requirements to establish social networking profiles and/or prevent older users from disguising themselves as teens.

Adam Thierer, director of The Progress & Freedom Foundation's Center for Digital Media Freedom, wrote a lengthy report titled "Social Networking and Age Verification: Many Hard Questions; No Easy Solutions," published in March, 2007. Thierer writes "Age verification is extremely complicated, and it would be even more complicated in this case because public officials are demanding the age verification of minors as well as adults, which presents a wide array of special challenges and concerns" (2007, p. 3). Thierer examines a variety of those challenges and summarizes his concerns with three generalizations about age verification, namely that such attempts would raise concerns of privacy issues as well as freedom of speech, it would not be foolproof, and finally that "education is absolutely necessary" (2007, p. 3) as the ultimate solution to preventing many of the problems that concern parents and politicians. Thierer also believes "that part of what is driving the push to regulate social networking sites is that many adults simply don't understand this new technology and have created a sort of 'moral panic' around it" (2007, p. 10). This misunderstanding, says Thierer, is also fear-driven by "a handful of highly publicized cases of minors being contacted and later abducted or abused by child predators on social networking sites" (2007, p. 5).

Tapscott (1998) implied the same reasons for adults' concerns over the then-new Internet. He believed the Internet posed "a challenge to the existing order on many forms" (1998, p. 50) and that adults who were more comfortable with their pre-existing forms of media and communication were "being made uneasy by a new generation and a new communications media that is controlled by no one" (1998, p. 50). Tapscott, like Thierer, also believed that "kids and the new technology are often unfavorably portrayed publicly" (1998, p. 45), and he noted that denial of the Internet to minors was often an answer to adults' concerns rather than education about online safety.

Attempts to curb cyberbullying are also being made by many U.S. states and schools (Norton, 2007). Although educators acknowledge the need for "guidelines" that would effectively help punish cyberbullying, others warn that such guidelines and laws cannot prevent cyberbullying, "You can't legislate norms, you can only teach norms" says a Rhone Island educator (Norton, 2007). The American Civil Liberties Union also believes it will be difficult to create legislation that would effectively prevent cyberbullying without imposing upon "free-speech rights" (Norton, 2007).

Perhaps due to negative media exposure, MySpace, one of the most popular of the social networking sites for teens, has developed several ways to make its site safer for minors. Partnering with the National Center for Missing & Exploited Children, MySpace will now post Amber Alerts of missing children (Lehman, 2007). The site has also attempted various verification systems that will prevent contact of older users with younger ones and allow parents to monitor their children's profiles to verify ages of other users (Lehman, 2007). MySpace has also initiated a "full privacy setting" and deleted hundreds of thousands of under-age users (Lehman, 2007). More recently, MySpace deleted over 29,000 registered sex offenders' profiles from its site (Associated Press, 2007). MySpace received especially negative media coverage when several families filed lawsuits against the company, claiming the site did not do enough to protect the families' teenage daughters from predators (Lee, 2007). One such lawsuit was dismissed by a Texas judge who declared, "If anyone had a duty to protect Julie Doe, it was her parents, not MySpace" (E. Lee, 2007). The dismissed lawsuit involved a 13-year-old girl who misrepresented herself as an 18-year-old on her MySpace page and was sexually assaulted by a 19-year-old man whom she met in person after being introduced to him on MySpace (E. Lee, 2007). In January, 2008, MySpace was subpoenaed by a United States federal grand jury in connection with the 2006 incident of a teenage girl who committed suicide after the boy with whom she had been corresponding on the social networking site rejected her (Glover & Huffstutter, 2008). It was later revealed that the "boy" with whom the girl had been corresponding was actually an adult woman who knew the girl (Glover & Huffstutter, 2008). No criminal charges were filed against that adult woman since prosecutors were "unable to find a statute under which to pursue a criminal case" (Glover & Huffstutter, 2008). However, prosecutors in the U.S. attorney's office of Los Angles, California believe there are possibilities of filing charges against the woman based upon wire fraud and cyber fraud (Glover & Huffstutter, 2008). Although the original case transpired in Missouri, the California prosecutors are assuming jurisdiction since the headquarters of MySpace are located in that state (Glover & Huffstutter, 2008). Other attorneys and prosecutors worry that 1st Amendment free speech issues may be compromised if an indictment in such a case were to occur (Glover & Huffstutter, 2008). The story of the subpoena, which appeared in a *Los Angeles Times* article, states that "it could be difficult to draw the line between constitutionally protected free speech and conduct that is illegal" (Glover & Huffstutter, 2008). Facebook also faces challenges. The New York State attorney general subpoenaed Facebook after undercover investigators "were solicited by adult sexual predators and could access pornographic images and videos" (Adegoke, 2007b). The subpoena is a result of a 50-state joint investigation and accuses Facebook of "not keeping young users safe from sexual predators and not responding to user complaints" (Adegoke, 2007b).

Some schools and public libraries are imposing their own Internet policies by restricting minors' use of social networking sites. According to the National School Boards Association, 52% of all U.S. school districts "specifically prohibit any use of social networking sites in school" (NSBA, 2007). At the beginning of 2006, a school district in Washington prohibited students from registering on Facebook with school e-mail addresses (Bahrampour et al., 2006). One parochial school even banned the use of social networking sites at students' homes (Bahrampour et al., 2006). MySpace was banned from some Florida schools after parents complained about the site (CBS, 2006), and a high school in Vermont banned blogging sites after deeming them non-educational (McKenna, 2005). At least one public library has banned MySpace from its public access computers. Wake County Public Library in Raleigh, North Carolina imposed such a ban after its library saw too much gang activity—activity the library's director says stemmed from postings on MySpace (Oleck, 2007a). The American Library Association (ALA) does not promote banning social networking sites from school and library computers. The ALA Council has passed a Resolution in Support of Online Social Networks which clearly affirms "the importance of online social networks to library users of all ages for developing and using essential information literacy skills" (ALA, 2006).

SOCIAL NETWORKS AS EDUCATIONAL SITES

Adults who realize the prominence of social networking sites in the lives of teens are choosing to use the sites as educational tools rather than banning them. ALA's division of Young Adult Library Services Association (YALSA) believes "social networking technologies have many positive uses in schools and libraries" (ALAALA: YALSA, 2007). YALSA encourages the use of social networking technologies by school and public libraries in order to help teens receive the following educational benefits: learning and creating together, receiving feedback, developing a "sense of community," learning from adults about safe and smart uses of social networking (ALA:YALSA, 2007, p. 2).Teens are already incorporating for themselves those first three benefits as they interact with each other on social networking sites. Steven Johnson wrote in a *Time* magazine article, that technology is "sharpening the minds of Generation M, not dumbing them down.… They're learning to analyze complex systems with many interacting variables, to master new interfaces, to find and validate information in vast databases, to build and maintain extensive social networks crossing both virtual and real-world environments, to adapt existing technology to new uses. And they're learning all this in their spare time—for fun!" (2006, p. 56).

The kind of learning that can occur from social networking sites is what Marc Prensky calls "engaging" (2005, p. 60). Prensky says Net Gen students are used to "being empowered to choose what they want … and to see what interests them …and to create their own personalized identity" (2005, p. 62), yet schools typically choose to teach subjects with traditional, non-tech methods—methods Prensky describes as "stale," "bland" and "yesterday's education for tomorrow's kids" (2005, p. 62).

The National School Boards Association (NSBA) conducted a study of United States students between the ages of nine and seventeen and found that 96% of them are using social networking sites (NSBA, 2007). One of the most encouraging outcomes of this report is that nearly 60% of these students are using social networking sites for educational purposes, with 50% of the students using the sites to "talk specifically about schoolwork" (NSBA, 2007). Among the many uses of their preferred social networking sites, these teens and preteens are sharing music, videos and photos; creating content (including site building), and blogging (NSBA, 2007). "There is no doubt that these online teen hangouts are having a huge influence on how kids today are creatively thinking and behaving," says the executive director of NSBA, Anne Bryant (Hunter, 2007). Bryant believes the "challenge" for educators is to "keep pace with how students are using these tools in positive ways and consider how they might incorporate this technology into the school setting" (Hunter, 2007).

Stephen Abram, a librarian and vice-president, innovation, for SirsiDynix, has written much about educational uses of technology with teens. He offers tips for using social networking sites to teach students information fluency (2006). Abram suggests that educators teach a program for teens about *pimping* (decorating) MySpace pages and interject online safety components into the program (2006). "A few asides can offer a lot of cyberknowledge," says Abram (2006, para. 4). Abram also suggests that using virtual worlds to create an avatar "with a great back story" could help students learn more about characterization in novels (2006, para. 5). He says students are already researching information about the characters and avatars that are found on many video games and "this creative act demonstrates that kids actually will do research for fun" (2006, para. 5). Some teachers have successfully created interest in literature by assigning students the task of creating a MySpace profile page for a character from a book (Kelsey, 2007, p. 26). Teens have readily accepted the assignment, created impressive projects and learned about literary tools in the process (Kelsey, 2007, p. 26).

YALSA published a "toolkit" guide to using social networks as a means to facilitate learning in schools and libraries (ALAALA: YALSA, 2007). The organization cites several ways in which social networking services can be used to enhance learning among teens. For example, school newspapers can be published online as blogs, wikis can encourage student reading and writing, teen advisory groups can host and post to MySpace profiles on behalf of libraries or school clubs, and book and author discussion groups can occur through blogs and MySpace accounts (ALA:YALSA, 2007).

The *Chicago Tribune* featured an article about the use of blogs among educators as a means to allow "kids a chance to share what's important to them" (Black, 2007). A teacher who successfully uses blogs in the classroom chose this medium in order to allow otherwise quiet students a chance to participate in class discussions. "The student who may be quiet in class will sometimes be liberated by it," says the teacher (Black, 2007).

School Library Journal included an article that encouraged using MySpace to teach aspects of art, social studies and music (Harris, 2006, p. 30). Teens who were asked why technology is an important part of their education noted that they had observed struggling students become better students through the use of computers (D. Oblinger, & J. Oblinger, 2005, p. 2.3). Modesto City Schools (California) became one of the first school districts in the United States to use the virtual world Teen Second Life (Balassone, 2007). Modesto partnered with Kyoto Gakuen High School in Japan to conduct synchronous student exchanges in Teen Second Life (Balassone, 2007). The collaborating English teacher at the school in Kyoto believes Second Life's "interactive nature" and game-like elements can make his students more likely to want to study English (Balassone, 2007). Universities are beginning to see the benefits of virtual worlds. Hundreds of colleges and universities, including Harvard Law School and New York University, are already conducting classes in Second Life (Balassone, 2007). Eye4You Alliance created an entire island in Teen Second Life that is devoted to education (Hale, 2007). The first college fair held in Teen Second Life occurred on that island in October, 2007 and had approximately 150 teen avatars in attendance (Hale, 2007). The University of Kentucky (UK) was one college that participated in the fair. The school sponsored university representatives (in the form of avatars) at its display, featured video display, gave a synchronous presentation, and even passed out UK t-shirts to visiting avatars (Hale, 2007). "I personally talked with teens from the Netherlands, England, New York and Texas," said one of the school's representatives (Hale, 2007). Having a presence in Second Life gave the school an opportunity to expand its geographic boundaries in ways it might not have been able to do in the real world.

Some public libraries are utilizing social networking to create online book discussion sites. Such sites have proven effective in outreach to young adults. Message boards, blogs, MySpace profiles, and book review capabilities linked from library online catalogs are just some of the ways online social networks are being used to encourage reading among teens (Rettberg, 2006). As of July 2007, 55 American public libraries and one Canadian library have profiles on MySpace (Oleck, 2007b). Hennepin County's public library in Minnesota created a teen-friendly MySpace page in 2006 and has seen "more than 21,000 monthly MySpace page views…and 500 weekly pass-throughs" from the profile to its library Web page (Oleck, 2007b). Libraries have embedded their online catalogs into social networking sites such as MySpace and linked their databases from similar sites (Farkas, 2007). "Creating presence in social networking software makes the library more visible and more convenient to access" says Meredith Farkas, a distance learning librarian (2007). A message on a youth librarians' electronic mailing list included comments from librarians who have had positive experiences using social networking services as outreach to teens. Those librarians who had incorporated the use of online social networks into their teen services commented that teens deemed libraries "cool" for having a MySpace page; teen participation at libraries increased because of a presence on a social networking site; the sites proved to be a tremendous means of reaching teens and promoting reading and library programs to students (Neville, 2006).

Teens use social networking services to write poetry, create instructional videos, compose songs, develop interactive Web sites for activities and organizations that interest them, and counsel other teens online. In fact, the National Suicide Prevention Lifeline has reported that one of the reasons for an increase in calls to their hotline has been teens spotting distress signals on other teens' social networking profiles (Magid, &

Collier, 2007, p. 174). As some teens openly express their suicidal thoughts on their profiles, other teens are paying attention to those signals and offering referral help. Australia's Inspire Foundation created a game-like virtual world known as Reach Out Central to promote mental health issues and management specifically among young people (Hoffman, 2007). It is the first such game created to assist with mental health issues (Hoffman, 2007).

Teens seek advice from each other online about issues pertaining to drugs and alcohol. They post messages to their social networking sites about the dangers of recreational drug use and where to go for help for loved ones suffering from substance abuse (Simon, & Majewski, 2007). They also use social networking services as places to grieve and mourn. Online social networks "have become as important to young people in death as they were in life" (Heher, 2007). Tom Anderson, president of MySpace, was recently quoted in a *Miami Herald* article as saying, "We often hear from families that a user's profile is a way for friends to celebrate the person's life, giving friends a positive outlet to connect with one another and find comfort during the grieving process" (Beras, 2007). Teens are one of the generations most likely to use social networking services for bereavement purposes (Beras, 2007).

Chris DeWolfe, one of the creators of MySpace, thinks "the mainstream media have so far missed the boat on the extent to which MySpace serves as a platform for doing good" (2007, p. 74). He argues that the younger generation who frequents MySpace is not self-absorbed and disconnected from society; rather, he states that this generation cares "about community, and they're actively engaged in civic causes" (2007, p. 74). DeWolfe cites examples of his company's social networking site being used to further such causes as feeding the homeless and promoting democracy worldwide.

MOVING FORWARD WITH TEENS AND TECHNOLOGY

It is obvious that Next generation's use of social networking sites affects the way they interact with each other, the way they learn, and the way they access and assess information. These effects will transform the future workforce. In fact, such transformations and acceptance of technology in the workplace are already visible now that many Net generation students have graduated from college. For example, in October 2007, the United States National Center for Health Statistics released statistics about physicians who use electronic medical records (EMR) in their practices. The study showed a 60% increase in the use of EMR as compared to usage in 2001, with age of the physician being a definite factor in usage (Hing, Burt, & Woodwell, 2007). EMR are used more than twice as much among physicians under age 35 as compared to doctors between 55 to 64 years of age (Hing et al., 2007).

In their book *Wikinomics: How Mass Collaboration Changes Everything,* Tapscott and Williams (2006) describe seven Net generation "norms" in the workplace: speed, freedom, openness, innovation, mobility, authenticity, and playfulness (p. 54). These norms or expectations are the result of mass collaboration, peer production and the interactivity of Web 2.0 applications this generation has come to take for granted. Tapscott and Williams refer to mass collaboration as a "participation revolution" and believe that "new models of peer production can bring the prepared manager rich new possibilities to unlock innovative potential in a wide range of resources that thrive inside and outside the firm" (2006, p. 17). They call these models "wikinomics"—a "new art and science of collaboration" (2006, p. 18). When Facebook incorporated a wikinomics-type of business by releasing its code to outside developers, it saw a 28% increase in users within two months (Kharif, 2007). Yahoo has plans for opening its site to outside developers, and Google is also introducing software they call OpenSocial which allows music and video creations to be distributed on multiple sites (Google launches social-networking software, 2007). Openness, as noted by Tapscott and Williams, is what the Net generation desires. "Having been nourished on instant messaging, chat groups, playlists, peer-to-peer file sharing, and online multiplayer video games, [the Net Gen] will increasingly bring a new collaborative ethos into the workplace. Working together and sharing their knowledge across organizational boundaries—in much the same way as they swap songs and videos over the Internet—will be perfectly normal for tomorrow's workforce" (Tapscott & Williams, 2006, p. 247).

One source for collaborative sharing is virtual worlds or immersive worlds—3-D interactive sites where users engage within the site through use of an avatar. EMarketer estimates that 24% of under-age-eighteen people access virtual worlds monthly, and they predict usage will continue to increase (Williamson, 2007). Linden Labs' "Second Life" virtual world has a population that is "growing by 15 to 20 percent per month" (Tapscott & Williams, 2006, p. 126) and has over eight million avatars or registered members (Jana, 2007). Second Life, an adult virtual world, has a counterpart known as Teen Second Life for people under age 18. Other popular virtual worlds include World of Warcraft and Vside, a music-oriented world that its creators hope "will become a destination for teens and young adults who want a next-generation entertainment experience" (Takahashi, 2007). Gaia, another popular teen virtual world, increased its number of unique users from .5 million to 2.5 million in less than a year's time (Liew, 2007). Many of the extremely successful virtual worlds are "targeted at kids and teens" (Liew, 2007), the generation most eager to adopt interactive technology, a fact not overlooked by businesses. When Active Worlds created a 3-D application for Facebook, it was noted as "a new milestone on 3-D Internet implementation" (Virtual Worlds Management, 2007). "The push is on for interoperability and a set of standards which will drive Virtual World technology into the future" said Active World's chairman, J.P. McCormick (Virtual Worlds Management, 2007). It is anticipated that businesses will turn more and more to virtual worlds as they seek to attract teen users. North American and European respondents to the Online Research Barometer survey predict increases in the use of "online respondent providers," and European researchers anticipate a decline in the use of telephone and face-to-face methodologies in favor of online research (Greenfield Online-Ciao, 2007).

A company in Finland is already using its virtual world, Habbo, to solicit marketing information from teens. Through Habbo, the company was able to "survey more than 42,000 [teens—via avatars] in 22 countries" (Jana, 2007). Habbo boasts 76 million avatars from 29 nations worldwide (Jana, 2007). Habbo's creator, the Sulake company, "realized it could tap its millions of avatars for information on real-life teen trends around the world" (Jana, 2007). Sulake found that 60% of its respondents were between ages 13-15 (Jana, 2007). Responses came from countries such as Britain (which had the most respondents), United States, Norway, Venezuela, Portugal and Austria with gender responses being nearly evenly divided (51% female and 49% male) (Jana, 2007). Using virtual worlds to obtain teen-trend data is a current and future strategy (Jana, 2007). "The membrane between our real and our virtual worlds has become very thin, especially for teens today. For this generation, interacting in the virtual world isn't just a trend. It's their life," says Robyn Waters, head of a trend-watching firm (Jana, 2007).

Social networking sites are definitely big business. In 2005, News Corp. spent $580 million to purchase MySpace, and in 2006 Google purchased YouTube for $1.65 billion (Noguchi, 2006). Microsoft agreed to pay $240 million to Facebook for a mere "1.6 percent stake in the Web phenomenon" (Wakabayashi, 2007). Microsoft believes Facebook will become a "hub for all sorts of Web activity" and eventually attract 300 million users (Wakabayashi, 2007). Corporations realize that teen users of social networking sites, however, can be fickle. Nielsen-NetRatings' list of "most popular teen sites" often contains sites that are listed one year but are never mentioned the following year as teens' tastes change (Noguchi, 2006). "They're not loyal. Young audiences search for innovative and new features. They're constantly looking for new ways to communicate and share content they find or create, and because of that group mentality, friends shift from service to service in blocs [*sic*]," says Ben Bajarin, market analyst for Creative Strategies, Inc. (Noguchi, 2006). At the 2006 Piper Jaffray Global Internet Summit in California, there was debate over the future of social networks, with some skeptics wondering if such sites are merely fads (Olsen, 2006). Older teen attendees at the summit gave indication they are already growing out of their MySpace phase, although younger teens indicated they were still big users of the site (Olsen, 2006). By 2007, teens in the United Kingdom were already transferring loyalties from MySpace to Bebo and Facebook (Moulds, 2007). "You are getting a lot of younger people who are shunning MySpace because it is seen to be part of the establishment," says John Delaney, a technology analyst (Moulds, 2007). Other reasons for teens' abandonment of MySpace include the increasing numbers of parents and teachers reading teens' profiles, risks of predators, and new services from other sites (Noguchi, 2006). Sweden's Stardoll, a virtual world aimed at teen and preteen girls, acquired over seven million users from several countries within its first four years of existence, and the site's chief executive attributes part of its success to the fact that users of previous social networking sites "are maybe getting tired of having pages where they feel forced to look sexy or cool or write some outrageous stuff in order to stand out" (Adegoke, 2007a). Datamonitor released a report in 2007 by analyst Ri Pierce-Grove who said, "The extraordinary proliferation of online social networks is fueled by real innovation and is substantially changing the way we communicate. However, the hothouse atmosphere of easy capital, media attention and user curiosity which stimulates creativity will not be sustained" (Lomas, 2007). Pierce-Grove's report expects the number of registrants for social networking services to "plateau" by 2012" (Lomas, 2007).

Realizing the transience of social networking sites, MySpace has already begun to expand its services internationally in the hopes of maintaining it popularity. MySpace has communities in Europe, Latin America, North and South America, and Asia and plans to expand into additional countries (Dudeck & Akselrud, 2007). MySpace's managing director for international, Travis Katz, says the move to rewrite its code into non-Western languages "was the right thing to do; international growth is the key to our future" (Abboud, 2007). Internet companies based in America usually focus first on English-speaking markets before expanding to international non-English speaking possibilities (Abboud, 2007). European markets can provide a huge base of users, but the variety of languages spoken within those countries often pose "linguistic barriers" for start-up countries outside of North America (Abboud, 2007). Netlog is one company that has broken through those barriers and has created one of the largest social networking sites in Europe (Abboud, 2007). Using college exchange students to translate the site rather than the entire code, Netlog has attracted users between ages 14-24 as its typical market (Abboud, 2007).

Mobile markets are another area of increase in social networking services. Mobikade is "a free off portal social networking service" in Japan that acquired 500,000 members in its first six months (Inbabble, 2007). It already has plans to expand into the UK, Italy, Germany and the U.S. (Inbabble, 2007). Japanese teens are accustomed to using mobile Internet, and Mobikade predicts that European teens will become likewise. Mobikade's head of business, Atul Sasane says, "We have experienced the growth of the off portal market in Japan and this puts us in a very strong position to create strategies to capitalize on the opportunities unfolding in the UK market" (Inbabble, 2007). It is this high acceptance of mobility in Japan that led Transcosmos Inc. to create Meet-Me, a Japanese version of Second Life. Being deemed very American with its pioneering "ability to create something from nothing," Second Life has seen only 7% of its users come from Japan (Terada, 2007). Ken Aihara, who oversees Virtual Tokyo in Second Life, does not think Second Life will "take off among Japanese users until it becomes accessible from mobile phones" which are more popular than desktop computers among Japanese teens (Terada, 2007). Worldwide, Second Life has its largest audience in Europe, although America and Germany tie as countries with the highest number of in-world users (Lipsman, 2007a).

CONCLUSION

Having grown up with technology, Net generation teens have developed different habits and characteristics than their predecessors. But, according to Goodstein, "not much has really changed about being a teenager" (2007, p. 12). "Deep down most of us experienced the similar impulsiveness, invincibility, and highs and lows otherwise known as teen angst, puberty, or if you believe in modern psychology, a phase called adolescent development" (Goodstein, 2007, p. 12). What has changed, notes Goodstein, is that technology has "magnified and publicized" teen behavior (2007, p. 12) which raises "new issues for our society around privacy, safety, and parenting" (2007, p. 15).

Undoubtedly, much debate will continue to revolve around the issue of social networks and teens, with adults offering a variety of solutions. A decade ago, Tapscott offered viable advice to those who wondered "What is happening to our children?" (1998, p. 7). While he admitted there was "much to be learned" and that "many real dangers" would require "good management" by adults, he answered adults' fears with the following paragraph:

Everybody relax. The kids are all right. They are learning, developing, and thriving in the digital world. They need better tools, better access, more services, and more freedom to explore, not the opposite. Rather than hostility and mistrust on the part of adults, we need a change in thinking and in behavior on the part of parents, educators, lawmakers, and business leaders alike. (Tapscott, 1998, p. 7)

Thierer agrees. "There is simply no substitute for education" (2007, p. 25), he says. Thierer believes that if the government, media and schools want to improve and safeguard teens' use of social networking sites, those organizations need to actively promote programs that teach students about critical thinking skills and parents about parental controls (Thierer, 2007, p. 25). Says Thierer, "Lawmakers and educators need to focus on finding the 'teachable moments'" (2007, pp. 25, 26), and parents need to be more involved with their children (2007, p. 28).

Additionally, workplaces need to prepare for this generation's entry. "N-Gen's norms reflect a desire for creativity, social connectivity, fun, freedom, speed, and diversity in their workplaces. Attracting, engaging, and retaining these employees in an increasingly competitive environment will demand that companies understand the Net Generation and the individuals who will emerge as its leaders" (Tapscott & Williams, 2006, p. 248).

Chapter 1.17
Social Networking and Personal Learning Environment

Antonio Fini
University of Florence, Italy

ABSTRACT

In social studies a social network is the set of relations that links people, through their interactions and familiarity of various kind. Today, however, social networking indicates a growing phenomenon, characterised by Web technologies that create and keep together groups of people on the basis of common interests. These tools (social software technologies) include for instance: blogs, podcasts, RSS feeds, social bookmarking, and offer new opportunities to promote collaboration, to assist conversations, to help in the sharing of knowledge, in work and learning contexts, both formal and informal. Although some of these tools are often used in LMSs, the main idea of this new approach is to consider the advantages coming from general purpose tools, widely available on the net, and characterised by an intrinsic vitality and spontaneity. In this context, also linked to a growing criticism of the current e-learning model, based on the extensive use of VLEs (virtual learning environments), new proposals oriented towards the definition of new models of Web spaces for personal learning (personal learning environment or virtual learning landscape) are being put forward. In these new systems the individual has a central place, in a network of resources and of social and friendly interactions that offer support on the emotional as well as on the cognitive level.

INTRODUCTION

In social studies a *social network* is the set of relations that links people, through their interactions and familiarity of various kind. Today, however, social networking indicates a growing phenomenon, characterised by Web technologies that create and keep together groups of people on the basis of common interests. These tools (*social software technologies*) include for instance: blogs, *podcasts*, RSS feeds, social bookmarking, and offer new opportunities to promote collaboration, to assist conversations, to help in the sharing of knowledge, in work and learning contexts, both formal and informal. Although some of these tools are often used in LMSs, the main idea of this new approach is to consider the advantages coming from general purpose tools, widely available on the net, and characterised by an intrinsic vitality and spontaneity. In this context, also linked to a growing criticism of the current e-learning model, based on the extensive use of VLEs (*virtual learning environments),* new proposals oriented towards the definition of new models of Web spaces for personal learning (*personal learning environment* or *virtual learning landscape)* are being put forward. In these new systems the individual has a central place, in a network of resources and of social and friendly interactions that offer support on the emotional as well as on the cognitive level.

SOCIAL-SOFTWARE

In recent years, the availability of services and tools that enhance the creation of Web content by common users has grown enormously. Most of these "personal contributions" implicitly create interactions and connections among individuals on the net. It is not accidental that one talks of *social software,* referring to applications that make possible for people to interact and collaborate on line, particularly to create on-line communities. "Social software" is a term with a broad meaning, which includes systems and technologies used in various contexts: for this reason Terry Anderson (2005) has introduced the concept of e*ducational social software: "On line tools that support and encourage individuals to learn together with others, maintaining their control over time, space, presence, activities, identity and relationships".*

In this sense, specific tools such as *wiki*s (1) *and blogs,* acquire particular relevance.

Wiki

A Wiki is a special Web site that allows multiple users, to create and edit pages in real time. It has become emblematic of collaborative authoring of hypertextual documents, because one of the most widespread use is to allow different people to work at a distance, concurrently, on the same body of pages interconnected via hyperlinks. The system keeps track of the modifications carried out and of previous versions (*versioning*) making it possible for a coordinator to accept or, if necessary, to reject the changes made by the collaborators. The use of wikis in e-learning is linked to collaboration, the feature that more than anything else distinguishes this technology. In all those instances in which there is a need to collectively write a text, wikis offer a valuable technical solution. Through the versioning mechanism it possible to follow the process of the elaboration of the text, whilst the hyperlink management system allows for the planning and the preparation of complex investigations. The ease with which one can create glossaries, dictionaries, terminological indexes or organized collections of thematic pages, makes it possible, in many subject domains, to develop very interesting research activities. Compared to the traditional face-to-face group work, wikis offer higher capabilities, because they allow a reflection starting from the very textual nature of the product, and the possibility to operate simultaneously amongst many individuals, remotely.

Teachers as well can find wikis very useful for working on projects, preparing articles, putting together course materials. A wiki is ideal, for instance, for collecting proposals and ideas for a conference or within a research project. However, the main strongness of wikis can also be seen as a weak point: the possibility offered to all to modify content. For this reason the majority of sites is somehow monitored to avoid intrusions, spam, and other abuses.

Blog

The term *blog* is the contraction of *Web log,* that is *"a log on the Web."* Blogs offer the possibility of writing quickly, without having any specific technical knowledge, notes, thoughts, reflections, texts of any kind, in the form of a Web page. The blog is probably the application that marks, more than any other, the transition from the *read only*

Web to the *read and write Web*, where everyone can be an author, in addition to being a reader. The user thus writes new articles, whenever the user wishes, giving to the blog its characteristic appearance of a sequence of brief entries, similar to annotations in a diary. The blog is generally open to contributions from other users, who can add comments to the articles (if the author allows it), or can even be managed by many users, with writing rights.

The current use of blogs goes well beyond that of a "diary". The old "personal homepage" is increasingly giving way to blogs; journalists, public figures, politicians frequently use blogs, both as an extension of articles printed on paper, or as an alternative means of communication. It is a particularly significant phenomenon, because one notices how access to the production of Web content is available now to a large segment of users who were previously excluded. If the "personal Web sites" were generally a prerogative of ICT practitioners, today blogs are published mostly by nontechnical people.

It is very frequent, in addition, the contamination with other tools, such as *podcasting* and systems for archiving and sharing of digital photographs and videos (the new term videoblog or *vlog* has already been coined) (2).

The widespread use of these tools has given rise to information indexing and searching services inside what is now referred to as the *blogosphere*. With this "collective name" one indicates the entire blog community that increasingly takes the form of a *social network.* The majority of blogs are in fact densely interconnected: *bloggers* (3) very frequently read other blogs and link to them, reference them, post comments on them, thus forming a highly animated *agorà*. Blogs can thus become the true individual's on line "identity": according to a suggestive expression used by Granieri (2005), the blog is the stable "point of presence of a person". This is all the more true in personal blogs, when the blog is understood as a collection of content items, that range from professional, to spare time interests; differently from the "thematic" blogs, but still very interesting at the collective level, a multidisciplinary, personal blog can be a holistic representation of the individual, making it possible for him to participate (through cross links) in different social networks. One could hazard saying, that it is the very concept of identity that changes meaning on line, from "belonging to" or "being part of", it becomes being "linked to...".

Even in the field of formal learning the use of blogs presents some very interesting features: in the school blogs easily can allow teachers and students to become authors of log-books. This space can be understood also as a store of materials and exercises: an archive, or a course portfolio. Blogs can be an occasion for reflecting on lessons and a place for discussing and study in-depth certain topics.

This is the case of class blogs that enable teachers to actively exploit Internet potentialities, transforming students from passive users into authors.

Blogs have also an important role for providing the means to come into contact with experiences taking place "outside" one's own class. The coming into contact with research and didactic material developed by other work groups (for example by other schools) can become, in turn, an occasion for reflection and investigation, that teachers can suggest and organize.

In the informal learning context, instead, blogs represent an important space for the dissemination of ideas and research findings. Many researchers and scholars, in the ICT field in particular, use blogs to present and discuss the outline of their inquiry. Finally, other possible uses of blogs are linked to writing, as an introspective tool of investigation and, with its availability on line, to the dynamics of a social space (the blogosphere).

Tagging

Tagging is another example of the users' direct participation in the definition of Web content. In this case, however, it is not exactly concerned with the creation of content but, rather, of information relating to the classification of content. The question of classification and search for information on the Web became very early of crucial importance: search engines and *directories* (4) have been for many years the main point of access to the immense quantity of information contained in the Web. Search engines and indexers operate in a top-down way, implicitly imposing on users, in response to a query, their classification and their criterion of relevance (5).

Tagging completely reverses this approach: it is the single user that, with a *bottom up approach,* defines the link between the digital resources (Websites, images, films, music) and the terms used to describe them, which are exactly the *tags,* simple labels (single words or short sentences). Since tagging comes through the Web, above all through systems for the sharing of bookmarks called *social bookmarking,* the collaborative aspect emerges as well. This mechanism of spontaneous and collective categorisation done by means of tags is called *folksonomy* (a neologism from the root "folks"—people—combined with the word taxonomy; it indicates a system of classification (taxonomy) which is informal and managed autonomously by groups of people, who collaborate, spontaneously, in the organization of information. It is the opposite of the formal, a-priori, classification systems, in which the taxonomy is predetermined; it is also different from search engine indexing based on terms contained in the text: through folksonomy, meanings are continuously created by the users. The dishomogeneity and possible dispersivity are nonetheless the chief critical elements of folksonomy. In the absence of rules, each user is free to interpret the information tagging it freely. The lack of standards for the tag definition can lead to confusion: for instance a user can classify a resource using the singular, other the plural, there are generally no rules for using compound words or to represent hierarchical concept structures

Tagging is not an exclusivity of social bookmarking, for instance it is widely used also by blog authors to classify the articles and the pages they have inserted.

Systems based on tagging and social bookmarking, can thus be used as an alternative to normal search engines—still, this systems offers greater potentialities. For example, as the social bookmarking services keep track of who has created each reference and allows access to that person's other bookmarks, a form of *connection* with others interested in different topics is established. Users find as well a "measurement" of the popularity of a given resource, since the number of users that have tagged and saved each link, found in the system, is always shown. The act itself of tagging has potentially a value, as it obliges the user to reflect on the meaning of the information he is saving. Each time that a user comes across a Web page that he thinks is interesting, the user can with a simple gesture, catalogue it, and share this information with others: it is apparently a inconsequential step but it has an enormous reach in the sharing of knowledge. Finally, the significance of resources on the Web is decided socially and transparently, subtracting the decision to experts and to the complex algorithms used by search engines.

SOCIAL NETWORKING

The concept of a "social network" stems from the studies in socio-psychology, sociology, and anthropology as early as the beginning of the '900. The studies on the analysis of the interactions between individuals in a community are more recent, such as the Social Network analysis that deals with the study of the structure of the network of interactions (of various kind) which is established amongst individuals (Scott, 1997). In recent years, in addition, the theory of connectivism is gaining momentum, as the theoretical basis to consider the net itself as a tool for learning (Siemens, 2004).

The online version of the social networks is known today by the name *social networking* and it refers to technologies and services available on the net that make possible for individuals to participate in real and proper virtual communities.

It is a multifaceted phenomenon corresponding more or less to the equivalent contexts of human relations, although the boundaries are a bit blurred:

- In the professional context, with the creation of communities of colleagues or thematic communities;
- In the context of free time activities, for friendly and sentimental interpersonal relations and the exchange of informal relations (6).

Web sites that offer social networking services do not normally use particularly innovative technologies. Basically the user, after signing up, is invited to insert as much information as possible about the user, in order to draft a personal profile that is as detailed as possible. One starts from personal details to arrive to interests and hobbies, passions, and preferences of any kind (this is especially so in communities dealing with spare time interests), or a detailed curriculum (for communities in the professional sphere) The next step usually consists in inviting other people to sign up for the service. Generally one contacts his friend or colleagues inviting them to do the same, in a sort of endless progression that, ideally, could include the entire world population. The mechanism of the social networking is in synthesis the following one: "I sign up, I invite my friends, who in turn invite their friends an so on, to arrive to create a wide network of friendships."

Through some services one can even make acquaintances, be means of algorithms, varying in their degree of sophistication, that manage to match up the different personal profiles.

To indicate the members of a community, one usually uses the term "friends": the members are thus linked by a bond of "friendship" that, nonetheless, is limited to those who are registered for the same service. Each one can thus belong to different communities, through the registration to different social networking Websites. There is no lack, however, of standardization proposals to universalize the concept of friendship, at the base of *social networking,* which is now currently limited to the services offered by individual Websites. An example is the proposal named FOAF (friend of a friend), a project that aims at creating documents in XML format aimed at describing people and their connections (http://www.foaf-project.org) (7).

Content: Aggregation, Use and Reuse

The protection of personal data and the attention to the safeguard of intellectual property rights are usually a major concern on the net. Surprisingly, however, in many new Web applications there is, instead, an increasing "opening up" of corporate Databases.

Striking examples are offered by Google Maps (that allow the re-use of maps to add commercial and/or other type of information, in a perspective of *georeferencing*), Ebay, and Amazon: they both allow public access to their DBs, to the extent that Web sites that use data coming from these two organisations, to provide added value services, have been created.

The possibility of allowing the use of information, or parts of the services normally offered, can be regarded as a strong, rather than a weak point. The trend is to invest in the fact that users, anyway, use the data (O'Reilly, 2005). A specific term for this concept has also been coined: this "remix" of content and services is called *mashup.* One could observe that the re use of images, films, news, graphics and other types of content, provided that the source is cited, is part of the ethics of the *hacker* (Himanen, 2003) by which concepts such as "freedom of speech", "freedom

Table 1. PLE characteristic elements

Objective	Main tool /technology	PLE perspective
Learner-centred	Blog	It is the key concept of a PLE. From this point of view the environment is able to perform the functions of an e-portfolio, combined and/or implemented by means of a **blog**. The blog is seen as an essential element to overcome the difficulties that still limit the use on a wide scale of the e-portfolio. Differently from the latter, generally perceived as an "institutional" tool, a blog is considered a true "personal area", informal, where no limitations are imposed on spontaneity. The success of informal environment shows how important it is to be able to choose the place and the way we wish to present ourselves. It is typical of blogs to be able to find different aspects of the author's personality: alongside ideas and reflections related to one's own study and profession, one often finds notes on interests, hobbies, and personal aspirations.
Informal learning	RSS	PLEs/blogs are able to integrate elements coming from informal learning situations on the net, for example the aggregation of RSS feeds coming from Websites that do not belong to formal learning systems. It is up to the user/owner, through appropriate presentation tools, to highlight the significant elements of the user's own educational path, to be found both in formal and informal activities.
Collaborative learning	Social networking and social software	PLEs are open to social networking; systems and they support and integrate them. They are *natively* a typology of social software and foresee the possibility of sharing resources, including social bookmarking.
Micro-contents	RSS / Mashup	PLEs are based on microcontents. Their structure is based on, or inspired by, the model of a Web Service and the opening to any other system, in addition to the intrinsic orientation toward RSS as a powerful tool for the aggregation of content.
Open	Web Service	The *openness* is the chief feature of a PLE. If it is viewed as a technological system, it must interface with the greatest possible number of heterogeneous systems, for example with numerous LMS platforms, for the *formal* element and with public services of social software for the *informal* element.

of action" and "self realisation", through one's own contribution to the creation of the net, are the parameters that since the 1980s populate the dreams of those who believe in the development of a *network society* free from monopolies and restrictions (8). The new network develops new rules. The Open Access Initiative, born from the Berlin Declaration in 2003, to promote free circulation and dissemination of human knowledge and of the cultural assets produced by the scientific community (9); projects like the already cited Free Software Foundation, active since 1985 aimed at the promotion of the user's right to use, study, copy, modify, and redistribute software (10), and finally the Creative Commons licences proposed by the nonprofit organization known by the same name, as alternatives to the traditional copyright, share this new spirit of the Web, seen as an open network based on the participation and the creative involvement of the users (11).

According to a research study of the *Pew Internet & American Life Project* on the use of Internet by young Americans (12-17 years old), 57% of them use the PC for "recreational" activities, such as the management of a Blog or the production of music and videos; 20% of them affirms, in addition, that they normally use materials produced by others, feeling free to download from the net and to manipulate texts, images, and audio to be recombined in their production (Pew Research, 2005).

An Application of Social Networking in Online Learning Systems

Starting from 2004, thanks above all to the activity of the British research community, the concept of *personal learning environment (PLE)* is gradually taking ground. Starting from the experiences and the studies on the e-portfolio, and including new life-long learning issues, with the PLE there is an effort to highlight even further the centrality of the individual. The acronym itself is not accidental: the assonance with VLE (*virtual learning environment*) is deliberate and wanted. The PLEs, in their being environments centred on the student, are contrasted to VLEs, considered institutionalised learning environments, that leave very little control to the student.

In 2005, Scott Wilson, published in his blog dedicated to the research in this field, a diagram that thanks also to successive re-elaborations, is now very well known in the blogosphere: In synthesis, a PLE (the "future of VLE", at the centre in Wilson's representation) should function as an "operational centre", managed and controlled entirely by the student. The system should be able to interact with a series of external systems, partly related to formal learning activities (for instance the e-learning platforms and/or the institutional services provided by schools and universities attended by the student) and partly relating to social networking services and Websites in which the student could be registered and actively using, which represent the area of informal learning.

Some authors stress that it is important to keep the concept well separated from the technical system: there are different ways to implement a PLE, some are based on an ad hoc software, and others, on the contrary, use a mix of already available desktop software and Web services which, one hopes will develop further in the future (Attwell, 2006). The risk is that PLE might become in the end something very similar to the very thing they want to contrast (VLE): a new form of *walled garden* in which to isolate students from the rest of the external world (ibidem). In a more radical fashion, Blackall (2006) maintains that, after all, Iternet itself is a complete personal learning environment, and, therefore, no intermediate dedicated system is necessary.

The PLE Components

The basic matrix that comes out from the proposals at the theoretical level, but also from the early implementations carried out, is based on the *e-portfolio* model. The PLE are seen as an extension of the latter but revisited in the light of the social software.

The following table sums up the main functions attributed to PLE, in relation to some key objectives identified in the debate on this new vision of e-leaning.

CONCLUSION

The proposal of the *personal learning environment* presents itself as a "bridge-solution" between two worlds. Although highlighting in their name the contrast with institutional Virtual Learning Environments there is, however, the attempt to recuperate, as much as possible all the learner-*centered* elements present in the worlds of the e-learning, namely the e-portfolios, combined with the technologies and, above all, the practices of social networking: from the closed environments represented by the platforms that keep students "separated" from the real world, one moves instead to open environments that, on the contrary, can include connections with a VLE, but keep the door always open towards the external world, towards a Web rich with information, but above all, with links to people and not only pages. Blogs, social bookmarking, RSS, as "universal source" of information", seem to be the bases on which to build systems that are able to accompany people's real life, providing them with an on-line identity, an authentic telematic alter-ego

The debate has just started: for example it should not be taken for granted that PLE must be developed as true and proper applications, but it is equally true that it is not realistic to think that the system of VLEs can soon cease to exist. The very emphasis on informal learning can't be to the detriment of formal learning: schools and universities will probably continue to exist for a long time. What is certain is that "integration" is the key word for the future: tools, methodologies, and opportunities for learning.

KEY TERMS AND DEFINITIONS

E-Portfolio: A collection of material in the guise of *digital artefacts* (documents, multimedia clips, links to resources, notes, etc.) related to a person's educational path. It can be referred to a specific course, or it can be seen as a permanent support for the individual, in the perspective of lifelong learning.

Folksonomy: A neologism that indicates the contribution from people (*folks*) in the definition of meaning and in the classification of information on the Web. It is contrasted to a-priori taxonomies complied by experts (for example in the library field).

Microcontents: In the perspective of *mashup*, the microcontent is the ideal unit for the re-use of information (MacManus e Porter, 2005). The Web is no longer viewed as a set of pages, but instead of even smaller units (for example a single post in a blog or a pod-cast).

Podcasting: The term podcasting groups all the techniques aimed at the production, the sharing and the use of audio/and or video material. The basic element of this technique is an audio or video recording—varying in the degree of expertise with which it is made, that can be used directly online or downloaded for listening or viewing off-line. This denomination is derived from the well known digital music reader Apple iPod; with the suffix "casting", derived from broadcasting, it comes to indicate a system for the transmission of audio material that can be listened to on many different devices, from the PC to a digital reader, to mobile phones.

RSS: RSS stands for *RDF Site Summary*, a format for the diffusion of content through the Web. From a technical point of view, RSS is based on the XML mark up language, well known for being the "foundation stone" on which the present Web could rise, separating content from presentation and graphical aspects. The RSS technology has as its fundamental aim the feeding on the Web of headlines of articles, news, links and, more generally, any sort of "what's new" of any site. It works as a kind of "announcement" that some new content has been added on a certain site. Blogs combine perfectly with RSS: each blog is equipped in fact with its RSS system that make it possible to keep up-to-date with the new articles that have been posted, without any need of visiting the Website directly. An alternative interpretation of the acronym RSS is *really simple syndication*: the term syndication is borrowed from the press (it would stand for "diffusion through a press office"). Leaving aside definitions and interpretations, the fundamental element is the means to disseminate "What's new" on different Web sites.

Social Bookmarking: Those that once were known as bookmarks, or preferred sites that each user used to save inside the user's own browser are now increasingly shared through specialised Websites. *Social bookmarking*, that is in pooling one's own bookmarks, together with the tags freely supplied by the users. One of the main sites of social bookmarking is http://del.icio.us.

Virtual Learning Environment (VLE): In general, Web systems used for the management of courses in schools and in Universities. They are often also referred to by the acronym LMS (*learning management system*).

ENDNOTES

1 The fortune of Wikis is mostly due to the project *Wikipedia,* the "free " encyclopaedia compiled with contributions from common users (www.wikipedia.org) and based on a wiki system for the compilation of pages (www.mediawiki.org).

2 Amongst the most well known tools for the sharing of photographs stands out Flicker (http://www.flickr.com) or for the videos YouTube (http://www.youtube.com/. For sharing of audio Flickr (http://www.flickr.com) should be mentioned. Main Web sites for the aggregation and sharing of news items are: Digg (http://www.digg.com/), Slashdot (http://www.slashdot.com/).

3 A *Blogger* is the author/owner of a blog.

4 In the world of information searching on the Web two lines of action have gained ground: the first, a feature of "pure" search engines such as Google, based on whole text indexing of pages and the other, first proposed by Yahoo, based on directories, that is on a hierarchical classification through numerous levels of categories and sub-categories.

5 It is well known that Google's fortune might also be due to the use of an almost secret algorithm to establish the relevance of a Web site (and therefore its prominence in the search results). The basic element for the calculation of the so called *page ranking* is the number of direct links to the page, but it is not the only element taken into consideration.

6 One of the first services to be available online was Classmates (www.classmates.com), active since 1995 which made possible the search of old school mates. The true boom of social networking services, however, has

come after 2001, with sites like Friendster (www.friendster.com) MySpace (www.myspace.com), Facebook (www.facebook.com) and LinkedIn (www.linkedin.com)..

7 The aim of FOAF is to free personal details from the relational ones (that is the individual own social network) from the mebership to a certain community or service.

8 The term *hacker is commonly* associated in common usage to computer crimes. On the contrary (according to a distinction that is progressively more difficult to contrast, that confuses them with *crackers,* the real computer criminals) the hacker culture is part of that wide movement, formed almost by students, to whom we are in debt for the many innovations and software that we use daily.

Chapter 1.18
Web 2.0 Social Networking Sites

D. Sandy Staples
Queens University, Canada

ABSTRACT

This chapter describes one of the Web 2.0 technologies, Social Networking Sites (SNS). A definition of SNS is offered, as is a short history of these sites. The existing research is reviewed and organized to summarize what we know about SNS usage (from the perspectives of student use, general population use and organizational use), and what we know about the antecedents and outcomes of SNS use. The chapter concludes with discussion of new developments, challenges and opportunities. There are many opportunities for future research and organizational applications of SNS as SNS adoption grows at incredible rates.

INTRODUCTION

Offline social networks have existed since the beginning of humankind and have been the study of anthropologists and others for many years (Clemons, Barnett, & Appadurai, 2007). Social networks can be groups of people who have interacted in the past for some common purpose or interest, and that have ongoing relationships with members of the group. Membership in networks can be relatively permanent (i.e., family relations) or flexible and short-term (i.e., members come and go as their interests and need for membership changes). The shared experiences and perceived shared values or needs can build trust among members and value, such that members tend to rely on each other and perceive shared information to be reliable and trustworthy (Clemons et al., 2007).

In the past decade or so, advances in technology have made it possible to use electronic communication tools to create social network applications and online social networks. The applications, sometimes called social networking tools, are web-based locations that lets a user create a self-profile and connect to others (who are using the same application) to build and maintain a personal network (Skiba, 2007). This type of application is part of the Web 2.0 evolution toward more collaboration via the web and examples include MySpace, Facebook, and LinkedIn, to name just a few of the largest. While the terminology used to describe these sites

DOI: 10.4018/978-1-60566-272-5.ch005

varies, recently the term Social Networking Sites (SNS) has become the common way to refer to them. The focus of this chapter is on these SNS and the chapter is organized as follows. The next section discusses what SNS are and presents a brief history. The third section describes what is known in the literature about the usage of SNS. This is followed by a discussion of potential business uses and anticipated developments, discussing both opportunities and challenges.

WHAT IS A SOCIAL NETWORKING SITE (SNS)?

In this section, we first define SNS and then describe typical characteristics. The history of SNS is briefly discussed. Two of the current leading SNS are profiled in this history: MySpace and Facebook.

Social Networking Sites Defined

Boyd & Ellison (2007) appropriately defined SNS as "web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system." (p. 211). They prefer the word network over networking in SNS, although they acknowledge the terms are used interchangeably in the literature, because they argue that networking emphasizes the initiation of relationship, often between strangers and that not all users are doing this. Many users use SNS's to communicate with people that they already know (i.e., the people are already part of their offline social network).

Others argue that "networking" is more appropriate since the term social "network" site would be too broad a term, approaching the same meaning as Web 2.0 (Beer, 2008). Supporting this view, networking is defined by Dictionary.com and MS Word's reference function, respectively, as:

a supportive system of sharing information and services among individuals and groups having a common interest.[1]

the process or practice of building up or maintaining informal relationships, especially with people whose friendship could bring advantages such as job or business opportunities.

Neither of these definitions suggest that networking would have to include creating new relationships (in addition to maintaining existing relationships). Therefore, while we adopt boyd and Ellison's three key characteristics of SNS, we suggest that Social Networking Sites is a more appropriate term for SNS and this terminology will be adopted for this paper. We next expand on SNS characteristics and typical functions provided to the user.

Characteristics of Social Networking Sites

Social networking sites are organized around people. Earlier online communities and their websites were organized around interests and topics. A unique characteristic of SNS is that users can specify their social networks and make them visible to others (boyd & Ellison, 2007). This is done by users developing profiles of themselves and identifying acquaintances (termed Friends[2] in most SNSs). The starting point for a new user is to develop their profile which typically contains a picture of the user, some demographic information such as age, location, school affiliation/history, and personal interests.

Users then identify other system users that they have a relationship with or wish to develop a relationship with. Most SNSs required bi-directional confirmation, where a user requests a Friend connection. The system sends the request to the potential Friend, and if he/she accepts the request, then each other's profile becomes linked. In this way, the social network of a user becomes visible to their Friends and Friends can see overlap in their social networks and invite Friends of Friends to join their social networks, if they choose to. Typically, a powerful database makes every entry field in profiles searchable, making it possible for a user to see who shares interests and backgrounds. Visibility of profiles can vary depending on the system design and user privacy settings.

SNS also typically provide a single point of access to multiple communication tools and support a person's ability to construct a digital identity. To do this, other possible features include things such as instant messaging within members of the network (synchronous communication), semi-public asynchronous messaging (e.g., in Facebook, Friends can post comments on an area in a Friend's profile called the Wall which is visible to all Friends), private asynchronous messaging (email), and blog-like features (called notes in Facebook). Most SNS allow the posting of pictures and videos. The capabilities of SNS can also be extended greatly by adding applications (discussed further below).

A Brief History of SNS, MySpace and Facebook

The first SNS was SixDegrees.com launched in 1997. Over the last decade or so, many SNSs have started and many have failed or declined in popularity (e.g., Friendster). MySpace is currently the largest SNS, with Facebook following and growing rapidly. LinkedIn is another large SNS that specifically targets professional networking. Some Social Networking Sites are very specific, targeted for specific communities of users (e.g., Dogster, a SNS for dogs aimed at dog owners), ethnic groups (e.g., BlackPlanet, iMatter for Arab women) or specific geographic regions (e.g., LifeAt for apartment buildings) or linguistic groups (e.g., Cyworld in Korea). There is even one site, Ning, that provides a platform to host user-created SNSs (boyd & Ellison, 2007; Rosenfeld, 2008). See boyd and Ellison (2008) for a more complete SNS history. Although currently the web has more than 100 popular SNS (Wang, 2008), two of the leaders are MySpace and Facebook and these two SNS are featured more fully below.

MySpace was started in August 2003 and grew rapidly with the 100 millionth account being created in August 2006.[3] By mid-2008, it had grown to a world-wide community, with dedicated communities in over 25 countries using multiple languages. It has a strong artist/band community, with artists being able to post songs on their sites so fans can listen to their music. The company generates revenue through advertising and has a significant agreement with Google for advertising. Anyone can join MySpace and use the various features. The user profiles are highly customizable by incorporating html code or CSS (style sheets). In early 2008, MySpace created a developer platform based on Google's Open Social API to allow developers to build their own applications for MySpace, resulting in expanded functionality for users. Currently, there are over one thousand applications available to choose from, covering a wide range of topics including games, travel, shopping, job hunting, and politics.

Facebook was started in February 2004 using a network model. Facebook was originally designed to help students on college/university campuses network so members had to have a valid educational-institution email address to register. It expanded to high schools and in 2006, opened registration up so anyone could join. Non-educational registrants could join job-related networks or networks based on their geographic area. The network membership determined access to information (depending on how users set privacy on profiles). By May, 2008, there were 55,000 regional, work-related, collegiate and high school networks, and over 60% of Facebook users were outside colleges. Currently Facebook has over 70 million active users, it is the second most-trafficked SNS in the world, and is the number one photo sharing application on the web, with 14 million photos being uploaded daily. In mid-2006, Facebook launched its development platform which enabled outside developers to build applications and offer them to users. Currently, there are over 20,000 applications available and growing at a rate of 140 per day.[4] A key decision that facilitated the development of applications and resulting increased functionality for users was letting developers keep all the advertising revenues they might earn (Anonymous, 2007a).

USAGE OF SOCIAL NETWORKING SITES

This section reviews current knowledge about the amount of usage and the various uses of SNS. Details are based on a review of the academic and practitioner literature conducted in early 2008. Specifically, searches were done in several electronic databases including ProQuest, PsychInfo, and Scholar's Portal. The electronic libraries of three associations were searched since these contain many conference proceedings (as well as journals): ACM, IEEE and AIS. Key words such as social networking, facebook and myspace were used. Other online sources were also used (e.g., CIO.com, Gartner) and targeted searches were done by examining the lists of references in relevant articles. Discussion below is organized into trends with students, the general public and organizations.

Student Usage and Uses

Estimates of the number of US college students using Facebook are very high, varying between 80 and 92 percent (Cain, 2008; Eberhardt, 2007). US students at one college reported spending between 10 and 30 minutes each day on average on Facebook, and having between 150 and 200 Friends (Ellison, Steinfield, & Lampe, 2006).

Student uses in the USA include checking for comments, messages and updates from Friends, arranging events, parties and dates, keeping in touch with people they already know, and checking out people before meeting them (Raskin, 2006). Participants used the SNS to maintain relationships by doing things such as recognizing special events like birthdays and re-connecting with old friends. Developing new relationships was also a use, although users suggested the friendships were superficial (Dwyer, 2007). Generally students use Facebook more to keep in touch with people that they know offline than meeting new people. Consistent with this, survey results from 225 undergraduate US students indicated SNS was as useful for learning about classmates, friends, current or potential romantic partner as other media options, and that they were likely to use SNS for seeking information about these types of people. SNS were not considered useful for seeking information on family members (Westerman, 2008).

The majority of SNS communication appears not to be related to academic activities. For example, a study of 694 Facebook student users in the UK and the postings on their Wall found that only 4% (n=2496) of the Wall interactions were academically-related. This sub-set of Wall posting was analyzed and organized into five topic themes. These were: recounting and reflecting on the university experience (e.g., discussing a recently finished lecture), exchanging practical, logistical information (e.g., scheduling of lectures), exchanging academic information (e.g., course requirements), displays of supplication and/or disengagement (e.g., seeking moral rather than intellectual support), and banter (e.g., humorous, sarcastic and/or ironic exchanges) (Selwyn, 2007).

Not all SNS have the same structure, target audience or history. To examine this, a study of the potential differences between college student users of different SNS on the same US campus found several significant predictors (Hargittai, 2007). Eighty-eight percent of college students were users, and 74% reported using at least one

SNS often. Women were more likely to use SNS, consistent with literature indicating women have higher propensity to communicate online person-to-person. Students who lived at home were less likely to use SNS than those living in residence or on their own. Ethnic group usage also varied for different SNS; specifically, Hispanic students were found to be more likely to use MySpace while Whites were more likely to use Facebook. Asians/Asian Americans were less likely to use Facebook and more likely to use Xanga and Friendster (possibly because these SNS are more popular in some of the Asian countries). Parental education was also found to predict some types of use, with MySpace users having parents with lower levels of schooling and Facebook users having parents with higher levels of education (Hargittai, 2007).

SNS Usage and Uses in the General Population

Research suggests that most SNSs are used to maintain relationships that existed previously offline (boyd & Ellison, 2007). While these relationships may not be very strong (i.e., weak ties), there is some offline connection (e.g., through a previous school or job). Also, part of the motivation for people to join online communities is that people want access to information that interests them (Wise, Hamman, & Thorson, 2006). For example, a study of 226 MySpace and Facebook users suggested that effectiveness and efficiency in developing and maintaining relationships were the main reasons for use. Convenience comes from having the information they want to share with friends in one place, also making the task quicker too (Dwyer, 2008). Significant positive correlations were found between the fit of the site functionality and self-presentation goals (i.e., resulting impression given by profile), the fit between the site and the use to meet people, and the effectiveness of the site to keep in touch with close friends. The results supported parts of the authors' suggested Fit Appropriation Model called the Social Software Performance Model (Dwyer, 2008).

SNS usage is fairly high in the US. More than 50% of US teens have a profile on at least one SNS and close to 25% of US adults use a SNS (Schafer, 2008). However, the US is not the most active country in SNS use. A 2006 international survey found South Korea ranked first in people visiting a social networking site, followed by Brazil, China and Mexico. USA was fifth, with 20% of active Internet users visiting a social networking site within the past 30 days. General uses vary across countries. For example, in China, 80% discuss hobbies and 78% used SNS to meet new people. SNS usage for these activities is lower in the USA (37% and 33%, respectively). In the USA, 36% use a SNS to chat with people they know or connect with people they have lost touch with, 18% discuss work-related topics online, and 23% discuss personal issues online (Russell, 2007).

A second study also explored cross-cultural SNS usage (Chapman & Lahav, 2008). Thirty-six SNS users in the US, France, South Korea and China were interviewed and observed. Results suggest that SNS in the US were used primarily to share personal information, whereas Chinese users were much less likely to post personal information. Chinese respondents used SNS to have personal discussions with people they did not know well, possibly because having these sort of discussions with close friends is difficult in their culture. In Korea, the most common use was sharing of photos. Users in France tended to discuss interests and hobbies and were somewhat less personal than US users. These results demonstrate the need to understand local cultures and preferences in order to successfully introduce a social networking site into a new country.

Several studies have examined SNS usage in specific countries and again found differences, reflective of the differences in national cultures and communication processes. For example, Cyworld is a very popular SNS in South Korea serving nearly 50% of the entire population and nearly 90% of people in the 24-29 age range. Cyworld users have dual motivations for use: maintaining existing social networks (those that pre-existed offline), and reflecting on themselves via a diary-like feature. Users suggested that they could be more uninhibited with their thoughts and self-reflections in Cyworld than they could offline. The Korean culture prefers indirect communication in face-to-face communications. Being able to express feelings more directly in Cyworld, and having the asynchronous benefit of being able to edit expression was seen as very valuable to Cyworld users (Kim & Yun, 2007).

A survey of 55 Orkut (a SNS owned by Google) users in India and Pakistan found that most of these users were IT professionals. Advertising among Friends was extremely unwelcome, reflective of the cultural and religious backgrounds of the countries. The ability to search Friends was a very valuable feature, and a significant percentage of users (45.7%) would find Facebook's feature of no publicly viewable profiles desirable (Wang, 2008).

Interviews with 33 15-24 year old Australian young adults (Arthur, Sherman, Appel, & Moore, 2006) suggest that this group used MySpace for the following five reasons, all of which they value: to express their identities, for social interaction which is fun, for immediacy and constant entertainment, to discover new things, and to be creative and be able to create a record of who they are.

Churn between sites has been high. For example, half of the users regularly visit more than one site and one in six actively use three or more sites. Friendster peaked at 20 million users a few years ago and in late 2006 was down to less than 1 million (Russell, 2007). Helping us understand why churn may be high, a 2007 study of 200 users from four Norwegian online communities investigated why users leave or reduce their participation in online communities. Approximately one-quarter to one-fifth of respondents indicated reasons for leaving or lower use were lack of interesting people/friends attending, low quality content, and low usability in terms of user interface. Other reasons for leaving given less frequently were harassment/bullying, time-consuming/isolating, low trust and over-commercialization. These results indicate that low satisfaction with the nature of the social interaction is the highest factor for reduced use; however, site designers should also be aware of the importance of usability, the danger of over-commercializing, and the need to have some mechanism to police harassment (Brandtzeg & Heim, 2007).

What people put in their profiles and who is in their social networks creates impressions with others. Friend connections helps define one's identity in SNS. People also infer meaning from not only what users post on their profiles, but also what is on their Friends' profiles and what Friends post on their walls (boyd, 2006). A study of the lists of interests in MySpace profiles also found that users were significantly different than their top friends, indicating that users develop their lists of interests to differentiate themselves and that users tend to list interests to assert their prestige (Liu, 2007).

Some SNS allow users to create fake profiles, whereas others require authentic information (to varying degrees). The ability to create false profiles, the inability to authenticate relationships in some SNS, and the tendency to accept almost anyone as Friends, devalues the value of Friend connections because trust can not be assumed (boyd, 2006). Facebook information has been found to be mostly genuine, which may be why users tend to trust Facebook more than some other SNS.

Differences in use based on age was investigated in one study. 240 MySpace profiles were randomly-selected and analyzed. Results indicate that older (60+ years of age) users have fewer Friends (average = 18) compared to teenagers (aged 13 – 19) who had 95 Friends on average. Teenager's Friends were also mostly in their own age range, whereas older users had a wide age distribution among their Friends, likely due to the higher number of life experiences and resulting higher complexity of existing offline social networks (Arjan, Pfeil, & Zaphiris, 2008).

Another use of SNS has been for customer advocacy and activism (Eberhardt, 2007). In one example, a Facebook user connected with several hundred similar investors who were concerned about the status of their investment in non-bank asset-backed commercial paper (since the ability to recover investments was in question). By sharing information, event updates, emotional support, and possible tactics, the group was able to recover their investment (Simon, 2008).

Organizational SNS Usage and Uses

While it is difficult to find conclusive evidence about organizational use of SNS, likely because it is evolving so fast, one study found 20% of employees at large companies said they contribute regularly to blogs, social networks, wikis and other web 2.0 services (Green, 2007). A 2007 global survey by McKinsey of executives (44% of responses were C-level) found that 37% of 2,173 respondents were using or planning to use social networking in their organizations, while 39% said this Web 2.0 technology was not under consideration. Nineteen percent of respondents said their companies had invested in social networks. Of the respondents that used any Web 2.0 technologies, the various way the technologies were being used were: to interface with customers (70%), to interface with suppliers and partners (51%), and to manage collaboration internally (75%). Although respondents indicated calculating returns from the investments in SNS and other Web 2.0 technologies was very difficult, they suggested the benefits were clear in terms of better communication with customers, more efficient collaboration within the company, stronger sense of community, and improved abilities to manage online reputation (Martin, 2007).

The discussion above suggests rapid growth of SNS adoption in organizations. Three major current uses seem to be: recruiting, advertising, and internal collaboration. To assist corporate recruiting, employees can tell their contacts about job openings via their network. Companies can also create Facebook groups at no or little cost, which can help to promote their opening and opportunities (and enhance their brand image). Recruiting companies can also create applications (mini-programs) that users can add to their profiles at no charge. For example, Jobster has created an application that sends a message to a user whenever a job position is created that is potentially of interest to them (Rocha, 2007). Ernst & Young has a very active Facebook service page, and even the CIA recruits on Facebook. Recruiters tend to prefer Facebook over MySpace, even thought it has fewer users, because it is somewhat cleaner and more organized, and has a more mature member-body (Rocha, 2007). Employee-referred hires are more successful (80% versus 50% for non-referrals) (Anonymous, 2007b), suggesting that increasing the number of referrals via avenues like SNS will have significant value for companies.

A survey of executives found that 35% thought social networking sites would be most useful in the recruiting efforts over the next three years (Anonymous, 2008h). A Manpower survey in the UK found that 17% of users use their SNS to research potential employers and 10% use it for networking and generating new business. This suggests that the practice of using SNS to aid recruiting is likely to grow. However, companies should be sensitive to the fact that some potential employees feel the information they put on the SNS profiles should not be used for making recruiting decisions. One study found that over half SNS users would consider it unethical if employers used SNS to learn about potential or existing employees' activities (Anonymous, 2008i). And another study found 60% of students felt that Facebook information should not be used in hiring decisions (versus 28% of employers)

(Cain, 2008). Interestingly, recruiting of high school students by colleges and universities via Facebook and MySpace methods was acceptable to the majority of students (Roach, 2006).

Advertising is the main source of revenue for large SNS like Facebook. Emarketers suggest MySpace and Facebook got 72% of all ad revenues for social network sites in 2007 in the USA (Russell, 2007). Companies can potentially mine profile pages to identify potential customers. Users of SNS represent an important demographic for marketers (Raskin, 2006). There are few studies that have established the effectiveness of this advertising, as of yet.

Using SNS internally to mine in-house expertise, sharing information internally, and save time now spent in mailing documents and emailing comments all has significant potential (more efficient collaboration). Serena Software and Nissan are two other examples that are featured in the literature for their use of SNS.

Serena Software Inc. is a global company with 800 employees that is using Facebook to connect coworkers at various sites. They are making Facebook the company's intranet and encouraging use through Facebook Fridays where employees are encouraged to spend one hour of personal time on their profiles and connect with others. The aim is to let employees get to know each other as people, help them understand the business and products, and help to serve customers, on demand. The corporate culture is evolving to foster a sense of community and fun, which the CEO believes will help them get more done (Anonymous, 2007c).

Nissan launched a social networking site, called N-Square, to connect up to 50,000 of its 180,000 employees globally. Users are able to create online profiles, blogs, communities, discussion groups and share data files. A main reason for launching the site was to provide employees with a way to avoid bureaucratic channels and create new partnerships, hopefully reducing the inefficiency of traditional tools and channels. N-Square may also help employees feel more connected to their jobs, perhaps reducing turnover and facilitating retention of top people. Nissan's initiative was sparked by seeing what IBM was doing with their social networking applications (Anonymous, 2008g).

Companies are also trying various ways to take advantage of SNS potential to reach the users on SNS. For example, companies, such as MTV, Warner Bros and Woolworths, are developing applications for Facebook that push products to users, such as TV shows and album releases. However, the uptake of these applications by users has been very low, typically only a few active users per day, making the recovery of the cost to develop the branded application unlikely (Anonymous, 2008a). A health planner/reminder application to help people keep track of appointments, has been developed by Healthplan provide HAS in the UK (Anonymous, 2008d). And Amazon has developed Facebook applications that make it easy for users to see shopping wish lists and link them through to make a purchase at Amazon (facilitating online social shopping) (Birchall, 2008)

Only one study was found that examined corporate SNS use from the perspective of the user. A study of 68 Facebook users within IBM in 2007 found three different patterns of use. The first (and largest) group, called "Reliving the College Days" had a high number of school contacts and few connections in the corporate network. These were the youngest and appear to have started using Facebook during their college studies, and continued to use it to maintain contact with college friends. The second group, called Dress to Impress, had a mix of school and work Friends, had fewer Friends than the first group, and listed more information about their job. The third group, called Living in the Business World, appeared to have recently joined Facebook and only had Friends within the corporation. They appeared to join to be part of the online community of coworkers. The latter two groups appear to be managing their image recognizing that professional colleagues are viewing their profile, whereas users in the College Days group have profiles with much more personal information, with very little work-related information. The Dress to Impress group appear to manage their profile different than they did in college (more professional), whereas the College Days users appear to not have changed their use of the SNS. The Living in the Business World group appear to have used Facebook to enhance their existing relationships with coworkers by keeping in touch with both local and remote coworkers. It is expected this type of usage will grow in organizations and help people create common ground and mutual interest. This study illustrates the difficulty of using a single site for professional and non-professional use. While it is possible in Facebook to create limited access profiles, this takes extra time to both create and maintain (DiMicco & Millen, 2007).

Antecedents and Outcomes of SNS Use

While the research on what influences SNS use and the outcomes is limited, it is undoubtedly growing fast. Five topics related to SNS use were found in the research: the development of social capital, perceptions created by profile content, student perceptions of faculty due to faculty use, privacy concerns due to use, and productivity impacts of use.

One study examined the relationship between SNS use and social capital. Social capital refers to resources gathered through interpersonal relationships and is seen to generally have a positive impact on people in social networks (via increased trust, mutual support, goodwill, etc.) A study of 286 US undergraduate students found their use of Facebook was a significant positive predictor of social capital, suggesting that using Facebook helped students maintain and strengthen relationships, both weak and close ones. (Ellison, Steinfield, & Lampe, 2007; Ellison et al., 2006). This study supports the proposition that SNS use does strengthen social networks and is beneficial, especially in an undergraduate setting.

SNS users create an image for others via the personal information they choose to share on their profiles and whom they link to as Friends. Several studies have examined the impressions created from different angles, including the number of friends, profile content, and appearance. For example, experimental results with 153 U.S. undergraduate students found that the number of Friends on Facebook can provide a significant cue by which others make social judgements. Individuals who had too few Friends (approximately 100) or too many Friends (greater than 500) were perceived more negatively in terms of social attractiveness, indicating a curvilinear effect. A somewhat similar relationship was found with perceived extraversion, although the negative effect after the 500 Friend level was considerably more level (Tong, Van Der Heide, Langwell, & Walther, 2008). The respondents had an average number of Friends on their Facebook accounts of 395, suggesting that people judge other's social attractiveness on the number of Friends they have and use their own number of Friends possibly as a reference point.

The relationship between number of Friends and profile structure (i.e., which fields are completed) has also been investigated to determine if the completion of certain profile fields predicts Friendship, via creating common ground or signaling (Lampe, Ellison, & Steinfield, 2007). Over 30,000 profiles at a US university were examined. On average, users completed 50% of the fields available in Facebook. Positive associations were found between the number of fields completed and the number of Friends. Causality can not be inferred from this, as there are several plausible explanations including: a more complete profile generates more Friends, more active users could both complete more fields and seek out Friends, and people with more Friends could feel more pressure to add more information to their profiles.

Semi-structured interviews of 19 US students were conducted to examine how the participants used SNS to present themselves to others and manage the impressions created (Dwyer, 2007). Subjects suggested that creating a good impression was important. One subject said: "You can't just completely be yourself, you have to play the game, and have some sort of cool factor [so that] people are interested in speaking to you." (p. 5). Participants were concerned about privacy but suggested that it was up to them to control it by not posting any information they felt was private. Based on these results, the author suggested that key attitudes which influence the management of interpersonal relationships are concerns for information privacy and impression management. SNS technology features that can enable interpersonal relationship management included profile management, visibility management and identity management (Dwyer, 2007).

Impression formation was further studied by examining the impact of how what people write on Facebook walls and the physical attractiveness of Friends affected perceptions about the profile owner (Walther, Van Der Heide, Kim, Westerman, & Tong, 2008). 342 undergraduate US students participated in this experiment. Results suggest that having physically attractive Friends is positively associated with perceptions of the profile owner's physical attractiveness (and had no effect on task attractiveness – the ability to complete work reliably). Prosocial statements by Friends about profile owners was positively associated with social and task attractiveness, as well as credibility. Gender did moderate some of the effects, consistent with the sexual double standard (i.e., some remarks were seen as negative for women and positive for men – e.g., remarks about excessive drinking, promiscuous sexual behaviour).

Two studies have examined the impact of university faculty having Facebook accounts on student perceptions. A 2006 study of 166 US students on Facebook indicated that seeing their professors on Facebook (i.e., viewing their profile, etc.) had neither a positive or negative effect on student ratings (Hewitt & Forte, 2006). However, an effect was found when the content of the professor's profile was studied. An experimental study was conducted with 133 US college students where teacher self-disclosure on Facebook was manipulated via different photos, biographical profile information and Wall postings. High disclosure involved including information about social gatherings with comments, group membership and personal information (the amount of information provided was less in the low and medium disclosure conditions). Students viewing the high disclosure profiles believed the classroom climate would be more positive, anticipated higher levels of affective learning with those teachers, and had higher anticipated motivation levels. Most (84%) of the comments from students viewing the high disclosure profiles were positive, whereas a small number were negative, expressing concerns about loss of professional image (Mazer, Murphy, & Simonds, 2007).

Given the ability to make a considerable amount of personal information available to others (which many users do), privacy is a natural concern in SNS. Early work (Gross, Acquisti, & Heinz, 2005) found that US university students on Facebook disclosed a great deal of personal information on their profiles (e.g., pictures of themselves – 90.8%, birth dates 87.7%, residence addresses – 50.8%, and phone numbers – 39.9%). Analysis implies that almost all of this information is genuine. Only a few percent of people used available privacy settings to restrict the ability to view their profiles within their network, indicating that most users were either unaware or unconcerned about their personal privacy.

Another survey of US college students was conducted to make Facebook users aware of the privacy options available to them and alert them to possible privacy issues. The profiles of participants were then examined after they completed the study to see if they changed the amount of information on their profile (presumably from being made aware of privacy issues and being concerned about the potential privacy problems). Of the 84% of participants that knew they could change the privacy settings within Facebook, less than 48% had made any changes prior to the survey (indicating they left the privacy settings on default which provides visibility of the profile to anyone in their networks). Only a few percent of participants made changes to their profiles within 5 days after the survey was conducted inferring that most users were comfortable with the amount of information they were sharing (Govani & Pashley, 2005).

Another US study of privacy concerns surveyed 294 students found that privacy concerns were stronger in non-users than users of Facebook (although the differences were not statistically significant within undergraduate respondents). Therefore, privacy concerns appeared to be affecting Facebook use in non-undergraduates. For undergrads, even those students who had privacy concerns provided a significant amount of personal information in their profile. The strongest motivation in providing information was to have fun and provide enough information so that people benefit from Facebook (Acquisti & Gross, 2006)

Antecedents of information sharing and the development of new relationships were studied in 117 MySpace and Facebook users. Concerns about privacy, trust in the SNS, and trust in other members of the SNS were proposed as antecedents to sharing and relationship development. Facebook users had higher SNS trust and they disclosed more personal information such as real name and email address. MySpace members were more likely to disclose their relationship status. MySpace users also were more likely to agree that they could easily meet new people with their SNS and were more likely to extend new online relationships by contacting the person via other communication channels (e.g., telephone, F2F, instant messaging (IM), email). Results are consistent with previous research suggesting Facebook users use the SNS to extend existing offline relationship more frequently than initiating new online relationships. However, in MySpace, where trust is lower, there was a fair amount of activity establishing new online relationships. Few significant relationships were found with respect to privacy concerns, the exception being that people with high privacy concerns were less likely to share their IM screen name (Dwyer, Hiltz, & Passerini, 2007).

Time spent on SNS is a growing concern to many companies. With SNS usage growing, organizations see both threats and opportunities. Corporations are creating, and adopting SNSs to stimulate internal usage and are advertising on SNSs to reach target markets. However, companies also see threats in terms of wasted time and security concerns, to the degree that some companies have blocked access to SNSs during work time (e.g., the US Military, the Canadian government) (boyd & Ellison, 2007). Two-thirds of UK companies surveyed are banning the use of Facebook during office hours, although other companies feel this is too extreme since people's working and personal lives are blurring, making it difficult to leave personal life outside when they enter the work site (Brockett, 2007). Another survey, done in July 2007, suggests that approximately 50% of companies are blocking access to SNS at work (Green, 2007).

One poll in the UK estimated that Facebook and MySpace use was costing UK companies approximately 6.5 billion pounds annually in lost productivity, based on a finding that office workers are spending at least 30 minutes per day on social networking (Hathi, 2008). The assumption behind this claim is that the time spent on SNS is of no benefit to the organization. Counterarguments suggest that time spent on SNS can help with recruitment, can improve employee morale and corporate loyalty, and improve company transparency. While IT departments typically would like to ban SNS (for security), use of SNS in organizations is often driven by HR. HR is concerned with team building, recruitment and retention, and corporate culture (Hathi, 2008).

Concern about the time spent on SNS also exists outside the corporate setting. The number of Friends in SNS is typically two to three hundred. The ability to create any real relationships with this many people is the subject of debate, and there is a concern that very close relationships (which typically are just a few) may get weakened as people spend more time and energy maintaining distant relationships (MacLeod, 2008).

NEW DEVELOPMENTS, CHALLENGES AND OPPORTUNITIES

This section is organized into three parts. Challenges and opportunities for using SNS in companies is first discussed. The second part deals with the privacy challenge of SNS use, since this is a major concern in the literature. The last section summarizes some of the recent and foreseeable developments that may lead to new opportunities for SNS use.

Using SNS in Organizations

There are many opportunities for companies to use SNS. Departments that should benefit from SNS include sales (identifying and engaging customers) and operations (so employees can help each other and find more effective ways of working). Research and development could also use SNS to gather ideas and insights from customers (Bernoff & Li, 2008).

Companies could use existing SNS like MySpace and Facebook to reach current and potential customers. While SNS advertising is growing, companies need to interact with customers in meaningful ways, such as creating conversations and affinity-based networks. SNS can potentially be used to reach customers and get advice on new products, feedback on existing products, and ideas about brand building (Webb, 2007). Knowing whom to reach out to is important too. While it is relatively easy to mine existing profiles and the data in fields to segment targets, it would be valuable to also identify what people do on their sites (versus whom they say they are). In this way, marketers could identify the creators and key influencers and target these people based on how they act. So far, SNS operators have not been willing to provide marketers with this sort of data (Klaassen, 2008).

However, companies have to be sensitive to the culture of existing SNS and the receptiveness of members to advertising. Clemons et al. (2007) caution that SNS have risks for advertisers, as the effectiveness of the advertising is largely unproven and is in need of future research. While offline social networks are based on and create trust and credibility, it is unclear how much of an online SNS is built on trust. If SNS are built on trust, there are concerns that commercializing the network via push advertising may undermine that trust. And, as mentioned above, one of the reasons found for leaving a SNS is over-commercialization.

SNS can also help companies collaborate internally. Small companies could use an SNS like Facebook as their collaborative platform and this is starting to happen (Anonymous, 2007b). The email and document management capabilities fit these needs well and could enhance the ability to work in teams and from remote locations. The research showing that students develop social capital through SNS use is encouraging for corporate use. Users could use SNS internally to maintain weak ties with colleagues and to learn about expertise within the organization (like a knowledge management system).

Using an externally hosted SNS can create security and privacy concerns for corporations. Depending on the nature of the business, there may be a need to build safeguards to ensure discussions and document sharing is tracked, to be certain employees meet government regulations and don't create legal problems (Green, 2007). There are SNS options from major software vendors so companies do not have to use externally hosted SNS like Facebook. For example, IBM has a product called Lotus Connections which provides a number of Web 2.0 tools, including profiles and social networking[5] (Everest, 2008). A company could use a product like this to create an internal SNS which would facilitate collaboration internally while controlling security (since the application would be within the corporate firewall and not open to people from outside the company).

Another opportunity for companies is to partner with existing SNS and develop applications that offer customers more value. For example, CIO magazine has partnered with LinkedIn to connect relevant events and articles. LinkedIn widgets and the CIO.com website allow users to see who at a company featured in a CIO article is part of the LinkedIn network. Users can also view want ads and see who is connected to the advertising company. CIO media events are enhanced by LinkedIn's Event service that shows a user who else in the network is planning on attending, as well as manage the networking potential at the event (Anonymous, 2008c).

The Privacy Challenge of SNS Use

SNS are mediated public sites where technology allows people to gather publicly. Unique properties of mediated publics include persistence, searchability, replicability and invisible audiences (Cain, 2008). As previously mentioned, all of these properties can create privacy issues, challenges and concerns. Information is in SNS that is typically not included in resumes or uncovered by general background checks (Cain, 2008). Professional and private lives can blur together, especially if prospective employers see photos of actions that might cause them to question the candidate's judgment.

Digital identities (i.e., profiles and reported activities) are increasingly viewed by third-parties that the profile owner is not aware of. The legality of this is still unclear and undoubtedly will vary across countries depending on privacy legislation (Hodge, 2006-2007). Companies routinely use search engines to do background checks on applicants and police and university authorities have used Facebook profiles to collect evidence and leads. Even if a user removes some potentially compromising information from his/her site, there is always the danger the information has been captured elsewhere, creating a digital record that is out the control of the creator. Users need to recognize that they are not operating in a protected environment (Rosenblum, 2007).

In response to user privacy concerns, SNS companies such as Facebook have developed various privacy settings, such that now it is possible to control what is viewable by whom to a much greater extent than it was several years ago. However, research has found that many users do not change the privacy settings and many users are very open to accepting Friend requests from total strangers, thereby giving the stranger access to the personal information on their profile (Gross et al., 2005). This can lead to data re-identification, where a third party connects information from different sources and has the potential for identity theft and/or fraud. Other risks include damage to reputation, receiving unsolicited message and offers, and being exploited by social predators. The latter is rare but there have been reported cases of sexual predators, stalkers, child molesters and pornographers using SNS to approach minors (Rosenblum, 2007).

Installing applications also causes privacy and security concerns. For example, users should also be aware that installing Facebook applications gives the application access to some of the profile (some information can be restricted). The application developers can then use the information to target ads. There is a fair bit of uncertainty about how the data is kept safe and the potential exists for it to be combined with information about individuals, which could lead to problems such as identity theft or spoofing and phishing (Irvine, 2008). Users should also be aware of the potential for downloading applications on SNS that are malware programs. Although users have become aware of this danger when using email, the same degree of caution is not currently prevalent in SNS use. And many of the young SNS users are fairly inexperienced and naïve about the risks of using electronic media (Douglis, 2008).

Given all these risks, organizational users (as well as individual users) need guidelines to protect the users and the company. For example, guidelines about what information can and can not be posted should be specified. Privacy protection recommendations include assuming anything you post is public so you have to exercise good judgment in what personal information is shared in a SNS, do not have an open profile (i.e., use the available privacy setting to control who has access to information), do not accept Friend requests from strangers, and avoid installing applications (Munro, 2008).

Developments in SNS

While most users stick with a single site (Watson, 2008), they may move from one to another as popularity declines and builds. Maintaining multiple sites takes time and effort since currently sites are independent applications using their own architectures. However, companies are trying to create integration mechanisms that would allow information from different SNSs to be shared via one platform. Developments are coming that will allow users to pull information about friends and colleagues from numerous SNS and other websites. FriendFeed is one of the first of these (Green, 2008). Google is developing an open source framework, OpenSocial and SocialStream, that would allow many of the popular SNS to be connected into a unified social network (Russell, 2007; Weaver, 2008).

Mobile access, via mobile phones, to SNS such as MySpace and Facebook is growing (Anonymous, 2008b; 2008f). Mobile social networking will help put users' content into context since their social interactions will be able to occur in real time (DeJean, 2008). Mobile social networking systems are also developing that, among other things, allow users to be aware in real time of social activities. Slam is one of these systems, and while not a full SNS (given the lack of profile and social network visibility), some of the features and functionality are similar (Counts, 2008).

SNS are also evolving to attempt to offer more value to users. For example, MySpace is developing a music service with Universal, Song BMG and Warner and is working with Merlin on future licencing arrangements (Cardew & Emanuel, 2008). SNS are spreading to new countries and cultures (e.g., MySpace recently launched a dedicated community for Indian users (Anonymous, 2008e)). And given the high level of Facebook use in university settings, it is natural that educators are considering if and how to use Facebook as a learning tool. One developer recently received funding to work on a learning management system based on Facebook (Goth, 2008). Potential other applications include health care (Watson, 2008) where users can get personal health information from SNS like Facebook (Sinnema, 2008).

CONCLUSION

What SNS are and what we currently know about them has been presented. SNS usage is fairly new and growing incredibly fast. There are many possible benefits of use and some significant areas of concern. Research opportunities are also numerous. For example, the focus of research so far has largely been on the SNS user. While the user is obviously very important to the story, and current data is needed as usage and concerns evolve, there are other stakeholders that warrant research attention. This would include designers and operators of SNS and the underlying infrastructures, developers of algorithms, conduct of third parties using SNS, and marketers and advertisers who are trying to strengthen their brands (Beer, 2008). The majority of research has been with students in the US, leaving many opportunities for studies of corporate use (especially as this use grows), and use in other countries. The future of SNS appears to be bright, and the future for SNS researchers should be exciting!

Chapter 1.19
Mobile Social Networks:
A New Locus of Innovation

Nina D. Ziv
New York University, USA

ABSTRACT

This chapter discusses how virtual social networks have evolved from their original purpose of being online meeting places where people interact with one another to becoming an important locus for innovation. It delineates the salient characteristics of these networks (both Web-based and mobile) and suggests that the advent of these networks has shifted the balance of value creation away from traditional companies and towards the creation of companies which provide technology platforms and services for user-centric innovation. The chapter discusses how users on these virtual networks have become important sources of innovation in a variety of ways: they develop content which they share with others and participate in virtual community centers; they interact with companies who are developing products and provide valuable feedback; and they are the impetus for the creation of new kinds of marketing tools as businesses try to tap into these virtual networks in order to better understand what products will sell to these users. In addition, the chapter discusses the implications of these developments for managers, especially those in content-intensive industries such as financial services and media. Examples will be given to support these ideas from case studies on Upoc, a New York City-based mobile services company which hosts social networks for a wide variety of users; Dodgeball, another New York City-based company (recently acquired by Google) which is one of the pioneers in the mobile social networking arena; and Tapuz Mobile, an Israeli-based social network.

DOI:

INTRODUCTION

During the mid-1990s, the Internet emerged as a robust technological platform and almost immediately gained traction as a value creation engine. Firms in such diverse industries as financial services, media, and healthcare, began to invest their resources in generating unique digital-based products and services into their cadre of physically-based businesses (Andal-Ancion, Cartwright, & Yip, 2003). Indeed, managers at such firms recognized that technology-enabled innovation was now an essential part of their firm's strategy (Freeman & Soete, 1999). These new users of technology also realized that in order to compete with companies that were basing their business models on digital products, they would have to venture beyond their traditional, circumscribed organizational structures which resided in brick and mortar environments and tap into the resources that existed in a larger more networked business environment (Gemunden, Ritter, & Heydebreck, 1996).

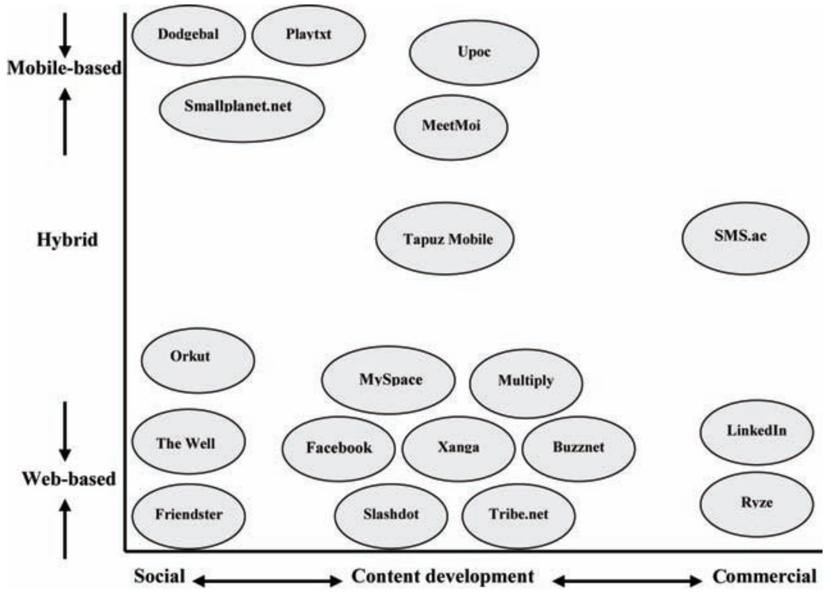
As the locus of innovation shifted from so-called 'brick and mortar' delineated companies to a more networked ecological model, a further organizational shift occurred toward a more powerful user presence within these networks. Various types of online communities appeared including special interest groups such as usenet groups; professional associations and online forums where people could exchange ideas on specific topics of interest to them; portals which provided a single point of entry for individuals and businesses to interact with one another; chat rooms, where users sought new communities and contacts; and short-term groups where users participated in one time events such as online competitions, quizzes and polls (Hamman, 2001). These communities consisted of individuals who might be scattered geographically but used the Internet as a platform for discussion. Howard Rheingold, who pioneered such online communities, defined them as "… cultural aggregations that emerge when enough people bump into each other often enough in cyberspace" (Rheingold, 1994). Some of these communities had moderators and others were more dependent on users to keep them going. For example, The Well which still exists, is essentially an online set of forums which are available to users who pay a monthly fee to participate in discussions on such wide-ranging topics as entertainment and media, computer tools, and politics (www.well.com/aboutwell.html).These online communities were initially only accessible through Web sites and therefore uni-dimensional from a technological point of view.

More recently, there has been growth in companies on the Internet which have focused on the development of virtual social networks. Such networks range in purpose from being purely social in nature to those which are commercially oriented with content development being a key purpose for these networks. Thus, such companies as Facebook and MySpace have reached out to users in the 18-24 year-old range who create their own content, for example, personal profiles, photos, blogs, and journals and share it as well as other aspects of their lives with their friends as well as with the rest of the world (Hansell, 2006). Ryze and LinkedIn have enabled business users to establish networks of business associated and potential clients. While these virtual social networks are intrinsically interesting as places where young people socialize with one another in an online setting and are seen by marketeers as a perfect target for advertising products and services designed specifically for this population (Elliott, 2007), more importantly, they have become a new and fertile locus for innovation.

This chapter will explore the development of mobile social networks, a subset of virtual social networks. In an initial study of online social networks (Ziv & Mulloth, 2006) social networking companies were plotted along two matrices: technological and purpose (Figure 1). On the technological matrix, social networks were plotted along an axis which ranged from Web-based to mobile-based and included a middle ground, that is, a hybrid scenario where social networking companies incorporated both the Web and the mobile platform.

It is clear from this chart that mobile social networks are in the minority in the overall social networking industry as presently constituted. However, this chapter will discuss how this subset of companies is at the forefront of innovation in social networking. It will delineate the salient characteristics of these networks and discuss how users who populate these networks have become significant sources of innovation in several ways:

Figure 1. Social network matrix (partial list)



they have begun to shift the balance of value creation away from traditional companies and toward the creation of companies which provide technology platforms and services for user-centric innovation; as they engage in community building, these users develop new business content and knowledge; and they have been the catalyst for transforming organizations and rethinking managerial competencies.

The chapter is divided into four sections. The first section provides a brief overview of the effect of digital-based innovation on the business environment especially with regard to the changing role of customer/users and the transformation of firms into more networked, ecological organizations. These trends in the business environment have played a significant part in the establishment of virtual social networks. The second section discusses the emergence of the mobile platform and other technologies which enabled mobile social networks to develop. The third section focuses on three mobile social networking companies, Dodgeball and Upoc, New York City-based companies and Tapuz Mobile, an Israeli-based company, and defines the salient characteristics of these companies. Field research was conducted on all three companies. In the final part of the chapter, some conclusions are drawn about mobile social networking organizations, which can serve as a beginning point for further research on the entire universe of social networking organizations. Moreover, these conclusions have implications for managers in technology-enabled organizations who wish to foster an innovative environment in their companies.

The Impact of Digital-Based Innovation

As background for the development of virtual social networks, three major ideas on the nature of innovation with relation to managerial competencies and the development of the firm will be discussed. The first idea concerns business networks of innovation which have emerged as a result of the Internet and have enabled companies to go beyond their traditional 'brick and mortar' boundaries in order to access innovative capabilities from sources such as partners, vendors, experts, universities and most significantly customers/

users. Indeed, until recent developments in digital-based innovation, which have led to a redefinition of how firms compete and are configured, firms were defined by how they made use of "productive resources for the purpose of supplying goods and services to the economy in accordance with plans developed and put into effect within the firm" (Penrose, 1959). The resources that the firm had within its span of control were physical in nature, that is, they consisted of tangible things such as plants, equipment, land and natural resources, and raw materials as well as human resources (Penrose, 1959). This view of the firm also posited that firms had very clear administrative structures with a central management structure which was responsible for the general policies under which the firm's hierarchy operated (Penrose, 1959) and well-defined reporting relationships and job responsibilities (Schoonhoven & Jelinek, 1997). Moreover, firms were thought of as isolated "islands of hierarchical control embedded in a market structure and interacting with each other through the price mechanism" (Teece, 1998).

In the post-industrial business environment, which is characterized by an emphasis on digital-based innovation and hybrid (digital and physical) innovation, the role of the firm and consequently its structure has had to change dramatically. Huber forecasted that this new business environment would be one where there will be more available knowledge, increasing complexity, and increasing turbulence (Huber, 1984). He suggests that because of these three factors, organizational decision making will be faster and more complex and therefore organizational structures will have to change to accommodate this new kind of decision making (Huber, 1984). In this new environment, innovation is characterized by uncertainty, interrelatedness between various sub-systems, and often relies on tacit knowledge accumulated by various members of the organization who may reside in different structural units (Teece, 1998). Instead of residing in a structured hierarchical organization, innovation now takes place with a larger networked environment (Benkler, 2006).

Therefore, for firms to be successful and differentiate themselves in the marketplace, it has become increasingly clear that along with having a set of core competencies, such firms would also need to acquire a network competence, which would enable them to exploit the set of relationships among customers, suppliers, vendors, and other so-called 'nodes' on the network (Ritter, 1999). Managers now understand that developing such relationships is crucial for enabling the continuous transfer of knowledge to their firms thereby providing a richer environment for the creation of innovative products and services (Kodama, 2005; (Rothschild & Darr, 2005). Such networks have enabled various constituencies to become nodal points on the technological platform and interact continually with one another in order to create value.

The second major idea is related to the development of these business networks: it is the ability of customers to provide instantaneous feedback to firms and be so-called co-creators with the members of these firms. While traditional firms had always 'pushed' their products to customers, the Internet has suddenly enabled such customers/users to become significant nodes in the business network of many firms. Thus along with communicating in a new way with businesses, users themselves have become an important source of innovation.

The notion of users as sources of innovation is not new. In his landmark book, *The Sources of Innovation*, Eric Von Hippel discusses how the users he studied had a great advantage over manufacture-centered development because they could create exactly what they wanted and could benefit from exchanges of ideas with other users in the community (von Hippel, 1988). Such users developed new products in order to satisfy their own needs and ultimately offered their innovations to companies who then marketed them. Improvements in software and hardware as well as cheaper tools that enable users to create new products, led to a 'democratization of innovation' in which users not only have the opportunity to make exactly the right products for themselves but also create communities which foster an environment in which creativity and continuous learning take place (von Hippel, 2005). Such communities of user-innovators have been very important especially in the beginning stages of new industries. For example, in the early days of Silicon Valley, informal networks of engineers and other like-minded affinity groups traded ideas with each other in settings outside of the workplace. The ideas which came out of these networks had a significant impact on the development of some of the hardware and software products which made Silicon Valley a hotbed of innovation in the 1990s (Saxenian, 1994).

The third major idea concerns the development of user communities. As the technological platform underlying the World Wide Web became more robust, such communities have become important entities not only with regard to the business networks described above but also as seedbeds of innovation. A prime example of community-based innovation is Linux. In 1991, Linus Torvalds, a computer programmer in Finland, released an operating system kernel and made it available on the World Wide Web for anyone who wanted to view it and/or add to it. Thousands of computer programmers around the world began to contribute to the kernel and the Linux operating system evolved into an alternative to proprietary operating systems such as Windows. Torvalds became the moderator/facilitator of the Open Source project and the Open Source software movement has developed into a global community of software developers who contribute freely and voluntarily to an operating system kernel known as Linux because they derive personal satisfaction and enhance their reputations as software developers from making such contributions (von Hippel, 2001). A recent manifestation of the Open Source network structure is Wikipedia, which is an online encyclopedia to which users contribute voluntarily (Levine, 2006). Another well-known technologically- based user community was started by Shawn Fanning, a college student, whose original aim was to share his music with his circle of friends. His development of a peer-to-peer platform enabled Napster to become an application on which users could send each other music files (Menn, 2003). Later, other companies such as Apple, developed ancillary services to supplement the original file sharing application (Fried, 2003).

In summary, digital-based innovations, in particular the Internet, have led to a significant change in how some industries and firms conduct business. Along with fostering a new mindset among managers about how to create value, the development of networks of innovation has shifted to some degree, the center of creativity and product development into the hands of users who can now drive innovation and play a key role in successful value creation. As users became active participants in networks of innovation, they have formed virtual communities like those in the physical world in which they have created new kinds of knowledge and content. Such communities are slated to play a more significant role in the future of organizations as they become more networked and access a variety of constituents as sources of innovation.

The Emergence of the Mobile Platform

This section will focus on the emergence of the mobile platform and other related technologies which enabled the development of mobile social networks. In the early stages of the social networking arena, mobile social networking did not develop at the pace of Web-based applications. This was in large part due to the static nature of innovation on the mobile platform. Historically, much of the innovation on the mobile platform focused on the development of infrastructure and devices. In the United States, telecommunications carriers such as Verizon, Sprint and AT&T

all invested significant resources into wireless technologies, primarily by building out the telecommunications infrastructure to accommodate the increasing demand for wireless services, and acting as service providers. Other technology companies such as Nokia and Ericsson in Europe and Samsung in Korea developed handsets. Indeed, in the early days of the mobile platform, the emphasis was almost exclusively on technology and making sure that a user could complete a phone call without being ‘dropped’ in the middle of it (Cook & Ghosh, 2001).

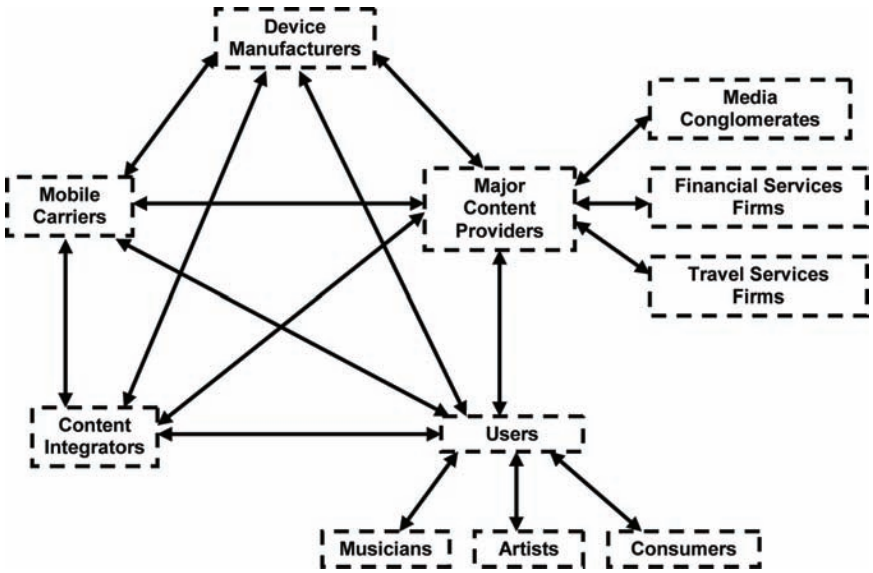
Because of the emphasis on technology, there was not much content available to the general user population and usage was limited to cell phone calls. In many ways, the process of adoption of this technological innovation was very similar to what occurred with the World Wide Web, where initially there was also a dearth of content available to mainstream users. In fact, some analysts contended that the wireless platform was just a ‘watered down Web’ with little content that users wanted to access or pay for (Mobile content, 2000).

As the mobile platform developed, voice traffic became more and more of a commodity and mobile operators looked to new sources of revenue. One of most lucrative appeared to be in the area of content provisioning. Realizing this was an important new trend, mobile operators became the center of a paradigm of innovation in which content providers and handset manufacturers were providing their products to the mobile operators and users of these services had no choice but to access services and content from the operators. In this paradigm, the carriers provide the content and devices and the users have little contact with handset/device manufacturers or content providers. While this paradigm presumably worked in the early days of the platform when technology drove the business, with the development of new kinds of content for mobile devices, it was suggested that this paradigm may stifle innovation for all constituencies and what was needed is a new paradigm that is more networked and porous in structure and is characterized by continual interaction between content providers, handset manufacturers, other device manufacturers, for example, Nokia, Apple and most importantly, users. In addition, so-called content integrators/infomediaries who provide technical- and content-related services to both content providers and carriers as well create their own portfolios of content were deemed to be important constituents in the paradigm (Ziv, 2005).

This shift toward a more ecological and fluid model began to occur. Carriers began to create more equitable partnerships with content providers and allow small companies to use their network for distributing a variety of applications to users. Large content providers also recognized the need to access the expertise of content developers outside of the traditional boundaries of their organizations in order to find creative ways of using the premium content that is their most important asset. Users began to assume a more active role in content creation and the use of the mobile platform (Figure 2).

Along with the advent of an increasingly stable mobile platform and the rapid adoption of mobile devices such as cell phones, gaming machines and handheld computers by a wide variety of users, a new set of technologies, that is, Location-Based Services (LBS) emerged which further provided the impetus for the creation of mobile social networking applications and companies. LBS technologies allow programmers to capture the location of a particular user and integrate the position information into a wide variety of applications (Geier, 2004). Such technologies include GPS (Global Positioning Systems) which allow customers to find their way to their destinations and alert friends and colleagues to their whereabouts and Wi-Fi, which can be used as the basis for determining position and acts like an indoor form of GPS, with access points acting as satellites. With this approach, the server software keeps track of client device positions and also transmits this information to specific clients (Geier, 2004).

Figure 2. Networked model of innovation on the mobile platform



The availability of LBS applications transformed virtual social networking from being a people-to-people phenomenon which exists irrespective of geographical place to one in which individuals use technology to maintain a network of strong social ties within a local geographical context such as a city or a university community (Jones & Grandhi, 2005). Coupled with a more robust mobile platform and better devices, mobile applications began to proliferate. The next section will describe the characteristics of mobile social networks.

Characteristics of Mobile Social Networks

From an analysis of three mobile social networking companies—Dodgeball, Tapuz Mobile, and Upoc—a number of salient characteristics emerged. One of these characteristics in a larger sense defines the entire genre of these companies. It is the overall notion that unlike other organizations whose core competency is based on the development of products which the company decides is important for its customers (Prahalad, 1997), these companies' core competency is to provide services for users who 'create the products'. Thus value creation depends almost entirely on the users themselves and their co-creation with the company which hosts them. A prime example is Dodgeball, a New York-based subsidiary of Google, an early instance of a company which provided a technological platform and some services to its users. Essentially, the service that Dodgeball offers to users is the ability to connect to one another while on the go in an urban environment. In order to make it simple for users to connect to one another, each bar, coffee shop and major place of interest, for example, museum, sports arena, restaurant in a particular city was geo-coded by the company. The major 'product' of the company is the user profiles which are listed on the Web site. Users fill out profiles, post photographs and list their friends and their cell phone numbers. When Dodgeball users 'check in' at a given locale, they send a text message which goes to all their pre-selected friends as well as any friends of friends in a ten block radius telling all these people where the message sender is located. The system then finds other users who have checked in during the last three hours and compares their locations on a virtual map to see if these users are within a 0.8 kilometer radius. Another major 'product' of Dodgeball is the interaction that occurs between the users when they meet or exchange information about one another. In addition, the users themselves create mini Web sites which contain not only their own profiles and pictures of their friends and friends of friends, but also a listing of the places they frequent and their own personal commentary about particular places such as a review of a restaurant (Ziv, 2006).

For Tapuz Mobile, which is based in Ramat Gan, Israel, the major goal is to provide services for its users which they can employ to develop new 'products' and participate in online communities. Thus, the company offers services which enable its users to create communities where they can discuss topics of interest to them. Tapuz has over 1,100 managed forums as well as 5,000 private forums called communas which focus on particular topics related to Israeli politics, culture and society. The company has over 1.6 million unique users per month who participate in the communities. Along with providing platforms for community building, Tapuz also provides its users with a variety of mobile and Web-based applications. One such application is BLOGTV, which enables users to create a live TV show and broadcast it on the Web and on mobile phones. A user entering the BLOGTV site can interact with the broadcaster and contribute to the ongoing text chat. Other applications include Getit, a mobile auction site, and Flix, a video sharing platform, has a Web site which has a video channel with continuously running videos created by users (Ziv, 2006).

Upoc is a subsidiary of Dada, an Italian-based provider of Web and mobile entertainment services. Dada is a fairly large public company based in Florence, Italy which packages and distributes ring tones, wallpapers and Java games in 12 different countries around the world. In addition, they own the equivalent of the online dating personals service, Match.com in Italy and they also own a blogging company—Life—which compares with the U.S.-based company MySpace.com. Upoc hosts social networking groups for New York City-based users, as well as provides ISP services on the mobile platform. Upoc was one of the first mobile social networks established in the United States and today has a user base of 4 million unique users. Upoc has positioned itself as a multi-faceted mobile services provider and has developed a cohesive approach for mobile media, community, marketing and third-party services for its customers and business partners (Ziv, 2007).

The core of Upoc (which means Universal Point of Contact) is the social networking service which enables users to send text messages to their friends and start any number of mobile groups for friends or family on an unlimited range of topics. Currently at Upoc, there are around 40,000 groups with categories such as music and dating being the most popular. There are also religious groups, and groups which discuss controversial topics. Like other mobile social networking organizations, Upoc is very user-centric especially with regard to the products which define the company. In Upoc's case, users define their mobile identities and participate in creating content and establishing permanent communities. Upoc's services are designed to enable the creation of user-based output. For example, Upoc provides a service called Up2 which enables users to microblog and share their thoughts on a real-time basis with their friends and others. In addition, there are subscription services available to users, for example, dating services, which enhance the mobile social networking user experience.

Thus, mobile social networks such as Dodgeball, Tapuz and Upoc provide tools that enable people to collectively construct a range of resources that were too difficult or expensive, or simply impossible to develop previously (Terdiman, 2004). Users who participate in these networks have the opportunity to generate personalized content such as mobile blogs and/or collaborate on the mobile platform to develop exciting new kinds of content.

A second major characteristic of these companies and related to the notion of user-centricity, is that users are not only active members of their communities and participate in them, they also give valuable feedback to their organizations which enables innovation to occur. Tapuz for example, attributes its success to not only offering superior technology but also being very attentive to the requests and needs of their users. The majority of Tapuz users are young people (the average age is 22) who are early adopters of technology and provide continual feedback to the company on a regular basis on Tapuz's applications and services. The Tapuz management team considers these users a prime source of innovation and often implements suggestions from users into the suite of applications on the Web site. Indeed, Tapuz is an example of a new kind of firm which exists in complete partnership with its users.

In addition, Tapuz's communities while overwhelmingly social in nature, have sparked the interest of firms in the mobile product development arena who participate in some of these communities in order to get feedback about the mobile technology arena. Thus, one community which is a group devoted to a discussion of cell phones has among its users members of the cell phone manufacturing industry who listen to the dialogue and incorporate the suggestions and ideas they hear from the community in their designs of mobile devices for the marketplace.

Given that the users are central to the strategy of these companies, one of the most important aspects of these social networking companies is that they are able to provide the technological infrastructure for product development as well as services which will enable such development. Thus, a third major characteristic of these companies is that they are techno-centric, that is, these companies could not exist or provide services without developing a sophisticated technology strategy. For both Dodgeball and Tapuz, this strategy consists of using the mobile platform exclusively or a hybrid model in which a company provides a Web-based product which enables users to sign up for a particular service and then use the mobile platform. Dodgeball, for example, uses mobile services such as Location-Based Services and short messaging services (SMS) in order to reach their customer base. Dodgeball's services include a Web site which was built using off-the-shelf open source tools which were cobbled together to provide a platform that is accessible to everyone who owns a cell phone. While users may sign up initially via a Web site, once they are signed up, the service exists entirely on the mobile technology platform (Geier, 2004).

Tapuz has developed an advanced mobile platform which enables users to interact seamlessly with one another and also has partnered with Israeli telecommunications operators such as Cellcom, Pelephone, and Orange to develop robust applications and enable subscribers of these operators access Tapuz's applications through operator portals which are available on their handsets. However, as the mobile platform has become more robust, hybrid online/mobile communities have emerged with users participating both through a Web site and by using their mobile devices, for example, PDAs, and cell phones. Indeed, Tapuz offers full synergy between the web and mobile devices. Thus, users who are on the web-based chat platform can talk with users who are surfing from their mobile phones as well as send them messages. An example of a major service of Tapuz is Panet, an Arabic Internet portal which has more than 500,000 daily visitors. Tapuz constructed the application so that the mobile portal is a mirror site of the Web-based portal (www.tapuz.co.il).

Upoc is also techno-centric and has a complex technology strategy for servicing both its users and also its partners, for example, the carriers, media companies and marketing organizations As a multi-faceted mobile services provider, Upoc has developed a comprehensive mobile technology solution for carriers, consumers, media companies and marketers to communicate through various applications including SMS (text messaging), WAP (wireless Internet), voice, and MMS (multimedia messaging). Upoc's technology platform integrates text, voice, Web, and wireless Internet and works on any mobile phone, Internet-enabled phone, wireless PDA, two-way or text pager. Upoc was the first company in North America to have direct connections to all the carriers for facilitating text messaging and in the early days of mobile text messaging, the company was actually generating a significant percentage of the SMS traffic in the United States.

In developing their technology platforms, both Upoc and Tapuz recognized that they would need to integrate the capabilities of their organizations with those of the mobile carriers in their respective countries. This integration enabled both organizations to have viable business models which could sustain them and enable them to provide top notch services for their clients. Thus Tapuz has partnerships with Cellcom and other carriers in Israel and has developed revenue sharing models with these companies. Upoc has a complex business model. It has partnerships with all the major carriers including Verizon, Sprint, T-Mobile and Cingular and is the only company in the United States which actually gets paid by the carriers for generating SMS messages. In addition, Upoc provides local subscription services in which users can download Bible quotes and dating services using premium SMS and also provides advertising services for the carriers.

As a result of its acquisition by Dada, Upoc has become the proprietary aggregator of Dada's billing services for Cingular in the United States and for Dada's local TV promotions. As the intermediary services provider, Upoc gets a percentage of the overall profits. Clearly, the role which Upoc plays as a technology intermediary to the carriers as well as a partner to them in revenue generation extends the model of the mobile social networking organizations beyond simply being a platform for its users to create content and communities.

While users participate as individuals in communities or generate their own content using the various services of the companies, they also are members of communities and engage in continual community building. This virtual community building is another very important characteristic of mobile social networking organizations. Each organization tends to attract a different demographic for its communities. Thus Dodgeball's constituents are mostly young urbanites in the 18-24 year-old age range while at Upoc, the service attracts blue collar workers such as truck drivers, firemen, and police officers who do not necessarily spend a lot of time in front of a computer but do see the need to communicate in the mobile environment for a variety of reasons. Upoc's users are generally Black and Hispanic people in the 20 to 40 year-old age group and remain part of the community for an extended period of time. Tapuz attracts a wide range of people who span various ages, interests, and demographics throughout the Israeli community.

Along with socially-oriented communities, a number of business environments have established mobile social networking communities to enhance their employees' communication with one another and build new knowledge. Thus Upoc's multi-platform cross-carrier group SMS capabilities enable groups of real estate agents and sales teams to be in constant communication with one another. Professionals such as doctors and lawyers have also created these on-the-go communities to exchange and share their knowledge with one another (www.upocnetworks.com). Many of these professionals are not necessarily able to access their Web-based fixed line computers but are able to participate in dialogues with fellow professionals while out in the field.

Community building for these different groups of people is challenging. Most mobile social networking communities are self-policing and support open communication among their members. Users have complete control of how they communicate with one another and what type of content they access. Thus users can change their messaging options at any time, block messages from members they do not like, remove people from messaging groups and unsubscribe from any content they do not want.

A key aspect of community building entails having a community manager who moderates the discussions of these communities, keeps the conversation going and makes sure that there is nothing fraudulent or illegal occurring. Mobile social networking services do vary in how they approach the issue of community managers. At Tapuz, after an incident in which a community moderator who was a woman turned out to be a male, the management at Tapuz decided to meet with each moderator in order to make sure they are aware of their responsibilities and guard against misrepresentation (Ziv, 2006a). At Upoc, any user can create a community on any topic and then become the owner and moderator of the community. However, Upoc maintains a staff of community managers who check in on groups to ensure that the discussions are proceeding appropriately. If a person becomes offensive, the company's community managers can step in and either ask the person to leave or blacklist the person from ever joining the community again. An example of someone who could be blacklisted is a person who tries to sell drugs to community members or makes offensive remarks. Unlike a PC, where a user can assume a different identity, the interaction on a mobile phone can be traced to a network identifiable device so it is easy to track down a person and exclude him or her from the conversation.

The importance of community managers in the life of the communities has become apparent to the management team at Upoc. Steve Spencer, the CEO of the company, suggested that without these managers, many of the communities would not be viable. During the 2007 holiday season, themed communities with Upoc community managers were created around such subjects as Thanksgiving, Hanukkah, and Christmas. Community managers moderated these groups to ensure that anti-social behavior was not tolerated. In fact, about 100 people were expelled from the community because of inappropriate behavior. As a result, these communities became social safety nets for new users who knew that the communities would welcome them. For the Christmas themed community, which was entitled 'What do you want from Santa Claus?', the CEO of the company became the community manager and assumed the identity of Santa Claus. He was able to reach out to people across the United States who shared their stories of heartbreak and joy during the season (Ziv, 2008) .Other functions served by community managers include helping people to understand how to use the functions on their mobile phones and reporting errors and glitches in the system (Alleven, 2007).

By participating in the communities, which are the core service of their company, community managers at Upoc and at Tapuz have begun to change the nature of their companies' organizations.

Rather than the usual management team being the focus of the organization's hierarchical structure, the communities of users who populate the technological platforms of each of these companies have in effect, became the most important nodes on a network which includes the management team. Indeed, all three of the companies that were researched had lean management teams. At Upoc for example, the management team consists of the CEO and a small team of managers who oversee operations, engineering, quality assurance, customer service, and business development.

A final characteristic of mobile social networks is that they are multi-locational. By taking advantage of the mobile platform, they can be intensely urban-centric and operate in a very localized manner or they can connect users on a national level who are subscribers in a national wireless network. Thus Dodgeball's social networks are made up of people who interact in densely packed urban environments. Indeed, in New York City and other large metropolises in the United States, the young generation, largely referred to as Generation @, increasingly looks at such networks as a medium through which they can establish their social identities. These social networks act as virtual community centers, a place for the Generation @ to socialize online as well as use it to tap into information, buy books, send flowers or even breakup with a boyfriend. Dodgeball and other services like it depend on people wanting to meet with one another at particular locations in an urban setting.

Tapuz and Upoc operate on multiple levels. Upoc's communities are sometimes localized in one city where local nurses, for example, may communicate regularly with one another. Other times they operate on a national level across the wireless network which enables users whose mobile phones are tied to different carriers to interact with one another. In the case of the themed Christmas community, some of the users were in rural locations and used pre-paid phone cards as a way of communicating with those in urban environments. For Tapuz, there are local communities as well as national communities and because community members can interact with one another through the company's Web site, many Israelis abroad participate in the communities thus enabling such communities to assume a global stance.

CONCLUSION

As demonstrated by the discussion of mobile social networking organizations such as Dodgeball, Tapuz Mobile and Upoc, the mobile social networking arena is a burgeoning one and poised to evolve into a more robust and developed industry sub-sector in the near future. Of the three companies studied, Upoc is most advanced in terms of providing a comprehensive set of services and also having a sustainable business model. It may be that some companies which provide social networking services such Tapuz Mobile will choose to remain purely social and influence the development of the sector in less tangible ways while others will become more commercialized in nature. Indeed, as the sub-sector evolves, there may be a spectrum of social networking organizations ranging from those established purely by users for their own needs to those which offer more substantial products and services.

For managers, it is clear that in this new business environment, where users are a key component of value creation and user-centric companies are proliferating, it is essential to reach out into the larger networked environment in which these users thrive and seek the sources of innovation outside of the traditional organizational structures. While user-based innovation overall is not new, what is new is the increasing importance and centrality of users with regard to the competitive strategy of these companies. Managers need to rethink the core competency of their companies to include a significant set of user-based innovations. Indeed, they may also have to restructure their organizations to incorporate such user communities and the range of innovation that occurs in them. Thus, users may share products that they have developed with the community at large, for example, Upoc, and Dodgeball users generate profiles of themselves which contain personal information that they upload to the technological platform for sharing with the rest of the community. Innovation in this case takes place on an individual level as individual users create value for others. On the community level, users who interact with one another build new knowledge and content which contributes to the overall knowledge base of the community members.

In addition to the social nature of many of these communities, those communities established by professionals become laboratories for learning about how groups of people interact with one another and how knowledge sharing in a corporate setting can be enhanced. In a sense, community building and sharing of ideas and knowledge becomes a new form of R&D in the corporate environment where users/customers who represent another community node on the larger network interact with internal communities of the organization and continually create new knowledge and ideas. As the economy becomes more service-based, such interaction between external and internal communities becomes essential for the optimal development and deployment of products and services.

Beyond providing a source of innovation, these user communities also provide excellent opportunities for the business community as they enable firms to directly tap into markets and better understand what products will be successful for particular customers. Companies that recognize the importance of community-based innovation include Proctor and Gamble which recently launched two Web sites which are designed to serve as platforms for the creation of user communities made up of their customers (Vranica, 2007) and Cisco, which is providing a variety of services for its customers aimed at helping them bring their users together in online communities (Stone, 2007). The recent partnership forged by Microsoft to provide advertising services for Facebook.com and Google's deal to be the exclusive provider of search capabilities for MySpace.com indicates that major players in the software arena have recognized the importance and potentially lucrative nature of these user communities (Seelye, 2006).

Along with recognizing the value creation done by users, this chapter suggests that these mobile social networking companies represent a significant change in how companies organize themselves and that they are at the leading edge of organizational transformation. Formed to service communities, such companies have a minimalist organizational structure, and a rich technological environment which is designed to encourage customers, that is, the members of these user communities, to innovate. In the future, managers who once headed traditional hierarchical organizations may have to assume new roles which are more in line with the community manager of these social networks who acts as a facilitator of the members of the organization. While making sure the community functions properly, the 'manager' lets the members of the community freely interact with one another to create innovative products and services. For many companies such radical changes may come about in incremental stages. For example, one way such user-centric organizations can help larger organizations become more innovative and competitive is to become an important 'subsidiary' within a larger organization. Companies such as Newscorp have recognized the power of these user-centric organizations and have acquired MySpace.com, a social networking site (Siklos, 2007).

One aspect of mobile social networking which needs further exploration is the locational issue. Services such as Dodgeball show that digital networks actually make cities more attractive than ever before, as opposed to a widely held belief that the technology platform now in place which provides connectivity for vast numbers of users who are not necessarily in the same place or even time zone, and especially the mobile platform which encourages people to be dispersed, were going to make the whole idea of densely packed urban locations obsolete. Instead, such mobile social networks promote the positive aspects of interaction and add credence to the Porterian notion of clustering of individuals and businesses in geographical proximity in order to achieve economic success (Porter, 1998) as well as to the idea that groups of people using mobile social networks will find new ways of organizing and interacting, and in doing so, will in some way change the nature of the social order (Rheingold, 2002). In the spectrum of mobile social networking organizations, more dispersed communities especially on the national level, can bring various people together in powerful groups which can unite for a common purpose or serve as a national sounding board for a company seeking to reach a customer base that is nation-wide and solicit ideas from this base in order to create products and services that will be successful beyond the local business environment.

While mobile social networking companies as described above continue to develop on the national level, it is clear that innovation is now viewed as a global endeavor and companies which want to compete successfully must learn to operate within this new environment. This is especially true in industries which rely on the collection, distribution and processing of information such as the music industry where the value chain has been reconfigured to reflect new modes of delivering products and services (Mol, Winjberg, & Carroll, 2005). Such reconfiguration calls for firms to have new approaches to creating value and to use the technology platform, that is, the Internet, as a tool for developing and accessing sources of innovation around the world. This might entail reaching out beyond the bounds of the traditional corporation to access the R&D talent that is dispersed globally in order to solve technological problems (Moitra & Krishnamoorthy, 2004) or restructuring the process of gathering knowledge about a new product or service by creating a 'web of innovation' which will facilitate the optimal interchange of ideas from experts in various locations (Farris, Hartz, & Whitwell, 2003). As a result of its acquisition by Dada, Upoc has ventured into globalizing its offerings. Its plans include developing mobile social networking applications in Brazil, Italy, and Spain (Ziv, 2008).

As the mobile social networking arena evolves, challenges clearly remain. Although a variety of personal computing devices enable users to stay connected to the community through the Web, limitations such as small screens on mobile devices, poor connectivity and issues of privacy and security will continue to be of concern to users who employ the mobile platform exclusively. New advances in technology both on the infrastructure side and the device side are needed in order for the mobile social networking industry to advance. Clearly more research needs to be done to understand how the mobile social networking arena is evolving, and its potential impact on the future environment of a variety of industries and on managerial imperatives.

Chapter 1.20
Mobile Social Networks and Services

Lee Humphreys
Cornell University, USA

ABSTRACT

Mobile social networks allow users to connect with each other, share information, and create technologically enabled mobile communities. With the introduction of the iPhone in 2007, the public dream of the likelihood of mobile computing was realized. This chapter reviews mobile social networks ranging from early examples to current services; and, it identifies and categorizes them according to a specific media type, mode, and code. The challenges of categorization in light of technology convergence are discussed. Issues of privacy, compatibility, and pricing are presented as they relate to mobile social networks. Potential strategies are suggested for dealing with these challenges. Finally, future trends of mobile social services are identified.

BACKGROUND

Mobile communication is becoming ubiquitous in many parts of the world today with over 3 billion mobile phone users worldwide (Tsai, 2008; Wolverton, 2008). Over 255 million mobile subscribers live in the U.S. (CTIA, 2008), which means more Americans own a mobile phone than have an Internet connection (*On the Move: The Role of Cellular Communications in American Life*, 2006). Considerable research has explored the social effects of mobile phone use (e.g., Goggin, 2006; Ito, Okabe, & Matsuda, 2005; Katz, 2003; Katz, 2006; Katz & Aakhus, 2002; Ling, 2004, 2008). Some have argued that mobile phones may lead to the atomization and privatization among users by discouraging face-to-face communication in urban environments (Banjo, Hu, & Sundar, 2006; Bull, 2004; Puro, 2002).

As mobile technology advances, however, new services for mobile phones have been developed which allow people to create, develop, and strengthen social ties. Similar to social networking sites on the Internet (Benkler, 2006; Boyd, 2004; Boyd & Ellison, 2007; Castells, 2000; Rheingold, 2002; Rosenbush, 2005; Saveri, Rheingold, & Vian, 2005), these mobile services may help users to build valuable networks to share information and resources (Ziv, 2009).

DOI: 10.4018/978-1-60566-368-5.ch003

One of the first mobile social devices to appear was the Lovegety in Japan (Iwatani, 1998; Reuters, 1998). The Lovegety was a stand-alone device that would fit in the palm of the hand and beep when it was within 5 meters of another device. There were "pink girl" devices and "blue boy" devices each with three settings: "let's chat", "let's karaoke", or "get2". The devices beeped and flashed green when two co-located devices were on the same setting (e.g., both devices were set to "let's chat"). The devices would beep and flash red when they were on different settings. According to one account, users would turn down the volumes, hide the devices, and pretend they did not have a device if they did not want to contact another Lovegety user (Iwatani, 1998).

There were two kinds of information exchanged using the Lovegety. First, information regarding the identification of people who were interested in using a mobile device to meet other people; second, information regarding what kind of social interaction each person was looking for. The information exchanged was rather simplistic, but it allowed people to have interactions with strangers in public spaces mediated by mobile devices without divulging personal identifying information, such as mobile phone numbers or even names.

MIT's Media Lab and Intel Corporation each developed two other early mobile social networks. Social Serendipity was MIT's Bluetooth-based social service meant to harness the power of mobile technology and social information (Eagle & Pentland, 2005). Social Serendipity facilitated social interaction among geographically proximate users by matching user profiles and then exchanging profile information with similar matches. Intel's Jabberwocky sought to monitor and broadcast a user's movement to identify "familiar strangers" and encourage a sense of urban community (Paulos & Goodman, 2004). Both of these technologies relied on the mobility of the devices to ascertain locational information to facilitate social connections among users.

Early versions of mobile social services, such as the Lovegety, Seredipity, and Jabberwocky, were often made as stand-alone mobile devices. As mobile phones have advanced, however, there has been a movement away from separate mobiles devices that facilitate social connectivity and towards mobile social services that work on mobile phones. The mobile phone has joined the ranks of keys and wallets as items most people do not leave home without (Lohr, 2005). Therefore, most publicly available mobile social services have been developed to be used with mobile phones. The present chapter reviews a range of mobile social services, from the early examples to most current, and identifies and categorizes various mobile social networks and services.

Mobile Social Services

Mobile social services refer to software, applications, or systems for mobile phones that allow users to connect with other people, share information, and create technologically enabled mobile communities. Many different terms are used to describe these kinds of services including: *mobile social network*, *mobile social software*, *mobile social network service*, and *mobile blog* (or *mo-blog*).

The term *mobile social network* has evolved in reference to the rise of such social networking services (SNS) as Facebook, MySpace, and Friendster. Boyd and Ellison (2007) define *social network sites* as "web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system." The most obvious difference between a mobile social network and a SNS is that the latter is web-based and the former is primarily mobile phone-based.

Boyd and Ellison's (2007) definition also is helpful to differentiate between mobile social networks and mobile social software (MoSoSo). Mobile social networks give users the ability both to identify those users with whom they are connected and to traverse the list of connections within the system. Sometimes this navigation occurs via an application on the mobile phone and sometimes it occurs on an affiliated website accessed through a computer. (As mobile technology is advancing, however, the ability to access more information through mobile devices is increasing; thus more and more of these services will be entirely mobile phone-based.) MoSoSo differ from mobile social networks in that MoSoSo are typically downloaded to one's mobile device (or pre-installed on the phone prior to purchase) whereas a mobile social network does not require a special application or program running on the phone in order to work. Sometimes mobile social networks rely on text messaging, multimedia messaging services, or voice transmissions. MoSoSo also do not necessarily meet the three criteria of a SNS that Boyd and Ellison (2007) identify. Mobile social software may not have articulated lists of social connections among users. The purpose of mobile social software is to support social interactions among interconnected mobile phone users. For example, both Jabberwocky and Social Serendipity would be classified as mobile social software, not mobile social networks. Both facilitate the exchange of social information between groups of mobile users, but do not articulate users' various social connections.

Howard Rheingold's book, *Smart Mobs,* (2002) was one of the first attempts to identify and describe the power of mobile connectivity among groups of users. He details the integral role of mobile phones in organizing the overthrow of President Joseph Estrada in the Philippines and the 1999 World Trade Organization (WTO) protests in Seattle. Mobile technology allows for rapid exchange of information through the devices that people carry with them everyday which in turn allows them to socialize in ways previously unavailable. Mobile social services or MoSoSo can help people to connect with new people as well as to connect with old friends. Ellison, Steinfield and Lampe (2007) found that most of the connections on Facebook were among people who had offline ties (i.e., they had not "met" online). Similarly, mobile social networks can connect people who are already friends or acquaintances. In fact, most mobile social networks brand themselves as helping friends to connect with friends and not necessarily to make new relationships.

Media, Modes, and Codes

There are a myriad of new mobile social services, but there are differences between these systems. Using traditional media typology, three broad factors can be identified to categorize these mobile systems: media, modes, and codes (Gross, 1973).

The first factor of mobile social network categorization considers the *media* through which these systems operate. The term *media* is defined here as a means of communication, such as a mobile phone, computer, or wireless device. Despite an overall trend towards technological convergence, some mobile social networks solely rely on mobile phones to provide the technological means of connection between users. Some wireless devices use Bluetooth to connect users. Most mobile social networks, however, also allow for Internet-based connections. Often there is a web component of the mobile social network and it is not solely mobile phone-based.

By identifying the particular media used in a variety of mobile social networks, one can begin to differentiate between the systems. It is also important to note that the media of mobile social networks facilitate the exchange of messages from one-to-one (interpersonal) to one-to-many (broadcasting). The mobile phone is often perceived as an interpersonal means of communication through which one person communicates via text message or voice to another person. The ability of mobile social networks to broadcast information to many people represents an important shift in mobile communicative practices. The mobile broadcast ability of messages is an important factor in mobile social networks because it allows *groups* of users to communicate quickly and easily.

The second factor with which to categorize mobile social networks is the mode of communication. The *mode* of communication refers to the various forms of communication by which members are able to interact with one another, including text, image, voice (or audio), and video. Some mobile social networks facilitate communication via limited modes whereas others offer a variety of modes through which to interact. The mode of communication shapes the kinds of interactions that members have on mobile social networks. For example, sometimes there are limits on the number of characters that users can send over mobile social networks. Each of these modal differences shapes the kind of communication that occurs over the mobile social network.

The third factor that differentiates mobile social networks is its code. The *codes* of communication are the symbolic systems of communicating social connections. Mobile social networks have various means through which members communicate their social network connections. Some systems display the particular relations of the users, while other mobile social networks display member profiles but not in relation to others. If no connection is displayed, the system would be classified as a mobile social service or software rather than a mobile social network. Another differentiating code is whether these systems require mutual connections or one-way connections. For example, some mobile social networks allow users to send messages to certain people but receive them from other people. Some services call this *watching* or *following*. A user might watch the messages of a small number of users, but might be watched by a larger number of users or visa versa. For example, Malcolm Gladwell, an author and writer for *The New Yorker Magazine*, is followed on Twitter by 421 users but follows one user (Gladwell, 2008). A mutual network system does not allow this one-way messaging. For these mutual systems, users send and receive messages to and from the same people. The code of a mobile social network differentiates a variety of different services, all of which help users to connect with other members based upon common interests or geographic proximity.

Table 1 categorizes the following mobile social services according to the type of media, mode, and code: Pownce.com, Twitxr, Twitter, Jaiku, MySay, Utterz, Crومple, Facebook Mobile, MySpace Mobile, Dodgeball, Socialight, Loopt, Kyte, and Radar. As such, Gross's (1973) typology becomes a helpful tool with which to describe these services. For example, there are important differences in the mode of communication. Early mobile social networks, such as Dodgeball, were primarily text-based (Humphreys, 2007). Increasingly, these services are multi-modal, offering users the ability to broadcast text, images, audio, and video. For example, MySay and Utterz try to differentiate themselves from the other mobile social networks by allowing users to record their voices on their mobile phones and then broadcast them to the web.

This categorization of networks also highlights the convergence of media. Increasingly, designers of mobile social networks are developing specific application-versions of their services, which can be integrated into other websites such as blogs or social network sites. For example, no longer do people have to go to the Twitter website to join, but they can download the application from the Facebook website itself. Thus not only are these services increasingly multi-modal, but they are also multi-media. This points to the convergent nature of communication technology (Jenkins, 2006). The lines between various modes and various media are blurring. Social network sites, for example, Facebook and MySpace, have added distinct mobile components to their services. In fact, MySpace is the largest mobile social network in the U.S. with a mobile audience of 3.7 million

Table 1. Categorization of mobile social services

Name	Description	Media	Mode	Code
Kyte	"Share pictures & video online or from your mobile"	Web, mobile phone	Text, video, images, audio	No public display of social connections
MySay	"Talk to the web"	Mobile phone, web	Audio (voice), text, images, video	No public display of social connections
Cromple	"Keep friends updated with this simple blog system"	Web, mobile phone	Text	One-way friend networks
Jaiku	"Your conversation"	Web, mobile phone, Internet (IM)	Text, images	One-way friend networks
Pownce	"Send stuff to your friends"	Mobile, web, IM	Text, images, video, audio	One-way friend networks
Twitter	"What are you doing?"	Mobile, web, IM	Text, images	One-way friend networks
Twitxr	"A picture is worth a thousand word"	Mobile, web	Images, text	One-way friend networks
Utterz	"Share your news"	Mobile, web	Image, video, audio, text	One-way friend networks
Dodgeball	"Connect with your friends"	Mobile phone, web	Text	Mutual friend networks
Facebook Mobile	"Use Facebook on the go"	Mobile phone primarily (supplement to Facebook.com)	Text, images	Mutual friend network
Loopt	"Turn your mobile phone into a social compass"	Mobile phone (GPS), web, IM	Text, image	Mutual friend networks
MySpace Mobile	"A place for friends"	Mobile phone primarily (supplement to MySpace.com)	Text	Mutual friend networks
Radar	"Instant picture conversations with your favorite people and no one else"	Mobile, web, IM	Images, video, text, audio	Mutual friend networks
Socialight	"Discover right here right now information about places all around you"	Mobile phone (GPS), web	Images, text	Mutual friend networks

users (Minney, 2007). Facebook is the second most popular mobile social network in the U.S. with a mobile audience of 2 million users (Minney). The numerical success of these mobile platforms on MySpace and Facebook may have less to do with the need for mobility of the social network service than it does with the sheer success of these sites on the web. MySpace Mobile and Facebook Mobile are popular because their web services are popular. They each have developed a massive base of users, which is necessary for the success of all social media whether they are web or mobile based.

The question then arises as to whether the term *mobile social network* is an appropriate way to describe multi-media social network services that are accessible on a variety of technological platforms? Despite the convergence of media, *mobile social network* is still a helpful term because it highlights the mobility, individuality, and accessibility of mobile device-based systems. Mobile phones are defined by their mobility. They are not confined to the kitchen, office, or even the phone booth, but can be found in all kinds of spaces. Unlike landlines, mobile phones are also primarily assigned to a particular body. Individuals often have their own mobile phones as opposed to private landlines which are typically assigned to a particular place (Wellman et al., 2003). Mobile phones are also often nearby and accessible. In fact, users have described being away from their mobile phones as anxiety inducing events (Cohen & Lemish, 2004; Humphreys, 2003; Rainie & Keeter, 2006). The accessibility, individuality, and mobility of mobile phones make them particularly powerful communication technologies which differ from more traditional PC technologies.

ISSUES AND CHALLENGES

While much hype surrounds mobile social networks (e.g., Goodale, 2007; B. Johnson, 2007; Klaassen, 2006), several challenges regarding the development and use of mobile social networks persist.

One of the largest challenges for mobile social networks is privacy. Some mobile social services allow and even encourage users to share copious amounts of information about themselves with those in their networks. Sometimes these services involve sharing locational information about where people are at certain points in time. Inevitably, concerns arise regarding who has access to this information and what is it being used for. For example, stalking may become a concern. Generally speaking, however, most of the services require users to actively identify who is in their network and will receive their messages, thus allowing users of mobile social networks to control their flows of information. Users can easily block other users from seeing their personal messages. Privacy issues, however, concern not only which *users* have access to information through these systems, but corporate surveillance of users as well. For example, when members use Dodgeball, they do not just tell everyone in their Dodgeball networks their location; they tell Dodgeball who tells everyone in their network. Dodgeball is owned by Google, which means members are also telling Google where they are whenever they check in with their friends using Dodgeball.

Another challenge for mobile social networks in the U.S. concerns media and model capability. Some mobile social services in the U.S. are only available on certain kinds of phones. For example, Loopt, a mobile geosocial networking services compatible with most Nextel and Sprint cellular phones in the U.S.; however, it is only compatible with AT&T's Blackberries and iPhones. The reason that Loopt is not compatible with most AT&T phones is that Loopt relies on Global Positioning System (GPS) technology, which is not standard on most AT&T mobile devices as it is on Nextel and Sprint mobile phones. Therefore, the majority of AT&T mobile customers cannot use Loopt. This is certainly a challenge to Loopt's growth and development. Until nearly all mobile phones in the U.S. have GPS, mobile social networks which rely on this satellite technology will be hampered. Similarly, while cameras on mobile phones in the U.S. have become increasingly standardized, mobile video is less common. Thus mobile social services (e.g., Kyte, Pownce and Radar), which encourage the sharing of mobile video, may have less of a market for their services until mobile video becomes more available.

A final challenge for mobile social networks in the U.S. is the pricing for mobile services. Most mobile phone users in the U.S. have ongoing subscriptions or contracts with the mobile service providers rather than pre-paid mobile phone service, which is more common in the rest of the world (CTIA, 2008; Kokko, 2004). Therefore most people in the U.S. pay for their mobile phone use about 30 days after they have incurred the charges. (This is sometimes referred to as a *post-paid system*.) All of the mobile social services discussed here are "free" to use. "Free" here refers to the fact that users do not pay the mobile social service to join or to send messages through their system. This, however, does not mean that the mobile social services are entirely free to use.

Mobile phone users incur charges for each minute they speak, each text message they send, and each data bit they download. What sometimes can happen is that new mobile social network users will not realize how much they will use these services and how much it might cost them, especially if they go over their voice, text or data limits. Sometimes users do not realize they have gone over their limits until they receive their bills the following month at which point it is too late. They receive a mobile phone bill much larger than they expect and are required to pay for their use. This can sometimes lead new mobile social network users to change their plan to unlimited or at least increased voice, text or data services. In some circumstances, an exorbitant mobile phone bill can lead new users to stop using the mobile social network altogether (Humphreys, 2008). Despite warnings from the mobile social networks, this kind of opaque billing system may discourage mobile social network adoption and use.

SOLUTIONS AND RECOMMENDATIONS

Mobile social network adoption and usage are increasing despite challenges (Minney, 2007). There are several steps that users, developers and regulators can take to further encourage the growth of mobile social networks. In the past, privacy campaigns by privacy advocates and government regulators have helped to encourage a shift in privacy policies of Google (C.Y. Johnson, 2007). Similar public advocacy could encourage more transparency in privacy policies of mobile social networks. There has also been a recent move among colleges and universities in the U.S. to create recommendations for information management on social network sites. For example, the University of Wisconsin-Madison, recommends that students be "conscientious" when posting messages on Facebook and MySpace and encourages students to reset the privacy settings to "avoid having your contact information given out to other companies" (University of Wisconsin-Madison, 2008). Similar privacy awareness campaigns may help mobile social network users to be conscientious about their privacy and mobile communication practices.

With any emerging technology, technical features take time to develop and standardize. Companies that provide GPS-based mobile social services are betting that a GPS (Global Positioning System) will become an increasingly standardized feature on mobile phones. Pew's Internet and American Life Project found that mobile mapping was one feature that most mobile phone users wanted but did not yet have (Rainie & Keeter, 2006). Given the demand for mapping features, GPS is likely to become a more common feature on mobile phones. For example, when Apple introduced its second generation of iPhones, it had added GPS to the phone's capabilities. Another change to the iPhone 3G signifies a second potential trend in mobile communication which may help with standardization and compatibility. iPhone 2.0 software update added an App Store – an application which allows users to quickly and easily download files (German & Bell, 2008). The iPhone App Store which offers applications designed for iPhone may encourage further innovation, development, and adoption of mobile social services.

As mobile social services gain in popularity, pricing will become increasingly important. From 1998 until 2007, the average monthly mobile phone bill in the U.S. ranged between $40 and $50 (CTIA, 2008). In February 2008 both AT&T and Verizon began to offer unlimited voice for $99 (AT&T, 2008; Verizon, 2008). Unlimited data are an additional charge. Therefore the unlimited plans are a significant increase in price from what mobile phone users have been typically paying for service. That said, these unlimited mobile services have decreased in price. While it is still greater than the average monthly mobile bill, the lowering of costs to $99 per month for unlimited voice suggests that unlimited services may become a more popular plan among U.S. mobile phone users. Unlimited mobile services for a set price is likely to encourage the adoption and use of mobile social services because people could use the services as much as possible and would know exactly how much it will cost them.

FUTURE TRENDS

There are several important areas for both the development and research of mobile social networks. With GPS technology and the triangulation of cell phone towers, the location of mobile phone users is identifiable. This opens up possibilities for the collection and use of location-aware services, which could be quite helpful for mobile social network users to communicate and access new kinds of information. Location-based services are a growing area of mobile technology development. Mapping services and geotagging allow users to interact with the physical space around them in new mediated ways. Socialight is one early example of a mobile social network with location aware messaging.

Another potential area for the future development of mobile social networks is among specific populations. Already the use of mobile social networks at high-tech conferences has begun to rise (McCarthy, 2007). Mobile social networks can improve information flow efficiency among groups of people trying to connect with one another. One could also imagine that mobile social networks could be helpful to the elderly and youth populations as a means of maintaining family communications. An at-risk population constitutes another potential group that might benefit from the use of mobile social networks. For example, experimental research suggests that Alcoholics Anonymous members are less likely to fail when they use mobile phones to contact their support networks in time of need (Campbell & Kelley, 2006).

CONCLUSION

With the introduction of the iPhone in June 2007, the public imagination of the possibility of mobile computing blossomed in the U.S. People suddenly had a tangible example of a mobile phone through which one could easily access the web. As mobile hardware and software become more advanced and user-friendly, mobile social networks will continue to grow. These services will increasingly become useful communication tools through which people manage their social relations.

KEY TERMS AND DEFINITIONS

Bluetooth: A wireless protocol which allows short-range connections to be made between mobile phones, laptops, and other portable devices.

Global Positioning System (GPS): A satellite-based navigation system used to triangulate particular points on Earth using longitudes and latitudes; increasingly, GPS is used to identify mobile phone users' locations, so as to access and share location-based information.

Micro-Blog: A personal chronological log of thoughts, activities, or reflections which are limited in size (for example, to 140 characters).

Mobile Blog (or Mo-Blog): A personal chronological log of thoughts, activities, or reflections sent from one's mobile phone to either a website, blog, or mobile device; depending on the system, mo-blogs may include text, audio, still images, and video; mo-blogs are often micro-blogs

Mobile Social Network: A mobile phone-based service that allows individuals to construct a public or semi-public profile within a bounded system, articulate a list of users with whom they share a connection and view and traverse their list of connections and those made by others within the system.

Mobile Social Service: Mobile Internet systems that allow users to connect with others and create virtual communities.

Mobile Social Software (or MoSoSo): A mobile phone application which supports social interaction among interconnected mobile phone users.

Multimedia Messaging Service (MMS): Video or picture messages sent over mobile phone networks.

Short Messaging Service (SMS): Text messages sent over mobile phone networks.

Social Networking Services (SNS): Online services that facilitate social interaction and networking.

Chapter 1.21
Mobile Social Web:
Opportunities and Drawbacks

Thorsten Caus

Svenja Hagenhoff
Georg August University of Göttingen, Germany

ABSTRACT

As mobile Internet usage continues to grow, the phenomenon of accessing online communities through mobile devices draws researchers' attention. Statistics show that close to 60 percent of all mobile Internet traffic worldwide is related to the use of mobile social networks. In this chapter, the mobile social Web is defined, categories of mobile communities explained, and success factors and drawbacks discussed from the technical, social, and economic perspectives. Challenges, including low transmission rates, changes in usage patterns, search for new revenue sources, as well as the need for development of original mobile Web content and applications are addressed. The technical requirements for the mobile use of online communities are identified. The chapter closes with a summary of potential economic and social prospects of the emerging mobile social Web.

DOI: 10.4018/978-1-60566-368-5.ch002

INTRODUCTION

Until recently, the Internet was a domain restricted to stationary computers, but nowadays it can also be accessed through mobile devices equipped with web browsing capabilities. Now it is not only possible to surf the web using wireless access and mobile devices, but there is also a growing number of mobile Internet applications and services. Increasingly, mobile social networking applications have been made available to a large number of mobile phone users.

Internet users have accepted online communities and internalized the concept of the Social Web also referred to as Web 2.0 (Koesch, Magdanz, & Stadler, 2007). Private as well as business users have become familiar with various online communities (Patrzek, 2007; von Tetzchner, 2008). On the one hand, mobile social networks are becoming more widespread because of the increasing dissemination of new wireless communication technologies

(Heng, 2006, p. 5). On the other hand, a large number of devices are designed to implement new communications technologies, for example, the Universal Mobile Telecommunications System (UMTS) in Europe (Heng, 2006, p. 1).

Studies conducted by Opera Software, an Internet software and services company, demonstrate that 40 percent of all mobile Internet traffic worldwide is related to the use of online communities. In some countries the share is as high as 60 percent: for example, in the United States, South Africa, and Indonesia (von Tetzchner, 2008). Research into the various ways of using the Social Web in a mobile context is now of paramount importance. In this chapter, *mobile social web* is defined, categories of mobile online communities and their success factors explained, and selected opportunities and drawbacks of the mobile online communities discussed from a technical, social, and economic perspectives.

BACKGROUND

The Social Web can be viewed as a concept and a platform that utilizes social software (e.g., forums, wikis, blogs, etc.) to fulfill or support some of the important human needs, such as: self-realization, acceptance, social connectedness, and safety (Maslow, 1943, p. 372-383). The purpose of the Social Web is to support human communication and facilitate social contact. The Social Web encompasses numerous Internet applications, such as social networking sites, massively multiplayer online role-playing games, photo and video sharing, online stores and auction houses, virtual worlds, and wiki collaborations. The most popular and widespread actualizations are online communities (e.g., MySpace, Facebook, StudiVZ or XING). The term "Social Web" is often used in everyday language as well as in scholarly literature as a synonym for "virtual" and "online communities" (Hummel, 2005, p. 5), although these terms do not differ greatly (Fremuth & Tasch, 2002, pp. 5-6).

In the past years many academic disciplines have dealt with the Social Web. Various attempts to provide a definition have resulted in three different approaches: technical, social, and economic. The technical approach focuses on the Internet as a medium or platform for a community. The sociological point of view stresses the forming and functioning of communities, whereas the economic perspective examines potential gains and intended profits (Hummel, 2005, p. 8-11).

These three perspectives have led to a variety of definitions of online communities with differing points of emphasis. A detailed overview of common definitions is given by Fremuth and Tasch (2002), Hummel (2005) and Markus (2002). In identifying an *online community* one perspective emphasizes that it is formed by a group of people, while another stresses its web platform. The definition used in this chapter combines both approaches, for an *online community* is seen as a social group that interacts through a web platform over an extended period of time.

An online community can be characterized by four elements (Gebert & von Rosenstiel, 1992, p. 122-123; Hamman, 2000, p. 225):

- group of people with shared objectives (e.g., interests, goals)
- interaction over an extended period of time
- closeness due to bonds and relationships
- shared space for interactions governed by certain rules (for example, role definitions).

Without shared objectives there would be no interaction and relationship and, subsequently, no community at all (Markus, 2002, p. 36). Interactions within the community are seen as topic-oriented communication as well as the execution of actions (Kim, 2000, p. 5). Both can take place independently of time and location (Winkler & Mandl, 2004, p. 14). The process of founding and maintaining such online communities usually takes place on the Internet (Eigner & Nausner,

Table 1. Success factors on online communities (adopted from Koch, Groh, & Hillebrand, 2002; Leitner, 2003)

Users' point of view	Corporations' point of view
• Advantages of usage, for example in the form of problem solving or entertainment • Simple compilation of contributions • Easy technical access, usage and adequate stability • Equality, credibility and trust • Non-commercial orientation	• Personal network and personal characteristics of entrepreneurial team • Product or service idea in business model • Available resources and capabilities • Marketing strategy with viral emphasis • Potential for speedy marketing

2003, p. 58). The second defining characteristic is the web platform, which can be seen as an Internet communication system which acts as an intermediary. It enables and facilitates meetings, the maintenance of the community, and its interaction with other people (Reichwald, Fremuth, & Ney, 2002, p. 8).

There are different ways of categorizing online communities (Brunold, Merz, & Wagner, 2000, p. 30-37; Fremuth & Tasch, 2002, p. 21; Hummel, 2005, p. 46). A reasonable approach is to categorize them according to similarities, for they play a major role in online communities. Therefore, an online community can be geographic (bound to an area), demographic (classification according to nationality, age, gender), or based on shared interests or activities (Kim, 2000, p. 5).

Online communities can be viewed as social systems. Relationships and interactions can only develop once a web platform has been established, which makes it difficult to start a community (Leitner, 2003, p. 36). The network-effect character of online communities shows this very clearly. There will only be accelerated growth once a critical amount of relationships and interactions between users has been achieved. This is due to the fact that users do not benefit before this point is reached (Reichwald, Fremuth, & Ney, 2002, p. 8). Even though this development is difficult to predict, an operator is able to influence the development of an online community by making it more attractive (Reichwald, Fremuth, & Ney, 2002, p. 9-10). The success factors that have been identified are listed in Table 1.

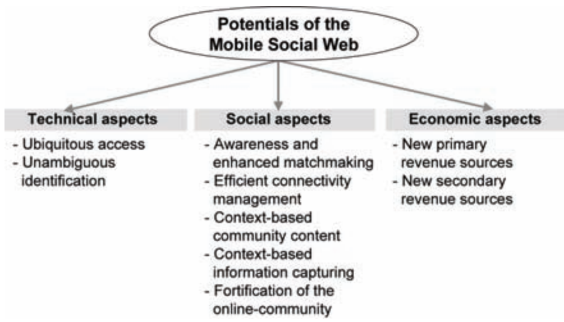
THE MOBILE SOCIAL WEB

The mobile use of online communities can be referred to as the *mobile social web*. In this context, *mobility* is understood as the unrestricted transfer of text, voice or data independent of user's physical location (Kurose & Ross, 2005, pp. 536-538). Therefore, mobile online communities are free of interruption caused by the movement of the user from one location to another. The devices employed can be either wireless or wired (Kurose & Ross, 2005, p. 504). Suitable types of devices are mobile phones, smart phones (Michelsen & Schaale, 2002, p. 51) and personal digital assistants, as these can always stay switched on and do not need to be booted. Although mobility does not necessarily require wireless connections to these devices, wireless mobile networks are used most commonly (Gerum, Sjurts, & Stieglitz, 2003, p. 145). European standards, for instance, include the Global System for Mobile Communication (GSM) extensions, Enhanced Data Rates for GSM Evolution (EDGE) standard (Herzig, 2001, p. 399), General Radio Packet Service (GPRS) protocol (Stader, 2001, p. 37), and the 3rd generation Universal Mobile Telecommunications System (UMTS) technology (Kurose & Ross, 2005, pp. 534-535). The mobile social web involves opportunities as well as drawbacks, as will be discussed below.

Opportunities of the Mobile Social Web

The features of mobile communities generally correspond to those of traditional online communities. They are enhanced by a new way of accessing the community-web-platform through mobile, wireless devices. On closer examination,

Figure 1. Overview of the mobile social web potentials



these communities do not only seem to benefit from mobile access, but also from additional potentials resulting from mobility and localization possibilities. Furthermore the question arises, whether this newly opened potential encompasses not only technical and social aspects but economic aspects as well (see Figure 1).

Technical Aspects

Mobile wireless devices facilitate ubiquitous access to online communities (Koch, Groh, & Hillebrand, 2002, p. 2). The user is able to gain access anywhere and any time, while being liberated from the world of stationary Internet and permanently installed devices (Reichwald, Fremuth & Ney, 2002, p. 6). Furthermore, users benefit from being reachable at all times by being armed with mobile wireless devices (Wiedmann, Buckler, & Buxel, 2000, p. 86). Therefore, the users can stay online and be accessible continuously and without interruption. No time is lost: for example, by turning the devices on or logging in. Thus, interaction becomes more spontaneous and expressive.

Mobile wireless devices make it possible to identify the user via his PIN and SIM card, both of which are requirements of mobile communications (Tasch & Brakel, 2004, p. 4). This explicit possibility of identification can be used to identify the user in an online community. The user's mobile device then serves as a membership card or an individual entrance ticket (Reichwald, Fremuth, & Ney, 2002, p. 7). Identifying the user can be automated, making it more reliable. It is also more authentic and results in more confidence within the community (Hummel, 2005, p. 72).

Social Aspects

A local context can be defined by identifying a user's current whereabouts (Koch, Groh, & Hillebrand, 2002, p. 3). A user's whereabouts could be presented to other users through geomapping or textually. Furthermore, an awareness service could be employed in addition to existing information services, such as "buddy lists" (Tasch & Brakel, 2004, p. 7). Contacts and friends in the vicinity of the user can be shown on the mobile device. Mobile online communities could thus improve interactions between community members and extend social ties. For example, people with similar interests can get together spontaneously. Contexts can be used to find out about the accessibility of mobile community users (Groh, 2003, p. 9). Depending on the user's current whereabouts a service can provide information about if and how a person may be contacted and the user can decide how to do this. The contact information can simply rely on such area aspects as availability of UMTS. Personal preferences can also be used for this purpose.

Another potential feature is to filter content according to current contexts (Groh, 2003, p. 9). A personal information service can select information about places of interest in the vicinity of the user's current location and report it to the user (context specific presentation of information). Moreover, context specific capturing of content is conceivable (Groh, 2003, p. 8). Metadata (e.g., location data or location names) and information and news services form the basis for this idea. For example, an entry reviewing the quality of food and drinks in a local café could be generated automatically by entering the name of the café or its location.

Personal meetings can be organized more easily as the awareness of a person's location increases, matching the users' interests is extended, and the management of accessibility becomes more efficient. Stronger relationships between persons will typically result when they are geographically close and have personal encounters (Larsen, Urry, & Axhausen, 2006, pp. 12-13). These aspects are not available in stationary online communities because they depend on time and location. Face-to-face communication can lead to an improved quality of relationships because interactions become closer and more intense. All of the above will result in the strengthening of a community (Schneider, 2003, p. 99).

Economic Aspects

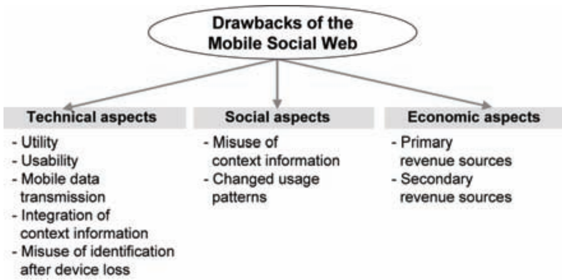
Mobile communities allow an opportunity for spontaneous, affective, and meaningful community activities, which may result in closer relationships between community members than in the case of traditional online communities. Data input and output can be accomplished more easily through context specific services (Diekmann et al., 2006). Therefore, community mobile operators assume that users will be more willing to pay for participation in mobile communities than in stationary online communities (Reichwald, Fremuth, & Ney, 2002, p. 12). The following list provides details of primary and secondary revenue sources for mobile operators (Reichwald, Fremuth, & Ney, 2002).

Primary revenue sources arise from operating a mobile online community (Reichwald, Fremuth, & Ney, 2002, p. 11). Three possibilities can be identified:

- *To levy usage fees:* Users pay for the usage of mobile information and interactivity services and for community content. The fees depend on the usage of the services or they are usage-independent (Reichwald et al., 2002, pp. 24-25). Users pay either for the usage of each single service or for using services during a certain period of time. Both approaches have proved unsuccessful in the case of non-mobile online communities (Reichwald et al., 2002, pp. 23-24). It may be expected that the advantages of mobile communities and their improved attractiveness are great enough to generate an increased willingness to pay (Reichwald, Fremuth, & Ney, 2002, p. 12). Moreover, users are generally accustomed to paying for mobile services.
- *Advertising and sponsoring:* Even now, non-mobile online communities allow the generation of advertisements tailored for special target groups by analyzing user profiles. In comparison to mass advertisements, this approach involves less wastefulness (Schubert & Ginsburg, 2000, pp. 51-52). For example, depending on the user's current location, advertisements can be provided. Companies willing to sponsor certain activities are another potential source of revenue (Reichwald et al., 2002, p. 20).
- *Data transmission fees:* Fees for using telecommunication (TC) services have to be paid to the TC companies. The operator of a mobile online community could negotiate a share of the revenues. For this revenue sharing purpose, cooperation between the TC company and the community operator is needed, and accounting models have to be developed.

The users themselves can become the potential generators of possibilities to earn money for the community. Their content contributions can be used for market research as well as ideas about new services and products. Documented behavior, usage patterns, and preferences can be used to filter properties of target groups. The main potential for community operators has to be made up by selling

Figure 2. Overview of the drawbacks of the mobile social web



the gathered knowledge as consulting services or by using it for themselves (Reichwald, Fremuth, & Ney 2002, p. 12). Mobile communities can facilitate activities at a higher level of utility and quality, as data are potentially more differentiated and reliable compared to stationary activities.

Drawbacks of the Mobile Social Web

Mobile online communities have drawbacks, as summarized in Figure 2.

Technical Aspects

The utility of a service is a success factor as well as a challenge. It has to be decided which services should be accessible in a mobile community to make it attractive (Yom, 2002, p. 177). Not only information and interaction services have to be selected, content needs to be chosen, too. Restricted possibilities of data presentation and device handling as well as limited capacities of mobile devices affect the utility.

Other factors influencing usability are data transmission costs, low data transmission rates, device handling problems, and inconvenient data input and output possibilities (Bliemel & Fassott, 2002, p. 14). The fees of mobile network operators are mostly based on data volume. Therefore, a community user will have to pay fees depending on the intensity of his or her usage.

Low data transmission rates are often a problem for mobile device users. Established GSM services, such as Short Message Service (SMS), provide an adequate transmission rate; however, there are only limited possibilities for data presentation. Consequently, it makes more sense to opt for 3rd generation technologies like GPRS and UMTS, especially as the increasing dissemination of these technologies renders this alternative increasingly feasible.

An appropriate localization technology must be integrated in order to realize enhanced mobile services and provide new functionalities of mobile online communities, such as contextual community content, context-oriented information collection, or efficient connectivity management. The localization of end devices connected to cellular networks via their radio cell is currently still expensive. However, free and precise localization using Global Positioning System (GPS) is not yet feasible, as the vast majority of users do not have GPS-compatible end devices.

The possibility of unambiguous identification poses another problem. In case a mobile device gets lost, unauthorized persons may pretend to be the original user, as mobile devices usually have only a very low degree of security (Reisinger, 2007). This is especially a problem when users believe in the trustworthiness of the identification using mobile end devices.

Social Aspects

The electronic capturing and processing of the user context as well as the opening of communities for mobile usage can lead to negative consequences. Publishing the actual location of a user means an intrusion into his or her privacy and a limitation to intimacy. Being spied upon undiscovered could be the result of using contextual services. Parents could use these services to locate their children. Partners in a relationship could use it to track each other. The risks involved may lead to a fear of misuse or limited intimacy, resulting in the merely conditional use of contextual services. In stationary online communities, we observe that little emphasis is put on intimacy - users publish a multitude of personal data (Gross & Acquisti, 2005, p. 4-8). Hence, it remains open whether the added value of contextual services or the fear of misuse and limited intimacy will prevail.

At present mobile radio services, including SMS or telephony, are preferably used for contacting persons one already knows (Tasch & Brakel, 2004, p. 4). Stationary online communities are commonly used to create new relationships: i.e. contacting persons hitherto unknown to the user (Fremuth & Tasch, 2002, p. 24). The projection of mobile radio usage patterns onto stationary online communities could lead to the change from a preferably theme-oriented usage towards a person-oriented or communication-oriented usage of mobile online communities (Reichwald et al., 2002, p. 13). Mobile community activities would then be realized preferentially with already known persons. Such trends could jeopardize the establishment of theme-orientated mobile online communities.

Economic Aspects

A commercial design of mobile online communities has to identify primary and secondary revenue sources for their operators. Commercial intentions should be declared and openly communicated to the community (Leitner, 2003, pp. 43-44). This is the only way to grant trust and authenticity from the very beginning. Using primary revenue sources involves the following challenges:

- **Collection of usage fees:** So far, the stationary Internet largely provides free content and services (Reichwald, Fremuth, & Ney, 2002, p. 11). Internet users are accustomed to free services. There is a possibility that this factor will have a negative impact on the willingness to pay for mobile services. Users already pay for mobile data services such as SMS or mobile Internet access (Reichwald et al., 2002, p. 27). Fees for the use of services or content would increase these costs.
- **Advertising and sponsoring:** Advertising in online communities was often frowned upon in the past (Leitner, 2003, pp. 41-42). Even now, although an increased number of advertising banners are placed, the acceptance of advertising does not seem to be self-evident. Moreover, advertising messages on mobile devices are still fairly uncommon. It is unclear whether a satisfactory advertising effect can be achieved by mobile advertising in online communities. It is assumed that the perception duration of advertisement tends to drop with mobile usage compared to the stationary Internet (Heinonen & Stransdvik, 2007, p. 610; Reichwald et al., 2002, p. 22). Even when advertisements are noticed, little space for advertising messages is available due to the small displays of mobile devices (Michelsen & Schaale, 2002, p. 20).
- **Mobile data transmission fees:** As yet volume-billing models for the use of the mobile Internet are widespread; this could be a restriction to the time-consuming use of a mobile online community (Reichwald et al., 2002, p. 28). This can lead to lower data volumes, resulting in fewer payments to mobile radio operators. As a consequence, these operators would be less willing to forward payments to a community operator. It remains to be seen how this revenue potential develops through billing models for mobile Internet usage and cooperation.

There are also new challenges for the secondary revenue sources: Using a mobile online community as an instrument for market research can be profitable for an operator, but it seems reasonable that the users need to know that this is drafted on the basis of content and the analysis of their usage habits (Leitner, 2003, p. 43-44). This could especially affect success factors of an online community like equality, credibility and trust. Sharing part of the revenues with users could be a solution.

FUTURE TRENDS

A growing number of Internet services make their applications available to mobile users. This can be attributed to the increasing proliferation of mobile broadband Internet access (especially UMTS in Europe). Three variants of mobile implementation are available. Users can browse profile pages and photo albums via WAP and add new images and texts by means of SMS and Multimedia Message Service (MMS). The ShoZu service,[1] in contrast, performs as an integration platform and allows mobile users to upload and download content at multiple online communities with a single message. One Connect™ provided by Yahoo is another illustration which integrates social communities (e.g., MySpace, Dopplr, Facebook or Last.fm), instant messaging services (e.g., Yahoo! Messenger, MSN Messenger), and the ordinary communication channels of mobile phones. Finally, as the example of the COSMOS project[2] shows, a comprehensive use of mobile technical and social opportunities appears to be no so distant future—the COSMOS project integrates contextual services into the existing mobile social web. Users are informed about the geographical distance between them and may send messages to contacts within their own vicinity. The above-mentioned trends are expected to advance in the future; yet, the possible dominance of one of them cannot be predicted.

CONCLUSION

The analysis of the potentials of mobile online communities leads to the conclusion that the social significance of the mobile Internet goes further than providing communities with an additional access channel. Besides mobile access and instant connectivity, unambiguous identification and contextual services can also be realized.

The mobile web platform gains efficiency and facilitates not only flexible, spontaneous, and emotional interactions, but also credible and intensive ones. Reckoning with these possibilities, a community mobile operator can take an economic perspective and identify revenue sources that make the commercialization of mobile communities feasible.

However, the specific technical and social characteristics of mobile communities can cast doubt upon their prospective potentials. Commercialization appears less promising as the willingness of users to pay fees is rather low. Mobile advertising poses additional problems despite its context-relatedness. Moreover, the realization of secondary revenue sources can lead to problems of trust.

The assumption that the social significance of the mobile Internet will go beyond providing an additional access channel to online communities has so far only partially been confirmed. Many challenges to mobile communities remain to be resolved in the future for the economic perspective to gain relevance and the commercial interpretation to become a success.

KEY TERMS AND DEFINITIONS

COSMOS: The Community-Driven Systems Management in Open Source (COSMOS) project is a collaboration of software developers aimed to create standards-based tools for system management.

Mobile Internet: Use of TCP/IP based services and protocols with mobile devices via wireless communications technologies.

Mobile Social Web: Refers to mobile social networks and other Web 2.0-based applications in which people access and form online communities by using mobile devices.

Mobile Wireless Devices: Handheld electronic devices with wireless capability to connect to the Internet. Examples include mobile phones, smart phones, and personal digital assistants.

Mobility: Unrestricted transfer of text, voice or data independent of user's physical location.

Online Community: A social group that interacts through a web platform over an extended period of time.

Social Web: Refers to Web 2.0-based technologies and applications that are used to support communication and facilitate social contact, such as, social networking sites, massively multiplayer online role-playing games, photo and video sharing, online stores and auction houses, virtual worlds, and collaborative wikis.

Chapter 1.22
Social Software (and Web 2.0)

Jürgen Dorn
Vienna University of Technology, Austria

INTRODUCTION

Social software is a class of information systems supporting the establishment and management of online communities for people in performing certain tasks. One of the first application types were bulletin boards. Social software may provide different services for community members such as finding members with similar interests, finding information on interesting subjects, discussing common problems, or simply the storing of private or publicly-accessible documents. Another similar term, *collaborative software*, applies to cooperative work systems, and is applied to software that supports working functions often restricted to private networks. *Web 2.0* is a term coined only recently, and with this concept promoters try to focus on the change of use of the Internet. While Web 1.0 was a medium where few users published information in Web sites and many users read and surfed through these publications, in Web 2.0 many users also publish their opinions, information, and documents somewhere in the Internet. By motivating large communities for submissions and by structuring the content, the body of the aggregated information achieves considerable worth. A good example for such a community project is Wikipedia, where thousands of contributors deliver millions of articles, forming an encyclopaedia that is worth millions of dollars.

MOTIVATIONS

The term *social software* was created only recently; however, applications that follow this paradigm are much older. Due to different reasons, there is some hype about these applications now. Thus, new start-up companies offering such information systems achieve a very high financial rating through their large number of users and the large body of information. However, this is only one group of social software that achieves very high volumes of users. Social software is also used to build smaller communities with a restricted access. Thus, a company may invite its customers into such a community for online support on products and services of the company. Social software is also used to support knowledge exchange between employees of companies (Wenger, 2004).

DOI: 10.4018/978-1-60566-014-1.ch178

Technical Issues

The increasing number of social software applications is partly motivated by the progress of computer hardware, broadband communication, and the number of Internet users. Especially, progress in Internet standards, standard software, and new Internet browser technologies helped to attract a larger audience.

Web 2.0 subsumes a number of new technologies making Web browser user interfaces more user-friendly and, at the same time, reducing traffic load in the Internet. The basic HTTP-protocol that is used to fetch HTML pages from servers to clients is stateless (i.e., the client cannot store a state such as some user preferences). This means, if a user enters anything in a Web page and sends this data to the server, and the server sends in response a new page to the client, then the client software has no knowledge about what the user has entered. In recent years, different technologies were developed to hold either a state at the client by means of cookies or by managing the state at the server side. The problem with both kinds of technologies is that, after each user action, the server has to resend a new page.

New technologies of Web 2.0 support richer clients in the Internet. Thus, more control logic can be executed at the client. JavaScript was one the first solutions to control a Web client's logic. It may be used, for example, to check for correct input syntax of online forms. XML and the processing of DOM structures (the tree structure of well-formed XML or HTML documents), where the structure of XML as well as HTML documents can be changed on-the-fly, enable a more sophisticated control. *AJAX* (Asynchronous JavaScript and XML) is an approach to develop rich clients using recent HTML browsers and the XMLHTTPRequest Api (Raymond, 2007). This means that some requirements (XML, JavaScript and DOM support, Cookies and CSS) have to be met by the client to use the rich HTML client interface. The AJAX approach avoids loading the complete HTML page for every action. Layout information is loaded just once, and only the data required due to the user's action is transferred from the server to the client. This transfer may also happen during the time when the user is already reading the new page. *Web services* are a further technology applied to enable an easy integration of software components to build larger applications. One prominent example is Google Earth that can be used to translate addresses into coordinates (i.e., geo-coding) and to construct maps around a certain coordinate on-the-fly. The latest service is that a user can create his/her own maps where existing maps are enriched by user data. Geographical information systems and its components are very illustrative examples for the construction of social software systems from existing reusable components (Scharl & Tochtermann, 2007). Systems constructed from such building blocks are called *mash-ups*.

Social Issues

Communities are built around common interests. Often, it is, however, unclear what the common interests are and whether all community members share the same interests. For example, Wikipedia has only a small group of writers and a very large number of readers. For the success of Wikipedia, there are enough writers, but this may not always be the case in new community systems.

This problem is also investigated in *knowledge management* theory. A company should be interested that information is shared between its employees. Knowledge management systems have to be designed in such a way that individual members of the staff are motivated to share relevant knowledge through these systems. Davenport and Prusak (1998) describe three motivations that lead to successful knowledge sharing: reciprocity (if I submit something, then other community members are also obliged to share information), reputation (if I submit much information, I will be accepted as an expert), and altruism (I want to support this highly-relevant community without any immediate benefits). These motivations are also valid for social software applications. A fourth motivation for participating in social software systems is the provision of special services such as data storage, e-mail management, and others.

For user acceptance of such systems, the ease of use is also very important. Technological improvements as described above address this issue. Thus, these technologies allow Web browser applications to behave in the same way as standard personal computer software systems.

On the other side, providers of such information systems must also get some revenue to provide these services. The number of users is most important for financial evaluation of such companies. Google, for example, is the company having one of the largest user groups at the moment. Thus, a provider is motivated to attract as many users as possible with good services. One of the most important services on the Internet seems to be the provision of relevant information. And the easiest way to provide such information is to let the users create the content. Google uses, on the one side, Web pages created by its users and, on the other side, the behaviour of Internet users to decide which content is most relevant. The users are, in this case, not aware of what services they deliver to Google. Someone who writes a submission for Wikipedia is aware of the value of his service to the community and will provide this service only in the case that some of the mentioned motivations are present and services are designed accordingly.

A further issue is the behaviour of community members. *Netiquette* (Internet etiquette) is a term for the conventions of politeness and respect in such virtual communities. These conventions address the relationship between personal behaviour and community interests, and outline a dynamic set of guidelines. Examples of these guidelines are not posting spam mails, avoiding commercial advertising outside business groups, and many more (Hambridge, 1995). Using emoticons (emotional icons) are a result of such virtual communities to show, with limited character sets, a kind of emotion in text-based communication.

Trust and Privacy

An important aspect of social systems in general is the *trust* that members of a community have in participation of other members. This is an issue discussed especially for Wikipedia and similar projects. An encyclopaedia has the expectation that descriptions of things of the world are objective and not subjective presentations that try to favour certain technologies or concepts in contrast to others. For example, people may present themselves as very important researchers in the Wikipedia, or a company may describe its products as superior to others.

On the one side, it is argued that the large community is an adjustment factor that corrects, in a very short reaction time, any subjective malpractice. On the other side, Wikipedia has introduced a new group of users that has greater privileges than conventional users. Moreover, new projects arise that try to focus on a more expert-based encyclopaedia. Nevertheless, there are also strong arguments for open communities. For example, recognized experts might use a different (more formal) language or a jargon that simple users do not understand.

Trust in the provider of such community systems becomes sensible if certain private documents such as e-mail or pictures are stored on a server. Access control with passwords avoids certain misuses; however, a misuse by the provider cannot be assured. Therefore, really critical documents will never be stored unless some kind of encryption is supported in these systems.

CLASSIFICATION OF SOCIAL SOFTWARE APPLICATIONS

In the following section, some specialized groups of social software applications are outlined to show the manifold of concepts. The names used in the following classification describe a kind of information system, but often also some kind of software, which can be used to create such an information system. Differences in the systems are:

- the type of the objects exchanged in the community (text, structured documents, audio, pictures, etc.);
- push or pull service (who starts the communication);
- the rules for access (open or closed communities); and
- whether senders know recipients.

Newsgroups

First approaches of such online communities were *newsgroups*. Usenet was established before the World Wide Web was introduced and the general public had access to the Internet. Besides mail and file transfers, it offered announcements through the news software. Submissions that users post are organized into newsgroups, which are organized into hierarchies of subjects. For example, comp.ai (artificial intelligence) and comp.lang (computer languages) are within the comp hierarchy, for computers. A user may subscribe to one or more newsgroups, and the news client software keeps track of which articles this user has read. Newsgroups are organized in threads, a submission with a number of responses to the original posting.

The importance of newsgroups has diminished in respect to other community tools. The current format and transmission of news articles is very similar to that of e-mail messages. However, news articles are posted for general consumption, and a user has access to all newsgroups, in contrast to e-mail, which requires a list of known recipients. Newsgroups have the advantage that they require no personal registration and that archives are always available. Due to the problem of spam mail, however, newsgroups are often moderated so that only fitting submissions are accepted.

Internet Forum

An *Internet forum* is a system supporting discussions and posting of user-generated content. A forum provides a similar function as newsgroups and is usually also structured in threads. A spirit of virtual community often develops around forums that have regular users such as forums on computer games, cooking, healthcare, or politics. Internet forums support the specification of different privileges for user groups.

Internet forums are also commonly referred to as Web forums, message boards, discussion boards, (electronic) discussion groups, discussion forums, or bulletin boards.

Wiki

A *Wiki* is a Web site that allows the visitors to easily add, remove, and otherwise edit and change available content in a similar way as a blackboard at school. Wiki software usually supports the differentiation between registered and unregistered users. For a wiki page, different access rules may be specified. Wikis have their own language for specifying links and certain layouts. This ease of interaction and operation makes a wiki an effective tool for mass collaborative authoring and knowledge management. Since the problem of vandalism may be an issue, wikis support a function to protocol and archive each change, which can be restored.

Web Syndication

Web syndication integrates different sources of structured Internet resources. RSS (Really Simple

Syndication) is a specification of formats used to publish frequently-updated digital content, such as Weblogs, news feeds, or Podcasts. A client program is used to subscribe to one or more feeds. This client then checks if any of those feeds have new content since the last time it checked. RSS formats are specified in XML. RSS software delivers its information as an XML file called "RSS feed" or "RSS channel."

Weblog

A *Weblog* (or blog) is a user-generated Web site where entries are made in journal style and displayed in a reverse chronological order (Powers, Doctorow, Johnson, Trott, Trott, & Dornfest, 2002). They often provide commentary information or news on a particular subject, such as politics or local news. Weblogs are often used as personal online diaries. A typical Weblog combines text, images, and links to other Weblogs, Web pages, and other media related to a topic. Readers may leave comments in an interactive format in a Weblog.

Podcast

A *Podcast* is an audio file that is distributed by subscription over the Internet using syndication feeds for playback on mobile devices and personal computers. The author of a podcast is often called a podcaster. The term "podcast" is derived from Apple's portable music player, the iPod. A podcast can be downloaded automatically, using software capable of reading feed formats such as RSS.

Instant Messaging

Instant messaging (IM) is a form of real-time communication between two or more people based on typed text (chatting). The text is transmitted over the Internet. Instant messaging requires the use of a client program that subscribes to an instant messaging service and differs from e-mail in that conversations are then able to happen synchronously. Most services offer a feature, indicating whether people on a user's contact list are currently online and available for chat. A user may also set a status message indicating further states.

Social Tagging and Bookmarking

Social bookmarking systems store, classify, share, and search links in the Internet or Intranet. Besides Web page bookmarks, services specialized to a specific kind of object or format such as syndication feeds, books, videos, and more can be found. In a social bookmarking system, users store lists with links to Internet resources that they find useful. These lists are either accessible to the public or a specific network. Other community members with similar interests can view the links by category. Some allow for privacy restrictions.

Social bookmarking systems categorize their resources by the use of informally-assigned, user-defined keywords or *tags*. This aggregation of keywords is also called *folksonomy* in contrast to an ontology that would be created by one or more experts in a certain area. Most social bookmarking services allow users to search for bookmarks which are associated with given "tags" and rank the resources by the number of users that have bookmarked them. Many social bookmarking services cluster particular keywords by analysing relations between them. Further services supplied are rating of contents, commenting, the ability to import and export, add notes, reviews, e-mail links, automatic notification, and create groups.

Prediction Markets

Prediction markets are virtual markets where users buy virtual goods or vote for certain decisions in order to predict which goods are successful. Assets are created whose final value is tied to a parameter (e.g., total sales of product in the next year) or to a particular event (e.g., who will win the next election). The current market prices can then be interpreted as predictions of the probability of the event or the expected value of the parameter.

Members buying low and selling high are rewarded for improving the market prediction, while those who buy high and sell low are punished. Prediction markets seem to be at least as accurate as other institutions predicting the same events with a similar pool of participants (Surowiecki, 2004). Prediction markets are rapidly becoming useful decision support tools for companies. Also online role *games* are sometimes classified as social software systems. For example, Second Life, where people can invent a second virtual life for themselves, is such an online community system. In this virtual world, users can buy almost the same things as in the real world. Well-known companies are using this online world to evaluate whether customers will accept certain new products. At the moment, there is a great hype in using these systems; however, the future is uncertain because the users of the system represent only a small group of consumers and, moreover, it is not clear whether certain investments in development in Second Life will be secure since there is no guarantee how long this virtual world will remain.

FUTURE TRENDS

Web 2.0 is a relatively new buzz word, but the successor is already in development. Web 3.0 embraces different ideas from the Semantic Web approach (Berners-Lee, Hendler, & Lassila, 2001). By using semantics (e.g., ontologies), the classification and retrieval of Internet resources can be improved. Moreover, certain processes such as configuration of complex objects (processes, products, and services) may be automated. Ontologies may also support social communities. Folksonomies as used in actual systems may be replaced by ontologies. However, this is also a question of ease of use and user acceptance. In principle, an ontology developed by experts may be more accurate, but users may have different backgrounds which let them communicate with different terms than those of the experts.

Another future trend will be the integration of further media. Thus, we will see the integration of digital television, voice communication, and also communication media for handicapped persons, such as Braille, into such systems. Many existing systems already incorporate mobile clients (e.g., for finding other people in the streets); however, this may be extended further in the future (Eagle & Pentland, 2005).

KEY TERMS

Folksonomy: A collection of tags (terms) to describe objects of a domain; these are created by a community and not as taxonomies, which are created by experts of a domain.

Mash-up: A social software application that uses components of other applications to offer new aggregated services to its members.

Social Bookmarking: A kind of collaborative indexing of Web pages where users share their Web bookmarks with other members of a community.

Social Software: Software for a certain class of information systems that support the creation of virtual communities.

Social Tagging: Collaboratively defining tags as a meta-information on shared Internet resources.

Syndication: An activity to monitor and feed an application from a number of structured Internet sources.

Web 2.0: A number of recent Internet technologies used to improve the interactivity of Web browsers and the user-friendliness of current Web information systems.

Web Service: A software component or procedure in the Internet that can be called by other software programs; the component and its usage conditions may be announced in a registry. Input and output arguments, as well as service level agreements, are described with XML.

Wiki: An Internet blackboard system where users collectively create a number of interlinked Web pages.

Chapter 1.23
Self-Organization in Social Software for Learning

Jon Dron
Athabasca University, Canada

INTRODUCTION

The Internet has long been touted as an answer to the needs of adult learners, providing a wealth of resources and the means to communicate in many ways with many people. This promise has been rarely fulfilled and, when it is, often by mimicking traditional instructor-led processes of education.

As a large network, the Internet has characteristics that differentiate it from other learning environments, most notably due to its size: the sum of the value of a network increases as the square of the number of members (Kelly, 1998), even before aggregate effects are considered. Churchill (1943) said, "We shape our dwellings and afterwards our dwellings shape us." If this is true of buildings then it is even more so of the fluid and ever-changing virtual environments made possible by the Internet. Our dwellings are no longer fixed but may be molded by the people that inhabit them. This article discusses a range of approaches that make use of this affordance to provide environments that support groups of adult learners in their learning needs.

BACKGROUND

Darby (2003) identifies three generations of networked learning environments used in adult education. First-generation systems are direct analogues of traditional courses, simply translating existing structures and course materials. Like their traditionally delivered forebears, they are dependent on individual authors. Second-generation systems tend to be team-built and designed for the medium from pedagogical first principles, but still within a traditional course-based format. Third-generation systems break away from such course-led conventions and provide such things as just-in-time learning, guided paths through knowledge management systems, and personalized curricula. This article is concerned primarily with such third-generation environments.

Saba's interpretation of Moore's theory of transactional distance predicts that in an educational transaction, as structure increases, dialogue decreases and vice versa (Moore & Kearsley, 1996; Saba & Shearer, 1994). What is significant in differentiating learning experiences is not the *physical* distance between learners and teachers, but the *transactional* distance, measured by the degree of interaction between them. Highly structured educational activities have a high transactional distance, while those involving much discussion have a lower transactional distance.

In a traditional learning environment, the structure of the experience is provided by the teacher or the instructional designer. However, learners will not benefit equally from any given structure, as different learners learn differently. It would be better if learners could select appropriate approaches for their needs—to choose whether or not to choose, to control or to be controlled (Dron, 2007a). Without a teacher, help with this might be provided by the opinions of other learners. However, eliciting those opinions, assessing their reliability/relevance, actually finding the resources in the first place, and once found, fitting them into a structured learning experience is difficult. Several approaches to these problems are available, but first it is necessary to introduce a few concepts of self-organization.

SELF-ORGANIZING PROCESSES

Self-organization processes are emergent: the interactions of many autonomous agents lead to structure, not due to central control, but to the nature of the system itself. Such processes are very common in nature and in human social systems. Two in particular are of interest here, *evolution* and *stigmergy.*

Based primarily on work following that of Darwin (1872), evolution is one of the most powerful self-organizing principles, whereby a process of replication with variation combined with natural selection (survival of the fittest) leads to a finely balanced self-adjusting system. It is important to note that "fittest" does not mean "best" by any other measure than the ability to survive in a given environment.

Stigmergy, a form of indirect communication through signs left in the environment (Grassé, 1959), leads to self-organized behavior—examples range from ant trails and termite mounds to forest footpaths, money markets, and bank-runs. For example, ants wander randomly until they find food, after which they return to the nest, leaving a trail of pheromones. Other ants are more likely to wander where such pheromone trails mark the route. When they too find food, they too leave a trail. The stronger the trail, the more other ants are drawn to it. This positive feedback loop continues until the food runs out, after which the trail evaporates.

A full discussion of the many factors that result in a successful self-organizing system is beyond the scope of this article. However, the following brief discussion should give a flavor of what is involved.

Self-organizing processes occur through local interactions. For systems to develop any sort of complexity, it is necessary for these interactions to occur at a number of scales. For instance, the interactions of bacteria in an ant's gut affect the ant, groups of ants can affect tree growth, tree growth can affect climate. Local interactions should form small clusters, which in turn interact with each other, leading to ever-increasing scales of self-organization. However, in general, the large and slow-moving affect the small and fast far more than vice versa, which is a common feature of self-organizing systems, from forests to cities (Brand, 1997). Parcellation is also an important feature of such systems (Calvin, 1997). As Darwin found in the Galapagos Islands, isolated populations tend to develop differently and more rapidly than their mainland counterparts. Any self-organizing system relies on interactions between more or less autonomous agents. The precise level of interactivity varies, but it is interesting to note that, for a system which teeters at the edge of chaos, neither too stable to change nor too changeable to develop, the average number of connections between interacting agents tends to stabilize around just over two (Kauffman, 1995). Systems must be capable of change, being in a more or less permanently unfinished state. Already perfect systems cannot evolve (Shirky, 1996). Equally, systems in perpetual flux can never achieve the stability to achieve self-organization.

SOCIAL SOFTWARE AND THE IMPORTANCE OF THE GROUP

Social software has been defined by Clay Shirky as that in which the group is a first-class object within the system (Allen, 2004). Early social systems such as discussion forums and mailing lists tended to provide a means of supporting individual interactions, with little consideration of the combinatorial effects of the behavior of the many. Typically, they scaled badly, suffering equally from too many as from too few users. In newer social software that underpins the hype-laden term 'Web 2.0', emergent patterns are capitalized upon and reified. For example, tag clouds provide a snapshot of aggregates of classifications by many individuals, social networking software provides structured webs that are generated from individual links between users, wikis gain their structure from individual decisions to link pages, and clusters of linked blogs give texture to the blogosphere. In all cases, the primary determinant of structure is the bottom-up, local behavior of the many. This means that (in general) social software gets better as more people use it.

Interactions within an e-learning environment have previously only considered agents such as the individual learner, the teacher, and the software with each other and with others of the same kind (Anderson, 2003). If the group is a distinct entity from the individuals of which it is composed, then there are more potential interactions to consider. In particular, the group may be seen as, in some ways, a potential teacher within the system (Dron, 2006a).

SOME EXAMPLES OF SELF-ORGANIZED LEARNING IN PRACTICE

For many knowledge-seekers, the starting point is often Google (*http://www.google.com*), perhaps the largest and most pre-eminent example of social software available today. Google's PageRank™ algorithm (Brin & Page, 2000) is based on the assumption that most Web pages provide links to other sites when those sites are considered in some way valuable. Implicitly, the more links that point to a given site, the higher its approval rating. Combined with a content-based search for keywords, documents returned therefore should have a high degree of relevance and reliability. This approach is self-organized, incorporating evolution as unlinked sites "die" and stigmergy as more-visited sites get more links pointing to them (Gregorio, 2003). It is social, not relying on a central controlling authority to provide decisions on resources' usefulness or give a structure to the content that is returned. However, limited parcellation, problems with term ambiguity, and the lack of a support for identifying relevant resources for specific learner needs beyond content-based searching make Google a relatively poor learning tool.

Social navigation, which explicitly capitalizes on stigmergy to enable the navigation or classification behavior of previous users to influence those who follow, is becoming almost ubiquitous on social sites. Tag clouds of the sort found on del.icio.us (*http://del.icio.us*), Flickr (*http://www.flickr.com*), or MySpace (*http://www.myspace.com*) emphasize popular tags by increasing the font size relative to those that are less popular and limiting the display to popular tags, providing a constantly changing map of a community's interests. Applied in an educational setting, such systems offer many benefits, but at the cost of many distractions, inappropriate content, and a breadth of focus that is as likely to discourage as to enthuse learners.

Wikis allow anyone, or sometimes a more closed community, to edit any page. The potential for chaos is enormous, and yet Wikipedia (*http://www.wikipedia.org*), an encyclopedia generated by thousands of volunteers with little central authority, is hugely successful. At the time of writing, the English version of the site had well over a million articles. Soft-security (Cunningham, 2006) allows the wisdom of the crowd to override intentional or unintentional errors introduced by the individual: the fact that it is easier to undo changes than to make them, combined with a large community, leads to a highly reliable and comprehensive source of knowledge (Giles, 2005), which is widely used by learners as a means of tapping into collective expertise. Wikipedia's success is in part due to its strong structure and simple policies. Interestingly, it makes use of a meta-wikipedia where Wikipedians may discuss issues relating to articles to be posted. This scaled parcellation contributes greatly to the evolution of ideas.

Blogging communities form through links between blogs. These may occur inline, or through trackbacks (two-way hyperlinks between blog postings) or blogrolls (explicit lists of links to related sites), which together generate emergent webs of related blogs. As links between blogs grow, they start to form small, stigmergic clusters (Gregorio, 2003). As long as an appropriate cluster can be found, such networks provide a powerful means of finding structure in a subject. This may be facilitated through a recommender system or dedicated blog search tool such as Technorati (*http://www.technorati.com*), which itself uses social navigation in the form of tag clouds. Blogs usually offer interaction and can enable learners to discover and actively participate in relevant communities to help them to learn.

Collaborative filters are recommender systems that make use of implicit and/or explicit preferences to provide recommendations based on similarities between user models. Collaborative filters are very useful for matching users' preferences, but tend to be less successful when seeking learning resources, because to learn is to change. My previous preferences for particular resources will be a less reliable guide to my future needs than preferences for books, movies, or Web sites because the act of using a learning resource will (if successful) change me in ways that are likely to differ from how they have changed you. Nonetheless, systems such as Altered Vista (Recker, Walker, & Wiley, 2000) and RACOFI (Anderson et al., 2003) have achieved some success in this area.

Social networking sites, which are concerned with finding like-minded or otherwise related people, offer another means of structuring the environment from the bottom up. Sites such as MySpace, Orkut (*http://www.orkut.com*), Ecademy (*http://www.ecademy.com*), and FriendsReunited (*http://www.friendsreunited.co.uk*) are concerned with establishing webs of links between people. Again, no centralized controller determines the structure, which forms because of local links provided by individual users. When used to seek fellow learners or experts, such systems offer promising benefits for the learner.

EXPLICITLY EMERGENT LEARNING ENVIRONMENTS

Some social software explicitly exploits self-organizing principles for learning. The selection presented here is a relatively small subset that indicates how this area is developing.

An exception to the rule that collaborative filters cannot cope well with changing needs is CoFIND (Dron, Mitchell, & Boyne, 2003), which combines both evolutionary and stigmergic principles to provide both social navigation and collaborative filtering. Rather than simple good-bad ratings, it employs a multi-dimensional matrix of "qualities," which loosely translate into those things that learners find useful about a resource—for instance, if it is good for beginners, detailed, exciting, and so on. Because qualities are created by learners and used by other learners to provide explicit ratings, they provide a kind of footprint of the learning needs that led to a particular resource being recommended. This remains even after the learner has moved on. By basing its recommendations on an explicit metadata model, rather than a user model, it overcomes the problem of changing user needs that afflicts other collaborative filters. In keeping with evolutionary principles, not just the resources in the system but the metadata which describe them are in competition with each other. Combined with positive feedback loops generated by social navigation using stigmergy, this means that each CoFIND instance develops into a unique ecosystem composed of smaller, interacting ecosystems.

Elgg (*http://elgg.net*) is a powerful social networking system that enables learners to blog, podcast, share resources, and find other users with similar interests. Like many systems, it uses tags and stigmergic tag clouds to identify shared interests. With a focus on the educational sector, every resource, be it a file, a podcast, a blog entry, or a comment, offers fine-grained user control over the permissions to view or change it that are offered. It thus supports strong parcellation as communities can be as private or public as their members wish, while always providing weaker connections between clusters of interest. It has been used extensively around the world in educational settings (Anderson, 2006; Campbell, 2005; Dron, 2006b) as a means of breaking free of the strictures of more top-down learning management systems and of giving control to the end user.

Wiki-based systems for education are becoming increasingly sophisticated. For example, Sloep, van Rosmalen, Kester, Brouns, & Koper (2006) describe an application of latent semantic analysis to automatically generate wiki pages from a knowledge base in response to questions which may then be edited by humans to become more relevant, thus creating a hybrid combination of the strengths of automation with those of human experts. OurWeb (Miettinen, Kurhila, Nokelainen, & Tirri, 2005) overlays footprints and annotations on a wiki page, providing stigmergic social navigation to structure a constantly evolving environment. Emergent patterns of use lend structure to temper the potential chaos of unconstrained wiki growth.

The Knowledge Sea II uses navigation behavior to identify resources of interest to a community of C programmers, using a combination of explicit and implicit ratings to generate a visualization resembling a sea, with greater depth of color representing greater levels of interest. Again, stigmergic self-organization develops through individual interactions with the system (Brusilovsky, Chavan, & Farzan, 2004).

EDUCO (Kurhila, Miettinen, Nokelainen, & Tirri, 2002) uses social navigation to provide not only visual indicators of the relative popularity of documents within the system, but also real-time indicators of who is currently viewing them. This is combined with a chat system that enables interactions between users, providing a powerful incentive to visit pages that are currently being viewed. A similar technique is employed in Dron's (2005, 2007b) Dwellings, which makes use of stigmergic self-organizing principles suggested by Jacobs (1961) in *The Death and Life of Great American Cities.*

The Comtella system uses peer-to-peer protocols to enable its users to share documents, and thence to find documents that others have found useful. Incorporating a ranking system partly inspired by self-organizing market mechanisms, Comtella is replete with emergent structure based on the aggregated behavior of individuals (Vassileva, 2004). Comtella is extensible and has spawned an interesting discussion forum that uses similar mechanisms to help find relevant people and postings (Webster & Vassileva, 2006).

FUTURE TRENDS

The tensions between bottom-up design and the top-down needs of educational institutions and organizations make it uncertain that, despite widespread use, self-organizing, social software will notably impact existing institutional education structures. The large and slow will always dominate the small and fast. Darby's third generation of learning environments already exists, but the majority of effort is still being expended on first- and (occasionally) second-generation systems. However, as the need for lifelong, just-in-time learning becomes ever more significant, it is certain that software combining the wisdom of crowds will have an important role to play in all walks of life.

With a trend towards meaningful metadata being appended to resources using tags or standards such as RDF (Resource Description Framework), the relevance of search results may be improved over the coming years. However, to turn such information into useful knowledge and learning, social software is needed that combines the knowledge of many people, effectively amplifying intelligence and operating in some senses as a kind of group mind. The massive growth in the use of social software and the technologies of Web 2.0 seems irrepressible, offering structure through dialogic processes, with many consequent benefits, enabling the learner to choose whether to be in control or to accept control by the emergent systems that arise (Dron, 2006a).

Interoperability is central: increasing use will be made of mashups, combinations of Web services, and RSS feeds that merge content from many sources (O'Reilly, 2005). Applications that are composed of constantly changing hosted services are quick to build and therefore easy to evolve as needs and communities change. This merging of parcellated populations offers many opportunities for cross-fertilization between systems and communities, as can be seen in sites such as Mappr (*http://www.mappr.com/*), The Daily Mashup (*http://dailymashup.com/*), or Doggdot (*http://doggdot.us/*). Evolutionary change in systems employing mashups occurs on a different scale from that of its individual components, potentially enabling richer and more complex structures to develop at more hierarchical layers. Exactly how this will be adopted in educational settings remains to be seen, but there are already some effective uses of the principle. Elgg, for example, integrates RSS feeds from other sites seamlessly into the local environment, allowing local, parcellated, evolutionary processes to transform the structure from another site into one that is more relevant to a given community's needs.

CONCLUSION

The World Wide Web is becoming ever-more dynamic. Because of social software, the generation of resources to learn from is moving away from rule-based machine- or human-governed information to a more symbiotic relationship, where the strengths of machines and the strengths of people are combined and, in the process, mutually enhanced. In the process, the high transactional distance of resource-based learning is reduced by glimpses of the footprints of others. In a world where roles are changing faster than the traditional course-based approaches to the delivery of learning can address, the resulting group mind can adapt itself more readily and effectively than any single person to the needs of individual learners.

KEY TERMS

Collaborative Filter: A form of recommender system that uses implicit or explicit recommendations of others to provide advice based on similarities between user models.

Emergent Behavior: Behavior that arises out of the interactions between parts of a system and which cannot easily be predicted or extrapolated from the behavior of those individual parts.

Latent Human Annotation (LHA): The unintentional communication of a recommendation or other information as a by-product of another process, for example the provision of hyperlinks in a Web page that are then used by search engines to provide rankings of the linked pages.

Recommender System: A computer program that recommends some sort of resource based on algorithms that rely on some sort of user model, some sort of content model, and some means of matching the two.

Social Navigation: The transformation of an interface (usually Web based) by using the actions of visitors.

Social Software: Software in which the group is a distinct entity within the system.

Stigmergy: A form of indirect communication whereby signs left in the environment influence the behavior of others who follow.

Transactional Distance: A measure of the relative amounts of dialogue and structure in an educational activity. Of necessity, as one increases, the other decreases and vice versa. More autonomous learners require less dialogue than more dependent learners.

Chapter 1.24
Living, Working, Teaching and Learning by Social Software

Helen Keegan
University of Salford, UK

Bernard Lisewski
University of Salford, UK

ABSTRACT

This chapter explores emergent behaviours in the use of social software across multiple online communities of practice where informal learning occurs beyond traditional higher education (HE) institutional boundaries. Employing a combination of research literature, personal experience and direct observation, the authors investigate the blurring of boundaries between work/home/play as a result of increased connectivity and hyper availability in the "information age". Exploring the potentially disruptive nature of new media, social software and social networking practices, the authors ask what coping strategies are employed by the individual as their online social networks and learning communities increase in number and density? What are the implications for the identity and role of the tutor in online HE learning environments characterised by multiple platforms and fora? The authors conclude by posing a series of challenges for the HE sector and its participants in engaging with social software and social networking technologies.

Wholly new forms of encyclopaedias will appear, ready-made with a mesh of associative trails running through them… there is a new profession of trailblazers, those who find delight in the task of establishing useful trails through the enormous mass of the common record. The inheritance from the master becomes, not only his additions to the world record, but for his disciples the entire scaffolding by which they were erected….

–Vannevar Bush (1945)

INTRODUCTION

Online social networking is to some extent a cultural phenomenon. As emerging social web-based technologies are being explored and adopted by educators and learners, we are beginning to witness the emergence of new forms of cooperation and collaboration across boundaries of time and space. Much learning takes place beyond institutional boundaries, instead through social interaction across multiple online 'communities of practice' which Wenger, McDermott and Snyder (2002: 4) define as 'groups of people who share a concern, a set of problems, a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis'. The speed with which information is produced and accessed in an increasingly networked society, and the ease with which communications can take place across multiple platforms and fora, give rise to what Barnett (2000) refers to as 'supercomplexity' where the professional judgement of HE teachers involves using multiple data sources, and often conflictual decision-making choices. The vast amount of information available online, and the ease and speed with which learners and tutors can communicate in the co-construction of knowledge, both require productive boundary making processes in order to lessen the risk of information and communication overload. Alongside the inherent tensions of informal learning taking place across online social platforms which stand apart from the formalised structures of traditional institutions, questions are often raised regarding the authority of knowledge and the legitimacy of participants. These challenges require learners and tutors to demonstrate ongoing reflexivity in terms of the practice of educational interaction in dynamically changing environments and constantly changing information sources.

The use of social software in higher education, such as blogs, wikis and social networking services, has seen a surge in the number of active online learning communities and networks for both staff and students, where members are easily connected and engaging in the social construction of knowledge. Much learning is decentralised (the individual being the locus of control as opposed to the HE institution) and often informal in the sense that it is not prescribed or assessed. There is a resulting tension between the informal or 'feral' nature of social software-enabled learning webs, and the formal teaching accountability of HE institutions in terms of 'what is learned' and the respective assessment practices.

Within the context of his 'communities of practice' analytical tool, Wenger (1998: 267) describes such a tension as the 'interaction of the planned and the emergent - that is, the ability of teaching and learning to interact so as to become structuring resources for each other'. The authors have adopted Wenger's concept of a community of practice to characterise social networking processes as informal and organic 'constellations of inter-related communities of practice' (Wenger, 2000: 229) whereby communities of practice emerge across multiple online social platforms via the ways their participants use the virtual spaces on offer. Within such environments 'members have different interests, make diverse contributions to activity, and hold varied viewpoints… participation at multiple levels is entailed in membership in a community of practice. Nor does the term community imply necessarily co-presence, a well-defined, identifiable group, or socially visible boundaries. It does imply participation in an activity system about which participants share understandings concerning what they are doing and what that means in their lives and for their communities' Lave and Wenger, (1991: 98). Community membership is a matter of mutual engagement which does not necessarily entail homogeneity but diversity. Furthermore, 'since the life of a community of practice as it unfolds is, in essence, produced by its members through mutual engagement, it evolves in organic ways that tend to escape formal descriptions and control' (Wenger, 1998: 118).

These communities of practice can have different levels of expertise that can be simultaneously present, fluid peripheral to centre movement that symbolises the progression from being a novice to an expert and authentic tasks and communication (Johnson, 2001: 45). In effect, these online communities of practice can be conceptualised as 'shared histories of learning' (Wenger, 1998: 86) where both staff and students can participate in multiple communities at once and in doing so may portray different identities. Within these communities learning is a 'social phenomenon, reflecting our own deeply social nature as human beings capable of knowing' (Wenger,1998: 3) and is underpinned by the idea of 'situated cognition' where 'situations…co-produce knowledge through activity' given that 'learning and cognition… are fundamentally situated' (Brown, Collins and Duguid, 1989: 1). Therefore, knowledge is situated and results from the activity, context and culture in which it is developed and employed. Learning arises through 'legitimate peripheral participation' which Lave and Wenger (op cit: 29) characterize as an enculturation 'process by which new learners become part of a community of practice' and thereby 'acquire that particular community's subjective viewpoint and learn to speak its language' (Brown and Duguid, 1991: 48). Furthermore, joining a social networking community of practice involves entering, not only its internal configurations and interactions but also, by hyperlinking its relations with the rest of the digital world.

The ability of the learner to actively engage in dialogue with others in socially interactive online learning communities is seen to be democratising and empowering, echoing the ideas and implementations of radical pedagogical thinkers such as Ivan Illich (1971) and Paulo Freire (1993). Illich (op cit) put forward the idea of self-directed education, supported by intentional social relations, in fluid, informal arrangements - ideas which are found in today's cultures of lifelong and informal learning and the increasing emphasis which is now being placed on learner autonomy; in calling for the use of advanced technology to support 'learning webs', Illich demonstrated a pedagogical vision which is becoming a reality of our learning landscape. In contrast to institutional VLEs, the content of which is most often characterised by standalone modules and learning objects, students can roam freely across the web, accessing vast amounts of information, engaging in social interaction and metacognition through dialogue with others in online communities and participating in blog-based discussions which are characterised by commentary and hyperlinks; learning both formally and informally, and playing a dualistic role of both consumer and producer on the read/write web.

Traditional conceptions of learning, teaching and the role of educational institutions themselves are being challenged by new web-based pedagogies which are by their nature distributed and decentralised. As the use of online social networking services and other forms of social software have reached critical mass in mainstream society, an increasing number of learners and educators are using blogs, wikis and virtual worlds as spaces for communication and collaboration, complemented by faster forms of asynchronous discussion via instant messaging or chat (e.g. Skype, MSN) and now 'microblogging' (e.g. Twitter, Jaiku). Many of these technologies are applications which run outside of the virtual boundaries of the institution. Educators and learners will need to renegotiate shifting paradigms and boundaries such as formal vs. informal; VLE vs. PLE; and centralised vs. distributed interactions across multiple communities of practice. These boundaries may also be constantly shifting according to the level of participation within each community, while communication itself necessitates a degree of reflexivity due to expectations when using multiple and increasingly convergent technologies which are characteristic of a high-speed, always-on culture.

In an educational culture where online learning across multiple, hyper-connected communities may be energising as a result of seemingly never-ending opportunities for dialogue-based learning, there may also be a risk of communication and information overload. New boundaries need to be negotiated in order to allow for quality thinking time – time away from communication and information in order to reflect. If such boundaries are not set, the negative socio-emotional effects of information and communication overload may adversely affect the individual's ability to function and participate effectively within their multiple online communities and networks. Information and communication overload, coping strategies and boundary-setting within multiple online communities of practice (based on the authors' experiences of online social networking, social software and mobile technologies) are the focus of this chapter.

BACKGROUND

Information Overload: Myth or Reality?

Information overload is generally accepted to be "that moment when the amount of available information exceeds the user's ability to process it" (Klapp 1982, 63) and is commonly viewed as being a symptom of living in a high-tech age. Despite this, it is far from being a modern-day phenomenon; the concept of information overload has been traced back to ancient times (Bawden et. al. (1999) Nevertheless, as the means of communicating and disseminating information have increased through the ages, from the arrival of the printing press, through to the advent of telecommunications and now the internet, so too has the risk of feeling overwhelmed due to the ability to process information being limited as a result of cognitive and temporal constraints. The effects are further exacerbated in networked electronic environments by the speed and ease with which information may be accessed through multiple electronic devices in an increasingly networked culture (Castells, 1996), and complaints of information and communication overload have increased in line with the growth in information and communication devices and fora. Bawden et. al. (*op cit*) describe large scale reports from the 1990s which appear to confirm that information overload is becoming a very real problem, leading to feelings of being overwhelmed and resulting in damage to health.

Much recent literature on information overload has focused on the use of email in workplace and the effects of instant electronic communications on worker productivity (Levy, 2006; Zeldes, 2007). Mobile technologies and web-based communications have resulted in the boundaries between work, home and play being broken down due to the ease with which people can communicate; as web-based communication becomes the norm, work-related discussions via email may be entered into during leisure time, while users are able to use web-based technologies to engage socially online in the workplace. The accelerated nature of electronic communication is not without its consequences as people are both easily reached and immediately available. A pattern of behaviour emerges whereby rapid response times (to emails) breed rapid response times; meetings are arranged easily and rapidly, the irony of which is that through partaking in such rapid communications in order to arrange and negotiate tasks, actual output in terms of productivity may be reduced (Levy, *op cit*). Zeldes et al (*op cit*) state that "field research demonstrates that restoring daily segments of contiguous "Quiet Time" can have a major effect of increasing productivity in development teams (Perlow, 1999). Additional research shows a correlation between a fragmented work mode and reduced creativity (Amabile, 2002)." In relation to organisational networks, Watts (2004, p.274-275) discusses limitations in production and information processing, noting that "from a production perspective, efficiency requires that an organisation constrain the non-productive activities of its workers… network ties are costly, in terms of time and energy… individuals have finite amounts of both, it follows that the more relationships one actively maintains at work, the less actual production-related work one can do…"

MAIN THEMES

Considering Information Overload in the Context of HE

As the emerging social web-based technologies are explored and adopted by educators and learners, new forms of cooperation and collaboration are emerging across boundaries of time and space. Taking the 'blogosphere' as an example, growing numbers of groups, networks and communities are able to share and scaffold knowledge with increasing velocity as a result of the lack of physical and temporal barriers when communicating across cyberspace. Connections of thoughts and concepts, of individuals and networks, are formed at a seemingly exponential rate; a societal shift which is both energising and exciting, and yet can rapidly become exhausting as increased connectivity and hyper availability results in a culture which is information rich, yet time poor[1]. One of the concerns of living in a high-speed, always-on culture which is defined by immediacy and seemingly infinite amounts of information is the risk of spending so much time communicating and actively seeking information that little time remains to reflect (Levy, 2006; Eagleton, 2006). One of the paradoxes of the blogosphere is that blogs are commonly seen as a reflective medium, yet without setting boundaries it is quite possible to follow links ad infinitum from blog to blog, accessing seemingly unlimited amounts of information without taking time out to engage in reflection. A further consideration is that of much of the learning within blog-based communities coming from not only the posts themselves, but the comments that are left by others. Through following the ensuing dialogue within the commentary, participants are exposed to multiple viewpoints which, when viewed as a whole, serve as diverse and rich sources of new knowledge. This does however have implications for blog-based community participation, as members may be faced with considerably more information than is contained in the original post.

Many educators are exploring ways to harness the potential of social-software enabled 'feral learning' (Nunan 1996) and decentralised learning networks within formalised educational structures. The ability of tutors and students to roam freely among multiple online learning communities and seemingly never ending and constantly updated web-based information requires new skills in time and information management. Multiple fora and tools with which to communicate mean added complexity; when faced with more information that can be processed in the time available; the resulting overload may be a significant cause of stress (Bawden et. al. *op cit*; Klapp *op cit*; Savolainen *op cit*). This is not a phenomenon which is seen as being a result of the use of social software per se; more as a result of technological advancement as a whole, (McLuhan 1967; Poster 1995; Virilio 1995; Erikssen 2001).

The challenge for learners and educators is to harness the power of the network without becoming overwhelmed by the sheer volume of communication and information within the network itself. Just as businesses are beginning to designate 'quiet time' for their employees, away from email in order to focus on productivity (Wakefield, 2007); networked learning requires participants to agree on boundaries and employ methods to manage information and communication expectations in order to avoid both information and communication overload.

Multiple choices within multiple fora create supercomplexity; learners often use a variety of social networking sites (Facebook, MySpace), instant messaging clients (Skype, MSN) and have multiple email addresses independently of education. The introduction of online social tools into the learning process means that learners have additional networked information and communication technologies to negotiate which increases the likelihood of information overload. Learners and educators in a networked society adopt strategies for avoiding or coping with information overload, and commonly employed methods involve either filtering or withdrawal (Savolainen, 2007). Filtering is a characteristic of sound information and digital literacy, while withdrawal is more affectively oriented and may involve actions such as avoiding checking emails and logging into social networking sites, disguising online status and switching off mobile phones in an attempt to remove oneself from the perceived onslaught of communication. While filtering and withdrawal are common strategies for coping when bombarded with information and communications, it is important for learners and educators to ensure that the right sort of 'noise'[2] is filtered out, or that essential communications are not missed as a result of withdrawal.

One common paradox which has been noted by the author(s) is that whereby useful technologies are so heavily used that their usefulness is lessened in some way. Zeldes et. al. (*op cit*: 2007), describe a state where:

"Rapid communications (first order effect) mean more distractions and overload (second order effect) which reduces people's ability to react. This paradox causes people to adopt various strategies to communicate less (third order effect). The outcome is that people are less responsive to many messages than they were a decade ago, when communications were much slower."

This pattern, whereby a useful technology is used so heavily that it's usefulness is diminished, occurs frequently and rapidly with many web-based technologies; for example coping with email overload by 'chunking' and checking less frequently in order to focus on the task in hand reduces the validity of email as a rapid communications tool. The practice of 'chunking' is so widespread that email is now seen by many as a 'slow' technology in comparison to live chat applications such as Skype and MSN. In turn, as increasing numbers of people adopt these 'faster' communication technologies so the likelihood of noise is increased. Coping strategies are again adopted which often take the form of disguising one's online status or turning off messaging alerts in order to filter out noise.

A further example of this paradox in terms of useful technologies is that of RSS (Really Simple Syndication or Rich Site Summary). RSS feeds are used to bring relevant web content to the user, with the intention of creating more personalised information streams with reduced noise, thereby increasing efficiency and filtering out less-relevant information. One of the key uses of RSS is its role in blog aggregation; users can subscribe and follow multiple blogs easily. However, this tool which is designed to filter out noise is then used so much that it becomes a source of noise in itself, with an increasing number of bloggers complaining of RSS and blog overload (Richardson, 2007; Dawson, 2007; Hughes, 2004).

Information and communication overload may be more of an issue for those whom these technologies have appeared in later life, while the 'net generation' may be more at ease living in a culture which is characterized by multitasking, the use of multiple media simultaneously and constant digitally-enabled communication (Barnes et. al, 2007; Oblinger & Oblinger, 2005). Nevertheless, there may well be implications for the introduction of new and emerging technologies into education, due to the exponential nature of the viral-like growth of the network.

Essentially any individual is limited in the amount of networks within which they can actively participate at any one time, and as educators striving to bring communities of learners together through social software, tutors may be competing with online communities within which learners are already engaged informally such as MySpace and Facebook. While the 'net-generation' are generally perceived as being comfortable communicating across multiple platforms simultaneously, the ease with which users can participate within, and move between, online communities and the potential blurring of the boundaries between work and play as institutions try to engage learners through moving in to the realms of popular social networking sites has implications in terms of both student/tutor identity and the risk of information 'grazing', where learning becomes surface as a result of 'too many networks, too little time'.

How this translates in terms of pedagogy remains to be seen, but as an increasing number of educators introduce social software into the classroom it is not difficult to envisage a point at which some learners may feel 'blogged down and blogged out' (Richardson, *op cit*; Dawson, *op cit*.), drowning in a sea of communication and collaboration and reacting by withdrawing from the very learning communities to which they belong. The challenge for learners and educators using social software is the need to negotiate new pedagogies and educational boundaries (time, space, cultural differences) in a global web which is characterised by exponential growth and constantly changing information sources, in contrast to the relatively static nature of the local institution and the requirements of a HE system which requires transparency, accountability and easily measurable outcomes. Learner empowerment must involve a more equal relationship between the tutor and student, with the acknowledgement that, in the more open and global contexts, the tutor is not the sole provider of subject knowledge. That said, there is likely to remain a responsibility on the tutor to provide an enabling structure within which learners, especially those new to subject domains, are likely to develop learning independence.

Tutor as Educational Broker and 'Bridge': Searching for a New Identity within Dynamic Multiple Systems

Communication and social interaction lie at the core of web-based social constructivist pedagogies and communities of learners can be well-supported by new forms of social software; however, the majority of educators in everyday practice are subject to institutional constraints and accountability mechanisms which pose a real challenge to new forms of social and online learning. The role of the tutor in supporting learners through new forms of online learning may be one of guidance; helping learners to explore their own needs and navigate their personal learning pathways. However, many tutors are working in an educational climate characterised by reduced funding and the corresponding pressure to recruit in order to increase student numbers. The tension between what participants in online learning communities believe to be democratic and empowering, and the requirements of a HE system which emphasises easily measurable outcomes, is tangible. Accountability is key: institutional audits, benchmarking, league tables – such frameworks do not lend themselves easily to decentralised models of education and new conceptions of learning which are student-centred as opposed to autocratic, where the role of the tutor is that of a mentor or guide, as opposed to the authoritarian voice.

The exponential rise of social networking sites as informal environments for HE raises issues of teachers' identities and roles given their growing participation within multiple virtual communities of complex interactions. For example, Rheingold (1993: 61) foresaw enormous cultural changes of Internet usage on the individual: 'are relationships and commitments as we know them even possible in a place where identities are fluid?... We reduce and encode our identities as words on a screen, decode and unpack the identities of others'. On a grander scale, Anthony Giddens (1991) describes the over arching features of a dynamic modern society as being the separation of time and space, the disembedding of social systems and the reflexivity of institutions and individuals. Applied within the context of social networking processes we can see that the concept of space has undergone a transformation in that we can be in the same virtual space but not necessarily in the same locale. Furthermore, social relations within

HE learning contexts can no longer be limited to the local face to face interaction whereby we are faced with the 'lifting out of social relations from local contexts and their re-articulation across indefinite tracts of time-space' (Giddens, *op cit*: 18). Both these conditions require in particular not only the 'reflexive monitoring of action' (Giddens, *ibid*: 20) but the need for say teachers and learners in online environments to constantly collect, store and interpret ever larger amounts of information within the dialectic of the local and the global interaction of knowledge. This reflexivity of modernity involves a 'fundamental uncertainty about the truth of the new knowledge, because we cannot be sure that this knowledge will not be revised' (Kasperson, 2000: 89). Not only does this undermine the certainty of knowledge but Giddens also argues that it may also be 'existentially troubling' for individuals and thereby threaten their 'ontological security' which he defines as 'a sense of continuity and order in events, including those not directly within the perceptual environment of the individual' (*ibid*: 243).

In an environment of multiple virtual communities of practice; time-space distanciation and faceless commitments may undermine one's sense of self-identity and trust in both the authority of the knowledge and the legitimacy of the participants. Within these dynamic, changeable, and volatile conditions there will be a constant need to undertake a form of recurrent 'mental housekeeping' or 'sense-making' as new information and contributions come to light. Giddens (1990: 139) likens the dynamic features of modernity to 'riding a juggernaut' which 'sometimes seems to have a steady path', [but] 'there are times when it veers away erratically in directions we cannot foresee'. Such a scenario can be imagined within the context of different social networking tools where one has the ability to operate in multiple environments and make use of unfettered hyperlinking possibilities in the pursuit of authoritative knowledge construction.

Within multi-scenario and collaborative virtual communities of practice, there is a need for teachers to engage in ongoing reflexivity in how to practice educational interaction in dynamically changing environments and constantly changing information sources. This may involve developing productive 'boundary making' processes and negotiating with each other new cultural forms of managing online interaction. The very concept of a community of practice implies the existence of a boundary (Wenger, 2000: 232). That said, participation in an online community of practice involves engaging not only in its internal configurations but also with its external relationships, particularly given the many hyperlinking possibilities. Wenger (2000: 233) argues, that boundaries are important within learning systems because they connect communities and provide opportunities for learning. Practice boundaries are often informal and fuzzy and do not have to be disciplinary specific. Boundaries are the 'edges of communities of practice, to their point of contact with the rest of the world…no matter how negotiable or unspoken -refer to discontinuities, to lines of distinction between inside and outside, membership and non-membership, inclusion and exclusion (Wenger, 1998: 119).

Wenger, McDermott and Snyder (2002: 153) state that interacting across different practices and their respective boundaries initiate a 'deep source of learning' given that boundaries are 'learning assets in their own right'. However as Hayward (2000) points out, in her study of power, social boundaries (such as laws, rules, norms, routinised procedures, institutional arrangements) can constrain as well as enable participants within different social practices. In the context of social networking communities and their respective educational practices, agreed boundaries may on the one hand; provide a structure for neophyte learners, define what constitutes knowledge, create a space for action, establish the nature and urgency of problems and generate a collection of identities, whilst on the other hand, they can exclude participation, limit the further co-construction of knowledge and hamper innovation.

The key here is to connect boundary crossing and knowledge interaction between different virtual communities of practice some of which may be formal like institutional VLE's such as Blackboard and some of which may be informal such as social networking tools like Facebook. Wenger (2000: 235) offers three kinds of connections with regard to knowledge transfer: brokering, boundary objects and a variety of forms of interactions among people from different communities of practice (multi-membership). The focus here is on brokers who according to Wenger (1998:109) are people who are: 'able to make new connections across communities of practice, enable co-ordination…and open new possibilities for meaning'. Brokering can take various forms: such as 'roamers' who are able to create connections and move knowledge from one community to another and 'outposts' where community members can bring back news from the 'forefront' and explore new 'territories'.

Within the context of HE, this will involve - to different degrees - individuals such as tutors belonging to, and participating in, multiple virtual communities of practice simultaneously. Fox (2007) has drawn attention to students' use of social networking tools such as Facebook and compared it to their lack of participation within formalised institutional VLE's. Social networking sites like Facebook display informal, unmoderated and emergent participation with relatively open and fluid boundaries with virtual spaces used by students for socialising and learning - not controlled by the university whereas VLE's, such as Blackboard tend to have formal, tutor moderated and designed participation with relatively fixed and closed boundaries and hierarchical virtual spaces for structured learning - publicly owned, controlled and surveilled (Land and Bayne, 2001) by the University under licence.

Fox (*op cit*) notes that the popularity of the former was leading to her increasing lack of success in getting student interactions going in the latter. When she browsed Facebook, she found it a useful way of getting to know her students through their profiles. She reports that she was eventually invited to join the social networking group they had formed, associated with her module, and used it to integrate discussions for her seminars. She continues by saying: 'it is a tricky relationship to negotiate, you have to be sensitive because it is a personal space for students, so they don't want it to be too interactive' In effect, tutors must have 'legitimacy' with students whereby the tutor is not seen to be invading their virtual space. This example shows how 'tutors as brokers' are able to make new connections across virtual communities of practice, enable cross participation and open up new possibilities for knowledge co-construction within a more egalitarian HE learning context.

It may be that the tutors of the future will have to develop the skills of translation, co-ordination, and alignment between different perspectives and establish their participatory 'legitimacy' whilst undertaking simultaneous multi-membership of many virtual online social networking learning spaces. As Wenger (1998: 110) argues: 'Brokering therefore requires an ability to manage carefully the existence of membership and non-membership, yielding enough distance to bring a different perspective, but also enough legitimacy to be listened to'. Thus, the HE 'tutor as broker' will have to display the negotiating skills - and feel comfortable enough - to operate between informal and formal virtual communities and within, in particular, multiple informal ones. The challenge is thus to negotiate information and communication boundaries and expectations across the tensions between traditional HE institutions and formalised educational structures, and informal decentralised social learning platforms.

Saunders (2006: 17) in considering relationships between education, learning and work offers additional perspectives on boundary crossing processes. He emphasises the importance of two-dimensions: firstly, moving across boundaries 'yields the potential for learning as sense making processes' and secondly, 'informal learning is given impetus to produce 'ontological security' in the new environment'. He highlights the need for a wide range of 'bridging tools' to help learners, and those supporting them to navigate these transitions from one environment to another. The term 'bridging' is used as the relevant metaphor, because 'it implies a journey and a connection between places in two senses: just as a bridge takes an individual or group from one point to another, it also joins one place to another. This narrative has a strong vision of the world learners inhabit overwhelmingly characterised by rapid change' (Saunders, op cit: 18).

CONCLUSION: FUTURE TRENDS AND CHALLENGES

New forms of online learning, with social interaction and metacognition at their core, pose a significant challenge in terms of the volume, authority and legitimacy of information, relatively unbounded communications, traditional assessment practices and the role of the tutor. Within many online communities of practice learning is fluid and informal, while through participating in such communities tutors can observe learning 'as it happens', guiding students along the way. However, when faced with large student cohorts (which are increasingly commonplace as a result of reduced funding and widening participation in HE) tutors may need to explore alternative methods of monitoring and measuring learning within such communities, such as peer assessment, Summative self-reporting and more intentional uses of technology in ways designed to capture students' knowledge and what is learnt. Tensions between the formal and the informal, and centralised versus decentralised models of education, must be managed effectively, while boundaries need to be negotiated across communities of practice and information networks in order to avoid participants becoming overwhelmed by information and communication.

More pressingly, our conclusion offers a series of challenges for the HE sector in networking with these new forms of learning and social interaction:

1. How are HE institutions going to participate in these informal settings without 'disrupting' students' informal and voluntary engagements in them?
2. HE institutions are going to have to address issues around 'curricular control', assessment strategies, quality assurance, accountability and ownership of process and product within informal social networking groupings.
3. HE tutors, in particular, are going to have to develop as 'educational brokers' and 'information guides and nurture their own professional reflexivity and increased empathy with students operating within their own organically developing informal social networking communities. This may involve a more equalised teacher-learner relationship where teachers may have to concede some 'designing curricula' power within these contexts. That said, tutors may have to provide the 'bridging' function between the formal learning environments of HE practice and the informal learning environments within social networking contexts and their infinite hyperlinking possibilities.
4. Individuals are going to have to construct coping strategies in addressing 'information overload within the work/life, teaching/learning balance and engage in productive boundary making and negotiating across multiple and dynamic social networking communities.
5. Within the context of these informal and organic 'constellations of interconnected practices' and their relationships with the rest of the digital world, we are going to have to

develop what Gee (2000: 522) calls 'reflective communities of practice' and acquire 'reflection literacy' (Hasan, 1998) where both teachers and learners 'engage in both subject-centred design knowledge and the world-building design knowledge through which they imagine and enact new more moral worlds and futures'. This according to Gee (op cit: 517) is 'knowledge about how to design and transform environments, relationships…and identities'.

KEY TERMS

Blogs: Shortened term (weblogs) describing online journals displayed in reverse chronological order.

Boundaries: Practice boundaries are the 'edges' of communities of practice which can be fluid and fuzzy but offer the point of contact with other practice communities and provide lines of distinction between membership and non-membership.

Boundary Crossing: Different forms of interaction among people from different communities of practice.

Brokering: Those who are able to make connections and move knowledge across different practice communities by for example, introducing elements of one practice into another.

Communities of Practice: Organic developments composed of social and informal learning processes which revolve around joint enterprise, mutual engagement and produce a shared understanding and repertoire of communal meaning and resources.

Information Overload: When an individual is faced with more information than can be processed with available time and resources.

Ontological Security: An individual's sense of order, security and continuity within a rapidly changing perceived environment.

Reflexivity: The recurring examination and formation of self identity and social practices within a social environment of ever changing information.

Social Networking: Joining and participating in interconnected Internet communities (sometimes known as personal networks).

Social Software: Web-based applications which are characterised by personal publishing and the sharing and remixing of user-generated content (commonly referred to as 'Web 2.0').

ENDNOTES

1 There are fundamental concerns about the effects on the individual as a result of the increase of 'fast' time at the expense of 'slow' time (Eriksen, 2001). Paul Virilio (1986, 1995) is known for his explorations of the cultural implications of instantaneous digital communications, suggesting that the notion of real-time technology management shows an instrumental disregard for lived time and human experience, although it may be argued that Virilio misses the democratizing aspects of new computer and media technologies.

2 The signal-to-noise ratio is an often-used metaphor for describing information overload… In the context of the Information Age, the term is used to describe the proportion of useful information found to all information found' (Carslon, 2003)

ABSTRACT

Electronic Mailing lists are a key part of the Internet. They have enabled the development of social communities who share and exchange knowledge in specialized and general domains. In this chapter the auhtors describe methods to capture some of that knowledge which will enable the development of new datasets using Semantic Web technologies. In particular, the authors present the SWAML project, which collects data from mailing lists. They also describe smushing techniques that normalize RDF datasets capturing different resources that identify the same one. They have applied those techniques to identify persons through the mailing lists of open source communities. These techniques have been tested using a dataset automatically extracted from several online open source communities.

DOI: 10.4018/978-1-60566-272-5.ch004

INTRODUCTION

Early forms of electronic mailing lists were invented almost as soon as electronic Mail (e-Mail) and are a cornerstone of Internet, allowing a lot of people to keep up to date on news related with their interests. Besides direct messaging between individuals, mailing lists exist as private or public forums for information exchange in communities with shared interests. Mailing list archives are compilations of the previously posted messages that are often converted into static HTML pages for their publication on the web. They represent a noteworthy portion of the contents that are indexed by web search engines, and they capture an impressive body of knowledge that, however, is difficult to locate and browse.

The reason for this difficulty can be traced back to the translation procedure that run to transform the e-mail messages into static HTML pages. This task is fulfilled by scripts that create static HTML pages for each message in the archive. In addition, some indexes (by date, by author, by thread) are generated and usually split by date ranges to avoid excessive growth.

On the one hand, this fixed structure reduces the flexibility when users explore the mailing list archives using their web browsers. On the other hand, most of the meta-data that were associated to each e-mail message are lost when the message is rendered as HTML for presentational purposes.

We propose to use an ontology and RDF (Resource Description Framework, Klyne 2004) to publish the mailing list archives into the (Semantic) Web, retaining the meta-data that were present in the messages. Additionally, by doing so, the information can be merged and linked to other vocabularies, such as FOAF (Brickley and Miller, 2005).

The rest of the chapter is organized as follows: in section 2 we describe the main developments of Social Semantic Web related with mailing lists. In section 3, we explain several techniques to collect RDF datasets from mailing lists and other social sources. Section 4 contains a description of the SWAML project that collects those RDF datasets from mailing lists. In section 5, we describe several applications that consume that data. In section 6, we discuss some experiments that we have done over those datasets. Finally, in section 7 we present some conclusions and future work.

SOCIAL SEMANTIC WEB

The Semantic Web vision tries to develop new ways to integrate and reuse the information published on the web. To that end, the W3C has developed several technologies, like RDF, which enable to add metadata descriptions that contain meaningful values and global properties to resources. The resulting metadata forms a graph model which can be easily linked with other graphs (Berners-Lee, 2006) incrementing the knowledge represented by the original graph. Those values and properties formalize the knowledge of a particular. In 2004, the W3C consortium developed OWL (Patel-Schneider et al, 2004), a web ontology language which facilitates the definition of those formalizations, called ontologies. Based on description logics, OWL has been adopted as the standard ontology language with several available editors, reasoners and tools. There have been also a number of ontologies developed in OWL for different purposes and with different level of detail, from generic to domain-specific ones.

On the other hand, in the last years, the concept of Web 2.0 has attracted a lot of interest. One of the key aspects of Web 2.0 applications is the social part of the web. Users are not considered as mere consumers of information, but also as producers. People want to share knowledge, establish relationships, and even work together using web environments. It is necessary to develop people-oriented web technologies which can represent people interests and that enable the integration and reuse of people related information in the same way that the semantic web vision advocates. These technologies can be seen as social semantic web and we expect that there will be more and more applications making use of them.

One of the first developments is the FOAF vocabulary, which represents basic properties of people, like their name, homepage, etc. as well as the people they know. FOAF descriptions are very flexible and can be extended to other domains.

There are already web portals which export their user profiles in FOAF format and the number of FOAF applications is increasing.

Apart from FOAF, there are other ontologies related to the social semantic web. In particular, SIOC (Semantically-Interlinked Online Communities), provides a vocabulary to interconnect different discussion methods such as blogs, web-based forums and mailing lists (Breslin 2005, Breslin 2006). Although we will apply mainly SIOC to mailing-lists, it has a wider scope than just mailing lists, and generalizes all kinds of online discussion primitives in the more abstract sioc:Forum concept. Each forum represents an online community of people that communicate and share a common interest. The goal of SIOC is to interconnect these online communities.

Other relevant concepts of the ontology are sioc:User and sioc:Post, which model respectively the members of the communities and the content they produce. Instances of these three classes (forums, users and posts) can be linked together using several properties.

The SIOC ontology was designed to express the information contained both explicitly and implicitly in Internet discussion methods. Several software applications, usually deployed as plug-ins, are already available to export SIOC data from some popular blogging platforms and content management systems. The effort, however, is focused on web-based communities (blogs, discussion forums), while little has been done so far to extend the coverage to legacy non-web communities, such as mailing lists and Usenet groups.

SIOC classes and properties are defined in OWL, and their instances can be expressed in RDF. Therefore, they can be easily linked to other ontologies. The obvious choice here is FOAF, which provides powerful means to describe the personal data of the members of a community.

Mailing lists can be easily described by instantiation of the SIOC classes and properties. Each mailing list can be represented by an instance of sioc:Forum (a subclass of Forum might be used instead, although it is not required). Messages sent to the list and their replies become instances of sioc:Post.

Finally, people involved into the list are instances of sioc:User. The SIOC ontology provides a property to link forums and users, namely sioc:has_subscriber. We argue that being subscribed to a mailing list is just one of the roles a user can play with respect to a forum. Moreover, the list of subscribers is often available only to the system administrator for privacy reasons. On the other hand, it is easy to collect the set of people who post to the list, i.e., the people actively involved in the forum. Depending on the settings, the latter may be a subset of the former, in particular in those mailing lists that forbid posting privileges to non-subscribers. Ideally, these two different semantics would be captured using new properties. However, for practical reasons, and to avoid privacy issues, we consider just the already existent sioc:has_subscriber property, and we populate it with the set of active members of a forum. Consequently, inactive members of the forum remain hidden, but this does not represent a problem due to the open world assumption.

Additionally, the Dublin Core (Dublin Core Metadata Element Set, Version 1.1, 2006) and Dublin Core Terms vocabularies are used to capture meta-data such as the message date (dcterms:created) and title (dc:title).

Given the distributed nature of RDF, it is expected that there will be different RDF datasets describing aspects of the same resources. The term *smushing* has been defined as the process of normalizing an RDF dataset in order to unify *a priori* different RDF resources which actually represent the same thing. The application which executes a *data smushing* process is called a *smusher*. The process comprises two stages:

First, redundant resources are identified; then, the dataset is updated to reflect the recently acquired knowledge. The latter is usually achieved by adding new triples to the model to relate the pairs of redundant resources. The OWL property owl:sameAs is often used for this purpose, although other properties without built-in logic interpretations can be used as well (e.g.: ex:hasSimilarName). Redundant resources can be spotted using a number of techniques. In this chapter, we explore two of them: (1) using logic inference and (2) comparing labels.

COLLECTING DATA INTO THE SOCIAL SEMANTIC WEB

Since SIOC is a recent specification, its adoption is still low, and only a few sites export SIOC data. There exist a number of techniques that can be used to bootstrap a network of semantic descriptions from current social web sites. We classify them in two main categories: intrusive and non-intrusive techniques.

On the one hand, methods which require direct access to the underlying database behind the social web site are **intrusive** techniques. The web application acts as the controller and publishes different views of the model in formats such as HTML and RSS. In terms of this pattern, publishing SIOC data is as simple as adding a new view. From a functional point of view, this is the most powerful scenario, because it allows a lossless publication due to the direct access to the back-end database. The SIOC community has contributed a number of plugins for some popular web community-building applications, such as Drupal, WordPress and PhpBB2. Mailing lists are also covered by SWAML, which is described in the next section. There is, however, a major blocker for this approach. All these software components need a deployment in the server side (where the database is). This is a burden for system administrators, who are often unwilling to make a move that would make it more difficult to maintain, keep secure and upgrade their systems. This is particularly true when there is no obvious immediate benefit of exporting SIOC data.

On the other hand, methods which do not require direct access to the database and can operate on resources already published on the web are **non-intrusive**. One technique is the use of cooked HTML views of the information, the same ones that are rendered by web browsers for human consumption. An example could be RSS/Atom feeds, which have become very popular in the recent years. They can be easily translated into SIOC instances using XSLT stylesheets (for XML-based feeds) or SPARQL queries (for RSS 1.0, which is actually RDF). Unfortunately, these feeds often contain just partial descriptions. Another technique is the use of public APIs. The Web 2.0 trend has pushed some social web sites to export (part of) their functionality through APIs in order to enable their consumption by third-party mash-ups and applications. Where available, these APIs offer an excellent opportunity to create RDF views of the data. A shared aspect of these sources is their ubiquitous availability through web protocols and languages, such as HTTP and XML. Therefore, they can be consumed anywhere, and thus system administrators are freed of taking care of any additional deployment. In contrast, they cannot compete with the intrusive approaches in terms of information quality, as their access to the data is not primary.

SWAML PROJECT

SWAML (Fernández et al, 2008) is a Python tool that reads mailing list archives in raw format, typically stored in a “mailbox” (or “mbox”), as defined in RFC 4155 (Hall 2005). It parses mailboxes and outputs RDF descriptions of the messages, mailing lists and users as instances of the SIOC ontology. Internally, it re-constructs the structure of the conversations in a tree structure,

Figure 1. SIOC post example in RDF/XML

```
<rdf:RDF
  xmlns:dcterms='http://purl.org/dc/terms/'
  xmlns:sioc='http://rdfs.org/sioc/ns#'
  xmlns:rdf='http://www.w3.org/1999/02/22-rdf-syntax-ns#'
  xmlns:dc='http://purl.org/dc/elements/1.1/'
  xml:base='http://example.org/swaml-devel/'>
  <sioc:Post rdf:about="2006-Sep/post-52">
    <dc:title>Re: [swaml-devel] Changing SWAML ontology</dc:title>
    <sioc:has_creator rdf:resource="subscriber/s10"/>
    <dcterms:created>Wed, 6 Sep 2006 20:14:44 +0200</dcterms:created>
    <sioc:content><!-- ommitted --></sioc:content>
    <sioc:has_reply rdf:resource="2006-Sep/post-69"/>
    <sioc:previous_by_date rdf:resource="2006-Sep/post-51"/>
    <sioc:next_by_date rdf:resource="2006-Sep/post-53"/>
  </sioc:Post>
</rdf:RDF>
```

and it exploits this structure to produce links between the posts. This script is highly configurable and non-interactive, and has been designed to be invoked by the system task scheduler. This low-coupling with the software that runs the mailing list eases its portability and deployment.

SWAML could be classified as an intrusive technique because it requires access to the primary data source, even if in this case it is not a relational database but a text file (for instance, the approach followed by mle (Michael Hausenblas at al., 2007) is considered completely non-intrusive). Anyway, it is worth mentioning that some servers publish these text files (mailboxes) through HTTP. Therefore, sometimes it is possible to retrieve the mailbox and build a perfect replica of the primary database in another box. In such cases, SWAML can be used without the participation of the system administration of the original web server.

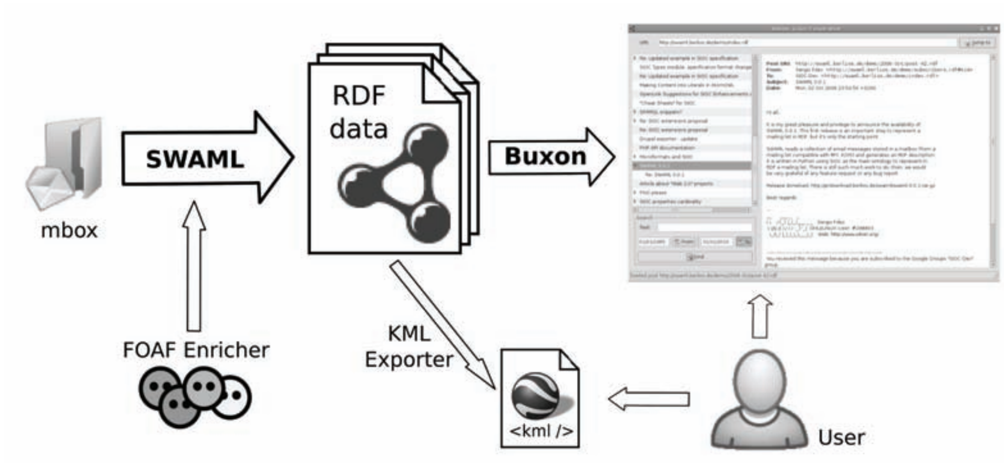
There are many ways in which a mailing list message might be related with other messages. However, we consider just two scenarios. The first one links a post with its replies (sioc:has_reply). Actually, due to sequential layout of the messages in the most widely used format to store mailing list archives (mailbox), it is easier to generate the inverse property (sioc:reply_of). Anyway, the has_reply property can be generated either by a description logics reasoner or by performing two passes over the sequence.

The second link among messages is established between a post and its immediate successor (or predecessor) in chronological order. It is worth to note that this link is not strictly necessary, because the following (or preceding) message can be obtained by sorting by date the sequence of posts. However, this is a rather expensive operation, because the whole set of posts is required in order to perform the sorting. The open world assumption makes this query even more challenging. Therefore, considering that browsing to the previous or next message is a common use case, and the complete set of posts can be very large or even unavailable, we introduced two new properties, next_by_date and prev_by_date. These properties where eventually accepted into the SIOC ontology. An RDF representation of a sample message is shown in Figure 1.

SWAML is essentially a mailbox parser and translator implemented in Python. Its output is a number of SIOC instances (Forum, Posts and Users) in a set of RDF files. SWAML can be invoked by the system task scheduler.

Parsing the mailbox and rebuilding the discussion threads may be sometimes tricky. Although each mail message has a supposedly unique iden-

Figure 2. Buxon is an end-user application that consumes sioc:Forum instances, which in turn can be generated from mailboxes using SWAML.



tifier in its header, the Message-ID, defined by RFC 2822 (Resnick, 2001), in practice its uniqueness cannot be taken for granted. Actually, we have found some messages with repeated identifiers in some mailing lists, probably due to non-RFC compliant or ill-configured mail transport agents. Therefore, SWAML assumes that any reference to a message (such as those created by the In-Reply-To header) is in fact a reference to the most recent message with that ID in the mailbox (obviously, only previous messages are considered). Using this rule of thumb, SWAML builds an in-memory tree representation of the conversation threads, so sioc:Posts can be properly linked.

Actually, SWAML goes further than just a format-translation tool. A dedicated subroutine that runs as part of the batch execution but may be also separately invoked on any sioc:Forum, tries to find a FOAF description for each sioc:User.

One important requirement of the semantic web is to be an extension (and not a replacement) of the current document-based web. Ideally, each user agent must be able to retrieve the information in their format of choice. For instance, current web browsers prefer (X)HTML documents, because they can be rendered and presented to the end user. However, semantic web agents require information to be available in a serialized RDF format, such as RDF/XML or N3. Furthermore, different representations of the same information resource should share a unique URI. Fortunately, the HTTP protocol supports this feature by using "content-negotiation". Clients of the protocol can declare their preferred formats in the headers of an HTTP request using the Accept header. Web servers will deliver the information in the most suited available format, using the Content-type header of the HTTP response to specify the actual format of the returned delivered content. MIME types such as text/html and application/rdf+xml are used as identifiers of the requested and available formats.

Setting up the content negotiation in the server-side usually requires some tuning of the web server configuration. It also depends on some choices made by the publisher of the information, such as the namespace scheme for the URIs or the fragmentation of the information. In (Miles et al, 2006) there is a list of some common scenarios, which are described to great detail, and configuration examples for the Apache web server are provided. The most suitable scenarios (or recipes,

Figure 3. A sample htaccess configuration file for Apache generated by SWAML. These two rules redirect the request to the proper file based on the content negotiation field of the HTTP request. Some lines have been wrapped for readability.

```
RewriteEngine On
RewriteBase /demos/swaml-devel/
AddType application/rdf+xml .rdf
Options -MultiViews

RewriteCond %{HTTP_USER_AGENT} ^Mozilla/.*
RewriteRule ^/([0-9]{4})-([A-Za-z]+)/post-([0-9]+)$
            $1-$2/post-$3.xhtml [R=303]

RewriteCond %{HTTP_ACCEPT} application/rdf\+xml
RewriteRule ^/([0-9]{4})-([A-Za-z]+)/post-([0-9]+)$
            $1-$2/post-$3.rdf [R=303]
```

as they are called) to publish mailing list metadata are the fifth and sixth, i.e., multiple documents available both in HTML and RDF.

The fifth scenario is extensively described in the referred source, and it has been implemented in SWAML. At the same time RDF and HTML files are written, SWAML also produces htaccess local configuration files for Apache. One of these configuration file is shown in Figure 3, while a sample request/response negotiation is depicted in Figure 4.

RDF metadata generated by SWAML can grow to a large size for lists with a high traffic and several years of operation, where there are tens of thousands of messages. The partition of the information might be an issue in such cases. On the one hand, information chunks are preferred to be small so any conceivable use case can be satisfied without retrieving a significant overload of unneeded information. However, scattering the metadata across a myriad of small files has some disadvantages. For instance, the number of resources that must be retrieved to fulfill a single query is greatly increased. Therefore, storing the RDF graph in a specialized database is an appealing alternative.

Fortunately, a common protocol to access semantic repositories using SPARQL as the query language is available (Clark 2006) and is gaining support by the RDF databases. This protocol

Figure 4. An HTTP dialog with content negotiation

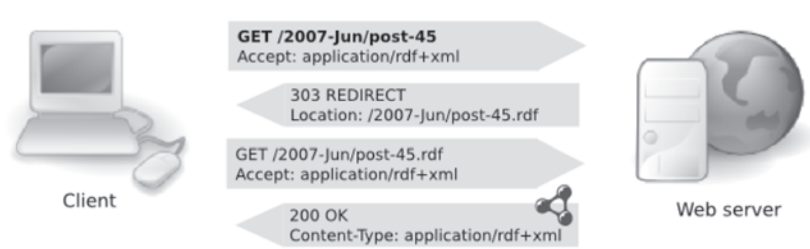

Figure 5. Sample Apache web server rewrite rule to translate HTTP request into SPARQL queries using a Sesame RDF repository. The last line has been wrapped for readability.

```
RewriteEngine On
RewriteBase /lists/archives

RewriteCond %{HTTP_ACCEPT} application/rdf\+xml
RewriteRule ^mylist/(.+)
      http://internal-server/sesame-server/repositories/mylist-rep/
      ?query=CONSTRUCT+{<http://example.org/lists/mylist/$1>+?y+?z}
      +WHERE+{<http://example.org/lists/mylist/$1>+?y+?z}
      &queryLn=sparql [R=303]
```

exposes a simple API to execute and retrieve the results of SPARQL queries (at the present moment, SPARQL is a read-only query language, although there are proposals to extend it with full CRUD capabilities such as those of SQL). This abstract query API may be realized by different means, such as SOAP bindings (described by a WSDL 2.0 interface) and HTTP bindings. The former enables interoperability with web service frameworks, while the latter can be exploited without the full-blown web service machinery.

Web service endpoints which implement the SPARQL protocol are sprouting on the web, some of them pouring huge amounts of data into the semantic web. We argue that metadata of large mailing lists can be conveniently exposed as SPARQL endpoints. That means to effectively translate the decision on data selection to the client (Pan 2006), and therefore minimizing the number of requests and the data overload. For instance, the client agent can retrieve all the headers of the messages in a given date range, but skip the body of the messages, saving a considerable amount of bandwidth.

However, non SPARQL-aware agents still need to access the information. This is the scenario of the sixth scenario (recipe) of the above cited document, but unfortunately this one is still being discussed. We propose a simple solution based on URL rewriting of the requests in order to translate conventional HTTP requests for resources into SPARQL queries that dynamically generate an RDF subgraph that contains the requested information about the resource. The rewriting mechanism, the SPARQL query and even the presence of a data repository instead of static files is kept completely hidden to the client. At the same time, by avoiding the undesirable data replication, this technique helps to keep the information consistent. The most representative feature of our proposal is that it does not require any kind of server side script or application to translate the queries, because the data repository can serve the information directly in the format desired by the client.

We have implemented this technique using the Apache web server and Sesame 2.0 RDF repository (Broekstra et al, 2006). Figure 6 reproduces the hand-made htaccess file (as opposed to the ones that are automatically produced by SWAML). Unfortunately, Of course, the rewrite rule must be fired only when RDF data is requested, while requests for HTML must go through it.

We note, however, that our proposal presents some security-related issues. In particular, it is easily vulnerable to SPARQL-injection. Therefore, we strongly discourage the use of this technique in production environments. Nevertheless, some changes in the regular expressions are possible in order to prevent this kind of attack.

There is another different approach to publishing metadata: to embed it into the HTML content. W3C is pushing two complementary technologies, RDFa (Adida & Birbeck, 2007) and GRDDL (Connolly, 2007), which respectively encode into, and extract RDF data from XHTML documents.

Figure 6. A single message rendered as XHTML code with RDFa and GRDDL markup by SWAML.

```

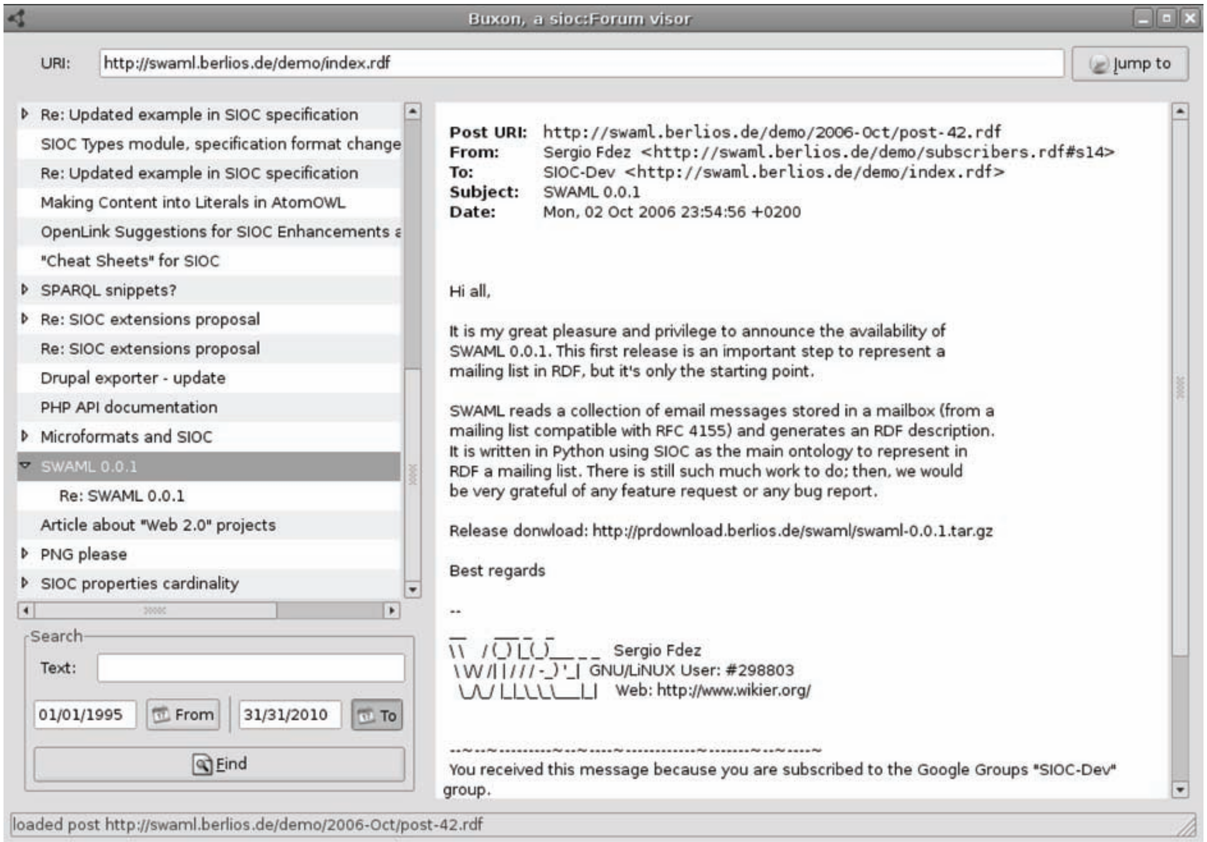
We have also explored this path. SWAML generates simple XHTML pages for each message to illustrate the usage of both RDFa and GRDDL. We must remark that these pages are just a proof-of-concept of the semantic enrichment, and they lack many of the fancy features and complex templates of the already-existent applications which generate plain HTML.

CONSUMING MAILING LIST METADATA

Buxon

Buxon is a multi-platform desktop application written in PyGTK. It allows end users to browse the archives of mailing lists as if they were using their desktop mail application. Buxon takes the URI of a sioc:Forum instance (for example, a mailing list exported by SWAML, although any sioc:Forum instance is accepted) and fetches the data, retrieving additional files if necessary. Then, it rebuilds the conversation structure and displays the familiar message thread list (see Figure 7).

Figure 7. Buxon browsing SIOC-Dev mailing list.



Buxon also gives users the ability to query the messages, searching for terms or filtering the messages in a date range. All these queries are internally translated to SPARQL (Prud'hommeaux & Seaborne, 2007) to be executed over the RDF graph. Newer versions of Buxon can send the sioc:Forum URI to PingTheSemanticWeb.com, a social web service that tracks semantic web documents. That way, Buxon contributes to establish an infrastructure that lets people easily create, find and publish RDF documents.

Other Browsers and Clients

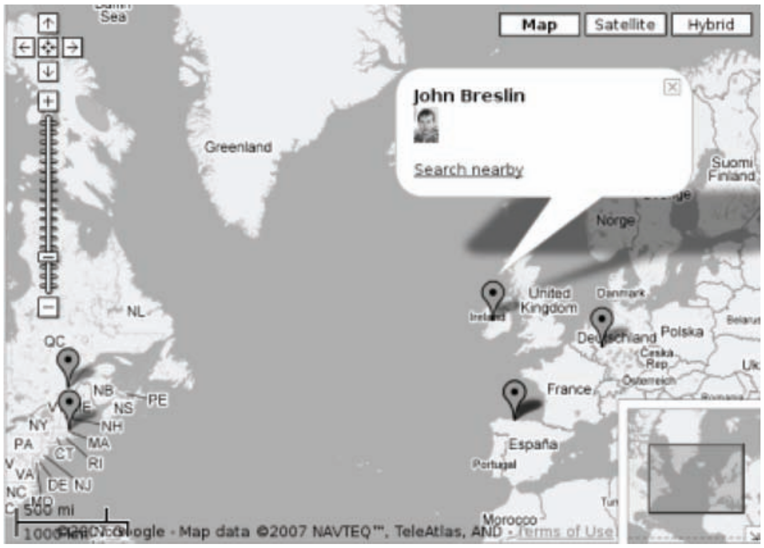
The SIOC RDF data can be explored and queried using any generic RDF browser, such as Tabulator (Berners-Lee et al., 2006). The most interesting applications appear when instances of sioc:User are linked to FOAF descriptions of these users. For instance, it is trivial to write a query to obtain the geographical coordinates of members of a mailing list and to codify them into a KML file (Ricket 2006), provided they describe their location in their FOAF file using the basic geo vocabulary (Brickley 2006). The KML file can be plotted using a map web service such as Google Maps (Figure 8).

It is also possible execute visualize the messages in a time line view using the Timeline DHTML widget by the MIT SIMILE project using a query like the one we propose in Figure 9.

EXPERIMENTATION

A corpus of RDF data with many foaf:Person instances was assembled by crawling and scrapping five online communities. There is a shared

Figure 8. Plotting the geographical coordinates of the members of a mailing list using KML and Google Maps.



topic in these communities, namely open source development; hence we expect them to have a significant number of people in common. We continue the work started in Berrueta et al (2007) to mine online discussion communities, and we extend it to new information sources. More details are described in Berrueta et al We use the following sources:

- *GNOME Desktop mailings lists:* All the authors of messages in four mailing lists (evolution-hackers, gnome-accessibility-devel, gtk-devel and xml) within the date range July 1998 to June 2008 were exported to RDF using SWAML.
- *Debian mailing lists:* All the authors of messages in four mailing lists (debian-devel, debian-gtk-gnome, debian-java and debian-user) during years 2005 and 2006 were scrapped from the HTML versions of the archives with a set of XSLT style sheets to produce RDF triples.
- *Advogato:* This community exports its data as FOAF files. We used an RDF crawler starting at Miguel de Icaza's profile. Although Advogato claims to have +13,000 registered users, only +4,000 were found by the crawler.
- *Ohloh:* The RDFohloh (S. Fernández, 2008) project exposes the information from this directory of open source projects and developers as Linked Data. Due to API usage restrictions, we could only get data about the +12,000 oldest user accounts.
- *Debian packages:* Descriptions of Debian packages maintainers were extracted from apt database of Debian packages in the main section of the unstable distribution.

Instances generated from these data sources were assigned a URI in a different namespace for each source. Some of these data sources do not directly produce instances of foaf:Person, but just instances of sioc:User. An assumption is made that there is a foaf:Person instance for each sioc:User, with the same e-mail address and name. These instances were automatically created when missing. This assumption obviously leads to redundant instances of foaf:Person which will be later detected by the smusher.

The ultimate goal of our experiments is to exercise the smushing processes described previously against a realistic dataset. Two million RDF triples were extracted from the sources described above, and put into OpenLink Virtuoso server which provides not only an effective triple store, but also a SPARQL endpoint that was used to execute queries using scripts.

We evaluated two smushers: the first one smushed foaf:Person instances assuming that foaf:mbox_sha1sum is an IFP; the second one smushed the same instances comparing their foaf:name labels for string strict equality, without any normalization. Both smushers were implemented using SPARQL CONSTRUCT rules. The newly created owl:sameAs triples were put in different named graphs. These links were analyzed to find co-occurrences of people in different communities.

Some communities use the e-mail address as their primary key to identify its users. However, other communities use a different primary key, thus allowing users to repeat their e-mail addresses. For instance, a small number of users have registered more than one account in Advogato with the same e-mail (these accounts have been manually reviewed, and they seem to be accounts created for testing purposes).

Our data acquisition process introduces a key difference between how user accounts are interpreted in Debian mailing lists and GNOME mailing lists. The former considers e-mail address as globally unique, i.e., the same e-mail address posting in different Debian mailing lists is assumed to belong to the same user.

On the other hand, a more strict interpretation of how Mailman works is made with respect to the GNOME mailing lists, where identical e-mail address posting in different mailing lists are assumed to belong to a priori different users. In the second case, we rely on the smushing process to merge the identities of these users.

Although they must be handled with extreme care due to the issues afore-mentioned, the combined results of the two smushing processes are consistent with the expected ones. For instance, there is a very high overlap between the Debian developers (maintainers of Debian packages) and the Debian mailing lists. Obviously, Debian developers are a relatively small group at the core of the Debian community, thus they are very active in its mailing lists. Another example is the overlap between Advogato and GNOME mailing lists. Advogato is a reputation-based social web site that blossomed at the same time that the GNOME project was gaining momentum. Advogato was

Figure 9. SPARQL query to extract the information required to visualize a time line of the messages posted to any sioc:Forum instance.

passionately embraced by the GNOME developers, who used Advogato to rate each others' development abilities.

We also studied whether there are some people that are present in many of the communities at the same time. We chose communities which are closely related to each other, consequently, we expected a high number of cross-community subscribers. There are several people who are present in many communities. We can conclude that almost all the most active open source developers in our dataset are core members of the Debian community. Another interesting fact is that only a few people among the top members of the communities consistently use a single e-mail address and just one variant of their names. This fact proves the difficulty of the smushing process, but also its usefulness.

CONCLUSION AND FUTURE WORK

There are a lot of ongoing efforts to translate data already reachable on the web into formats which are semantic web-friendly. Most of that work focuses on relational databases, micro-formats and web services. However, at the time of this writing and to the best of our knowledge, e-mail was almost excluded from the Semantic Web. Our project, in combination with the generic SIOC framework, fills this gap, conveniently providing an ontology and a parser to publish machine-readable versions of the archives of the countless mailing lists that exist on the Internet.

Furthermore, the SWAML project fulfills a much-needed requirement for the Semantic Web: to be able to refer to semantic versions of e-mail messages and their properties using resource URIs. By re-using the SIOC vocabulary for describing online discussions, SWAML allows any semantic web document (in particular, SIOC documents) to refer to e-mail messages from other discussions taking place on forums, blogs, etc., so that distributed conversations can occur across these discussion media. Also, by providing e-mail messages in RDF format, SWAML is providing a rich source of data, namely mailing lists, for use in SIOC applications.

The availability of these data leads to some benefits. In the first place, data can be fetched by user applications to provide handy browsing through the archives of the mailing lists, providing features that exceed what is now offered by static HTML versions of the archives on the web.

Secondly, the crawlers of the web search engines can use the enhanced expressivity of the RDF data to refine search results. For instance, precise semantic descriptions of the messages permit to filter out repeated messages, advance in the fight against spam, or introduce additional filter criteria in the search forms.

Another consequence of no lesser importance is that each e-mail message is assigned a URI that can be resolved to a machine-readable description of the message. This actually makes possible to link a message like any other web resource, and therefore enriches the expressivity of the web.

Integration of the SWAML process with popular HTML-based mailing list archivers, such as Hypermail or Pipermail, would be a giant push to speed up the adoption of SWAML. It is well known that one of the most awkward problems of any new technology is to gain a critical mass of users. The semantic web is not an exception. A good recipe to tackle this problem is to integrate the new technology into old tools, making a smooth transition without requiring any extra effort from users. Merging the SWAML process into the batch flow of tools such as Hypermail would allow users to generate both RDF and production-quality, semantically enriched HTML versions of the archives.

So far, no semantic annotation relative to the meaning of the messages is considered. Obviously, such information can not be automatically derived from a RFC 4155-compliant mailbox. However, it is conceivable that it could be added by other means, such as social tagging using folksonomies, or parsing the metadata added by the authors of the messages using micro-formats or RDFa when posting in XHTML format. The inherent community-based nature of mailing lists can be exploited to build recommendation systems (Celma 2006).

We have also explored smushing techniques to spot redundant RDF instances in large datasets. We have tested these techniques with more than 36,000 instances of foaf:Person in a dataset automatically extracted from different online open source communities. We have used only public data sources, consequently, these instances lack detailed personal information.

We are aware of the extreme simplicity of our experimentation using label comparison. In our opinion, however, it contributes to show the potential of this smushing technique. We note that it is possible to have more usages for it, for instance, smushing not just by people's names, but also by their publications, their organizations, etc. Surprisingly, the named-based smushing finds a high number of redundant resources even if the comparison strategy for labels (names) is very simplistic (in this case, case-sensitive string equality comparison). More intelligent comparison functions should lead to a higher recall. In this direction, we are evaluating some normalization functions for names. We have also evaluated classical information retrieval comparison functions that take into account the similarity of the strings (e.g., Levenshtein); nevertheless, their applicability to compare people's names is open to discussion.

We believe that the ratio of smushing can be further improved if the dataset is enriched with more detailed descriptions about people. Experiments are being carried out to retrieve additional RDF data from semantic web search engines as a previous step to smushing.

We have implemented a smusher application for persons, and we intend to use it to further investigate the potential for the optimization of the smushing process. The way in which these techniques are translated into actual algorithms is critical to achieve a promising performance of the smushing process, especially for very large datasets. In parallel, increasing the precision of smushing will require to study how to enable different smushing strategies to interrelate and reciprocally collaborate.

ACKNOWLEDGMENT

The authors would like to express their gratitude to Dr. John Breslin and Uldis Bojārs from DERI Galway, whose support and contributions have been a great help to this work. Also thanks to Ignacio Barrientos for his contribution packaging SWAML for Debian GNU/Linux.

Chapter 1.26
Social Semantic Web and Semantic Web Services

Stelios Sfakianakis
ICS-FORTH, Greece

ABSTRACT

In this chapter the authors aim to portray the social aspects of the World Wide Web and the current and emerging trends in "Social Web". The Social Web (or Web 2.0) is the term that is used frequently to characterize Web sites that feature user provided content as their primary data source and leverage the creation of online communities based on shared interests or other socially driven criteria. The need for adding more meaning and semantics to these social Web sites has been identified and to this end the Semantic Web initiative is described and its methodologies, standards, and architecture are examined in the context of the "Semantic Social Web". Finally the embellishment of Web Services with semantic annotations and semantic discovery functionality is described and the relevant technologies are explored.

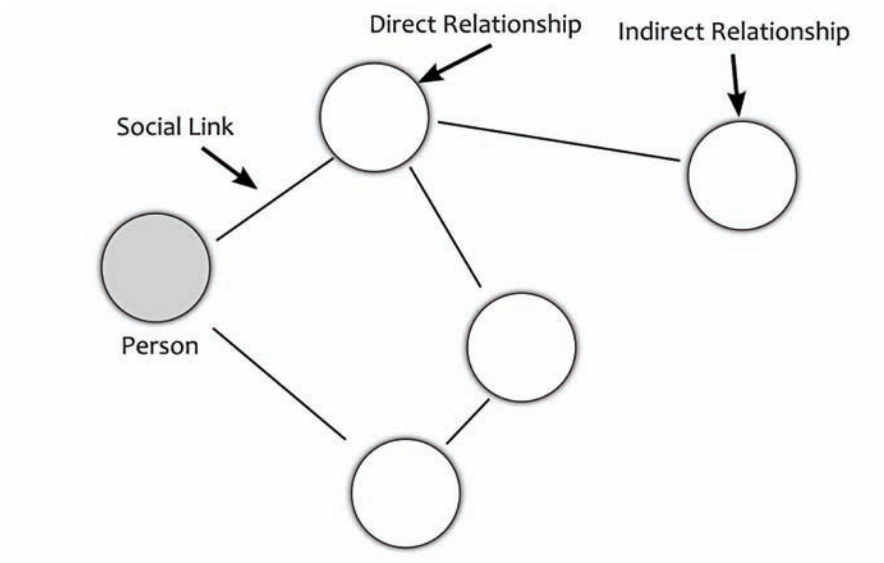
INTRODUCTION

The World Wide Web (WWW or, simply, the "Web") has been used extensively as a huge network of interconnected islands of data where documents are linked, searched for, and shared, forming a massive, albeit not always well organized, digital library. Sharing of digital content has always been the major requirement for the Web since its inception and will continue to be one of its most important features in the years to come. Nevertheless, what we experience nowadays is the endeavor for extending this sharing to cover also additional artifacts beyond plain documents, like data, information, and knowledge. The power of the hyperlinks, connecting different, possibly disparate entities, can also be exploited in order to connect information sources and people: not just "dumb" machine readable data but dynamic content like user profiles and ultimately people themselves for building virtual communities. The vision is that the current web of computers and documents will be broadened to the web of people. A "People Web" is the one where users are the nodes of the graph, the edges being their relationships and interactions in space and time, thus constructing new virtual societies (see Figure 1).

This new environment is leveraged by the introduction of an array of technologies collectively identified as Semantic Web (Berners-Lee, Hendler, & Lassila, 2001). The Semantic Web builds upon the existing Web and provides the necessary sub-

DOI: 10.4018/978-1-60566-340-1.ch011

Figure 1. A social graph



strate for giving "meaning" and "Semantics" to Web resources and Web interactions. The benefits will be many in a number of application domains and while the challenges, technological and other, are numerous, the momentum is strong and the Semantic Web slowly but steadily enters in a number of diverse domains like health and life sciences.

Furthermore the Semantic Web promises a great potential for supporting the construction and smooth operation of Web communities of people. In this chapter we study its fusion with social software and software for machine to machine communication over the Web for supporting this vision.

BACKGROUND

Since its launching in 1990, the Web has grown exponentially both in terms of size and in terms of use and utility to people and organizations. The inherent simplicity of hypertext and its feature limited, in comparison to previous hyper linking systems, one-way, inexpensive links (Universal Resource Identifiers – URIs) but also the employment of the Internet as its networking substrate led to its wide adoption and success.

In spite of its success and popularity the early version of the Web lacked in many respects, ranging from user accessibility and user interface design to the ability to repurpose and remix existing Web-based data in not pre-established ways. Although the hyper linking facility allowed the interconnection of different documents on the Web, the "traditional" Web suffers from fragmentation in the sense that the huge graph lacks any organization and discipline. This "anarchy" in the Web has also been its driving force for the success it has enjoyed so far but created the need for having special machinery, e.g. search engines like Google, to deal with the efficient indexing and discovery of the available information. Despite the fact that the search engine technology has made important steps in indexing and searching massive amounts of data on the Web, there's still the issue that keyword based searching is limited on its potential and usually finding "what the user wants" proves to be a tedious task. Another major limitation of this environment is that the people are not part of the equation. Users are expected to be the actors triggering the Web interactions but they are not allowed to participate and be involved enough in these interactions:

- Content delivered is not personalized. What the user gets back is usually not in-line with her interests or other preferences and there's no feedback link going from the user back to the system she interacts with so as to guide future interactions.
- Contextual information is not taken into consideration. The people as complex systems do not act in an easily predetermined way and the context of their actions is usually ignored or not taken advantage of. This context information ranges from the user's profile, which is also dynamic in nature, to the specific objective she/he is trying to achieve at a specific point in time.
- Content is passive and static, stored and maintained in back end databases, which the users do not have the ability to enrich or customize to their own needs
- Communication and collaboration of the users to build Web communities are not supported enough. Discussion forums were the sole way to build such communities but with no means to support intelligent integration of the different forums or to enhance the user collaboration experience.

These and other requirements are the ones that the Social Web tries to tackle. Social Web does not represent a shift or radical change in technology per se but rather a shift on the perception of the human – machine interaction by placing the users in the centre of the system and in control of these interactions. But from the other end of the spectrum there is also a clear need for making the Web itself more intelligent to support these machine facilitated social interactions. The Semantic Web could provide for such an enabling technology and recently the convergence of the Social and the Semantic Web and the experimentation of the two working in complementary ways have gained a lot of attention and research interest.

SOCIAL WEB OR WEB 2.0

The situation described in the previous section led to the emergence of a new breed of Web applications and sites that were collectively identified as "Web 2.0" by Tim O'Reilly (2005) and whose major design principle is to "*harness network effects to get better the more people use them"*. The value of "Web 2.0" sites and applications therefore comes to a large extent by the number of users participating and actively communicating and sharing through them so the term "*Social Web*" is actually a synonym. The social nature of this Web is evident when the collaboration of people and their active contribution is considered. The very essence of such sites is the building and maintenance of Web based *virtual communities* of people that produce and maintain *collective knowledge*. Examples of such community oriented and social networking sites include:

- Blogs, i.e. Web sites managed by individuals that provide news or opinions on certain subjects (typically personal online diaries), where typically other people are able to leave comments. In addition to comments, the hyperlinking facility of the Web has been extensively used to provide "trackbacks" (i.e. reverse hyperlinks that identify who is talking about me) and recommended blogs ("blogrolls"). Therefore blogging has been emerged as a method for anyone to publish content on the Web and building online communities of people that communicate, share, and integrate.
- "Social bookmarking" sites (e.g. http://del.icio.us/) where users can store and share their bookmarks with the additional possibility to provide metadata through the

means of tags, i.e. terms that denote concepts, meaning, intent, etc. These sites provide for user maintained and collaborative indexing of the Web content in a way that it may be more efficient to search there for something than in general purpose Web search engines.
- "Wikis" (e.g. http://en.Wikipedia.org), which are collaboratively built Web sites where the users, through custom made and user friendly interfaces, are able to create, share, enhance, and manage the content.
- Content sharing sites, e.g. YouTube (http://www.youtube.com/) for videos or Flickr (http://www.flickr.com/) for photographs, where the users upload their multimedia content and share it online with other users.
- Social networking sites, such as Facebook (http://www.facebook.com/) and MySpace, for online communities of people who share interests and activities or who are interested in exploring the interests and activities of others.
- Classified advertisement sites, e.g. Craigslist (http://www.craigslist.org), which offer advertisements for jobs, resumes, services, etc. grouped in categories.

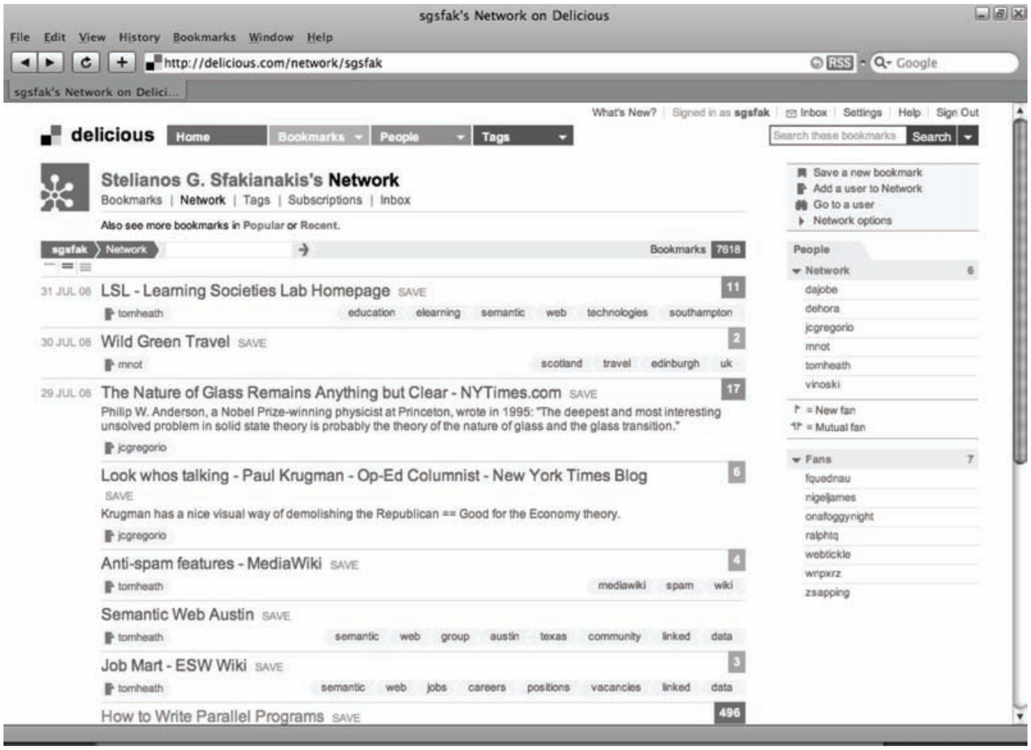
If we take only "Wikis" as an example we can see that these Web sites have been used in a multitude of ways:

- As online encyclopedias, e.g. Wikipedia
- As free dictionaries, e.g. Wiktionary (http://en.wiktionary.org)
- As free libraries of educational books, e.g. Wikibooks (http://en.Wikibooks.org)
- As software development repositories and issue tracking systems, e.g. Trac (http://trac.edgewall.org/)
- As open forums to promote research interests, like OpenNetWare (http://openwetware.org/) for biology and biological engineering
- As open educational centers to support learning activities, e.g. Wikiversity (http://en.Wikiversity.org/)
- As social event calendars, like Upcoming (http://upcoming.yahoo.com/)

The single distinctive feature of Wikis and a central trait of the social Web sites is the *user generated content* and its "open" editing: anyone can edit an existing Wiki article or create a new one for a particular topic if it doesn't exist already. The users therefore are responsible for adding content and maintaining the information that is available from these sites. Of course such an approach can raise a lot of concerns about the validity of the content, the lack of authority, etc.[1] and there have been cases in the past where such skepticism was proven true, such as the Seigenthaler incident[2]. Nevertheless this open model has worked quite well in practice and in general so that at the time of this writing Wikipedia is considered by many a serious competitor to the Encyclopedia Britannica. The reason for this can be explained as another instantiation of the "wisdom of crowds" phenomenon (Surowiecki, 2004): the participation of many people, possibly with different background, habits, way of thinking, and so on, in a decision making process usually yields better results than when the individual opinions are considered separately from one another.

The contribution of user content and the sharing of the uploaded information are the main forces for the formation of *online communities* of people. In Figure 2 an example of this community creation process is shown for the Del.icio.us online bookmarking site. Online bookmarking sites like this provide the means for storing and organizing bookmarks of Web sites on the Web instead of the users' desktop browsers. By storing their bookmarks in a central area the users are additionally enabled to create their online social

Figure 2. Del.icio.us networks of users



networks by registering other users as members of their network so that they can be notified about the bookmarking activity of these users. These networks therefore connect users with their friends, family, coworkers, or even totally strangers when they unexpectedly meet each other on the Internet and discover they have similar interests. Facilitated by these network links the users can subsequently observe each other's online behavior and even proactively send interesting Web sites addresses to their peers, easier and quicker than using email or instant messaging.

What the previous examples show is that in the Social Web users are in the limelight: they are the primary actors in the data sharing process through their contributions and online behavior. They are usually indulged by the low cost entry and participation in these Web sites, and, to a lesser extent, by the visual appeal the Web 2.0 sites offer to the viewer. The modern Web sites are actually Rich Internet Applications (RIA), where the majority of the business and control logic resides on the client (i.e. the Web browser), leveraged by technologies like AJaX[3] and Comet[4] which provide more responsive user interfaces.

The Social Web offers a meeting point for people to collaborate and share information in an open environment. The openness is a distinctive characteristic of Web 2.0 and it's supported by Open Data APIs like content syndication via RSS/Atom[5] and lightweight Web services interfaces like Open Search[6] . These technologies enable the view of Web sites as Web applications and their synthesis ("mashup") in more complex applications. An example of such combination of existing Web sites and their data to create new/aggregated content is Housing-Maps (http://www.housingmaps.com/) where houses to rent or buy are located through Craiglists and projected over geographic maps drawn from Google Maps (http://

maps.google.com) so that a user can easily locate the information he wants in an interactive and visual way. A more general and reusable way to combine and "mix" content from different Web sites is offered by Yahoo! Pipes[7] which can be thought of a simple but effective way to build "workflows" and "dataflows" on the Web.

The above discussion shows that collaboration between people but also between Web sites/applications supports the notion of "collective intelligence" to the Social Web. An instance of this intelligence built collectively is the creation of "folksonomies" for categorization of resources. A quite popular way of classifying content in Web 2.0 Web sites is through "tagging". A tag is a keyword which acts like a subject or category. The user is allowed to attach whatever keywords she wants to identifiable content such as links in the case of social bookmarking, or videos and photographs in the case of digital content sharing. The important thing is that tags can be shared, used in searches, or recommended based on the choices of other users for the same content.

The new term "folksonomy", as a fusion of the words "folks" and "taxonomy", has been suggested to describe this method of classifying content through tags that are collaboratively generated and shared. Of course these "poor man's" classification schemes are informal in nature, could contain duplication in meaning, or be simply erroneous but again they are contributed by the users and the more people contributing the more robust and stable these "folksonomies" become. A self adapting and auto regulating method is usually followed through the use of tag clouds (Figure 3). In simple terms a tag cloud is a visual representation of a user's tags where each tag is weighted based on the user preferences and how many times he has used the tag. Through such an approach "good" tags are likely to prevail assuming that the user participation is high.

Collaboration, sharing, "mashing", annotating and "tagging" content are roughly the distinctive features of Web 2.0 and although in most of the cases the approach is not formal or the solutions are suboptimal the user participation and their socialization needs have driven the evolution of Web of documents to the Web of People (Ramakrishnan & Tomkins, 2007).

SEMANTIC WEB

To the other end of the spectrum, with roots in Artificial Intelligence research, the Semantic Web emanated as an extension to the current version of the Web that aims to enhance it by the promotion of higher level sharing and integration of data and information. According to Berners-Lee et al. (2001):

The Semantic Web is not a separate Web but an extension of the current one, in which information is given well-defined meaning, better enabling computers and people to work in cooperation.

The Semantic Web aims to support the representation and exchange of information in a meaningful way so as to make possible the automated processing of descriptions on the Web. The objective is to enrich the unstructured information in the current Web with machine processable descriptions of the Semantics in order to make its navigation and exploration by software agents as easy as it's for the human users today, or even easier. In this context Semantic Web promotes a shift from the current "syntactic" world to the future "Semantic" world of services, applications, and people and aims to make the machine to machine communication feasible so that not only data but also information and finally knowledge are shared.

The Semantic Web Technology Infrastructure

In technological terms the Semantic Web architecture consists of an array of technologies that can roughly be visualized in a layered design layout as depicted in Figure 4. The basic infrastructure in

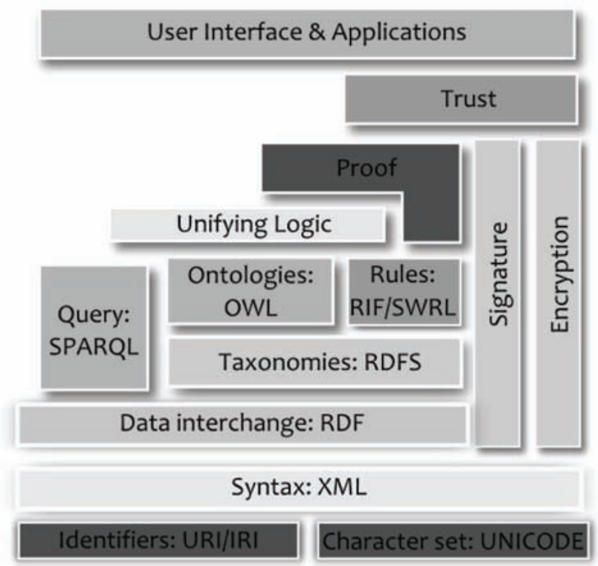
Figure 3. A tag "cloud"

the bottom layers in this stack of technologies is the exactly the same to the syntactic Web: Uniform Resource Identifiers (URIs) used for identification of Web resources, universal encoding schemes for characters, i.e. Unicode, and XML and its related technologies (e.g. XML Namespaces) as a ubiquitous data serialization format. Some of the upper layers like Proof and Trust are missing or are work in progress. Here we will concentrate on the middle layers where the core infrastructure technologies of the Semantic Web reside: RDF, RDF Schema/OWL, and SPARQL.

The *Resource Description Framework* (RDF) is a syntax neutral data model that enables the description of Web resources in a simple way (Lassila, Swick, et al., 1999). At the core of RDF there is a model for representing and describing *resources* through named *properties* (also known as *predicates*) and their values. The resources can be anything that can be identified with a URI. Although in the initial specification of RDF resources were limited to Web documents and Web sites, it is possible and quite frequent in practice to describe, by the means of RDF and the various URI schemes, real world entities like people, or more abstract things like relationships and concepts. The use of URIs and especially the HTTP based ones for identifying persons or other physical entities may seem strange at first but this is in compliance with the architecture of the World Wide Web (Berners-Lee et al., n.d.) which strongly suggests the use of URIs for identifying anything that can be of importance irrespective of how abstract or tangible it may be.

The properties serve both to represent attributes of resources and to represent relationships between resources. They are also identified though URIs to make them unique. The combination of resources and the properties that connect them builds the simple RDF data model. In this data model the primary informational building block is the "triple" which denotes the subject – property - object expressions (Figure 5). The subject denotes the resource, and the predicate denotes

Figure 4. The Semantic Web stack of technologies



traits or aspects of the resource and expresses a relationship between the subject and the object. Since an object of a triple can be the subject of another one, a set of RDF triples forms a *directed graph* where the RDF resources, both subjects and objects, are the nodes of the graph and the predicates are the labeled arcs. As an example, in Figure 6 there's a simple RDF graph. The graph shown in the figure describes an entity identified through the URI "http://ssfak.org/stelios/", apparently denoting a person, which has a "name" property with the value "Stelios Sfakianakis", a property denoting the homepage of an organization a person works for relating it to the resource "http://www.ics.forth.gr/cmi-hta/", and a "maker" property that connects it (backwards, as an object) to the resource identified as "http://ssfak.org".

RDF as an abstract model is independent of any specific serialization syntax. The normative representation syntax for RDF graphs is XML but more lightweight formats, such as Turtle (Beckett & Berners-Lee, 2008), exist.

The simplicity and flexibility of RDF is evident but in certain cases its generality must be formally confined so that software entities are able to correctly exchange the encoded information. For example, stating that an animal is the creator of a Web page does not make sense in the real world but RDF does not forbid anyone for making such a claim. Ontologies (Uschold & Gruninger, 1996) provide such a tool to specify what can be expressed in the context of an application domain or in a real world scenario, what is the underlying meaning, and how the information presented can

Figure 5. RDF Data Model

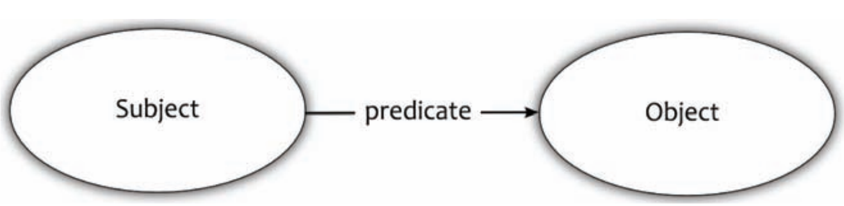


Figure 6. Abstract representation of RDF triples

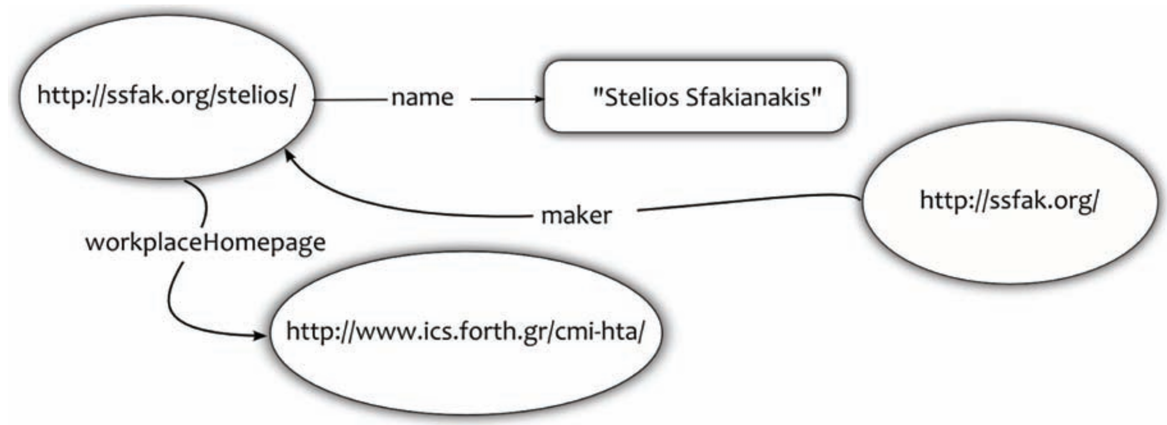


be further processed to generate more information. Moreover ontologies and their less powerful relatives like taxonomies and thesaurus provide the means for achieving a common interpretation of a domain and a shared understanding of the concepts and relationships involved. In the Semantic Web there are two main technologies for providing such rigor: RDF Schema and OWL (Brickley & Guha, 2004; Dean, Schreiber, et al., 2004). RDF Schema provides the means for defining classes, class hierarchies, properties, property hierarchies, and property restrictions. Its expressive power is basically limited to the representation of concepts, their relations, and taxonomies of concepts. On the other hand the Web Ontology Language (OWL) was introduced to address the need for more expressiveness and extends the RDF Schema by providing three variants: OWL-Lite, OWL-DL, and OWL-Full. Without delving into details, the different species of OWL provide different degrees of expressiveness and are able to define existential restrictions, cardinality constraints in properties, property types like inverse, transitive, and symmetric, and a lot more. The added features of OWL allow the ontologies built in conformance to it to be formally treated and the data represented are amenable to "reasoning" and inference, i.e. they can be processed according to formal logic rules to deduce new information. All these happen on the basis of the Web infrastructure: RDF resources and their URI references are used, the open world assumption is followed, since partial information on the Web is a quite frequent phenomenon, and the ontologies themselves can be freely intermixed and meshed since hyperlinks are employed everywhere.

Since RDF is the common interchange and representation model of information, the Semantic Web transforms the hyperlinked syntactic World Wide Web to a huge database or a Global Giant Graph, as Tim Berners-Lee put it. The standard query language for this huge database is SPARQL (Prudhommeaux & Seaborne, 2008), which is similar to SQL. In addition to the query language the SPARQL standard defines an application protocol for the submission of queries to RDF sources and the retrieval of results. With the query language and the access protocol defined, the SPARQL specifies a Web friendly interface to RDF information, whether this is actually stored as RDF triples or not. It is therefore feasible to make SPARQL queries to relational or other databases through an appropriate wrapper or transformation process that translates, either online or in some preprocessing step, the internal data to an RDF compliant format. As a result these Semantic Web technologies enable the connection of data between different and heterogeneous data sources, effectively allowing data in one data source to be linked to data in another data source. (Bizer, Heath, Idehen, & Berners-Lee, 2008)

SOCIAL SEMANTIC WEB

In recent years the cross pollination of Semantic Web technologies and Social Networking has emerged as an interesting roadmap. The Semantic Web technology can significantly enrich and expedite the Social Web in order to establish the *Semantic Social Web* (*Greaves, 2007;*Gruber, 2007*).* In the Semantics-enabled social Web content can be easily connected, integrated, navigated, and queried so that the benefits of today's Social Web can be greatly enhanced and augmented beyond the limited user experience offered by social networking sites alone or the restricted keyword based search and matching.

What does the Semantic Web offer to the Social Web? First and foremost, the Semantic Web technologies can be used to provide rigor and structure to the content of the user contributions in a form that enables more powerful computation. Currently social Web applications are more focused on the distribution and the management of content and the social interactions around it rather than the provision of Semantically rich descriptions of the data. Although there are popular, "low end" technologies like "microformats" and tagging/"folksonomies" to cater for the annotation and the description of data, these seem to be ad hoc and unstructured efforts in comparison to the formal Web ontologies and metadata descriptions. On the other hand, as already described, the Semantic Web promotes the global distribution and integration of resources in a single, giant, interoperable graph. So, additionally, the standards and infrastructure of the Semantic Web can enable data sharing and computation *across* independent, heterogeneous social Web applications.

Furthermore, the Semantic Web can enhance the Social Web with additional intelligence as Jemima Kiss (2008) wrote:

If Web 2.0 could be summarized as interaction, Web 3.0 must be about recommendation and personalization.

An example of such added value is the case of Semantic Wikis (e.g. Schaert, 2006; Völkel, M., Krötzsch, M., Vrandecic, D., Haller, H., & Studer, R., 2006). The Semantic Wikis support the annotation with Semantics descriptions the links and the content they provide and take advantage of these annotations for providing more intelligent search and navigation. The annotation is usually done by some extended version of the Wiki editing syntax so that every link to another page or any important attribute of the current page is annotated with a property identifier. For example in a Semantic Wiki's page about the Europe the amount of its population, which is a number, can be wrapped with the appropriate metadata that denote that this number represents the population. Such metadata annotation makes structured search easy, e.g. for queries like what is the population of Europe, or which continents have population above a certain amount. Additionally it facilitates the users in providing more active content in the pages by incorporating "online queries" in the Wiki pages, in the sense that the page's content can be dynamically generated by the results of these queries on the metadata annotations. Although the details may vary from one implementation to another, there's usually an underlying model based on RDF and OWL to support these Wikis and the content can be exported in a Semantic Web compliant format. DBPedia is an interesting example of a truly Semantic Web Wiki which offers the content of Wikipedia in a machine-readable and searchable format (Auer et. al., 2007).

In another application area, Semantic Web technologies can facilitate the browsing experience of people and the searching capabilities of the Web search engines. Unlike traditional search engines, which "crawl" the Web gathering Web pages information, Semantic Web search engines index RDF data stored on the Web and provide an interface to search through the crawled data. Because of the inherent Semantics of RDF and the other Semantic Web technologies, the search and information retrieval capabilities of these search engines are potentially much more powerful than those of current search engines. Examples of such early Semantic Search Engines include the Semantic Web Search Engine (SWSE, http://www.swse.org/), Swoogle (http://swoogle.umbc.edu/), and Zitgist Search (http://www.zitgist.com/). These and other Semantic Web search engines explore and index the documents of the Semantic Web and its ontologies by the means of user friendly interfaces that hide the details and complexities of the technology.

Blogs, which are one of the most prominent examples of the Social Web, can also be enhanced with Semantics. Augmenting a blog with content and structural metadata is usually called Semantic Blogging (Cayzer, 2004; Bojars, Breslin, & Moller, 2006). Putting Semantics in a blog's contents means that the topic of the content is described in a machine processable way. On the other hand describing the structure of the blog Semantically entails the description of the entities that compose it: the posts, the comments, the users, etc. To this end there are a number of efforts to make the Semantic Web more social by building new ontologies to support people in their social interactions and provide Semantics to the Social Web. Two of such ontologies, SIOC and FOAF, are of particular importance in the context of Semantic Blogging and are described below.

SIOC

Existing online community sites usually provide rich information for specific interest groups but they are isolated from one another, which makes difficult the linking and merging of complementary information among different sites. The Semantically-Interlinked Online Communities (SIOC) project aims to link online community sites using Semantic Web technologies. It defines methods to describe the information that communities have about their structure and contents, and to find related information and new connections between content items and other community objects. SIOC again is based around the use of *machine-readable information* provided by these sites.

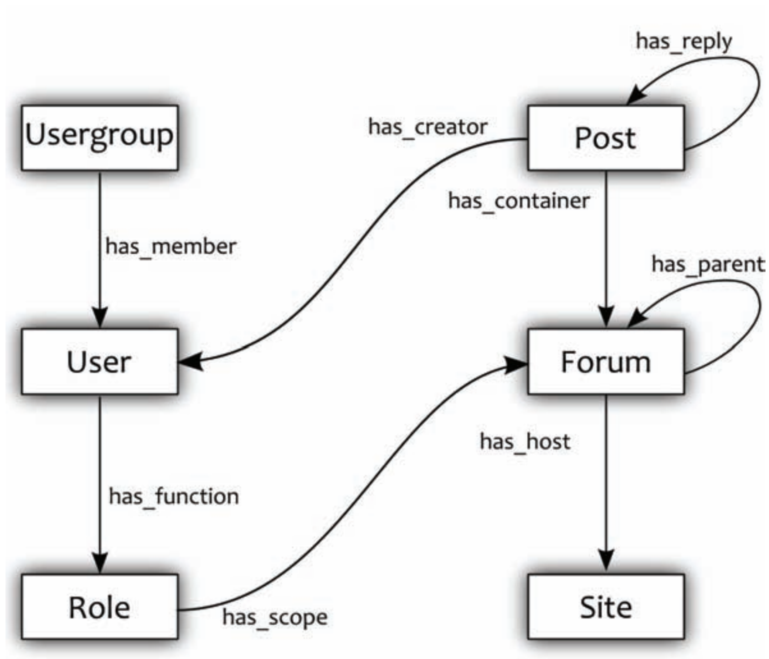
The main entities of SIOP are shown in Figure 7 and it's easy to see the role and the function of the main concepts. The entity Site refers to the location of an online community or set of communities, which hosts one or many blogs. A Forum can be thought of a discussion area on which posts are made. In a Forum a number of posts are contained where a Post represents an article or a message send by a user to the forum. Posts can be connected as people reply to previous posts and these connections can cross site boundaries since the identifiers of posts (as well as any Semantic Web resource) are universal and unique.

From the figure above it can be said that SIOP defines a common schema for the different blog sites and discussion forums. This of course needs not be their internal schema but a common, shared, and standard representation of their information model. Adopting SIOP therefore is a major step in achieving the integration of social content in Web 2.0.

FOAF

The Friend-Of-A-Friend (FOAF) project focuses on expressing mostly personal information and relationships in a machine-readable form. A central entity in the FOAF vocabulary and the one most frequently used is the Person (Figure 8). According to FOAF a Person may have names, e-mails, interests, publications, etc. It can also be connected to other resources like the Web site of the organiza-

Figure 7. The main classes and relationships of SIOC



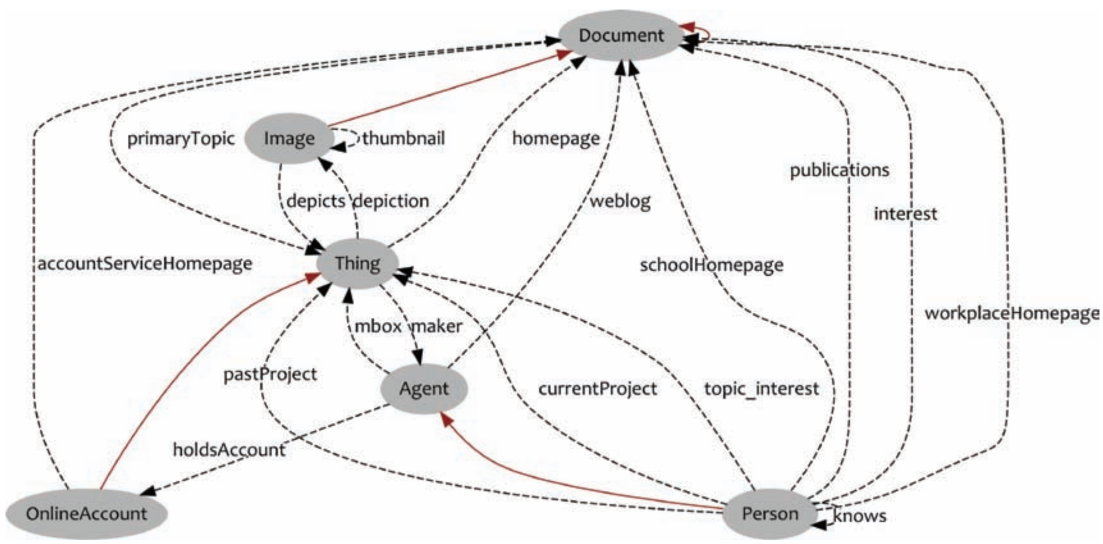
tion he/she works for (foaf:workplaceHomepage property), a personal blog site (foaf:weblog), the Website of his/her school (foaf:schoolHomepage), or to other people that he/she knows (foaf:knows). A lot of personal information can be therefore represented and parts of the real world's social graph can be inferred by following the foaf:knows relationship.

Of particular importance to the Social Web is the support the FOAF vocabulary offers to link the physical persons (foaf:Person) to the accounts they hold in a number of social Web sites (e.g. Flickr, Facebook) through the foaf:holdsAccount property. It is therefore possible through a single FOAF document that could be indexed in a Semantic Search engine to join all these different accounts and the information each of them exposes. Integration of different social content and behavior can be achieved and the resulting graph of information is searchable in an unambiguous and machine interpretable way.

Semantic Web Services

Application integration requires an agreed infrastructure to be in place for the exchange of information over the network. Over the last couple of decades there have been several attempts for defining such an infrastructure, such as Sun/RPC, CORBA, Microsoft's DCOM, Java RMI, and others. Currently Web Services are the favorite and most popular technology for building distributed systems over the Internet. As a middleware technology Web Services represent a new generation that tries to mitigate the problems of legacy integration technologies such as CORBA by adopting a more Web friendly substrate. Such a different approach seems to be needed in order to support business-to-business integration over the Internet where crossing organization borders has implications on the security, interoperability, scalability, maintenance, flexibility, and other aspects of application integration. In order to achieve these goals the Service Oriented Archi-

Figure 8. The main classes and relationships of FOAF



tecture (SOA) has been proposed. Informally speaking, in such architecture (Web) Services are network accessible entities that offer a number of functionalities to their callers. The SOA environment should be highly dynamic as suggested by a number of real world phenomena, like network instability, changing real world requirements and settings, etc. The need for "late binding" of services and clients is important and Figure 9, depicting the main entities of SOA and their interactions, shows that a middle service repository or registry is introduced. This repository stores "offers" of functionality as these are published by service providers, and subsequently performs matching with the corresponding "requests". After some matching has been performed the corresponding parties (services and their clients) are free to communicate and exchange data.

On the technology side Web Services put more emphasis on the following:

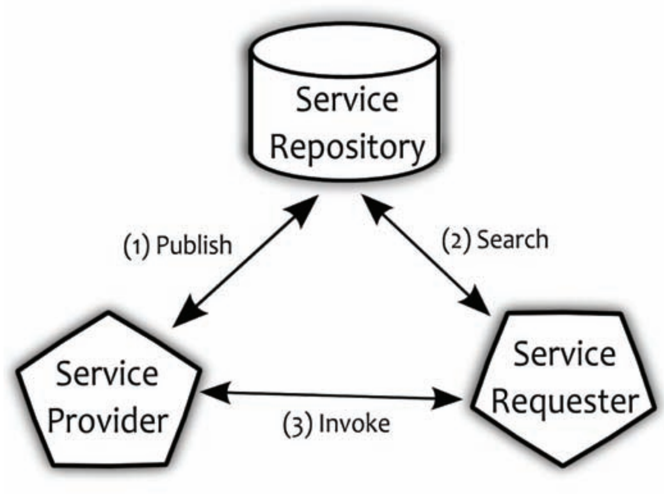
- Transport over widely accepted Web and Internet protocols like HTTP/HTTPS and SMTP
- XML message payloads to provide the extensibility, introspection, and interoperability required in building complex multi party systems
- Platform and programming language independence

The Web itself is built around these very directions: open protocols, text based (markup, e.g. HTML) message and document content, and abstraction over implementation details. In essence the underlying infrastructure is roughly based on the following technologies:

- SOAP messaging format, which is based on XML, to provide a wrapper format and protocol for data interchange between Web services
- Web Service Description Language (WSDL) documents to describe the services' functionality and data exchange

On top of these a number of standard technologies have been specified for handling discovery (UDDI), security (WS-Security), trust (WS-Trust), composition (WSBPEL, WSCL), etc. Nevertheless for this discussion the WSDL standard is the most pertinent specification because it specifies

Figure 9. Web service architecture



in a machine readable format the structure of the XML messages exchanged.

Integration of computation and functionality is an additional field where Semantic Web shows a great potential of use because the Web Services, at their present incarnation, provide syntactic interoperability only. The WSDL service descriptions are restricted to the syntactic aspects of service interaction: how the service can be invoked, which operations may be called, what are the number and the type of the parameters each operation needs, etc. However, what the service does and in what order its operations have to be called in order to achieve certain functionalities is usually described only in natural language either in the comments of a WSDL description or in UDDI entries or other documentation. *Semantic Web Services* (McIlraith, Cao Son, & Zeng, 2001) is an "umbrella" definition to include the annotation of existing Web services with Semantics and their publication, discovery, and composition.

The vision again is to make feasible the machine to machine communication by providing machine interpretable descriptions of the services. Such descriptions will make possible the automatic discovery, composition, and invocation of services. Because of this a lot of efforts in metadata descriptions are centered on the Semantic Web and its technologies, namely RDF and OWL. In the area of the Semantic Web Services the following technologies and standards are relevant to the Semantic description of Web services:

- **UDDI (Universal Description, Discovery and Integration)** allows the discovery of potential business partners on the basis of the services they provide. Each business description in UDDI consists of a businessEntity element that describes a business by name, a key value, categorization, services offered (businessServices) and contact information for the business. Each businessService element contains descriptive information such as names and descriptions, and also classification information describing the purpose of the relevant Web service. Using UDDI, a Web service provider registers its advertisements along with keywords for categorization. A Web services user retrieves advertisements out of the registry based on keyword search. So far, the UDDI search mechanism relied on predefined categorization through keywords, but more recently specifications to use OWL in UDDI are emerging as a uniform way to express business taxonomies.

- **Semantic Annotations for WSDL and XML Schema** (SAWDL; Kopecký et. al., 2007) is a means to add Semantics inline to WSDL. It is actually a set of extensions to WSDL 2.0 but can also be used for WSDL 1.1. With these extensions the service provider can attach references to Semantic concepts for the functionality of an operation or the type/meaning of a parameter and additional information for the transformation (mapping) of the XML data either to ("lift") or from ("lower") the corresponding Semantic terms. The Semantic domain model used is external to these annotations and could be expressed in OWL or other ontology language of choice.
- **OWL-S** (formerly DAML-S) builds on top of OWL and allows for the description of a Web service in terms of a Profile, which tells "what the service does/provides", a Process Model, which tells "how the service works", and a Grounding, which tells "how to access the service" (Martin et al., 2004). The service profile describes what is accomplished by the service, any limitations on service applicability and quality of service, and requirements that the service requester must satisfy in order to use the service successfully. The process model gives details about the Semantic content of requests, the conditions under which particular outcomes will occur, and, where necessary, the step by step processes leading to those outcomes. In the process model a service can be described as an atomic process that can be executed in a single step or a composite process that, similar to a workflow, can be decomposed in other processes based on control structures like 'if-then-else' and 'repeat-while'. Finally, Grounding descriptions supply information about the communication protocol and other transport information (such as port numbers) and the message formats and serialization methods used in contacting the service. The only currently specified grounding mechanism is based on WSDL 1.1 and will be extended to WSDL 2.0 as soon as it's finalized.
- **The Semantic Web Services Framework (SWSF)**, initiated by the Semantic Web Services Initiative (SWSI, 2004), includes the Semantic Web Services Language (SWSL) and the Semantic Web Services Ontology (SWSO). SWSL is a logic-based language for specifying formal characterizations of Web service concepts and descriptions of individual services. SWSO is an ontology of service concepts defined using SWSL and incorporates a formal characterization ("axiomatization") of these concepts in first-order logic.
- **WSMO (Web Services Modeling Ontology)** defines the modeling elements for describing several aspects of Semantic Web services (Feier et al., 2005). These elements are Ontologies, which provide the formal Semantics to the information used by all other elements, Goals which specify objectives that a client might have when consulting a Web service, Web services that represent the functional and behavioral aspects which must be Semantically described in order to allow semi-automated use, and Mediators that are used as connectors and they provide interoperability facilities among the other elements. It also defines the Web Service Modelling Language (WSML) which formalizes WSMO and aims to provide a rule-based language for the Semantic Web.
- **BioMOBY** (http://www.biomoby.org/) is a Web Service interoperability initiative in the field of bioinformatics aiming to facilitate the integration of Web-based bioinformatics resources. Currently there

are two approaches to achieve such integration: The first approach, based on the Web Services paradigm, is referred to as "MOBY Services" (MOBY-S), while the second one is called "Semantic MOBY" (S-MOBY) and is based on concepts from the Semantic Web. MOBY-S uses a set of simple, end-user-extensible ontologies as its framework to describe data Semantics, data structure, and classes of bioinformatics services. These ontologies are shared through a Web Service registry system, MOBY Central, which uses the ontologies to Semantically bind incoming service requests to service providers capable of executing them. S-MOBY on the other hand employs RDF and OWL and the document oriented infrastructure of the WWW (the GET/POST methods of HTTP) for publishing and retrieving information from its discovery servers.

As shown above this is an area of active research. So far SAWDL enjoys the approval of W3C being one of its recommendations but of course is lacking when compared with WSMO and OWL-S. Nevertheless SAWSDL can be combined with these most prominent technologies and it remains to be seen whether such approaches are adequate or something more powerful should be introduced.

CONCLUSION

The social aspects of the Web show an uprising evolution and all the indications imply that this trend will continue. The current Web 2.0 sites are quite successful in attracting people share their data and interests, and build online communities, but the next step will be to enrich them with more Semantics in the lines of the Semantic Web to provide a unifying platform for people and machines to use and collaborate. The need for Semantics (Breslin & Decker, 2007) is evident for enhancing the social networking sites with advanced filtering and recommendation services and also to provide data portability and integration between different sites and networks. This is an active area where the Semantic Web technologies can greatly help.

There have been a lot of discussions about what will be the "killer application" of the Semantic Web, which means some breakthrough in the domain that will show beyond any doubt the full potential of the Semantic Web. Nevertheless we think that Semantic Web technologies are used slowly and without much "noise" in a lot of different areas and as "extension to the existing Web" are not clearly visible but are certainly catching on. There is a common view nowadays that the Semantic Web will not supersede the Syntactic Web in any way but they will happily coexist in a symbiotic manner: the Web of documents will be enriched by the Web of data and information.

In terms of the core infrastructure what we see as emerging trend is the use of simple REST Web services (Fielding & Taylor, 2002) that present a small entry barrier and a transition from the SOAP and WSDL Web Services technologies backed by big commercial corporations like IBM and Microsoft to more flexible and agile architectures. These architectures are more bound to the existing Web and also are more Semantic Web friendly since they share common basic infrastructure and interaction protocols (e.g. Web protocols like HTTP used as application protocol and not for transport, full support for URI to access network resources and Semantic concepts, etc.). The whole history of the Web clearly shows that successful distributed systems of this scale are built on open access, open protocols, and open source methodologies combined with collaborative behavior by the people (developers, users) involved.

Research questions and issues for further investigation abound in this Semantic new world. First of all the issue of trust and security and how this is incorporated in the Semantic Web machinery should be tackled on. For example currently a user can claim anything in his FOAF document, or a malicious application can publish RDF information that contains false statements. The notion of identity and validation of the identity is important and there is ongoing work in this area, e.g. the incorporation of user certificates or Web based authentication mechanisms like OpenId[8]. Semantic Web has also increased demands for supporting indexing and reasoning over the managed content. The scalability concerns are real when we think about a Semantic Web search engine of the size of Google. Finally the adoption of these technologies by the users needs work to be done in the presentation layers as well. Easy to use, friendly, and functional user interfaces are necessary for making the transition to the Semantic Web more painless and transparent for the users.

KEY TERMS

Semantic Web (SW): The creator of the World Wide Web Tim Berners-Lee defines the SW as "a web of data that can be processed directly or indirectly by machines". A similar definition coming from the World Wide Web Consortium (W3C) describes the Semantic Web as "a Web that includes documents, or portions of documents, describing explicit relationships between things and containing Semantic information intended for automated processing by our machines."

Social Web/Web 2.0: The way people socialize and interact with each other through the World Wide Web. This term is also used to denote a large number of Web sites that are devoted to people and their social interactions through the creation of online communities of users that share digital content and information, discuss, or enable communication in any possible, Web-facilitated way.

Web Service (WS): A Web Service is defined by the World Wide Web Consortium (W3C) as "a software system designed to support interoperable machine-to-machine interaction over a network". Since this definition is quite general the term "Web Service" commonly refers to systems that communicate using XML messages that comply with the SOAP messaging format. In such systems, there is often machine-readable description of the operations offered by the service written in the Web Services Description Language (WSDL).

Chapter 1.27
Technological Social-ism

Judson Wright
Pump Orgin Computer Artist, USA

ABSTRACT

Culture is a byproduct of our brains. Moreover, we'll look at ways culture also employs ritual (from shamanistic practices to grocery shopping) to shape neural paths, and thus shape our brains. Music has a definite (well researched) role in this feedback loop. The ear learns how to discern music from noise in the very immediate context of the environment. This serves more than entertainment purposes however. At a glance, we often can discern visual noise from images, nonsense from words. The dynamics are hardly unique to audial compositions. There are many kinds of compositional rules that apply to all of the senses and well beyond. The brain develops these rule sets specific to the needs of the culture and in order to maintain it. These rules, rarely articulated, are stored in the form of icons, a somewhat abstracted, context-less abbreviation open to wide interpretation. It may seem somewhat amazing we can come up with compatible rules, by reading these icons from our unique personal perspectives. And often we don't, as we each have differing tastes and opinions. However, "drawing from the same well" defines abstract groupings, to which we choose to subscribe. We both subscribe to and influence which rule-sets we use to filter our perceptions and conclusions. But the way we (often unconsciously) choose is far more elusive and subtle.

INTRODUCTION

Language may have both a hard-wired component in our DNA, and a learned component (Chomsky, 1977). Neither is operable without the other. Or at least we don't get language without both. This is a debatable theory, yet very useful to us. If spoken languages could be thus constructed/understood, it seems sensible that non-verbal languages could also follow this organization. Fundamentally each are means of using symbols to represent ideas we want to transfer from our minds into another's (Calvin, 1996a).

Furthermore, it appears likely that where music operates neurologically on a (non-verbal) linguistic level, it too is organized in this dual fashion. Music also obeys both fundamental laws and is influenced by the immediate culture, while influencing it. Music serves cultural cohesion on a neuro-level (shown in many modern studies thanks to the fMRI (Levitin, 2006; Doidge 2007). In many cases, mu-

DOI: 10.4018/978-1-60566-352-4.ch020

sic, culture and the neural result are inextricable (Huron, 2008).

The way humans use musical instruments extends well beyond providing entertainment. We choose to employ a drum to speak to our own minds and the minds within others (more about this later), even if we are doing so with no knowledge of it, or intention in manipulating brain waves. But essentially, we mustn't forget that these instruments are tools at our disposal, they are also technology whether old or new. However we use the net, it is also a tool. Its ultimate product "cyberspace", shares many important features with music and cultural cohesion as well. Thus our big question becomes: if culture informs the web and visa versa, what neurological impact is it being used for?

In other words, asking a tribal member why a certain drumbeat is used in a ceremony gets you one answer. It is not at all the wrong answer (Narby, 2001). But asking an anthropologist or neurologist who studies the effects of "deep listening", gets a very different answer. The beat ultimately is used to hold the culture together hypnotically.

Let's consider the modern equivalent of a drum though. It is a tool, one that has neurological effects, which may be one reason we use it. Oddly though, we often do not employ computers as tools but as human substitutes. Instead, the tasks for which computers are commonly employed are strangely inappropriate. We pretend they function as specialized brains.

Human brains accomplish most thinking (perceptive and conceptual) by means of switching logically between inductive and deductive reasoning (Dewey 1910; Fodor, 2000; Hawkins, 2005). Computers, with no means of comprehending or creating anything remotely like context, accomplish tasks using only a limited version of deduction[1]. Some inductive reasoning can be accomplished with a computer by iterating through every single possibility (by making the question deductive). But in real life, this is absurd. Real problems have either infinite unknown possibilities or at least unpredictable ones. Computers simply can't solve things humans can. And we still have no clue as to how we do it.

John Dewey (usually required reading for educational studies) published a very good account of "How We Think" in 1910. It happens to stand as a very good description of how computers don't think. Boolean Logic (Hillis, 1998) and *modus ponens* have been common subjects in Philosophy, Logic, Psychology and Cog Sci for much longer than computers have been on the open market. But no one questions that there is more to human brains and thought than these formalizations. In other words, this is old news from rather common sources. So why have we resisted what should plainly be ingrained into our habits of thought, just to bang our heads against the wall?

On the flip-side, though most of us may want computers to accomplish human functions (as in security facial recognition or recognition of written words), we aren't all actually working on these things first hand. Instead, most of us are using these same machines primarily to store and send strings of text (email, the web, word processing, spread sheets, …). The processor is minimally involved in just delivering a copy from one terminal to another. This is hardly a harmful or bad use. But it certainly doesn't warrant the fancy hardware. Not even close.

The Bigger Picture

An oft posed question: are we guided by technology? is certainly a valid, common sense approach to the issue. However, the answers it produces are necessarily misleading. It is a question like 'When did you stop beating your wife?' There may well be an accurate way to answer, but no satisfying response. Why?

Every question belies a symptom of one particular perspective. From our traditional point of view, the question is rather logical. But in looking at this issue, we need to divorce ourselves from reductionism. Specific views, whether positive or negative vectors, typical of disciplines, cancel each other out. Such margins of error and signal noise are negligible when we get far enough away to view the bigger picture. Specificity is a good thing, but sticking to one small area is not. We need to continually ricochet to a much broader range of subjects. Not adhere to any exclusively. Thus, we will be drawing from neurology, mythology, anthropology, art history, and music theory alike. Applying the ideas of Eric Hoffer on political revolutions to Jeff Hawkins' modern perspective about computers and neurology, musically induced trance states to occurrences of mass hysteria, the psychological theories of Jung to Chomsky's linguistic theories, prove all the more enlightening when taken together.

Why do we choose to delineate between "science", "art", "social work", "exercise" at all and not make all disciplines one? After all much can be culled from one "expert", when applied to other subjects. Obviously, these delineations are breaking down. They are habits of traditional academic organizational systems that we are shedding.

There actually is a deeper rhyme to this reason, albeit a bit arbitrary. Since we humans can only focus on smaller numbers, we justifiably have used somewhat artificial schemes to break up the overwhelming sea of data into categories and subcategories, until the pieces are more easily digestible to the majority of human minds. *Chunking* is a function of our perceptivity and not an a priori reality in nature (Solso, 2003). Incidentally, we tend to project our own limitations onto our inventions. Computers do also have harsh limitations, but this is certainly not one of them[3].

We are finding there is no "normal" when it comes to our mental abilities (Gardner, 1983). Why this is so slowly seeping into our (Western?) culture is certainly a peculiar phenomenon. Despite what we may have been taught, all of us probably actually prefer to organize in a very personal way, though are often pressured into "doing it right". Others of us, who appear to "organized" people as being "disorganized", are often really "pile people". Stacks of papers are arranged not alphabetically, topically or chronologically, but in an ongoing process of convenience. In several ways, a computer is the ultimate pile person. Organization, merely a lens, does not even exist out side our minds (or at least we can never prove it) and can only really be seen by indirect means.

Piaget explained that children assume their thoughts are the only thoughts animating and motivating everything around them (toys, the rain, the moon, etc.) We adults do so too, not out of egocentrism, but often because we do not fully distinguish between our compulsive tendencies toward reductionism and our projection of reductive organization onto chaotic sensory input (Piaget, 1951). Taxonomies are really just more chaos lumped onto chaos – accept (sometimes) to us.

Pina Bausch is a choreographer. In a performance, the dancers appear on stage with piles of sand and begin making castles. (Bausch, 2002) Of course they didn't take classes to learn to play with sand, yet if they did, would this course "Sand Castles Building 101" be found under dance, architecture or child development? Labels, being another element in internal mental organization, are readily classifiable. But icons don't always fit nicely. A behavior pattern as a metaphor for play, childhood, exploration, discovery, all rolled into one, is an icon. The castle is hardly the end goal, but the activity is. The end is a verb, not a noun and not an end at all but an ongoing process. We traditionally categorize in terms of nouns, at least on paper, but not in our subconscious (Calvin, 1996; Sacks, 1996), and it doesn't happen in nature (Gordon, 1999; Johnson, 2001), only in our bloated cortexes.

Our use of the web casually confuses the label and the icon. Labeling icons, we often miss more important aspects of the data. The molecules of vapors, as well as their undulating interaction, that defines a cloud, are not organized according to the Dewey Decimal System. Placing them in some sort of linear framework renders the entire thing no longer a cloud at all.

Blind conviction goes much deeper than egotism or even ego-ism. In his history of psychology, Morton Hunt describes the birth of Gestalt psychology. In particular, a few researchers (Duncer is one) began looking at how we solve problems using tools.

In one situation, for instance, the subject was asked to mount three small candles on the door at eye level, ostensibly for 'visual experiments'. On the table were some candles, a few tacks, paper clips, pieces of paper, string, pencils, and some other objects, including the crucial ones: three small empty cardboard boxes. After fumbling around, every subject eventually restructured his view of the things at hand and saw that the boxes could be tacked to the door and used as little platforms to mount the candles on.

But in another version of the problem, the three boxes were filled, one with little candles, the second with tacks, and the third with matches. This time fewer than half of Duncer's subjects solved the problem. They had seen the boxes being used for a specific purpose, and that made it harder to see them as usable in an un-boxlike way. (Hunt, 1993, p. 298)

I. LOOKING BEYOND

The Collective Unconscious

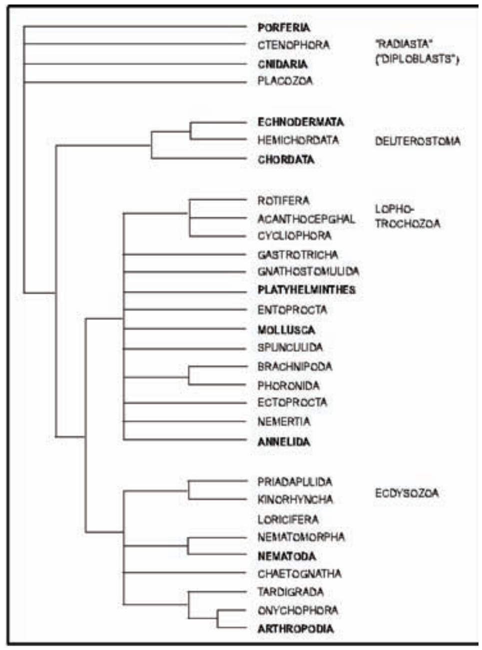
The term "Collective Unconscious" refers to a shared iconography across cultures, time, and distance (Campbell, 1972; Opler, 1994). The term was coined by Carl Jung (Jung, 1919)[2] who writes "In addition to the personal unconscious generally accepted by medical psychology, the existence of a second psychic system of a universal and impersonal nature is postulated. This collective unconscious is considered to consist of preexistent thought forms, called archetypes, which give form to certain psychic material which then enters the conscious. Archetypes are likened to instinctual behavior patterns." (Jung, 1968, p. 451). Jung's points are well taken, but his context is the milieu of psychology in Europe in the first part of the 20th century. He wasn't talking about technology at the beginning of the 21st. Yet, much can be culled by revisiting his ideas.

Jung begins by ruminating about "simple" instincts like thirst, shows that simplicity/complexity are entirely subjective human projections. He soon focuses on the *archetype*, a type of instinct. This may seem problematic, since archetype seems to necessarily imply analysis by the consciousness. But he seems to be discussing archetypes in some abstracted (*pre-conscious*?) form. Joseph Campbell explains this way.

All my life, as a student of mythologies, I have been working with these archetypes, and I can tell you, they do exist and are the same all over the world. In the various traditions they are variously represented, as, for instance, a Buddhist temple, medieval cathedral, Sumerian ziggurat, or Mayan pyramid. The images of divinities will vary in various parts of the world, according to the local flora, fauna, geography, racial features, etc. The myths and rites will be given different rational applications, different social customs to validate and enforce. And yet the archetypal, essential forms and ideas are the same – often stunningly so. And what then are they? What do they represent?

The psychologist who has best dealt with these, best described them and best interpreted them, is

Figure 1. Nature doesn't classify animals, we do. And we do it impulsively. This phylum diagram was surprisingly easy to compile because the hundreds of such charts throughout the world are all organized almost identically. Even cultures that do not share this biological data, arrange animal classifications this hierarchical way according to easily-observable classifications.



Carl G. Jung, who terms them 'archetypes of the collective unconscious,' as pertaining to those structures of the psyche that are not the products of merely individual experience but are common to all mankind. (Campbell, 1972, p. 216)

The Collective Unconscious has since taken on far broader applications. Other books that talk about the Collective Unconscious include *The Universal Collective Unconscious and Metaphysical Utopia*, *The Complete Idiot's Guide to Being Psychic*, *Buckland's Complete Book of Witchcraft*, *Mastering Astral Projection: 90-Day Guide to Out-of-Body Experience*, *Ouija: The Most Dangerous Game*. It may seem easy to be disparaging of these titles. However, like Jung's, they are driven by a core idea, and a very astute one. Where they take it is a detail, informed by a chosen culture.

While witches, evangelists and self-help authors have all taken the term Collective Unconscious to far broader definitions than the original conception. Collective Unconscious may not necessarily be limited to mythology per se, but need not be extended to speaking with the dead. Is there a similar a repository, broadly accessible to many, containing shared cultural information? Of course. The web.

Music's Role in Ritual

Now let's turn to the question of how we are effected by various kinds of collective unconsciousness-es. To begin to answer, we will look at how we humans determine and define our cultures, a matter of iconography and ritual. Why exactly do all cultures, often independently of others, make songs?

Perhaps you are familiar with such studies where music is the tool, used in rituals. Natives beat drums not just to entertain. In the West, *The Mozart Effect* (Campbell, 1991) is an interesting illustration of this phenomenon, but even war chants (Sacks, 2007) are fitting examples. Aside from its aesthetic role, music indirectly influences behavior on several levels. Prolonged attention to a beat, tends to excite the thalamus (or so many suspect), and/or bring about a *trance state* in the brain (Levetin, 2006). The neural activity creates subtle, yet complex electric frequencies. In particular, trance states marked by increased Theta waves, from 7-9 MHz. (Robbins, 2000). This occurs to varying degrees both in the performers and the individuals partaking in ritual.

Hypnosis is often seen as un-masculine and shunned in Europe and the US, but in most of the world and throughout most of human existence, it continues to play a leading role in social interaction. However, it still sneaks into our lives in many forms, from opera to rock stars (Hunt, 1993; Rouget, 1985). Like babbling language, perhaps we just can't help it (Crystal, 2005).

A good example of the integration of music and trance is the Balinese Bebuten ceremony. In it participants/dancers plunge daggers into themselves. They do so, acting out a fierce battle between mythical beasts and a witch who has placed a curse on the community (Becker, 2004). They are not so much intending to hurt themselves though. Even under hypnosis, they are fully aware. Maybe even more so. As such, they are transformed into limbs of the community atoning for the tribe, not as representatives, but as appendages of the given social system. By acting out this scene, they are hoping to suggest a new fate for the community and scaring the spirits that are responsible for their luck. The self is entirely enveloped into the "world" (environment) or nether worlds (as defined by the culture) at this point.

The actual logic behind this enactment is not really important, and that is precisely where many foreign observers studying these ceremonies become missionaries rather than scientists (Sells, 1996; Daniélou, 1991; Narby, 2001). Many seemingly obvious factors don't make perfect sense to a removed observer. Their desire to create and adopt shared goals overrides "logic". It actually appeals to a different memory system (LeDoux, 1996; Sacks, 2007). Though emotional memory and episodic memory can influence each other, often they don't. Thus we don't always realize we are reacting to memories. In effect, these performers are accessing a parallel mind. A mind unlocked by music.

One may decide that the participants' interpretations of their motivations are unrelated to the result. For example, that solidarity as a result of these highly emotional rituals may have more influence on defending against invaders than appeals to spirits. This would be a condescendingly smug view. If the enemy invaders are thwarted (or aren't) does it really matter why on a neurological level? Couldn't solidarity with ones peers be inseparable from favor from the gods? Perhaps the brain is merely a radio antenna tunable to the gods? The cynic very importantly chooses to be missing just as much as the fanatic.

In other cases, the subject undergoing the trance is the performer or shaman (Narby, 2001). A more modern example is the young James Brown (Lethem, 2006) whose act intentionally referenced Baptist revival services, which, in turn, borrowed heavily from trance-inducing rituals around the world, particularly from Africa in the 1700's. Brown's ritualistic performance, with his spasmodic yet intricate footwork, ultimately breaking down and covered by a cape, modeled on older rituals, was quite literally a religious experience for many.

Psyching the self up for these rituals is what gives them their effective power. Expectations and acoustics work in tandem. Though trance states are clearly a bio-mechanical function between the brain and the environment, seldom are the rituals effective without a learned expectation of effectiveness[4] (Becker, 2004; Alderage & Fachner, 2006). A ceremony is designed to drive the "witch doctor" to a frenzied state, where the audience is moved sympathetically (Levetin, 2006). As with James Brown, you might begin as an observer, enjoy the show, get more into it, and finally let loose dancing yourself as a very active participant. Perhaps even inspiring the dancer next to you to more enthusiasm. This process happens in many forms. Anecdotes about moving post-9/11 memorials tend to begin with the individual's surprise at their strong emotional reaction and go into how swept up the group became, usually involving singing or music. This is not to say that they weren't actually swept up. But to be swept up, often involves being carried away with others, often employing a hypnotic medium, such as song. Is hypnosis a relinquishing of control? One could just as easily say, this unleashes the "real" self, that's been suppressed.

These rituals serve a dual purpose. By yielding to the community, individuals' problems are, at least temporarily, put aside, for the sake of solidarity. They can also help curb out of control emotional feed-back loops on a neurological level[5], containing unleashed cycles. Fewer cases of pent up rage is certainly good for everyone in the community.

As individual desires are yielded to the will of a team (even if it is never spoken, articulated), we elect to hone the priorities of that culture, like healthier crops, appeasement of a spirit, etc. and develop strategies for working toward them. Common needs create a sense of community, a oneness, where one's super ego is dissolved into a greater life force.

The *deep listener* of pounding tribal drums or the healer's maracas becomes not so much at one with a god per se, but one with a culture (Becker, 2004). Dancing to the pounding bass frequencies of modern music, we may forget we are in a subway car. Individualism is (temporarily) lost, a drop that has been added to the sea. That drop may only wield so much influence alone, however as part of a tide yields unlimited influence. The same is true for the web.

"Teamwork" has a positive ring to it. In small scales, likely groups under 50 (Gladwell, 2000), it probably does more good than harm. Fusing an identity from a small group is hardly infallible, for example the Manson Family, but usually eliciting good (though rarely great, as we'll see later) results in the workplace. On a larger scale however, there may be more examples like the Moonies than Martin Luther King. But who could say? Certainly Gandhi, Lincoln, Roosevelt, etc had positive impacts, though also lead a lot of followers enthusiastically to their deaths.

The point here isn't that conformity or group-think is always bad, but that only individuals seem capable of assessing if the final decision warrants action. And we can't be both completely self-aware individuals and completely faithful members. Why do we gravitate toward such dual polarism (Goffman, 1959)? For some reason, we are fed the belief that individuality is situated at one end of a spectrum and often mutually exclusive from cohesion. But thus linearly arranged, the median of opinions as a result has no real value. There is no useful center point. Often the only way to maximize both positions is to move freely among these extremes, respecting and supporting each, but always with an eye open to abuses and harm that can come from either. While unwavering unconditional faith can be fool-hearty, a constantly critical stance would prohibit true immersion and lead to a false sense of understanding.

II. THE MIND

Linguistic Issues

There are an infinite number of alternative ways to convey very specific information. Data saved digitally is one such method, a protocol of binary *bytes*. Humans concoct languages. Each digit is independent of its neighbors. Humans concoct languages. Words are very dependant on their neighbors, not just for grammar agreement but for the general meaning of the sentence.

Importantly, the human method doesn't translate into digital form nicely (Fodor, 2000). But the distinction is far more complex, but the solution is alarmingly simple. We just have to fully grasp it and take advantage of it. As an example, smoke is not essential to friction, but when we see smoke coming from a mechanical object, our first guess is to look for what parts might be rubbing each other wrong. We don't really need machines to create more meaning (to determine how the smoke got there). They aren't good at it, but we do that just fine ourselves. Instead, what computers might be able to do is mimic the key that unlocks our language recognizing function (create virtual smoke, or rather generate fresh air free of smoke).

The software Eliza is a prime example of this. It was created to carry on a conversation, something computers can't usually do convincingly. But it uses a psychological trick, repeating parts of the human's previous replies at random. So the person conversing sees significance in the computer's words, even if the machine doesn't.

The Turing Test says if a panel of experts on a subject can carry on a conversation with an unknown entity, and they are unable to or inaccurately determine the entity's human-ness, the machine passes. Probably more informatively, I would propose the test should go something like this: Select 10 random high school students (I am assuming a Western audience, but any background would surely do). Play them 5 songs, chosen unpredictably on the spot: a pre-18th century Classical piece, a 20's recording of early jazz (including the crackle), a pop song from the 50's, the theme song from a 70's sit-com, and a current (but yet unreleased) rap tune, and ask them in under 15 seconds to determine the chronological order. The question would be if any machine could consistently score better than the high schoolers. Pretty much impossible.

Essentially, the high school students needn't recognize the actual songs, but the genres. Furthermore, one can usually tell at a glance (and we do channel surfing), if an image was filmed or videotaped and in what era, what the level of seriousness is, roughly if it would be interesting to us. Compare a gardening program from 1970 on BBC to a modern reality TV show set in a garden. Color tonality, transition frequency, and how close are the close-ups are all big clues – for humans.

But if those same high school kids were asked to compose a few seconds of early European classical music, that might convince the next group, in under 15 seconds, my money would be on the machine. In fact, the machine could come up with hundreds in a under second. In other words, there are two very distinct skills. Humans induce effortlessly. Computers stink at it. But computers assemble from deductions effortlessly. Humans get bogged down in possibilities.

Amazingly, nearly every known human language in the world and throughout time can be analyzed into remarkably identical parts of speech, take the form *subject-object-verb*[6]. Some use *subject-verb-object* and only a handful more variants of this order occur very rarely (Hunt, 1993; Pinker, 1995; Calvin, 1996) but many schemes never occur. Why?

Noam Chomsky's theories of an LAD (Language Acquisition Device) and "auto-generative" language demonstrate that an infinite number of variations could be created and still understood without explicitly understanding the rules and exceptions of grammar (in whatever native language) (Chomsky, 1977). Children often make mistakes in trivial ways (saying "foots" instead of "feet", mussing the *surface grammar*) but consistently maintaining, comprehending and employing the culturally defined organization of sentences (*deep structure*). A child may say "My foots hurt!" but never "Hurt feet my!". We understand "Jane said: see Spot Run", "See Spot run toward Dick.", "Jane told Dick about Spot running." without ever literally experiencing all of these specific, seemingly infinite variants. We recognize the deep structure. Marc Hauser describes Chomsky's theories further.

> This combinatorial machinery [a module in the human (but not other species) brain for LAD] provides algorithms for specifying the details of our communicative utterances. The fact that we use this machinery for communication is, however, incidental. … Put simply, even if Australopithecus afarensis – the famous "Lucy" – had a language organ, we would not be in the position to definitively assess its role in communication or, for that matter, any other behavioral expression. This point should be swallowed completely, especially in light of Chomsky's (1986, 1990) own belief that our use of the language organ for communication was quite accidental. *(Hauser, 1998, p. 34)*

If the brain simply applies this pattern recognition function to whatever stimuli is input, distinguishing relevant organization from randomness, it would stand to reason that the brain could be using the same module for differentiating say music from the sound of leaves in the wind.

Musical Grammar

No matter what culture, recognition of communication is a matter of projecting. The French hear vowels Americans can't, who hear L's in ways Japanese can't (Pinker 1995; Solso, 2003). Music is no different. The strategies are culturally specific, learned, articulated in retrospect. But they are absolutely concrete, not psychological effects. Sounds absolutely do not exist in the air. They exist as sound only in the brain of the listener (Levetin, 2006). Furthermore, composers, musicians and listeners need never even be aware of the rules they apply consistently.

In Western culture, the number of pitch and rhythmic options for a 2 bar melody is huge, but not at all infinite. In fact, we use a remarkably tiny fraction of the possibilities[7]. Which of these subsets of musical options we adopt, is defined by culture. Amazingly, across cultures, our music sounds unique yet identifiable to that culture, in part because our pools are roughly the same uncanny size.

Asian music and Middle Eastern music obey surprisingly similar rules, ones the listeners come to adopt subconsciously (May, 1980). The Westerner tends to hear sounds that do not correspond to normal Western music theory rules. The Eastern ear looks for anomalies according to Eastern Music Theory rules. These rules need not be articulateable. The individual may not even be aware they know that their brain is using these guidelines as a filter of the chaos of sensory data. Westerners tend not to notice subtleties in more complex rhythms but do in melodies. Whereas for Easterners the reverse is generally true (Aldrige & Fachner, 2007). This is important in that to see from one culturally informed perspective blinds us from others. We are compelled to choose a perspective, but there is absolutely never a "right" one.

Chunking (mentioned earlier) is the term for the brain's tendency to dissect incoming data into digestible bits (7 digit phone numbers, 7 note scales, 7 Wonders, 7 days a week, 7 dwarves. Seven is about average for people around the world, throughout time). This extends far into a myriad of unexpected non-verbal cues. Our brain applies the filter it obtains from experience and culture (in every part of the world, throughout history) to every detail, from understanding how complex Chinese characters can survive the centuries (Coe, 1999), limiting the pool of vocabulary of specific musics (Levetin, 2006) and dance (Shay 1999), recognizing someone in cartoon by their mannerisms (Fliecher, 1932; Linklater, 2002) and even Richard Gregory's *redintegration* experiments (Hunt, 2003; Carter, 1999). We invent "facts" according to what we see (Sully, 1881) revising the surprisingly innate and uniform assessment of beauty we are born with (Etcoff, 2000). Chunking and culture work together (creating icons) to make comprehension easier for us.

III. THE EMPEROR'S NEW PARADIGM

Shifting Between Perspectives

Individuals are free to apply the tools as best they know how to their own very personal situations. Just as the monkey may use a stick to reach a banana, the desire for the banana always precludes the decision how to use the stick. Needs change how we see the tools, not the other way around. In a movie, an ex-special ops mercenary poses as a substitute teacher and lectures the class about "perception".

"What do you think this is? [holds up a yo-yo]
It's a simple toy, man. [drinking from a bottle]
To you it is, but back in 1500 in the Philippines it was a weapon. [lashes out with the yo-yo and shatters the bottle] *(Pearl, 1998)*

We don't learn by rote that a screwdriver can be used as a hammer. We pick it up and try it. Nonetheless, once a method works at all, it is incredibly difficult for some to discard. Hence, more precisely useful methods are often met with irrationally vehement and disdain, in favor of impractical yet more immediately learn-able alternatives. The resulting perception is then that the object has one very specific purpose and that purpose is defined by a *stable state* (Dawkins, 1978; Gladwell, 2000).

It comes as no surprise that contributors don't want to see the issues complicated out of reach or lost in unfamiliar territory. Web designers want to continue proudly designing pages as if they are fixed layouts for print. More importantly, they have an industry and are paid by it. In recent years, the designer's role has shifted, but has not escaped the goal of making content easier to digest. We employ buffers from being thwarted by unfamiliar technical information in the forms of blogs (Weinberger, 2007). This static-ness is intrinsic to print, not the web at all.

Browsers get away from static-ness with easy to read defaults and allowing user customizations of the general appearance. Still designers insist on over-riding these features in favor of static-ness, especially using CSS (Castro, 2003). Personalized options offered are trivial. Customizing means presenting pages in our favorite colors. "Read more of this article" doesn't purport to alter or update the article in any way.

Though HTML technically does support interaction in the form of hyperlinks, it is the very lowest level of interactivity (Gleick, 2002). Compare the highly interactive question - "What was the most interesting thing you did today?" and the equivalent of hyperlinks - "Do you want fries with that?". You really have three ways to answer: "Yes, go ahead and continue whatever you have planned." (click), "No, wait to continue just yet." (don't click) or supply an answer that gets no meaningful response. However, a computer has no problem "listening for" millions of possible responses. Why would web pages so uniformly ignore what they are capable of, for limitations of linear design? HTML is hardly a bad thing, but it is a cherry on the top. CSS (generally flavorless) and JavaScript may be the colorful sprinkles, but there's still a lot more to a sundae. Yet we regularly throw the rest away.

Design is unavoidable (Tufte, 1990). Arranging any data on any page involves design. But there is design for design's sake (as in logos, marketing or dressing fashionably) to convey an essence by creating an icon and design for function's sake (as in architecture, form design, and even typography) where the graphics are a subservient means to the an unrelated end goal. Will it withstand rain? Does it need to convey specific words? These are questions that (can) trump aesthetics.

Though not entirely separable, design and function can be viewed distinctly. The problem arises, when design limitations are placed on function artificially. If designers of web pages only think in terms of static pages, that leaves very little function. But the page is still essentially static, serves no non-design function, utilizes neither the computer processor nor any significant peculiarities of a vast network. Later we'll talk about how the web can be used, but for the most part, we settle for a 300 billion gallon billboard soup.

We even go so far as to invent a mythological expertise, in order to defend our higher as well as lower techno-caste system (Goffman, 1959; Marvin, 1988). What's wrong with a little ignorance? Nothing, at all! But once we have invested so much in a bad idea, we would look ridiculous (to ourselves) to admit the farce. We need someone to play expert and tell us we are right. How much in time, money and effort would you estimate we have invested in the web? Add up the costs of every computer, not to mention connection hardware, hosting fees, etc. We simply must justify it to ourselves.

The same could be said of cars. Modern ones may work differently than the original models. But drivers benefit from changes not being too drastic, as with solar powered cars. Drivers want to remain safe knowing the steps for finding a mechanic will work every time. One can imagine that the car owners not even be drivers though. They may be using a car exclusively as a couch, while still insisting on their mechanics. After a few generations of this, any mechanic would reasonably claim the only definition of a mechanic is someone who fixes upholstery. The cars will certainly do the job, no harm could come of this. It is a blatant waste - but actually only if you have experience driving. Owners just argue that's the going price of a couch and resent being told they were fooled.

Most users of the web, may be content as infant passengers in the back seat. They have no idea there is interaction happening, but just enjoy just looking out the window (hands in lap). To them riding in a car, is nearly an identical activity as sitting on a couch watching TV. So, it seems fitting the web must be like that too. After all, the web isn't like anything we don't make it like. If we make a "hands-in-lap" web, the web really is like that (Greene, 2004).

Allowing for the widest possible re-purposing, is often a key to survival. VS Ramachandran says this about animal evolution:

A trait may represent a further refinement (through natural selection) of another trait that was selector for a completely different purpose. Feathers evolved from reptilian scales to keep birds warm but have since been co-opted and transformed into wing feathers for flying; this is called preadaption. (Ramachandran, & Blakeslee, 1998, p.209)

If the net bears any similarities to past technologies, it is absolutely only because this is how we have applied the tool. The computer is nothing like a phone. The computer doesn't work similarly to a TV. But we use computers mostly as substitutes for two tools that still work fine[8]. The net is only like the telegraph because we eventually understood the telegraph and applied that understanding to the net.

People called the railroad the 'iron horse' and the automobile the 'horseless carriage'. For decades the telephone was viewed in the context of the *telegraph, something that should only be used to communicate important news or emergencies; it wasn't until the 1920s that people started using it casually. Photography was at first used as a new kind of portraiture. And motion pictures were conceptualized as a variation of stage plays, which is why movie theaters had retracting curtains over the screens for much of the twentieth century. (Hawkins, 2004, p. 205)*

DIY

The acronym, normally used as an adjective, could well be turned around as a command. Do it your (own damn) self. The desire to bypass years of discipline to become an instant expert is everywhere. Judging by popular titles, we can learn or accomplish anything in 30 days (Shenk, 1999). Often even that much wait proves too excruciating (Glieck, 1999).

DIY grew out of a punk rejection of the influences of "the Man"/big brother. What's ironic is that in all likelihood, punk was probably born in a music industry board room when they decided to team Sid Vicious (he doesn't actually play on studio recordings, had almost no actual musical ability, but looked the part) and Johnny Rotten (also more for his act) with Malcolm MacLaren (who provided stylistic fine tuning rather than anything compositional) (Heylin, 2007). Punk was essentially the discovery that a cool attitude sells, while skills we once assumed were essential are optional.

The Sex Pistols were great! No question there. But the reason the meme spread all over the world depended on distribution. The reason punk was on sale in the big stores, was certainly not because it rejected the industry, it's because marketing departments guessed how to package it. "The Great Rock 'n' Roll Swindle" (Sex Pistols, 1993) was certainly fictionalized for the sake of drama, but like all mythologies there's factualness in the mythological-ness of it. Though most post-punk enthusiasts would be horrified to entertain the thought, there wasn't actually anything idealistic about it. We were all duped. We can argue angrily or lighten up and laugh at ourselves. In the case of the web, we tend to argue.

Looking into the machines themselves, and not the ideals obscuring them. People still commonly think employing a computer can be a "time saver". In cases like musical scoring with a professional MIDI sequencer or now user-friendly software like GarageBand, it can for most. A person fluent in reading and writing on staves will probably loose time. But for others it can make a helpful difference not to need to go through and decipher each note. Classically trained composers may argue that this brings the average quality of composing down, making it is more open to amateurs (Marvin, 1988; Hopkins, 1982). This view is hardly worth arguing for or against, as it misunderstands the essential shift in what is required of the "expert".

Neither side is more right than the other. Both are completely valid from their respective perspectives. By not recognizing schemas, computer technology works - as long as we don't insist on any correct point of view. Computers and a need for truth are simply incompatible. Computers can only provide hypotheticals and alternatives. Often attributed to an age/generation thing (which isn't really true of course), some folks get frustrated with machines, some with the search for fact, but both camps spend their money all the same.

While it is an arguable issue whether a Puritan work ethic results in more invested artists, and thus more profound art, this is not the only issue by far. It is often the only one addressed by fanatic proponents from either side of the argument though. Often extreme zeal and reverence are invoked to describe both the traditional values and the new shift to the new technology (Glieck, 2002; Tapscott & Williams, 2006) as if they are advertising a show on Broadway. The greatest hyperboles ever to appear on Earth!!! Rhetoric aside, one side argues for patience in acquiring skill. But such a work ethic is only interpreted as outdated elitism by others. The other side argues for the freedoms of expression newly available to the common man[9]. Mozart can be boring and therefore of no musical value to kids who want to dance. And Kanye West can be just noise, revealing no interesting musicality to Classicists. This point gets argued to death and leads nowhere.

Nonetheless, the sheer numbers of works, that explode like a burst dam, do have a very real negative effect. No curator (using the term loosely) of artworks or employer listing job openings can realistically expect that, where once they could manage to cull the best candidates out of 200, they can make any such claims when there are 200,000 of them. There just isn't time, nor the attention spans. Doing some quick math, it's plain that they can initially only give each candidate a .2 second glance. Obviously, some ideas take a few seconds to sink in, and those will surely be lost. In fact, which they see at all is either random or limited to the applicants they are already familiar with. By round two, the remaining survivors inevitably all start to look the same any way. And that does bring the quality down (Shermer, 2002).

Let's look at an illustration of this concept. Say in gym class you were the team captain, picking all of your players before anyone else from 100 students, you might pick the best team, and may thereby win more games. But picking from millions the odds of noticing who the key players are no longer significant. Among that huge crowd may be the Yankees, but who could ever notice when there are so many others. Every other captain has roughly the same slim odds. Likewise, ill-chosen HR employees are thereby theoretically less and less adept at what they do, at choosing the next generation of employees. So begins the exponential growth of mediocrity. Averages on the web, do not behave like the bell curves we expect. Nearly every aspect behaves like a steep slope.

Not that the web needs censorship, but why do we choose to "shit in our own bed"? We piously insist there is a new ultra-accessible frontier for gathering information and then set about to transforming it into a hiding place for information. There's a subtle difference. The messages on the net (whether spam or blog diaries) are actually often only meant for a small audience. For grandma, mention of our green socks may bring a little amusement. But it is as if we think we're still using previous media. These messages are not for everyone in the world. Nonetheless, we know full well that's where they go and brush this aside with no further thought of the result.

In targeting our messages, we might as well use a sawed-off shotgun to catch a fly. The question is, why do we pay $1000+ to have access to information that could be sent more efficiently to our target with a 40-cent stamp? Why spend more when we already have a more effective way to reach our specific audience? Skywriting is no way to create intimacy. Moreover, we've known this and seen this developing for decades now and only make the situation worse.

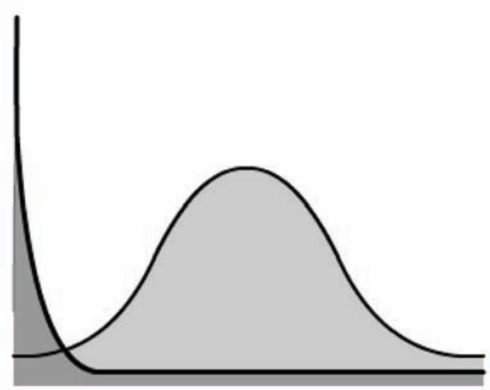
But is any kind of quality on the web even necessary for it's greater function? Maybe not? For example, who care's if someone in class says something other than "here" at role call, so long as their name is checked off, the result is successful. The existence of content is necessary but the content of the content is arbitrary (Calvin, 1996). Has a comparable situation come up before?

IV. DEVOLVING TENDENCIES

Time is a Wheel, not a Line

History always repeats. I am only glancing as far back as the Industrial Revolution, but as you probably already know, every promise the net makes, has been made over and over. What's remarkable is that technology again and again makes these claims as if it were offering a never-before possible opportunity, a new brighter horizon (Barbrook & Cameron, 1995).

Figure 2. The illusion of the bell curve has been reinforced by centuries of experience. Things do behave in such a way. But suddenly, a lot more things don't fit that model. We assume an average popular site will get an average number of visitors. Not at all. A handful of sites get a phenomenal number of visitors, some get very few, but most get next to none (glancers, who spend 20 seconds or less determining if your site fits with their search). The spread is more like an exponential curve. It may seem like anyone can climb to the top. A handful of anecdotal evidence are all the success stories we need (like Linux and Wikipedia) to ignore the billions of sites that were forgotten before they were ever remembered. The average Joe/Jane is still a serf doing the grunt work to support a remote aristocracy, it's just a very different looking aristocracy. The web certainly is communal, but it is an absolute mirage that everyone is represented. Our web projects never stand the same chances as the ones on top. In the same way. In music, the industry invests a lot of time and money determining what will be popular. Moreover, they have access to channels to test and market their products. Imagine trying to compete by simply playing loudly in the basement. Now imagine there are millions of basements next door (physically impossible but that's the web).



In the 1890's, advocates of electricity claimed it would eliminate the drudgery of manual work and create a world of abundance and peace. In the first decade of the 20th century, aircraft inspired similar flights of fancy. Rapid intercontinental travel would, it was claimed, eliminate international differences and misunderstandings. ... Similarly, television was expected to improve education, reduce social isolation, and enhance democracy. Nuclear power was supposed to usher in an age of plenty where electricity was 'too cheap to meter'. (Standage, 1998, p.211)

There is no horizon, neither brighter nor dimmer. And we know it. It's hard to hear the word "utopia" now without sniggering. But we rarely appreciate precisely why? It is because the promise is made obsolete by the development itself. Not by solving any conflicts, but by re-framing them. For instance, let's look at the last century's obsession with signal-to-noise ratio.

Once upon a time, recording audio onto wax cylinders proved too noisy. Progressing to the 60's, things improved and soon technology was such that we could hardly notice tape hiss above the recorded sound without listening for it (Spence & Swayne, 1981). Video, also recorded on magnetic tape, was subject to visual noise as well. This noise also accumulated with age. So at first eliminating it was a genuine problem to solve, even if just for archiving[10]. And soon enough we pretty much solved it. Nonetheless, we remained in the habit of facing that particular problem. We held on to it, long after the benefits hardly justified the efforts. Moreover, we didn't just want noise eliminated in recordings and edits made in studios fitted with carpeted walls and pro equipment, but wanted to do it at home, too.

We now rarely store mechanical or magnetic reproductions (like clay in a mold, on a macro- or microscopic level), we instead store the instructions to duplicate a subject (like recipes passed down for generations or DNA). In a picture, these instructions take the form of long lists of numbers which define grids of pixel values for red, green, blue and transparency, theoretically accounting for all possible colors an image could be (which is hardly true, such as warmer grays, florescent shades)[11]. A digital image (or sound) is a checkerboard of hues (or sine waves) (Aldrich, 2003; Myler & Weeks, 1993).

The resolution of the reproduction is no longer entirely in the quality of those pixels, but more importantly the sheer number of pixels (or sine waves). Hence "dots per inch"[12]. Despite claims, the noise to video/sound ratio has not been improved at all. Noise is just no longer much of an issue since the copy and the original[13] are now only related by coincidentally having similar colors/ sounds in similar places. In fact, once recorded, the "original" (which was really only a list of electrical charges) is discarded forever and playback of any kind absolutely requires constructing an entirely new copy,

At first, the resolution of this clone was limited.[14] In audio one may still notice the sample rate is four times lower for phones than CD recordings, about 11 thousand samples (MHz) and 44.1 (Aldrich, 2005). But this is most apparent in video, where you can often detect blocks of pixels and perpendicular edges in video. This was still a huge obstacle until a few years ago. So in retrospect, one has to ask, why did we support this tool that didn't work all that well for so long (Gleick, 2002)? It's hard to say if digital media (both audio and video) now, after years of improvement, offer better "imaging" than analog recordings. Trying to solve one thing, a new paradigm can often brings other things down. So you'd think there'd have to be a really compelling reason or really strong results. Nope.

Moreover, why choose to make things harder on ourselves with no apparent benefit (at least at first)? We are often comfortable knowing how exacto knives and paste-up boards work, and struggle with layout software. When the print doesn't look like the screen, we assume there must be something done wrong on the computer, without realizing it made exactly the mistake they told it to. That's what computers are good for.

Professional Art Directors, with years of experience and big salaries may not fully understand the impossibility of optics, or down/up-sampling (resolution, blockiness and size anomalies) are often to blame. Traditional methods work. Computer methods can but it requires patient un-learning. However, combining them (even attaching a printer to a computer) brings about the worst of both worlds. Most folks (especially people used to a paper mindset) are just not making the full transition, remain voluntarily stuck with baffling compromises.

Quality does not improve, criteria shift. A common view once was that acting on film for a silent movie was a legitimate expression, but the kind of acting in talkies was not. At first glance, this seems laudable. But remember, at this point, the camera still was considered rather like a replacement of the view of a live theater audience. The camera was not primarily used to focus attention, rather to show the whole scene, where the projection screen was a direct replacement for the live stage. For several years, the movie was yet another vaudeville act. Only gradually the live performance aspects faded away (Stokes & Maltby, 1999). (Though our computer screens are still influenced by the frame proportions.)

In his traditional manner, ... Elman [a violinist, subject of an early talking short features] chinned his violin, leaned back, and focused on a spot at the top of the balcony. The technicians explained he didn't have to do that anymore, that if he looked directly at the camera it would put his face in front of every member of the audience no matter where they were sitting. Elman couldn't grasp the concept. 'But I always look at someone in the top balcony when I give a concert,' he complained. He agreed to look at the camera, and as soon as the cameras began rolling, he reverted to looking at the balcony. (Eymann, 1997, p.79)

The advent of the talkie also drastically shifted the expertise. Acting was about muscle movement (like dance). Actors used a vocabulary of grandiose gestures to convey the grand emotions in scripts of the era. There even existed formal "code books" for each appropriate emotion and how to portray it (Lutz, 1927). Method actors like Marlon Brando would certainly only appear to them as a half-hearted, perhaps shy, understated attempt at "real" acting (Stanislavsky, 1936).

Adeptness came with years of study. A pleasant voice was simply something any layman had or didn't have, but acquiring it hardly seemed like a skill at all, just luck of the draw. Hence, success in this new paradigm was not based on traditional expertise but a random gift (Eymann, 1997). However, we still have acting schools. The "expertise" did not actually get supplanted, but merely shifted in specifics.

The casual use of the telephone seems so plainly obvious today, but wasn't always. Along the bumpy road to the perspective that we have now (which still stretches before us), telephone calls (like telegrams) were reserved for important or official news. However, an earlier idea folks tried was very different. There was a time you could subscribe to something like a radio station. You would be mailed a schedule, and say at 3:00, they would be playing a Mozart symphony (Kern, 2003, Fischer, 1992). Can you imagine sitting in your kitchen holding one of those old style phones[15] for say 20 minutes? But surely there are things we do with technology now that will seem just as absurd in years to come.

Precedents in Waste

Nowadays, stoves are rather the norm in 1st world households, but this was not always the case. When the gas stove was invented, there was already a strong social "ritual" in place, sharing the cooking area, the communal hearth. At the time when they first appeared on the market, Americans spent (relative) fortunes to have these cooking factories in their own homes (Fischer, 1992). Gradually, social functions shifted and eventually it seemed like an obvious necessity to have a stove in every home. "Fire is revered generally as a deity to this day. The lighting of the household fire is in many cultures a ritual act." (Campbell, 1972, pp 248-249).

Light bulbs had a similar effect. And though now we scarcely notice the costs, originally equipping a house for electric light was a major investment. The investment also dissolved the need for families to gather in the same room. In other words, we paid willingly for privacy.

The cost could not eclipse the desire. Similarly, we spend huge amounts on computers, only to use them insistently for a very minimal purpose. A purpose that often other tools, common household items, do much better and far more cheaply. Not to circumvent an identified inconvenience, but to add several new ones. Moreover, by bringing computers into our homes, we have hardly improved beyond older inventions. The video effects we use now at our desks are the same ones that were available to pin the 80's. Is this wrong? Of course not, it is up to each individual and their bank account. But it is an odd phenomenon that indicates cost is not nearly the deciding factor in this particular market.

There was once a time on the ARPANET (Hauben, URL), back when graphic editing was too much work for most machines, computers could connect to a server that was the workhorse (Abbate, 1999). We could stand to learn from those days.

If you wanted to create your programs interactively, he reasoned, and if nobody was going to give you your very own 704 [a big computer for back then] to do it with, then the obvious answer was to get together with a bunch of other users to share a machine. … Give everybody a remote terminal so they could tap into the big computer through telephone lines whenever they liked, wherever they liked. … And finally, when the users needed some actual processing power, dole it out to them via an artful trick. (Waldrop, 2001, pp.163-164)

In terms of processing muscle, current cell phones are far ahead of where computers were when they became a public commodity (Greene, 2004). So what's a computer got, that a phone ain't got? The QWERTY keyboards (Bluetooth or built in, as in a Blackberry) are a clumsy but usable option. Allowing full size versions would hardly be a technical wonder. Phone screens are small but there could easily be monitors that attach to less powerful computers and supply their own VRAM. Do folks remember duo docks[16]? Software is not a hindrance. With a phone version of a plain text editor (like BBEdit) and FTP (for uploading files)[17], one could replicate most any computer function. But these 3 obstacles are hardly enough to prevent folks from adding their content to the web. It's as if the Great Wall of China were made 3 inches high all over and that was actually enough to keep invaders out.

This has been going on for years though, around the late 90's, we could purchase a webTV system or stand-alone email unit, for a fraction of the cost of a computer. Yet apparently we didn't often enough and the merchandise flopped. We can again send email, take snapshots and even look up web pages, all from our pocket-sized devices, but are dissuaded from giving up on computers. If we were all helpless victims of the industry, stuck with whatever they offered, that would be understandable. But we could hack (and we even have the tools sitting under our finger tips). Creating software is free (even creating software to run on cell phones[18]). We can even benefit from other hackers, as in Bit Torrent. Why doesn't that save us?

One interesting thing about the net is that people can cluster to solve problems, Open Source. Linus Torvald's project Linux is everyone's favorite example (Tapscott & Williams, 2006). But even these instances are subject to shared social influences. Linux would not exist if the need for it wasn't already common. Needs (even if they aren't fully understood or recognized) always preclude effort. Linux could not have happened without a strong selling point and a bit of trend following. Culture, not just some of the individuals in it, needs to agree to the need first, for openness to thrive. In a disappointing but usual case, we upload an Open Source project and nothing happens. The need, even if erroneous, has to be adopted by culture first, before the droves of supporters clamor onto the bandwagon blindly. Though one can sometimes see how a figure like Hitler or even Bill Gates could have profound influence on developing a new culture, it has to be a culture already hungry. It is just waiting for someone to say "I can provide beyond your wildest dreams".

The Nature of the Wave

People upload the concerns at the forefront of their thoughts. If images are uploaded of refrigerators, it is not because these people are devoted to the appliances. They may be concerned about selling them, repairing them, etc. but the refrigerator itself is a tangential idea. However, the refrigerator is like the stuff of dreams. It can appear to the subconscious out of context. Thus it is an icon (Jung, 1919). It indicates something, but not always the significance or application of that thing. And this describes how, with enough amassed conscious concerns, you can re-contextualize and draw from a subconscious mythology.

Though very unconsciously, we can also choose perfunctory social banter, not unlike role call, over in-depth intimacy. This may seem deplorable if we assume the net is used as a socializing tool (Reeves & Nass, 1996). But if the net is simply a means for everyone to share an iconography, this chatty banter in social software may actually serve a very un-social function. It allows people to say "count me in with everyone else" and weeds out contributions that serve to dissuade cohesion (Jacobs, 1961). Such is the psychological force behind social software. To join the club, the requisite initiation is to encourage replies like "oh kool dood". Insightfulness and real passion may require longer posts, but only really serve to rock the boat, putting esteemed members at risk of drowning.

It would seem there must be an unfathomable tidal wave of ideas to which to give our attention on the web (Popper, 2007). We could be drowned in ideas if we resisted this wave, but we dive in head on. Which actual molecules make us wet? Without the tidal wave pushing from behind, those individual molecules would have no effect. It is the sea of them, many more than we perceive directly, that makes swimming possible. On the web, that means that the ideas that end up at the forefront are there somewhat arbitrarily.

We need not see the millions of pages uploaded to feel their effect. In fact, most of them are seen by under 50 people (and over 200 bots). A few sites are the hubs, seen by millions, the molecules that touch us, and are often only on in a position to touch us because of the combined effects of the other viewers (Barbási, 2002). Sites like Boing Boing may be the molecules making us wet, are only able to, because they reach us before so many ever can. They are the surface of the water, the foam on the shore.

Obviously, not all of the participants in a ritual are the shaman (or James Brown). A concert hardly has the same wild effects on us in an empty arena. The fame, visibility and attention given to the "star" in no way indicates the rest of the crowd is any less effective, just less identifiable. Which brings us back to the idea that anything labelable is really interchangeable. Categorization is essentially *surface grammar*.

Following the Fold

We tend to mistake the notion that we are simply "social creatures" for the underlying idea that we are creatures of opportunity. We often just adopt the first solution that doesn't immediately hurt us. In many cases, latching onto a culture proves far more practical way to go. Do I need my umbrella? Look outside and see if others are carrying theirs (Weinberger, 2007). We (aspire to) contribute symbiotically to the system that helps us. How much of this strategy is genetic is debatable. Some insist humans are social by nature, but that doesn't fully explain why and how we go grocery shopping.

Being social we are also vulnerable to succumbing to mass hysteria. Wacky but harmless notions are common (Heuer, 1951; Simons, 1993; Clancy 2005), but extreme examples include Holland's "tulipomania" of 1634-1636, witch hunts, the Florida real estate frenzy of 1924-1926, the panic caused by *the War of the Worlds* radio broadcast in 1938 can spiral into real trouble. Modern tech phenomena include decades of virus alerts (which ironically spread like viruses), the dot.com bubble burst, the Y2K scare. We seem to be drawn to distractions like OJ Simpson (Rushkoff, l994), not because of any personal impact, but to revisit our social bonds.

No person of any economic strata, age-group, educational level or time period is exempt from this behavior (Bulgatz, 1992), though often the poor and uneducated are hit the hardest in the mad rush to join the frenzy (Vronsky, 2004). In many cases, as with Jonestown, those people are specifically targeted with tragic results. Feelings of vulnerability often fuel the mass hysteria, but threats and fears can impinge on any classification of people. Stanley Milgram's famous Obedience experiments demonstrate that any of us, given the right external conditions, relinquish our own rationality for our best guess at what is expected of us by "authority" in our chosen culture (Blass, 2004).

Blind faith tends to create impenetrable illusions that ignorance has effortlessly been replaced with expertise (the "money for nothing" bait of successful cons) (Weill, 1948). When it comes to using the web, we are defiantly ignorant. Though many claim to know better, this is fool-hearty. Apparently, our ignorance does not prevent us from unconscious uses of the network though. We just may not realize why we do what we do. Rather, not fully understanding, we may be freer to use the tools to save our sanity. Unconsciousness often protects us from our conscious decisions to over-ride unconscious ones. We need to feel protected in a big social group and simultaneously can be overwhelmed with the demands from so many strangers. The two dynamics are at odds and would make us crazy, if we didn't devise buffers. Walking down a crowded street, talking on a cell phone is one strategy.

Revolution

The history of the net has been something of a "mass movement" as articulated by Eric Hoffer in 1951. In a mass movement, such as the Bolshevik, French, and Nazi revolutions, even Christianity, the status quo is upset by discontent with freedom. Though "more freedom!" may be their chant, freedom also puts responsibility on the shoulders of the individual. What revolutionaries actually want is less responsibility as an individual and broader anonymity. The effort to blend in, generally becomes an effort to make everyone the same, discrediting notions of elitism (whether imagined or real).

This is in stark contrast to the notion that revolution is a reaction to oppressive poverty and despotism. Of course it also echoes tenants of DIY-ism. In many cases, such as "lurkers" (often the vast majority by far) in on-line discussion groups, we voluntarily do not wish to actually be involved. We don't actually want the interactive benefits of the web to replace magazine subscription. We'd often rather just keep tabs on the movement, the discussion that serves to dictate how to behave. Furthermore, people intent on survival see no use in diverting attention to matters of no immediate consequence. In effect conservatism (in all its forms) is the petri dish that inflicts oppressive paranoia[19]. It is people with idle time and disposable incomes that spend their resources to maintain the computer industry. Hopefully, in this essay, you will see, I am not casting blame, I am part of this trend, but asking why.

The ARPANET's transition from a tool for scientists was gradually pried open from institutions who could spend large sums buying into it for large faculties, often with funding, rather than out-of-pocket money, to the hard core techies who weren't academically affiliated has been well documented (Rushkoff, 1994; Shirky, 1995; Waldrop, 2001; Greene, 2004). Then the internet unlocked the door at first to the basement "nerds" and gradually aspired to welcome the functionally technophobic with the advent of web 2.0. Though the cost was at first an obstacle, it has become a given, an expectation. For instance we may still buy Microsoft's Office, though OpenOffice has been free for years. It is also unusual, and thus uncomfortable for the new user to think free software could be better than expensive software.

The decisive factor at every step seemed to be, not minimizing cost, but minimizing unfamiliarity (even at the expense of confusion from horribly baffling and inflexible design).

As with any mass movement, opening to a wider base means generalizing for broader appeal. That means that once they have joined, everyone will be reciting the same simplified mantra. In effect, we all must share the same lowest common denominator intelligence, or rather suppress our tendencies to think too far "outside the box". This is not to say greater accessibility is a bad thing, nor a good thing, but that opening admission does result in letting individuals get "lost in the crowd" and "hidden in plain sight", and the "dumbing down" that is often a symptom can easily be mistaken for the disease.

It is not simply the oppressed versus the oppressor that brings out revolutions. The person who harbors no hope of improving their misery, is not a revolutionary prospect, would rather things stay the same. Life is hard enough as it is. Moving the horrible but consistent land mines all around them is a scary proposition. Miserable conditions become easier to live with as long as they remain familiar. Revolutionaries offer disruption only to those who are eager to gamble everything, and feel confident that whatever the outcome, their lives will remain fairly comfortable. Paradigm shifts that upset stability are brought about by folks with leisure on their minds[20]. But the specifics of a doctrine are pretty much arbitrary.

It is futile to judge the viability of a new movement by the truth of its doctrine and the feasibility of it's promises, What has to be judged is its corporate organization for quick and total absorption of the frustrated. Where new creeds vie with each other for the allegiance of the populace, the one that comes with the most perfected collective framework wins. (Hoffer, 1951, p. 41)

We have computers, connected to a network. The capabilities are enormous and yet email and static web pages remain their most common use? Fundamentally, communication over the web can never possibly work ideally on so many levels, but we obediently adjust our criteria to "good enough" (Reeves & Nass, 1996). We discontented yet hopeful seekers of change can all join the faceless crowd with Facebook. Not that Facebook ever intended to promote this anonymity, quite the opposite surely, but its success may stem from a popular need to be nullified. The pressures to subscribe to mass movements "produce both readiness to sacrifice the self and a willingness to dissolve it by losing one's individual distinctness in a compact collective whole." (Hoffer, 1951, p. 59)

Looking at ex.plode.us (a site that compiles the membership of several social software sites) may prove an ideal demonstration of this. Here are six of hundreds of pages retrieved from a single search.

V. TECHNOLOGICAL PERSPECTIVE

Using the Computer

Before going any further, I want to mention some positive examples. There is nothing wrong with buying things that we don't end up needing after all. We also own things, not because they fill any utilitarian purpose, but just because we like having them. Fun clothing, photos and artwork are particularly conspicuous examples. However, here is a case where we see a cool pair of bright red shoes, spend a significant sum on them, decide it is crucial to wear them for as many hours as practical (as if they provide essential nutrients by osmosis?) and wear them every night to sleep in, but remove them each morning. After a year, though the shoes are still quite fine, we replace them with an even more expensive pair. Huh? Let's look at alternatives.

Prominent sites that take advantage of the network of computers (like Amazon or Ebay), rather than solely providing sedatives in the guise of eye-candy, are rare but not impossible to find. More obscure are the personal examples, things we could all accomplish alone in an afternoon. The web can be used simply as a feature of software, a way to reach solutions, an ingredient to be fluent with in wielding this technology. The web is another folder on your desktop, but one so full of files, it has great uses.

Dan O'Sullivan, a professor at NYU's Interactive Telecommunications Program is certainly wielding the tools at hand. One fine afternoon, as a curator of a computer art show of about 150 pieces, he created a very web savvy utility to solve a very real problem, how to arrange these works in the finite space, given finite resources. Pieces often had very specific space, lighting and sound requirements. They all had extensive equipment requirements, needing various things from carpeting and green screens to a water supply, not to mention all the hardware like projectors, CPUs, speakers, cameras or things like wall space, tables, windows, web access.

So in the registration process, he included a software map of the gallery and fixtures. Each artist could place a marker on the map. Artists could return to see the latest version of the marked map. However, you could only edit your own marks (though O'Sullivan could edit all of them as needed). If artist clustered in one popular spot, others could decide to move to a less populated area. The solution to the problem was thus accomplished, finding an the ideal configuration, particularly given the limited efforts expended by everyone involved.

Another example happened when researchers looked into the game "Six Degrees of Kevin Bacon". In the game, a person mentions a movie, someone suggests a pair of actors that appeared in that movie and also were in a second movie together. More movies are mentioned, until the chain of paired actors includes Kevin Bacon. The goal is to see, from any initial movie, how few other movies can be linked to reach a co-starring role with Kevin Bacon.

Using the *IMDB* (Internet Movie Database), Duncan Watts was able to create these tables indefinitely and much more reliably than by poling humans. One thing he found is that Kevin Bacon is hardly the center hub of the Hollywood universe. In links to other actors he rates a little above average. In this way, Watts wielded the tools for the sake of his inquiry (Watts, 2003). He did not look for a pre-packaged research utility or even modify an existing one, he created the software from scratch that accessed the web.

Human Tasks vs. Computational Task

Many of us assume a computer can't consistently create masterpieces (Hawkins, 2004; Carter, 1999; LeDoux, 1996). A few remain convinced that a computer could theoretically create something like pop music and best sellers (Tapscott & Williams, 2006; Jenkins, 2006). How? On the net, one can randomly generate a song-worth of notes, or randomly put sentences together until 200 pages are reached. Then, as with Evolution, generate a variant. Thanks to the enormous number of potential judges available[21] on the net, humans can decide which iteration is the better one, and that becomes the new template for the next generation. Because there are so many, their votes will end up reasonably representative of the group consensus. Theoretically. This concept was made most famous with the (theoretical) *Turing Machine*, but even *Information Processing*[22] utilizes the computer in this way (Hunt, 1996).

Even if an individual voted "incorrectly", the overwhelming volume of votes would push the outcome, not towards the "better" (as if such a concept were even viable) but toward more popular. This is also why it would never create a "masterpiece". The masterpiece, steps well beyond the expected. A tiny minority may recognize it's "greatness", but most do not at the onset, without other leaders to follow[23]. Einstein and Monet are obvious examples, where public opinion gradually shifted in their favor, but didn't start as comprehension without a few model believers to imitate (Gardner, 1993; Solso, 2003).

The common needs (spoken or not) are what create deep comradery, and not the content of the messages. The net can transmit messages. Many propose that this can engender *social capitol*, a trust between members (Watts, 2003). But trust is not emotion. Membership and kinship are not synonymous. Certainly, the messages are no more faulty for conveying empirical matters (including chit-chat, but don't make sentiments too wordy or require more than a quick glance). Moreover though, the medium simply doesn't work for more complex messages. We don't get an email alert when visitors' to our web pages eyes glaze over. A face-to-face conversation is interactive on hundreds of levels (at least) and not one or two. If we were all Autistic maybe communication mediated by computers (as we do now) would suffice, but so far what the net does and what people do is very distinct (Boyd, 2005).

But there are two ways we use computers. One is the hands-on way but the other is the way we imagine computers in the abstract. For instance, we vaguely imagine computers at NASA or even at the bank are for. Most of us don't know or really even care in any detail, yet we have a sense of what we think their role is. We tend to assume our subconscious attitudes are informed by conscious ones. Hopefully not. Movies like *2001:A Space Oddessy, War Games* or *The Terminator* series reiterate remarkably similar anthropomorphic messages about our tools. This is the same technophobia as when people became afraid Nikola Tesla was out to destroy the human race (Tesla & Childress, 1996). It's silly in retrospect, but is an inevitable stage in any development.

An example of high-end computing is the *neural network*. At first glance, it would seem this idea would be of no use at all[24]. At second glance, you see it of use, if only it didn't have that preposterous name. A basic model of a neural network may look at a face with 4 binary features, one of two types of eyes, ears, nose, etc. (Adbi & Valentin & Edelman, 1999). Presented with randomly assorted faces of this kind, it guesses if a known face is the same as a new face, perhaps which features are more likely to appear together. The limited number of options is essential to "learning.

As the system "learns", it gives weight to it's predictions, called *Hebbian learning* (the *Widrow-Hoff* method is similar but adds a feedback loop. "Fuzzy logic" is similar but without necessarily networking (McNeal, 1994)). This is obviously a simplification to refer to the concepts, but there are countless pages written about this. However, that's not how brains work. We make unpredictable adjustments to the odds on the fly. "That might be Janet who might be wearing his clown make-up." Like language, there are infinite possibilities, but we use schemas to narrow our choices drastically (likely to chunk-sized options with every recall).

By creating context, we can pool sketchy *top-down* and *bottoms-up* knowledge and derive useful conclusions. A more comprehensive description of the *frame problem* (and the *conduit metaphor*) would require a whole book (Fodor, 2000; Ortony, 1993) so forgive me for trying to sum it up here. Computers can't know about anything beyond what they've been programmed explicitly. Without telling them about 4, they can't add 2 and 2. Thus there is a limit to what they can learn. Computers can only do an amazingly thorough job of re-combining facts they know. They can't consider of things outside of the frame they have been given. Computers just don't "frame" things and can't employ our method. And it ends up, this method is essential to how we conceive of problems (Dewey, 1910; Hawkins, 2004).

Again, this is hardly to say we are wrong in trying (for a while). It is just very peculiar behavior

Figure 3. Looking at ex.plode.us (a site that compiles the membership of several social software sites) may prove an ideal demonstration of this. Here are 6 of hundreds of pages retrieved from a single search.

on our part. It is not that we should "correct" our use, as much as we should wonder about how we landed on it, and why we have so tenaciously clung to it, for so incredibly long, when we should know these issues fully well. The points here are not recent or arcane discoveries at all. No industry or advertising is to blame. We choose what to buy and how to use the tools freely. But by clearly identifying our motives, we may be able to shed light on how best to achieve them, particularly by discovering ways to act in our own favor, and no longer in a veiled form of self-abuse.

CONCLUSION

There is a big difference between web 1.0 and 2.0. Its the difference between going to the lumber yard to get wood cut to build shelving and going to the ... store for shelving. In one case its ground up and custom and in the other its glitzy but you're working with pre-defined units. Its a different way of thinking - what gizmos/widgets can i find & add? – Katharine Staelin, Web designer since 1995.

Very true.

However, let's take another step and compare a 100-year-old oak bureau and a unit from Ikea. The Ikea model has benefits that most folks (including the retailer, manufacturer and shipper) need. It's cheap and more applicable to different (but pretty similar) situations like storing books, clothes, flatware, etc. What's worrisome is subtler. Where people once saw funny uses for peculiar furniture, now they just don't want to, are trained not to. They see an old bureau that is obviously a bedroom piece doesn't belong in a kitchen.

That said, most of us are mediocre carpenters. Our pre-fab furniture can only end up so bad. But it can only end up so good, too. At an insightful, yet perfunctory level, it's only the range of quality that is changed. And that's what has happened with the all-purpose look of blogs. But looking at it in reverse, where a page of no interest can be clicked away and immediately forgotten (has minimal effect), the odds are now remarkably slim that we'd land on a page that knocks our socks off.

I am picking on blogs and the web, but these are symptoms. There is a much deeper and more profound dynamic I am referring to here. In this process, we are being trained as to what we need to do to get more expected result, not more useful ones. Part of that training is selective attention. We smooth over differences between what we hope to find and what we are offered. Without noticing our habits shifting, our brains (subconsciously) re-work our inquiries to fit the answers given so things make sense to us (Gallison, 1997). We ask Google for things that cause Google to reward us or not punish us with confusion. This is the wave and we are already drenched.

By subscribing to this wave, we also downplay our individualistic differences. But here we must take caution. An emergent property of this cohesion is that the web now contains mechanisms for enforcing a cultural harmony, even amongst traditionally opposing views. Acceptance is a slippery slope. Ideally, we cast away bigotry but we can also give child molesters the stamp of approval. This dilemma is not a dilemma at all. It's simply that we are used to judging right/wrong, true/false, good/bad and the **net** is a way to discard these things. Truth doesn't matter. From a traditional perspective, the net absolutely is lawless anarchy. But the net is not about truth, it is about collecting points of view. The only fact lies in the idea that someone, somewhere wants to make a point of view more accessible. And that is completely trivial, beside the point. Authors and their beliefs are arbitrary because they have deliberately chosen to be so.

Whether a collective unconscious, a gas oven, a cultural ritual, a verbal language or a popular tune, these are all tools, we created at our disposal. We have a choice in how to employ them. As every one of us, in big cities and out in the sticks, is encroached on with greater the pressures of population density and *overload*, the more prone we become to use these tools as a shield, protecting our intimate individuality. Such a scheme is hardly a bad one. Quite the contrary, we may be desperately saving what little sanity is still salvageable.

Democracy is not freedom, but a strategy to allow anonymity. Or if you'd rather believe it is, freedom's key feature is to absorb most of the blows to individuality, by distributing them to the masses in imperceptible little inconveniences. Spam is an obvious illustration, but even the fact that people use blogs that don't precisely fit their needs, though are willing to adjust those needs, is a far more profound case. Or that people eagerly use web pages, a monthly fee and pricy computers instead of filling notebooks and leaving them on the street or sending postcards. What are we anxiously paying for?

Ultimately, we made this collective unconscious. The net is our resource, at our machines' disposal (and not at all visa versa). It is unprecedented-ly useful because it continually evolves, because no individual, consortium or law really has the effect on it of the totals of us, because we feed it, look after it and nurture it. What we created was certainly impressive. Technology is ours to transform, to some degree obviously at the content level, but much more importantly at the perspective level. We are heading further into aimlessness and danger, but aren't on a fixed course at all. Hopefully, a splash in the face, wakes us up. We can now choose to steer.

KEY TERMS

Consciousness: This word (often called "the C-word") gets people all flustered and surely needs definition. Many want to believe it is uncannily elusive. I disagree. Jeff Hawkins seems to as well and articulates it quite nicely. "Consciousness is not a big problem. I think consciousness is simply what it feels like to have a cortex." (Hawkins, 2004, p. 194) Of course "feels like" is even more problematic. I would alter this slightly. Consciousness is the result of whatever the neo-cortex does. We don't precisely know all the details, but whatever they end up being we can just call "consciousness."

Digital: This has to be one of the most abused buzz words ever. It has a very definite meaning that gets lost in a hazy fog. People often think it means something like "newer and better". Actually, it just means "less accurate (for a good reason though)". Theoretically, analog is any value from 0 to the highest, an infinite gradation of grays. In reality, we are limited by human perception and frustrated by mechanical limitations. Digital means that the same reading is now only 0 and 1, black or white. There is no question this is an imperfect alternative. What is useful though is that when done enough times, we can surpass previous limitations (though we don't always). Creating copies is far more reliable since there are so few possible states per *pixel* (see below). In fact, whereas before "copy" and "original" were useful ideas, now they really don't apply. The thing we play back now is always a copy. The original, which only existed as electrical pulses, is long discarded as soon as it is saved. But there is no longer any reason to distinguish, since they are identical clones.

Network Behavior: Individual entities (nodes) can be grouped to communicate with each other in a myriad of configurations. Two cans and a string is the simplest networking model, where there is only one link between the *nodes*. The phone system is a complex network, allowing any node to relay to any other. Or you can think of social networks. In cases where "she told two friends, then she told two friends and so on, and so on." In networks, tiny events can take on enormous proportions. Where a germ is passed between nodes, the epidemic charted over time, does not look like a gradual slope, but stays low, then suddenly explodes. The features of the network beyond the sum of its nodes are the *emergent* properties. For instance, telephones are only so handy in isolation but by connecting them in a network. That's a simple emergent idea, but there are more complex ones. For instance, you can scream at one end and raise a person's pulse at the other.

Neural Net(work): A computer system is often designed to mimic the workings of the brain, primarily for the task of statistical learning. However, this term is a bit misleading, since it is not at all likely that the brain learns in even a similar way to the way computers (even networked ones) save and retrieve data from memory. Nonetheless, whether accurately depictive or not, it is a remarkable programming. In very generalized terms, data comes from several distinct sources (often with their own processors analyzing *input*. Each source is called a *neuron* and has a weight of influence. The data is scaled according to the neurons current weight. The central computer determines the successfulness of this pool and updates the weights accordingly. Thus it seems to learn, which processes influence the outcome more heavily in complex tasks. Of course, this implies fore-knowledge of the goal, which brains don't consider and computers can't do without, However, the pooling and dynamic weighing process is no less effective once the analogy to the brain is discarded.

Pixel: Usually this word is used in the technical sense (and probably one you are well familiar with). But the general concept is often a hazy one. The term being popularly bandied about with careless excitement, refers digital-ity. It is the smallest indivisible element in a collection of like elements that comprise an entity. "All in all it's just another brick in the wall." You could say the places on a checkerboard are pixels. But they needn't even be square. City blocks may be considered pixels. But they needn't be configured in any orderly fashion. Cells in a cluster of tissue could be pixels. The audio equivalent of resolution is called the *sample rate*. Usually to call something a pixel, there needs to be an encompassing (explicit or implied) system. A colored dot of ink is not necessarily a pixel, until you consider it part of a larger picture, say in a newspaper.

Surface Grammar: and **Deep Structure:** These are terms coined by the linguist Noam Chomsky. Probably this entire essay is predicated on an understanding of these terms. It hardly matters if this theory proves correct for language, it is nonetheless a very useful way of looking at the issues. But if you aren't familiar with the terms, and many aren't, we'll try here. According to Chomsky, (non-human) animals certainly communicate but insists that these communications can not really be called language because the animals lack essential mental features. He has a point. It's a fine one and could easily be overturned some day. But it is based on the notion that there is a unique mental apparatus. A *Language Acquisition Device*. A bee dance or a bird call serve linguistic purposes, but bees' and birds' brains don't have enough parts. Each human language obeys a somewhat unique set of conventions. "Noam talks about language." is not the same as "Language talks about Noam." The difference in meaning is derived from their specific *surface grammar*. But the fact that we can put words together in some order and it will convey a message is *deep structure*. Though it is clearly impossible all the specifics of a language would be in our genes (no one is born speaking fluently, we need to learn), it is also unlikely we could learn so many detailed rules, so proficiently, with almost no trial-and-error for many aspects, in the few years we acquire language. "Colorless green ideas sleep furiously." Chomsky's famous example feels like it should make sense but does not. Possibly because, while we may figure out by "looking up" the references of our learning, that this is meaningless, we are "hard-wired" for the rules by which a languages rules are concocted. The brain doesn't actually know syntax from chaos, it simply applies this pattern recognition to whatever stimuli is input. Over the ages we have gradually adapted this mental tool to the task of communication via words.

Turing Machine: Probably, if you bought this book, you are someone who knows about Alan Turing's ideas more than I. It is a very popular concept in computing and for good reason. Turing's original example has been applied in countless variations, in countless disciplines over the years. But what the Turing Machine, from 1936, refers to is a proposed concept (never actually built), where a computer could use feedback with a conditional assessment function to "learn". Almost all computer learning is based on this idea in some way.

ENDNOTES

1 Object Oriented programming mainly differs from Procedural Programming (now all but extinct) in that there is a short hand method of grouping behaviors into "Classes". If the object in code is a member of the Cat class, any specific instance *inherits* all of the variables and functions of that Class. Thus if Mittens is of the Cat class, and Princess has a variable for breed, and a function purr(), Mittens probably has those things too. However, it would be convoluted to detect if there were purring happening anywhere in the program and then impossible

to determine if it is a Cat doing it. At least without setting up very externally specific and reasoned decisions. There is no identifyCatsByWhateverMeans() function.

2 Higher level programming languages have *data types*, which may seem comparable to chunking. There are huge, essential differences, but the main ones are that chunks are not a fixed size, and can expand/contract. There is no precise point at which they fail. And there is no analogy to *casting*, or switching between data types.

3 Jung notes that "resistance to its [archetypical] expression may result in neurosis", which, as we read on, resonates eerily. Sanity may depend on a degree of conformity" (*ibid.*) This notion, that archetypes are not created to serve luxury or interest, but from a genuine psychological need for our mental health, has great ramifications as we continue.

4 Before the Beatles and Elvis, during Frank Sinatra's early performances audiences, mostly of teenage girls, often screamed and fainted. His manager noted the phenomenon and made it more likely to occur by planting 16 young women who had been instructed to initiate this behavior. They were soon accompanied by authentic screamers and fainters. The antics spread to the thousands of others. As with the laugh track of television sit-coms, people will often follow the herd, even when the leader is obviously a fraud. Shows are funnier to us if the (artificial) crowd seems to enjoy them. We are constantly on the look-out, hungry, for cues to appropriate behavior, even when we "know" better.

5 Keeping control of neurological feedback loops is what drugs like Prozac are all about. LeDoux shows how potential fear stimuli triggers the amygdala, which sends two signals, one to create visceral effects and one to the pre-frontal cortex to assess the threat. There, the signal either is abandoned or sent again to the amygdala, completing a loop. There really is often nothing to fear, but fear itself. This is also why feelings of apprehension can take hold, without much antecedent. It is a runaway feedback loop. The amygdala keeps sending the signal to the rest of the body, increase the pulse rate, speed up breathing, dish out more adrenaline. But meditation and other like forms of trance states, has the ability to assuage those loops.

6 English only relatively recently switched from this structure.

7 Only about 100 of the thousands of frequencies are commonly used (Levetin, 2006). Though by tuning off concert pitch these dozen notes (times about 8 octaves) are relative and not absolute. Of the dozen tones, they are often further divided into patterns called scales (an example is all the white keys on a piano are C Major, the black keys are "accidentals" of that scale). Cultures tend to stick to the same 3 or so 7 note scales (Temperley, 2007). Though that leaves about 2.5 million possibilities for every interval. Quite a lot but hardly infinite.

Likewise, rhythms tend to be either on the beat, or a division of that by some factor of two (half a beat, half of half, half of half of half, etc). Occasionally factors of 3 or 5 (or even 7, 9 or 11) are used sparingly in Western music. Eastern and Middle Eastern music is more open to factors greater than 2, and tends to limit melodies to 5 of the 7 note scale (May, 1980; Arbabi, 1997). Again with regard to rhythm, the possibilities are enormous, but drastically fewer than infinite.

8 However, cell phones and TVs are now quite imitative of computers, this is not essential to their actual functions. A peculiar phenomenon. Traditionally, successful need fulfillment, drives manufacturing and thus marketing. This appears to work the other way around. However, as we'll talk about

later, a need may actually exist yet.

9 Ironically, but only examples disruptive to systems that have always worked are ever heard. Napster and Bit Torrent type file sharing is more about the fun of getting things for free. The resulting anarchy is an afterthought, and hardly as detrimental as if it were a bona fide strike against the industries. We literally could upload every song and movie as it comes out, but this may actually be self-defeating.

10 I would say, an important transition for us now, is to let go of the idea of archiving. While digital storage may be semi-permanent, the means to play it back is in hyper-flux mode. Digitization is paradoxically ephereralization. Or rather, the more non-linear and computer-centric the thing, the less likely it will be available for long. But calling archiving an obsolete game is akin to blasphemy.

11 Actually colors outside of the visible spectrum (like Infra-red and Ultra-violet) would be useful for many applications.

12 Though "inch" varies slightly, making matters even more complex for traditional designers.

13 There really is no original. The usefulness of digital-ness is like replacing an assembly line with a hall of mirrors. The fundamental way computers and the net operate, renders issues like copyright, moot points. Looking is "stealing" or rather there just is no useful way to talk about "stealing" anything that can be digitally recorded. This bothers a lot of folks who depend on things like royalties. Prolonged arguments simply conceal the issue. We can try to weave convoluted smoke-screens and offer excuses, but the concept is a simple one – if you understand how digital technology works, you understand that the word "original" has no real relevance. Without that word, any argument collapses like a house of cards.

14 Folks today complain that modern audio CD's suffer from a standard set decades ago, limited older capabilities.

15 Many arms must have grown sore. For a few decades, the phone featured one cup to speak into and another one held to the ear. Later, those two pieces were consolidated. The "French" style one piece receiver, that we still see sometimes in land lines, and ubiquitous until about 2000.

16 These were early Mac notebooks (1992-1994) with a garage-like box that acted as a monitor base and peripheral hub. I have a few and they still can be networked (LAN or internet). They have browsers, can send email, cost less than those $100 computers for Africa that every talks about. So why do I, along with so many of us, keep buying new machines?

17 Both programs are surely out there already but which would take a Python or J2ME programmer a day to write from scratch. Often these features are built in to programs such as Dreamweaver and many professional web designers simply aren't always aware they exist (much more usefully) outside of a specific program.

18 Free IDEs for cell phones are offered by Google (Android) and at Mobile Processing.

19 Paranoia from schizophrenia (and other psychological problems) may be awful for that individual, but that individual is seldom also able to organize unwilling masses to comply with their defensive strategies. Conservatives (again, loosely defined) tend to project their needs onto others who would be fine if they weren't being so regulated. Often the minority, they devise very calculated means of getting others to adopt their strategies. However, if conservatism implies a need to keep the status quo from change, the only way they can possible manage to keep things comfortable (or even bearable)

for themselves would be to convince the majority that change is a bad thing.

[20] Oddly, this is the exact effect that the adoption of the light bulb had as well. People could read by the fireplace with the family in the living room, but chose to move to secluded bedrooms. People could see by moonlight (and stars back then!) but street lights made it feel less scary to go out for an evening stroll. Note that most places on which livelihood depended, were closed by that hour. Certainly this was not a universal case, but you see how most of the light bulb's cultural impact came more from luxury than dire need.

[21] Note that these are people with idle time and attention. Perfect revolutionary fodder.

[22] A precursor to Artificial Intelligence, where Sociology and Computing initially met.

[23] Recall the plants at Sinatra shows from footnote 4.

[24] The problem can be summed up like this. "[neural nets] do not differ *essentially* from standard statistical models. … Networks usually have several layers. The first layer is called the *input* layer, the last one called the *output* layer." (Adbi & Valentin & Edelman, 1999, p. 2). Thus you see, the task at hand is not actually accomplished entirely asynchronously but remains essentially linear. And though we don't know much about how brains do what they do, we are sure of many ways they don't work. Brains are definitely not linear.

Section II
Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design of social computing tools and technologies. Throughout these contributions, fundamental development methodologies are presented and discussed. From broad examinations to specific discussions of particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful e-learning environments, social search engines, and social software are examined.

Chapter 2.1
Distributed Learning Environments and Social Software:
In Search for a Framework of Design

Sebastian Fiedler
Zentrum für Sozial Innovation – Centre for Social Innovation, Austria

Kai Pata
Center of Educational Technology, Tallinn University, Estonia

ABSTRACT

This chapter discusses how the construction of an adequate design and intervention framework for distributed learning environments might be approached. It proposes that activity theory has some interesting concepts and perspectives to offer in this regard. In addition, it discusses the concept of affordance, understood as perceived possibilities for action, and its potential consequences for learning environment design. Furthermore, some current technical and conceptual challenges for the implementation and maintenance of distributed learning environments are addressed. The authors consider their text as a proposal for a necessary reorientation and a call for contributions to the search for an adequate design and intervention framework for distributed learning environments.

INTRODUCTION

In recent years higher-education systems are undergoing a considerable transformation process on various levels. The implementation of leadership-, evaluation- and accreditation schemes that are mainly modelled after entrepreneurial solutions, are fundamentally re-shaping our higher educational institutions. This new regime also influences how communicative and productive practices like teaching, facilitating, and collaborating are technologically mediated. Many educational institutions apply now strategies and policies that aim for the implementation of large-scale, homogeneous, and centrally administered technological landscapes of tools and services to support and manage teaching and studying activities. Thereby they largely ignore that disciplines or areas of study still differ to a considerable degree on how they relate to certain occupations and professions, the labour market in general, and on what educational traditions they have developed over time Bleiklie (2004). From an observer's point of view, all actors appear primarily as "residents" of such an institutional landscape of pre-selected and decreed sets of tools and services. Everyone is expected to perform all necessary mediated activities within its boundaries.

Apart from general communication systems, content repositories and digital library systems, institutional landscapes of universities are still dominated by Course Management Systems, that are often somewhat misleadingly named Learning Management Systems (LMS). These Course Management Systems are the prototypical technological expression or "flag ships" of the mainstream institutional strive for centralisation and control. Thus, it comes as no surprise that the ongoing development of these all-comprising platforms is driven by a continuous desire for expansion and assimilation of additional features and functionalities. At the same time very few of the Course Management Systems currently in use, provide interfaces for interaction and data exchange with a wider ecology of networked tools and services. The majority of these platforms rather operate as "closed clubs" and try to restrain all activities within their particular boundaries.

All these systems feature an unequal distribution of power and ownership with a clear distinction of roles (such as educational authority vs. participants) producing asymmetric relationships (Wilson *et al.*, 2006). Furthermore, they foster a general educational intervention approach that seems largely based on the rather illusionary expectation that human change processes can, and indeed should be, modelled on the basis of simple cause-and-effect relationships. We would like to argue that the socio-technological practices that are encouraged by the majority of today's Course Management Systems in higher education demonstrate clearly that the majority of instructional design and educational intervention models are still conceptualising humans, or the social systems they form, as "trivial machines" (Foerster, 1999). It seems like decades of multi-disciplinary work on system theory (see e.g. Willke, 2005) constructivist theories of knowing (see e.g. Glasersfeld, 1995), second-order cybernetics (see e.g. Maturana & Varela, 1980), and aspects of self-direction (see e.g. Candy, 1991; Fischer & Scharff, 1998) and self-organisation (see e.g. Harri-Augstein & Thomas, 1991; Jünger, 2004) in education have simply been brushed aside or entirely ignored.

Instead of treating humans as systems of (self) organising complexity that develop particular qualities like operational closure (and thus self-referentiality and highly selective interaction patterns with their environments), technological mediation in higher education and its underlying (instructional) design is mainly based on the idea that human change processes, and the intentional interventions that are supposed to "cause" such changes, can be reduced to simple cause-and-effect relations, simple purpose and goal attribution, and simple sequential temporal patterns (Willke, 2005). Thus, many technologically mediated environments that follow a traditional instructional design approach are fostering almost exclusively the teaching of codified knowledge and skills. Emphasising a clear distinction between educational authorities and students and their respective responsibilities, expert instructional designers and course facilitators are responsible for guiding the participants through a sequence of pre-structured events and interactions with pre-selected materials, towards a set of pre-defined instructional goals (Kerres, 2007). In general this creates rather sheltered and non-challenging environments that offer only a limited amount of prescribed interaction patterns and forms of expression. This predominant institutional approach to technological mediation of teaching and studying appears to be rather incompatible with a variety of contemporary conceptualisations of how human- and social systems evolve and function and what this implies for intervention and intentional change. Apart from this conceptual incompatibility the status quo in many educational institutions contrasts sharply with two major ongoing developments.

SOCIO-POLITICAL AND SOCIO-TECHNOLOGICAL CHANGE

From a socio-political perspective we have to attest that all post-industrial societies have seen a dramatic shift towards more symbolically mediated and information driven work processes. We can observe a general increase of "constructive" or "design"-practices that focus on the production of artefacts in the ongoing work process. Architects produce technical drawings and sketches, psychologists create diagnostic reports or treatment plans, programmers develop new prototypes, and so forth. What all these activities have in common is an evolutionary design- and development process that inevitably produces challenges and demands for change and "learning" on a regular basis. The progression of such design- and development processes is generally hard to predict, since goals and strategies often have to be changed and expectations have to be adjusted. Authentic challenges and tasks often require collaboration, communication, acting under (at least partial) uncertainty, and an overall working style that has been described as bricolage (J. S. Brown, 1999). Bricolage refers to the localisation, selection and combination of artefacts and objects (things, tools, documents, programme-code, etc) in a novel context. Beyond accessible artefacts, the systematic integration of other people and what they know and are able to do (see e.g. the work on distributed cognition by Hutchins, 1991, 1995), becomes a core component for successful problem solutions in information-intensive work settings.

Thus, in numerous work and life settings new important "areas of challenge" emerge. Many people, for example, find themselves increasingly operating in distributed and technologically mediated environments. They need to build up viable dispositions for collaborating, self-directing (intentional change projects), and social-networking successfully within these environments, while making use of new potentials for mediated action on one hand, and compensating the limitations and constraints of such a mediated form of (inter-)action on the other. Some scholars, particularly in the area of vocational education, have acknowledged this trend. Their conceptualisation of competence, for example, explicitly emphasises the role of dispositions such as orientations, values, and volitional aspects for (self-organising) action that can be successful in situations that carry a high level of uncertainty and complexity (Erpenbeck & Heyse, 1999; Heyse *et al.*, 2002). Thus, these scholars try to shift our focus away from dispositions such as factual knowledge and procedural skills that made up the core of the old concept of "qualification". Of course, factual knowledge and procedural skills are necessary dispositions in all contexts, but they are not sufficient to act successfully in many authentic problem situations. They might offer a starting point and some guidance but certainly not a straight solution in many areas of life and work.

In parallel to the changing nature of work and life challenges, we can observe from a more socio-technological perspective the emergence of a myriad of decentralized, only loosely-coupled, networked tools and services. These tools and services increasingly provide individuals and collectives powerful means to augment a myriad of activities and practices that transcend all kinds of institutional and organisational boundaries. The emergence of these small, simple, and networked tools and services, often labelled as social software or social media, is generally considered to be an important expression of the ongoing evolution of the Web towards a general computing platform and a renaissance of some core ideas of the Two-Way-Web (Berners-Lee, 2000). This looming evolutionary step is frequently labelled with the rather fuzzy marketing term Web 2.0. However, we believe that this development could potentially fuel a counter-movement to the mainstream, application-centred, institutional approach to technology provision in higher education outlined above. Many interesting lightweight, cost-efficient systems and tools have emerged in the personal Web publishing realm, including varied content management systems, content syndication and aggregation services, and a range of tracking and mapping tools of hyperlink economies and social networks (Paquet, 2003). These tools offer powerful means for the support of collaborative and individual work and study activities as they occur within contemporary information-intensive design- and development work outside of formal educational settings (Mejias, 2005).

In recent years we saw the emergence of a growing "avant-garde" of people who indeed support and improve their own personal work- and "learning" environments with a patch-work of preferred, networked tools and services. Empirical data on the size of this group is hard to obtain, but there are many indicators that the way people are using the Web for (self-)educational matters and collaborative actions has begun to change (Downes, 2005). In this realm, personal and collaborative Web publishing activities like Weblog or Wiki authoring, Webfeed publication and aggregation, social book-marking and so forth, are currently the iconic practices. Some individuals and collectives already apply these emerging means in creative ways to support projects of all kinds, including their intentional advancement of competencies (in the sense of dispositions for self-organising actions) in formal and informal contexts. These individuals have acquired the means and capabilities to construct and maintain their personal landscapes of technological instruments. They make use of such networked tools and services to establish new relationships and to construct extended social networks to support their own educational projects. They take responsibility for all necessary instructional functions such as selecting and acquiring material resources, pacing and monitoring themselves, establishing criteria of evaluation, generating feedback, and so forth. From a technical point of view establishing such patterns of actions is entirely feasible and the palette of mediating tools and services is constantly expanding and evolving.

We have argued elsewhere (Efimova & Fiedler, 2004; Fiedler, 2003; Fiedler & Sharma, 2004) that these emerging and evolving personal landscapes of tools and services are well suited to support a more open, conversational approach to learning and change, inside and outside of formal educational settings. The authoring of Weblogs, for example, in combination with the surrounding practices of Webfeed monitoring, reading and aggregation, social book-marking, and so forth, can be meaningfully conceptualized from such a perspective (Fiedler & Sharma, 2005; Sharma & Fiedler, 2007). If used properly these practices can support ongoing "conversations" with self, others, and artefacts. However, bringing these practices into formal educational settings creates considerable difficulties and tensions. Since these practices originated in the context of technological landscapes that can be described as open, distributed, networked, and publicly accessible, they often tend to be perceived as disruptive to existing approaches to technologically mediated teaching and learning in educational institutions. Therefore, some institutions try to control, suppress, and even ban them entirely (Attwell, 2007).

We would like to argue that the continuously expanding array of social media and social software solutions offers an interesting and somewhat promising technological tool set for particular design and intervention purposes in higher education. However, we believe that the application of such a tool set needs to be set in an adequate conceptual framework. Making systematic use of social media and social software looks particularly promising, if the overall goal of one's design and intervention efforts is the establishment of learning environments that attempt to foster the advancement of dispositions (for self-organising action) that are required to cope with high levels of situational uncertainty and complexity. Furthermore, we think that the ongoing socio-political and socio-technological developments that we sketched above, merit such considerations. In the remaining chapter we want to outline what conceptual and theoretical aspects could be worked into a framework for the design and support of distributed learning environments that try to make systematic use of social media and social software following a particular set of educational intervention goals.

BUILDING A CONCEPTUAL FRAMEWORK FOR THE DESIGN OF DISTRIBUTED LEARNING ENVIRONMENTS WITH SOCIAL MEDIA AND SOCIAL SOFTWARE

We suggest that a framework for the design of distributed learning environments could make use of some core ideas of activity theory (Yrjö Engeström, 1987). According to this line of theorising, activity systems arise when an actors want to realize certain objectives. Since we are mainly concerned with formal educational settings in higher education, these objectives are predominantly educational. For fulfilling their personal or group objectives in technologically mediated settings, actors need to construct, adopt and adjust their landscapes of tools and services to meet these purposes, adapt their activities to the co-actors‘ preferences, and jointly plan and coordinate their activities with studying-partners and facilitators. Different artefacts mediate the processes in such an activity system. Artefacts, as the materialised outcomes or by-products of goal-driven actions, may also serve as new inputs for other activity systems.

To analyze how actors in a given activity system perceive themselves, the artefacts and tools in use, and other participants, we find it useful to integrate the concept of affordances into our considerations for a learning environment design model. Gibson (1986) originally defined affordances as opportunities for action for an observer, provided by an (physical) environment. Gaver (1996) emphasized that affordances emerge in human action and interaction and, thus, go beyond mere perception. This contrasts with the common interpretation that affordances simply refer to situations in which one can see what to do (Gibson, 1986). Neisser (1994) elaborated Gibson‘s concept of affordance and distinguished three perceptual modes: 1) Direct perception/action, which enables us to perceive and act effectively on the local environment; 2) Interpersonal perception/reactivity, which underlies our immediate social interactions with other human beings, and; 3) Representation/recognition, by which we identify and respond appropriately to familiar objects and situations. Besides the affordances related to the environment, Neisser’s interpretation introduces the interpersonal perception of subjects in action as an additional source of affordances in the social and regulative domain.

The mainstream view on affordances in educational technology seems to consider them as objective properties of the tools, which are perceptible in the context of certain activities. Thus, it is commonly suggested that tools have concrete technological affordances for certain performances that can be brought into an actor’s perception through specific instructions (Gaver, 1996; Norman, 1988). This use of the concept tends to ignore its self-referential and subjective nature and observer-dependence. It seems to imply that affordances should be located in the environment or specific artefacts or tools. Kirschner (2002), for example, defines pedagogical affordances as those characteristics of an artefact that determine if and how a particular learning behavior could possibly be enacted within a given context. Kreijns et al. (2002) have defined social affordances as the “properties” of a collaborative learning environment that act as contextual facilitators for social interactions. However, we do not want to follow this common (mis-)understanding of affordances being the “property” of a particular learning environment. From an interaction-centred view (Vyas & van der Veer, 2005) affordances are perceived possibilities for action. They refer to what people perceive and signify during their actual interaction with an artefact or tool. While interacting with an artefact or tool actors continuously interpret the situation, and construct or re-construct meanings. Thus, we propose that instead of relating affordances "objectively" with certain features of software applications or other complex tools and artefacts, they should rather be related to the activity system. Actors must realize how they perform joint actions with artefacts and tools in order to accomplish their shared objectives. Affordances then emerge and potentially become observable in actions that people undertake to realize shared objectives.

A conversational grounding of objectives and tools for particular actions inevitably brings along the development of certain implicit or explicit rules for effective action in particular settings. In return these rules constrain how tools can be used in specific actions. In educational settings constraints for using tools in a particular way also arise from the perception of predetermined tasks, objectives and artefacts that are meant to guide and contextualise the activities. Furthermore, activities within an activity system are also constrained by the technical functionalities of tools and services, and the artefacts conveying meanings in a specific domain context. Actors must develop a (at least partially) compatible understanding of the affordances (for action) within a given setting, to make effective, coordinated performances possible within an activity system. This holds true both for facilitators and participants who need to collaborate. In our framework for the design of distributed learning environments we acknowledge that facilitators cannot pre-define, but only somewhat anticipate affordances that might be perceived in a particular learning environment. A distributed learning environment, however, has to evolve and cannot be "ready" when the participants start to (inter-)act. Cook and Brown (1999) and Vyas and van der Veer (2005), for example, assume that affordances should be conceptualized as a somewhat dynamic concept. In an ongoing interaction with tools, artefacts, and other people, actors are not only affected by the dynamic situational changes but also by their personal dispositions. Our personal dispositions strongly influence what affordances we actually perceive in a given situation at a certain point in time. This dynamic understanding of the affordance concept appears to be entirely compatible with the ideas of Engeström et al. (1999), who describe the dynamic nature of interactions between the various components within activity systems.

We suggest that a framework for the design of distributed learning environments needs to take into consideration that the perceptions of all actors within a distributed learning environment dynamically change over time. From such a perspective iterative cycles of grounding and regulating through conversational actions become increasingly important for all actors. Though facilitators cannot fully pre-determine an "objective" range of affordances for all participants, the production and communication processes still need some structuring and guidance. We propose that these processes can be structured around activity descriptions. Such activity descriptions involve participants and facilitators, their objectives, mediators of their activity (tools and artefacts) and anticipated affordances that are likely to be perceived in relation to suggested actions. Instead of entering into a pre-defined landscape of tools and services where all objectives, actions and evaluation means are defined and selected by an instructor, actors in our distributed learning environments design framework would be offered activity descriptions that allow them to set up and carry out certain educational challenges or interventions. The realization of each activity description in a particular institutional setting requires a conversational grounding process for establishing and maintaining a distributed learning environment on the basis of loosely-coupled components that can interoperate and interrelate on various levels. To start this process an initial set of tools and services needs to be selected that can support the productive and conversational actions of participants and facilitators. In more traditional instructional design models the instructors are expected to plan appropriate support strategies and tools before the actual activity. These models suggest instructors (or designers) need to (and in fact can) predict the outcomes of learning, define the ways, how to reach these outcomes, and determine which tools are appropriate for mediating these processes. This approach mostly reduces learning environment design in technologically mediated education to the selection of a set of tools, which offer objective functionalities for doing something. The instructor's task is to make use of these tool functionalities in pedagogically sound ways, creating instructional intervention strategies for using these tools in the activities. In addition, instructors are supposed to make learners aware of these tool functionalities in order to guarantee their success.

In our framework for the design of distributed learning environments, however, we understand environments for intentional learning and change as a broad and subjectivist concept. A "personal learning environment" entails all the instruments, materials and human resources that an individual is aware of and has access to in the context of an educational project at a given point in time. We think that our psychological and somewhat ecological perspective on that matter sets us apart from the majority of the current contributions on "personal learning environments". Though some authors continuously point out that they consider "personal learning environments" as a conceptual approach rather than a piece of software or technological toolset, a review of the existing literature on the topic reveals an overall tendency to use figures of speech and expressions that suggest the contrary (see e.g. Chan *et al.*, 2005; Harmelen, 2008; Johnson *et al.*, 2006a; Johnson *et al.*, 2006b; Milligan *et al.*, 2006; see e.g. Wilson, 2008; Wilson *et al.*, 2006). While we certainly share the general analysis of the shortcomings of the mainstream approach to technologically mediated teaching and studying on one hand, and the proposed transformation of the technological landscape towards loosely-coupled services, interfaces, and tools on the other hand (Attwell, 2007; Wilson, 2008), we find it useful to start from a more comprehensive and radically individualistic perspective that treats the mediation of actions with the means of networked, digital technologies, as one particular realisation of what a person tries to achieve in her "personal learning environment" and what potentials for action (affordances) she perceives. A recent contribution from Johnson and Liber (2008) offers an interesting explication of a cybernetic and more comprehensive perspective on that matter that seems to be compatible with our thinking. It is quite clear, that networked communication and information technologies play an increasingly important role in this regard, but it is misleading to assume that all relevant actions in the context of human learning and change are inevitably technologically mediated all the time One author of this chapter explores this in more detail elsewhere (Fiedler, 2008).

Another important aspect that does not seem to get enough attention in the ongoing discourse on "personal learning environments", is the qualitative differences that emerge if the intended outcomes of work and study are to be produced through collaborative action among a group of actors. While many personal projects of learning and change greatly benefit from the engagement of peers, experts, and facilitators of all kinds, we would argue that the amount of regulation and coordination that is required for collaboration poses challenges and requirements that are qualitatively different from what an individual actor experiences if she is only following her individual trajectory of actions and goals. If, however, an individual takes part in some collaborative work- and study activities with other actors, some common goals and objectives for action need to be established and maintained. In this case parts of a personal learning environment inevitably start to show qualities of a human activity system. Again, if this takes place in a, at least partially, distributed setting, the conversational and productive actions will need to be technologically mediated. From an observer's perspective the actors involved have to form a distributed learning environment as long as the collaboration among these actors is still going on. One the productive goals of the collaboration have been reached such a distributed learning environment might dissolve entirely. On the other hand some weak-ties between the former collaborators might be maintained and become a more constant element of the personal learning environment of particular actors. Needless to say that successful collaboration might pre-dispose certain collaborative learning environments to be re-enacted again for other purposes.

From our perspective such distributed learning environments generally have the following characteristics:

- They cannot be set up and defined comprehensively before any activity is carried out together.
- Their components need to be grounded conversationally by participants and facilitators.
- They integrate diverse elements of distributed social software and social media tools and services that support social networking, collaborative artefact production, sharing hyperlinks and resources, self-reflecting, aggregating and monitoring of all kinds of information and activity flows, and so forth.
- They are constructed and run upon the conversationally grounded and continuously monitored objectives, activities and evaluation means of the collaborating actors
- They mediate activity descriptions, which are constrained by the affordances that are perceived in respect to tool functionalities and their interoperability, characteristics of the artefacts and objects, and the participating actors' dispositions, such as preferences for certain objectives, working-styles, tools, co-workers and so forth.

The systemic nature of such environments suggests that scaffolding issues and tool are highly interwoven. Our framework presupposes that the participants‘ perception of affordances in concrete activities need to be taken into account. For example, in the context of an educational challenge that focuses on mediated collaborative work, all actors and facilitators have to observe the participants' actions and infer the affordances they perceive (or not) in relation to the tools and services present in a given distributed environment. Furthermore, facilitators need to provide feedback and guidance if it appears that the affordances perceived by the various actors differ considerably and don't allow for an effective realisation of the overall activity goals.

Thus actors and facilitators who want to help to establish and support distributed learning environments need to consider the following issues:

- How can one infer the affordances perceived by various actors within different activities?
- How can actors judge the effectiveness of the inferred affordances for the realisation of the overall objectives of an ongoing collaborative project?
- What type of feedback has the potential to broaden or advance the actors' perception of affordances within a given distributed learning environment?
- What mental models guide the judgements of actors on the effectiveness of the observed actions within a distributed learning environment?
- How can one support actors in establishing consensus on the affordances within distributed learning environments during various activities?

REMAINING TECHNICAL AND CONCEPTUAL CHALLENGES

One of the major challenges for growing a particular distributed learning environment is the selection of appropriate and interoperable tools according to the actors‘ perceived affordances in a specific activity context. There is a need to reach a common understanding and to find a consensus among collaborators in respect to the perception of affordances. This raises the question of how to locate and make choices regarding the selection of tools and systems for intended activities. The application of a framework for the design of distributed learning environments requires practices that support setting up and shaping technological landscapes made of loosely-coupled, networked tools and services of various kinds. A new emerging generation of aggregation- and mash-up tools and services look very promising in this regard (Severance *et al.*, 2008). The mash-up tools that we envision would not only allow all participants full control over the selection of information flows and feeds but also over the combination of production tools and workflows for realising their shared objectives for action. Collaborating actors could simply combine tools and services according to their needs for conversational and productive actions. In turn, their collaborative actions and their tool selections could be recorded and used as the informational basis for the development of additional decision-support tools that help to select tools and services in relation to particular activities. Here we speculate that activity-based, decision-support tools could be beneficial. They could facilitate choosing tools from heterogeneous technological landscapes. The iCampFolio is an example of an early prototype of a decision support tool that attempts to facilitate the selection of tools and services (Väljataga *et al*., 2007). The main purpose of iCampFolio is to provide people with an opportunity to find tools according to their planned activities. Among other views, the tool provides a community perspective that enables users to position themselves within the tool landscape in comparison to the affordances perceived by other actors. Hence, it enables one to find people with a similar perception of affordances and a similar use of tools for supporting their activities. The main design principle behind that tool is the intentional attempt to couple certain activity descriptions with the affordances typically perceived in its context in relation to particular tools and services (instead of their mere functionalities). However, the usefulness of such tools still needs to be evaluated in the field.

We have indicated before that a critical factor for an effective use of diverse technological landscapes of networked tools and services for the design of distributed learning environments, is the possibility to monitor the selection and use of particular tools and services and the information flows between them in the cause of action. The same holds true for successful scaffolding and coaching in these kinds of setting. Thus, we think that the use of distributed and networked social software and social media components for collaborative projects of intentional learning and change could greatly benefit form the selective aggregation of visible traces of different activities, like Weblog authoring, commentaries with certain tags, artefacts created and stored in different repositories, Wiki-nodes, discourse logs, and so forth. In places where distributed content flows and artefacts meet again, actors can even propagate themselves as connectors between various activity systems or networks of interest. If they intentionally mix their distributed activity traces with the traces of other actors (like in the aggregated feeds of the micro-content publishing service Jaiku - http://jaiku.com/) the aggregated information flow might work as a trigger for perturbation and dissonance and thus for change and learning in the long run (Glasersfeld, 1995; Harri-Augstein & Thomas, 1991; Thomas & Harri-Augstein, 1985). As far as these content flows are openly accessible, this potential effect is not only limited to the group of actors that inhabit a particular distributed learning environment. As long as a distributed learning environment makes use of open publishing and open access principles it always carries a potential for transcending the immediate circle of actors that make up the actual activity system. In general, social-networking and cross-pollination with other individual actors or activity systems is entirely possible and a lot more likely if distributed learning environments are mediated by social software and social media applications. We think that a framework for the design of distributed learning environments should try to conceptually integrate such a perspective and explicate some of the principles that are required to ensure an appropriate level of "openness" and connectivity of these environments (Downes, 2007).

Some social software applications already enable the visualisation of the distribution of simple meaning making activities like tagging within larger groups of actors (see Klerkx & Duval, 2007). What is still needed, however, is the visualisation of activities and the anticipated or perceived potentials for action (affordances) in relation to various components of a given technological landscape. Certainly, such a mapping or visualisation would not indicate which of the available potentialities are actually put into action. If we wanted to gain some insight on that matter, we would need to study the actual interactions that are carried out via specific social media and software tools and the content flows between those tools. This would also pertain the use of asynchronous or synchronous interaction tools when working collaboratively with artefacts. A growing number of these tools can increasingly be integrated with different Web pages, social software applications and mash-up tools. However, the development of tools and services that can keep and display interrelations between recorded conversational exchanges (like a text chat) and productive actions that created a particular artefact should greatly enhance reflective and communicative actions within distributed landscapes.

CONCLUDING REMARKS AND OUTLOOK

Most technologically mediated learning environments in higher education still reflect a design- and intervention approach that either ignores or even contradicts significant social and technological changes. The rise of symbolically mediated and information driven processes in work and life increasingly produces challenges that call for a particular set of dispositions and coping styles. We increasingly rely on collaborating and communicating with others, and our general capacity to act under partial uncertainty. For more and more people all this takes place in distributed and technologically mediated environments. It seems quite obvious that traditional ideas of qualification that overly emphasised the acquisition of factual knowledge and procedural skills are falling short in the light of these developments. While factual knowledge and procedural skills are certainly not becoming obsolete, they need to be embedded in a broader set of dispositions including internalised orientations, values, and volitional aspects necessary for (self-organising) action (Erpenbeck & Rosenstiel, 2007; Heyse *et al*., 2002; Jünger, 2004). Furthermore, in many work and life contexts, action becomes progressively more symbolically and technologically mediated.

In recent years, one outstanding driving force for this development has been the gradual evolution of the Web into a general computational platform. Step by step the Web embraces a growing number of decentralized, and only loosely-coupled, networked tools and services. Needless to say that these tools and services can be, and in fact will be, instrumentalised for an ever-expanding range of human purposes. We have outlined above that we see the design of distributed learning environments in higher education as one potential and somewhat promising field of application. However, traditional instructional design approaches and their underlying set of assumptions do not appear to be overly compatible with the qualities and characteristics of the practices that are emerging around social media and social software applications. We suggest that the same incompatibility holds true for an educational intervention perspective that emphasises the advancement of dispositions for self-organising action beyond factual knowledge and procedural skills. Thus, we need to carefully reflect and analyse the theoretically assumptions that are still driving most design and intervention efforts in formal education and formulate new frameworks that allow us to respond to the significant changes that we have outlined above. We are fully aware that this is not an easy undertaking, since it requires the rethinking of some core ideas within pedagogy and instructional design, such as agency, predictability, control, direction, and so forth.

We consider our text to be a preliminary and rather modest proposal for such a reorientation and a call for contributions to the search for an adequate design and intervention framework for distributed learning environments. In this regard we think activity theory has some interesting concepts and perspectives to offer. In addition, we discussed the concept of affordance, understood as perceived possibilities for action, and its consequences if used in the context of learning environment design. We have briefly outlined our overlap and difficulties with current contributions on "personal learning environments" and proposed a more psychological use of the term that takes all aspects of an individuals environment into account that are relevant within the context of a given project of intentional learning and change. Technologically mediated actions are seen as a realisation or expression of the potentials for actions perceived by a human actor in her particular environment. We argued for the emergence of qualitatively different challenges and requirements if human actors place their learning and change in the context of collaboration (in the sense of shared production) with others. Furthermore, we addressed some current technical and conceptual challenges for the implementation and maintenance of distributed learning environments, such as the selection of tools and services in a particular activity context, a lack of robust and versatile mash-up tools for combining and integrating selected tools and services, the aggregation of distributed content flows and activity traces, the explication of design principles that can ensure an appropriate level of "openness" and connectivity of an environment, and the visualisation of activities within a given technological landscape.

Currently, our conceptual framework for the design of distributed learning environments is nothing more than an outline of core components and related concepts. However, within iCamp, an ICT design and development project funded under the 6th framework programme of the European Union, we are following a design-based research approach (A. L. Brown, 1992; Cobb *et al.*, 2003; Collings *et al.*, 2004; Edelson, 2002) that allows us to explore some of our core ideas in a series of field studies. In this context we design and implement some prototypical educational challenges on the basis of our current understanding of how distributed learning environments can be initiated and supported within formal education. The empirical insights that we gain through our field research are then fed back into the next round of improvement and refinement of the overall design framework. The revised framework in turn will guide and inform further field trials. We expect this iterative process to support a gradual abstraction of principles and concepts and the overall development of a robust framework. In the meantime we hope that our preliminary contribution can spur some interest and debate on the potentials and limitations of distributed learning environments in higher education.

Chapter 2.2
Pedagogical Responses to Social Software in Universities

Catherine McLoughlin
Australian Catholic University, Australia

Mark J. W. Lee
Charles Sturt University, Australia

ABSTRACT

Learning management systems (LMS's) that cater for geographically dispersed learners have been widely available for a number of years, but many higher education institutions are discovering that new models of teaching and learning are required to meet the needs of a generation of learners who seek greater autonomy, connectivity, and socio-experiential learning. The advent of Web 2.0, with its expanded potential for generativity and connectivity, propels pedagogical change and opens up the debate on how people conceptualize the dynamics of student learning. This chapter explores how such disruptive forces, fuelled by the affordances of social software tools, are challenging and redefining scholarship and pedagogy, and the accompanying need for learners to develop advanced digital literacy skills in preparation for work and life in the networked society. In response to these challenges, the authors propose a pedagogical framework, Pedagogy 2.0, which addresses the themes of participation in networked communities of learning, personalization of the learning experience, and learner productivity in the form of knowledge building and creativity.

DOI: 10.4018/978-1-60566-208-4.ch023

INTRODUCTION

In contrast to earlier e-learning efforts that simply replicated traditional models of learning and teaching in online environments, social software, together with other components of the Web 2.0 (O'Reilly, 2005) movement, offer rich opportunities to move away from the highly centralized industrial model of learning of the past decade, towards achieving individual empowerment of learners through designs that focus on collaborative, networked communication and interaction (cf. Rogers, Liddle, Chan, Doxey, & Isom, 2007; Sims, 2006). Hilton (2006) discusses how a number of "disruptive forces" are shaping the future of higher education. These include: the unbundling of content; the shift from "provider push" to "demand pull;" the arrival of ubiquitous access to information and services; and the rise of the "pure property" view of ideas that is incongruent with the Web 2.0 philosophy and spirit of collaboration and sharing.

For the purposes of the current discussion, the focus is on social software that enables participation, collaboration, personalization, creativity, and generativity, as these are arguably the key elements of what it means to be educated in a networked age (Bryant, 2006). Social software tools are a defining characteristic of Web 2.0, and many are already being widely used to support learning. For example, one of the most basic social software tools, the Weblog (blog), has been a resounding success in many colleges and universities, used to facilitate reflective writing and the building of e-Portfolios (Ganley, 2004; Richardson, 2006a). With the rich and varied functionality of social computing in mind, together with its "always on" culture and participatory attributes, it is useful to consider the potential value adding of these new and emerging tools and technologies for millennial learners.

HOW SOCIAL SOFTWARE TOOLS IMPACT ON LEARNING AND WAYS OF KNOWING

The affordances of Web 2.0 are now making learner-centered education a reality, with collaborative writing tools (wikis, Google Docs & Spreadsheets), media sharing applications (Flickr, YouTube, TeacherTube), and social networking sites (MySpace, Facebook, Friendster, Ning) capable of supporting multiple communities of learning. These tools enable and encourage informal conversation, dialogue, collaborative content generation, and the sharing of information, giving learners access to a wide raft of ideas and representations of knowledge.

The attributes and affordances of the new software tools and services also make possible an expanded repertoire of online behavior, distributed collaboration, and social interaction. Mejias (2005, p. 1) observed that "… social software can positively impact pedagogy by inculcating a desire to reconnect to the world as whole, not just the social part that exists online," referring to the isolating and decontextualized experience of much text-based traditional education. Many social software applications straddle the virtual and real social worlds, as they entail both online and offline interactions and visual/verbal connectivity. These new affordances are being harnessed for knowledge sharing, development of ideas, and creative production, while allowing for personal sense making and reflection.

There are also associated changes in what and how people learn, and the ways in which they access information. Knowledge is no longer controlled and stable, but open to interpretation, modification, and re-creation by anyone, anywhere. The traditional macro-structures of the disciplines are being replaced by dynamic microstructures created by networked individuals working collaboratively. These communication networks are able to link people and summon the "wisdom of crowds" (Surowiecki, 2004), so that the collective intelligence of groups can be harnessed to generate ideas that are fresher, richer, and more sophisticated than the contributions of individual users. Lindner (2006) quotes Parkin (2005), who observes: "it's not content or even context, but process that gets us going" (p. 31), indicating that participating, doing, and experiencing rather than knowing what or where, and creating knowledge rather than consuming it, is the new mindset and *modus operandi* of learners, online communities, and the knowledge economy at large. All in all, we have an environment in which digital technology and the flow of information are paramount, and in which "learning to learn" (know-how) is now far more important than memorizing explicit knowledge and facts (know-what).

Implications for the Design of Learning Environments

The expansion and growth in popularity of Web 2.0 services and the increased prevalence of user-generated content have implications for learning environments in higher education, and are already influencing pedagogical choices and approaches (Williams & Jacobs, 2004). In what can be described as a user-driven revolution, there is a shift away from the production of Web content by traditional, "authoritative" sources, towards content is that is generated by the users themselves. In academia, these users are students and they now have the tools, spaces, and skills to contribute ideas and publish their views, research, and interpretations online. It is important to remember that these tools can also be used in combination and engage people through communication, co-production, and sharing. Through these activities, social and cognitive benefits accrue to both individuals and to the community of users who support and take part in them (Boyd, 2007; Barsky & Purdon, 2006).

For example, course content and learning resources can come from many sources, and this is partly a result of the ease with which social software can be used to create, share, augment, tag, and upload content. In what has been described as a "rip, mix, and burn culture" and a "digital democracy," all participants can become creators of content (Goodman & Moed, 2006; Hughes & Lang, 2006; Lamb, 2007). In academia, this means moving beyond the confines of learning management systems (LMS's) and tapping into a wider pool of expertise, to include community-generated learning resources (Eisenstadt, 2007; Lamb, 2007). These changes are having a profound and immediate effect on the learning landscape, and on the nature of literacies and skills required of learners, as many authors and researchers have recently noted (Eisenstadt, 2007; Berg, Berquam, & Christoph, 2007; Lankshear & Knobel, 2007). As students engage with social technologies and begin to generate and re-mix content, share it with a global audience, and connect to a wide range of communities, their expectations for "always-on" services and relevant, participatory, interactive flexible learning experiences expand and become drivers of change in higher education (Milne, 2007; Tynan & Barnes, 2007).

Nevertheless, challenges remain for higher education institutions in terms of how they will manage change, and set up physical infrastructures and spaces for learners (Bleed, 2001; JISC, 2006; Australian Learning & Teaching Council, 2008) to maximize networking and knowledge exchange. In the United Kingdom in particular, research on the applications of social software is informing innovative approaches to education in all sectors, and is driving a strong agenda for personalization of curricula and the foregrounding of lifelong learning skills, innovation, and creativity as desirable learning outcomes (Owen, Grant, Sayers, & Facer, 2006).

RETHINKING PARADIGMS: LEARNING AS KNOWLEDGE CREATION

Before investigating the transformative impact of social software tools on existing practice and pedagogy, a conceptual overview of emerging practices in higher education, grounded in explanatory theoretical frameworks, will signpost changes that are already prevalent. A number of terms and metaphors signal the change from traditional pedagogies to more active forms of teaching and learning engagement, where learners have greater levels of agency, social connectedness, and autonomy.

How we conceptualize learning evokes a number of possible scenarios or metaphors. Sfard

(1998), for example, distinguished between two metaphors of learning, the acquisition metaphor and the participation metaphor. The former represents a view of learning that is mainly a process of acquiring chunks of information, typically delivered by a teacher. An alternative model, according to Sfard, is the participation metaphor, which sees learning as a process of participating in various cultural practices and shared learning activities. In order to keep pace with knowledge-building processes that are emerging in the Web 2.0 era, it now appears to be necessary to go beyond the acquisition and participation dichotomy. The knowledge creation metaphor of learning (Paavola & Hakkarainen, 2005) mirrors the societal shift towards a networked knowledge age, in which creativity, originality, and the capacity to gain knowledge from networks are highly valued. The concept builds on common elements of Bereiter's (2002) theory of knowledge building, Nonaka and Takeuchi's (1995) model of knowledge creation, and Engeström's (1987, 1999) theory of expansive learning. The "trialogic" nature of the knowledge creation metaphor reminds us that learning is an intensely social activity, as ideas are generated with others in the community through mutual exchange, contribution, and sharing of ideas.

Applying the Metaphor: Students as Knowledge Producers

Students, enabled by social software tools, are capable of being both producers and consumers ("prosumers") of knowledge, ideas, and artifacts. As newcomers to a community of practice, they not only engage in "legitimate peripheral participation" (Lave & Wenger, 1991) to develop their own mastery of knowledge and skills through interaction with experts such as their instructors, but also have a responsibility to play a part in the continued advancement of the community's existing body of knowledge, as they move toward full participation in the socio-cultural practices of this community (Lee, Eustace, Hay, & Fellows, 2005). In a knowledge building community, members are managers or "curators" of its knowledge artifacts (Eustace & Hay, 2000; Lee, et al.,, 2005), intent on making responsible decisions in addition to generating novel and innovative contributions to benefit the community as a whole.

"Knowledge creation" and "knowledge building" are now terms that are applied in management, corporate organizations, and institutions of higher learning that value innovation and creativity (Leadbeater, 2006; Nonaka & Toyama, 2003). The knowledge construction paradigm can be appropriately applied to learning environments where digital tools and affordances enable engagement in self-directed activities, and learners have freedom and choice to move beyond mere participation in communities of inquiry to become active creators of ideas, resources, and knowledge artifacts.

LEARNING THROUGH AND WITHIN COMMUNITIES AND NETWORKS

In the Web 2.0 era, new and dynamic forms of community are emerging that are self-directed and open to a global audience. These offer new forms of social and intellectual engagement to students, often based on sharing objects and artifacts, in what has been termed "object-centered sociality" (Engeström, 2005). Flickr allows the posting and sharing of photos and commentary; social bookmarking (Furl, del.icio.us) allows people to connect through shared metadata and user-driven tagging of Web-based resources; social writing platforms enable collaborative writing and editing, asynchronous creation of text, and personal written commentary. Social networking practices also enable the creation of virtual communities based on shared motives and/or common interests, leading to powerful forms of relationship building. Such social, informal experiences are very often the foundation of learning (Gee, 2003). Social software tools tend to prioritize the individual, as anytime, anyplace connectivity is the primary driver; however, these tools also motivate the individual to link personal interests to broader social networks, thereby situating responses and contributions within a dynamic community that provides feedback and reciprocity (Owen,et al., 2006). These new agendas are already impacting significantly on the reconceptualization of pedagogies and practices in future environments.

Contemporary learning environments for the profession, for industry, and for society in general must therefore take into account the networked nature of knowledge, opportunities afforded by teamwork, and the importance of participation in knowledge generation in technology-rich environments (van Weert, 2006). A theory that has emerged to describe the social, interconnected, and community-based characteristics of learning in contemporary times is connectivism. In the words of its originator, George Siemens (2005): "Personal knowledge is comprised of a network, which feeds into organizations and institutions, which in turn feed back into the network, and then continue to provide learning to individual. This cycle of knowledge development (personal to network to organization) allows learners to remain current in their field through the connections they have formed" (p. 7).

Connectivism strives to overcome the limitations of behaviorism, cognitivism, and constructivism. It synthesizes salient features and elements of several educational, social, and technological theories and concepts to create a new and dynamic theoretical construct for learning in the digital age. In connectivism, learning is the process of creating connections between nodes to form a network, a view that is congruent with the ways in which people engage in socialization and interaction in the Web 2.0 world through social networking sites and the "blogosphere." As in the knowledge creation metaphor, connectivism acknowledges the centrality of learning through the generation of ideas, supported by social activity, enabled by personal networks, interactivity, and engagement in experiential tasks.

In summary, current educational and social research is making an increasingly strong case for the conceptualization of learning as a networked, collaborative, and social activity, supported by a range of ICT affordances, including those provided by the new wave of social software tools (Mejias, 2005; Brown & Duguid, 2000). The importance of integrating digital resources and social software tools stems from the fact that such resources are part of the knowledge society and economy, and are beoming more and more tightly woven into how we communicate, think, and generate knowledge and ideas in everyday life. In an era in which changes to higher education are set against the backdrop of the digital age and Web 2.0 revolution, fueled by high connectivity and ubiquitous, demand-driven access to information and services, we are witnessing broader societal and technological trends mirrored in the growth of paradigms of active learning in ways that compel us to expand our vision of pedagogy.

NEW CONCEPTUALIZATIONS OF PEDAGOGY THAT RESONATE WITH WEB 2.0

Emerging paradigms conceive of learners as active participants or co-producers of knowledge rather than passive consumers of content, and learning is seen as a participatory, social process supporting personal life goals and needs. To provide an overview, Table 1 describes emerging conceptualizations of pedagogy inspired and enabled by Web 2.0 and social software, along with their associated values and principles. These terms signal changes in pedagogy from teacher controlled, prescriptive, and didactic modes to learner-driven social, collaborative, and participatory approaches to task design and learner engagement.

If we consider and compare the conceptualizations of learning depicted in Table 1 to the narrow, transmissive approaches that are often adopted in higher education, a number of discontinuities

Table 1. Terms indicating innovative conceptualizations of learning

Term	Author	Principles
Network learning	Polsani (2003)	A form of education whose site of production is the network, i.e. that enables lifelong and life-wide learning processes through connections and access to networks where there are multiple layers of information and knowledge.
e-learning 2.0	Downes (2005)	Learning content is created and distributed in a very different manner to "e-learning 1.0." Rather than being composed, organized, and packaged, content is syndicated, much like a blog post or podcast. It is aggregated by students, using their own personal tools and applications. From there, it is remixed and repurposed with the student's own individual learning needs in mind.
social learning 2.0	Anderson (2007)	Learning is essentially social and dialogic and moves beyond didactic modes to learner engagement with social tools. Courses must be negotiated and tap into wider social pools of knowledge, as student control and freedom are part of lifelong learning for the 21st century.
micro-learning	Hug, Lindner, and Bruck (2006); Lindner (2006)	A new paradigm that involves learning through relatively small learning units and short-term learning activities. Micro-learning processes often derive from interaction with micro-content, which involves small chunks of learning content and flexible technologies that can enable learners to access them easily, anywhere, on demand and on the move. In a wider sense, it describes the way in which informal and incidental learning and knowledge acquisition are increasingly occurring through micro-content, micro-media, or multitasking environments, especially those that are based on Web 2.0 and mobile technologies.
nano-learning	Masie (2005, 2006)	An analogue of nano-technology. Similar to micro-learning, in emphasizing the trend towards the atomization of learning beyond the learning object (Menell, 2005) to comprise personalized smaller units of information that can be learned and recombined. This enables greater relevance for learners as well as allowing for just-in-time learning.
University 2.0	Barnes and Tynan (2007)	A new generation of universities using social networking technologies, where pedagogy is reframed to meet the needs of millennial learners and connect them to wider social networks. The key idea is to start with the connections students have made through informal learning in their day-to-day lives.
Curriculum 2.0	Edson (2007)	Curriculum is negotiated, personalized, and driven by learner needs. It is based on providing learners with skills in managing and accessing knowledge, and allowing them to take control of their own learning pathways.

become apparent. The big change is occurring in e-learning paradigms where new tools and software enable students to create, share, and showcase their own ideas and content, for example through e-Portfolios, podcasting, and blogging. The learner is conceptualized as mobile, active, and engaging with peers in collaborative knowledge generation. Downes (2005) notes that social software tools allow learning content to be created and distributed in ways that move beyond pre-packaged course content consumed by students, promoting the view that learning and the content associated with it involve highly creative processes on the part of both students and teachers.

Arguing along similar lines, Boettcher (2006) suggests that there is a need to carefully re-evaluate the role of content in courses, particularly in a higher education climate in which the value of textbooks and prescribed content is being questioned (Moore, 2003; Fink, 2005), and in which the open source and open content movements (Beshears, 2005; Massachusetts Institute of Technology, 2008; *MERLOT*, 2008) are gaining momentum. Today's younger students perceive little value in the absorption or rote learning of factual information, given the accessibility and ease of use of search engines and Web-based reference sites such as Google and Wikipedia (Berg, et al., 2007). Instead, the real educational value lies in the facilitation of a learning experience in which the students are empowered to create content for themselves and for others.

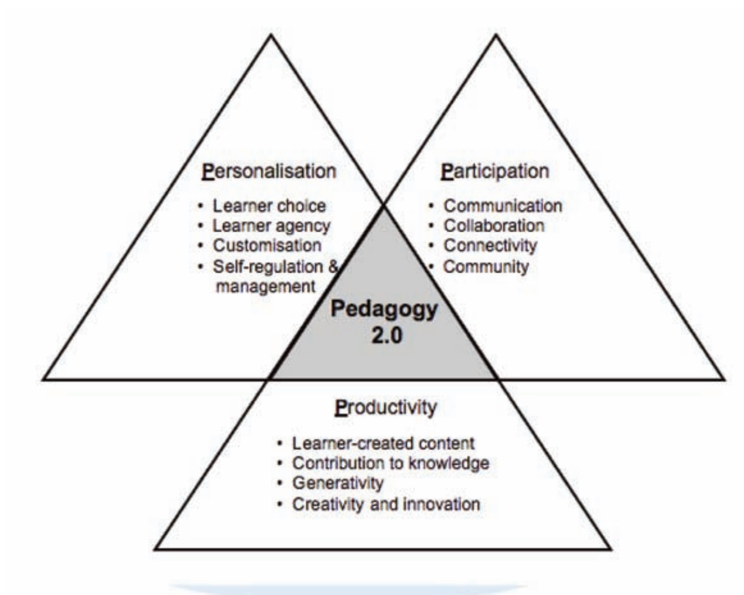
PEDAGOGY 2.0: A FRAMEWORK FOR INNOVATION

Evidence suggests that the boundaries of current pedagogies are being stretched and challenged by the potential offered by social software applications for dynamic, user-generated content, while pervasive computing and wireless networking tools ensure constant connectivity and promote participation in communities of learning and practice. With social software, there is a recognizable shift to include both formal and informal spaces for learning, and the tools afford greater learner autonomy and flexibility, as the learning experience becomes more personalized and responsive not only to the learners themselves, but also to their future needs in a knowledge based-society.

Earlier in this chapter, the importance of access to and use of social software tools and services was emphasized as these are integral to communicating, networking, and generating new ideas in the knowledge society. The need for pedagogical innovation is urgent and immediate. As Richardson (2006b) remarks: "In an environment where it's easy to publish to the globe, it feels more and more hollow to ask students to 'hand in' their homework to an audience of one. When we're faced with a flattening world where collaboration is becoming the norm, forcing students to work alone seems to miss the point. And when many of our students are already building networks far beyond our classroom walls, forming communities around their passions and their talents, it's not hard to understand why rows of desks and time-constrained schedules and standardized tests are feeling more and more limiting and ineffective" (para. 10).

The authors therefore propose a framework for innovative teaching and learning practices, *Pedagogy 2.0*, which capitalizes on the core energies and affordances of Web 2.0, while facilitating personal choice, collaboration and participation, as well as creative production. These overlapping elements are depicted in Figure 1.

Figure 1. Key elements of Pedagogy 2.0



Pedagogy 2.0 is envisioned as an overarching concept for an emerging cluster of practices that advocates learner choice and self-direction, and engagement in flexible, relevant learning tasks and strategies. Though it is intended neither as a prescriptive framework, nor a technology-driven mandate for change, it distills a number of guidelines characterizing effective learning environments, such as choice of resources, tasks, learning supports, and communication modalities. Each of the core elements, i.e., the three P's of personalization, participation, and productivity, can be applied to teacher and student roles and enables transformation and extension of current practices.

Participation as an Element of Pedagogy 2.0

More engaging, socially-based models for teaching and learning are needed to replace the traditional, "closed classroom" models, which place emphasis on the institution and instructor. A defining feature of Pedagogy 2.0 is that, alongside the increased socialization of learning and teaching, there is a focus on a less prescriptive approach, and greater emphasis on teacher-student partnerships in learning, with teachers as co-learners. As such, this element of Pedagogy 2.0 is reflective of the "participation model of learning" (Sfard, 1998), as opposed to the "acquisition" model.

While the use of popular social software technology in itself is of value in motivating learners, the tools also allow learners to engage deeply with their peers, instructors, other subject-matter experts, and with the wider community. The additional connectivity achieved by linking tools, people, and data is part of an emerging global network or "architecture of participation" (O'Reilly, 2005; Barsky & Purdon, 2006). Pedagogy 2.0 therefore adds a further dimension to participative learning by increasing the level of socialization and collaboration with experts, community, and peer groups, and by fostering connections that go beyond the walls of the classroom or institution.

Personalization as an Element of Pedagogy 2.0

The notion of personalization is not entirely new to educators and is often linked to the term "learner-centered" education, a desirable state where learners know how to choose and make decisions relating to their personal learning needs. However, there continue to be significant gaps and differences in espoused and enacted constructivist pedagogies (Lim & Chai, 2008). By harnessing digital technologies and social software tools, a number of key areas pivotal to the development of personalization through teaching are summarized by Green, Facer, Rudd, Dillon, and Humphreys (2005). According to them, pedagogy must:

- Ensure that learners are capable of making informed educational decisions;
- Diversify and recognize different forms of skills and knowledge;
- Include learner-focused forms of feedback and assessment.

For many students, the ability to socialize and study online already affords them a high level of personalization, as they can access resources aligned to their own needs and interests. In addition, Web 2.0 and social software tools enable choice and allow learners to make decisions about which tools best suit their goals and needs for connection and social interaction. Apart from choosing which resources and sites to subscribe and contribute to, which tools to use, and how and where to use them, we are witnessing a shift in the modalities of expression that are now available. Text alone is not always preferred mode of communication, as Web-based multimedia production and distribution tools incorporating rich audio (podcasting, Skype), photo (Flickr), and video (vodcasting, YouTube) capabilities are growing. Research attests to a growing appreciation of the learner's control over the whole learning process, with evidence suggesting that we can improve learning effectiveness by giving the learner control over, and responsibility for, his/her own learning. This is the foundation for such approaches as problem-based and inquiry-based learning (Desharnais & Limson, 2007), and is central to the grand vision of Pedagogy 2.0, where learners have the freedom to decide how to engage in personally meaningful learning.

One of the interesting developments in e-learning is the on-going discussion around the notion of Personal Learning Environments (PLE's). According to Siemens (2007), a PLE is "… a collection of tools, brought together under the conceptual notion of openness, interoperability, and learner control. As such, they are comprised of two elements – the tools and the conceptual notions that drive how and why we select individual parts" (para. 2). Moving on from LMS's, the PLE concept represents the latest step towards an alternative approach to e-learning. Unlike LMS's that take a course-centric view of learning, PLE's are learner-centric (Attwell, 2007). Instead of promoting centralized, instructor-controlled learning and relying on LMS's to deliver pre-packaged materials and activities, Pedagogy 2.0 challenges university and college teachers to harness the many resources that exist outside the formal spaces of the institution, to create opportunities for authentic learning that are relevant to learners personally, and to capitalize on the interests and digital competencies that learners already possess.

Productivity as an Element of Pedagogy 2.0

The knowledge creation metaphor of learning (Paavola & Hakkarainen, 2005) acknowledges that students are also capable of creating and generating ideas, concepts, and knowledge, and in the Web 2.0 era, the importance of encouraging and enabling this form of creativity and productivity is of vital significance. Educators are beginning to realize that instructor-supplied content has limitations, particularly if it pre-empts learner discovery and research, and active student involvement in the knowledge creation process. The importance and value of student-generated content, or student performance content (Boettcher, 2006) is becoming increasingly apparent.

For example, in recent years, the e-Portfolio (Love, McKean, & Gathercoal, 2002; Abrami & Barrett, 2005; Stefani, Mason, & Pegler, 2007) has emerged as popular strategy for capturing and organizing student-generated content, which, in addition to completed project/assignment work or deliverables, may also incorporate successive drafts of solutions, descriptions of mistakes made, or evidence of difficulties encountered. Such artifacts document the process of engaging in an authentic problem-based learning experience, and are representative of the complexity and "messiness" of an experience. Student-generated content may also include synchronous and asynchronous computer-mediated communication (CMC) discourse such as chat logs and discussion board postings, reflective writing in the form of diaries or blogs, summaries, and reviews, created by students working individually or in teams.

A few examples will illustrate the new forms of knowledge creation and productivity enabled by social software tools. Learners can now engage in creative authorship by being able to produce and manipulate digital images and video clips, tag them with chosen keywords, and make this content available to their friends and peers worldwide through Flickr, MySpace, and YouTube. Other individuals write blogs and create wiki spaces where like-minded individuals comment on, share and augment these sources, thereby creating a new genre of dynamic, self-published content. This outpouring of information and digital user-generated content between peers has been dubbed "personal publishing" (Downes, 2004). This trend stands in stark contrast to the control culture of education, where pre-packaged content and teacher-designed syllabi dominate, thereby denying students choice and autonomy in shaping their own learning trajectories. The challenge for educators is to enable self-direction, knowledge building, and learner control by providing options and choice while still supplying the necessary structure and scaffolding.

CURRENT EXAMPLES OF PEDAGOGY 2.0

Pedagogy 2.0 can be demonstrated by a number of exemplary practices by tertiary teachers at various institutions worldwide, as shown in Table 2. The 3 P's of Pedagogy 2.0 are exhibited by the examples in a variety of different ways. For example, to support his course in General Psychology at the University of Connecticut, Professor David B. Miller (2006, 2007) hosts weekly informal discussions with students following each week's lectures. During these discussions, students are able to seek clarification on the course material and talk about it in greater depth, while interacting and actively exploring and discussing issues not covered during the lecture that are of interest and relevance to the group (participation). The discussions are recorded and made available to other members of the class as a series of podcasts for individual listening at a convenient time and place (personalization). The process of creating and participating in the discussions becomes a form of student-generated content (productivity). All students in the cohort are welcome to submit questions in advance of the discussion via email; these questions, as well as those asked by students who attend in person, are answered during the discussion.

In another example, at the University of North Carolina at Pembroke (UNCP), Dr. Kenneth Mentor's courses make use of a wiki-based encyclopedia, with the goal being for students to create and maintain articles or entries on a variety of subjects related to law, criminal justice, sociology, and criminology. In previous courses, Mentor's students created Web pages as class assignments. The *Online Encyclopedia of Criminal Justice* (2007) project extends those efforts in two notably powerful ways: using a wiki enables the student-generated content to be readily shared in virtual "public spaces" and with a broader audience beyond the walls of the classroom, and the wiki's ease of use enables students to create substantial amounts of content within a short timeframe (productivity). In addition to generating and entering initial content, students also perform the roles of editing, revising, and organizing the content, which becomes part of the shared pool of resources accessible to all learners. The learning experience and activities are personalized in that students have a great deal of autonomy and choice in determining when, where, and how to contribute to the collection of information on the wiki, as well as in deciding which topics or entries to create, read, add to, and/or modify (personalization). Although UNCP students initially wrote all site content, the site is now available for educators to use for class assignments, and users outside the institution are allowed to register and contribute (Sener, 2007b). In this way, Mentor's students are active participants not only in the context of the course they are studying, but also in a wider, professional, academic community that transcends the walls of the classroom and institution in which they are based (participation).

POTENTIAL PROBLEMS AND PITFALLS IN IMPLEMENTING PEDAGOGY 2.0

It must be recognized that the implementation of a Pedagogy 2.0 approach is not without its issues and challenges. For example, although the advent of Web 2.0 and the open content movement significantly increases the volume of information available to students and exposes them to a raft of ideas and representations, many higher education students currently lack the competencies necessary

Table 2. Examples of Pedagogy 2.0 in tertiary teaching and learning

Reference/ author	Institution and Country	Description of technology use	Key pedagogical features
Read (2005)	Drexel University, USA	Drexel distributed iPod Photo players to their Education freshmen in September 2005. Read (2005) reported there were plans for a variety of learner-centered applications, including but not limited to having students record study-group sessions and interviews, as well as having them maintain audio blogs to connect with administrators and peers during the work experience semester.	Peer-to-peer learning; distributed intelligence approach
Lee, Chan, and McLoughlin (2006)	Charles Sturt University, Australia	Second year undergraduate students take charge of producing talkback radio-style podcasts to assist first year students undertaking a unit of study that the former group previously completed.	Learner-centered instruction; student-generated content
Evans (2006)	Swathmore College, USA	Students studying a literature course read short passages aloud and record them as podcasts, as well as creating separate podcasts discussing the passage they chose and its relationship to other material.	Development of digital and social competencies
Miller (2006, 2007)	University of Connecticut, USA	Three types of podcasts are used to support a General Psychology course: • *iCube podcasts* – Informal discussions with students following each week's lectures; • *Precasts* – Short enhanced podcasts previewing material prior to each lecture; • *Postcasts* – Short post-lecture podcasts containing re-explanations of selected concepts.	Blending of formal and informal learning; mobile, ubiquitous learning
Frydenberg (2006)	Bentley College, USA	Students in an introductory information technology class work in pairs or groups to produce vodcasts to teach topics from the course schedule to their peers.	Peer teaching; reciprocal learning
Edirisingha, Salmon, and Fothergill (2006)	University of Leicester, United Kingdom	Students make use of "profcasts," i.e. material designed to support learning distinct from that which is facilitated through structured on-campus or e-learning processes alone. e.g., weekly profcasts to supplement online teaching through updated information and guidance.	Extended learning, enrichment and extension activities; personalization of learning content
Kukulska-Hulme (2005)	Open University, United Kingdom	Students studying German and Spanish courses in distance mode use digital voice recorders and mini-camcorders to record interviews with other students and with native speakers, as well as to create audio-visual tours for sharing with their peers.	Peer-to-peer learning; student-generated content using mobile devices
McCarty (2005b, 2006); Sener (2007a)	Osaka Jogakuin College, Japan	Students are interviewed by their instructor, perform roles, and/or present their own creations, in contribution to the instructor's bilingual podcast feed and blog targeted to those studying Japanese or English as a foreign language. The podcast episodes cover Japanese culture, history, folklore, and comparative religions, as well as contemporary social issues such as the education system and the rights of minorities in Japan.	Role play and audio recording of students' own creations and interpretations of social and educational issues
McCarty (2005a); Sener (2007a)	Matsuyama Shinonome College, Japan	As part on an intensive course on translation, students from two East Asian cultures (Chinese and Japanese) participate in a recorded discussion in which they are asked to explain five proverbs in English as well as in their native language.	Cross-cultural collaborative work using student-generated content
Sener (2007b)	University of North Carolina at Pembroke, USA	A wiki-based encyclopedia is maintained by students, the goal being to create entries on a variety of subjects related to law, criminal justice, sociology, and criminology.	Student-generated content, collaborative writing, organizing and editing of content

Table 2. Examples of Pedagogy 2.0 in tertiary teaching and learning

Reference/ author	Institution and Country	Description of technology use	Key pedagogical features
Wenzloff (2005); Richardson (2006a)	Macomb Independent School District, Michigan, USA	Social bookmarking is used to compile and share resources with teacher training participants / student teachers. The instructor also subscribes to the RSS feeds of his pre-service teachers' Furl sites, to see what they are reading as well as their comments about the sites.	Resource-based and collaborative learning
Lin, Li, Hu, Chen, and Liu (2007)	National Central University, Taiwan	Students enrolled in an introductory computer science course make use of a wiki to provide assistance and support to one another as they learn introductory programming concepts and techniques. They form project groups, taking on roles that model "real-world" software development teams to produce a computer game that is "marketed" to the rest of the class. During the course of the software development project, the wiki serves as a repository for managing and sharing knowledge and reflections on experiences, and as a mechanism for submitting deliverables.	Community of learning; peer support and mentoring; authentic learning and assessment
Chan, Frydenberg, and Lee (2007)	Charles Sturt University, Australia and Bentley College, USA	Undergraduate students studying first year (freshman) level introductory information technology subjects at Charles Sturt University and Bentley College work in teams consisting of a mixture of students from each institution. Each team is given the task of collaboratively producing a short podcast, to be recorded over the voice over Internet Protocol (VoIP) tool Skype (i.e. a "Skypecast"), in which members discuss issues of relevance to topics that are common to the curricula at both institutions.	Cross-cultural, Internet-mediated collaborative learning and exchange
Helms (2007b); D. Helms, personal communication	Mt. San Jacinto College, USA	Students use the social networking site Ning to create Web 2.0-based web sites to teach others about the dangers associated with drug use and abuse. Working in groups, they each take on one of four roles: Web Designer, Multimedia Designer, Researcher, and Copyrighter. The instructor assigns each group with a specific drug to research and provides "job descriptions" for each of the four roles. The instructor produces a sample Ning site for students to view as an example of the possibilities of the medium (Helms, 2007a). Students also use the blogging and threaded discussion features of Ning to engage in constructive and reflective discourse	Authentic, inquiry-oriented, and project-based learning, with an emphasis on student-generated content (The instructor also employs a form of modeling in the use of a sample Ning site.)
Chao (2007)	Bowling Green State University, USA	Wikis were used by students in a project-based software engineering course. The students used the wiki to support and augment collaborative software development activities, including but not limited to project planning, requirements management, test case management, and defect tracking, as well as the development of user documentation. While the instructor and the students were fully aware that there were a number of Computer-Aided Software Engineering (CASE) tools designed specifically for the above activities, the fact that wikis are available free of charge, combined with their ease of use and flexibility, made them an ideal choice for supporting the dispersed student project teams in this course.	Collaborative learning, authentic learning, project-based learning
Mateer (2008)	The Pennsylvania State University, USA	Dirk Mateer uses YouTube to support his teaching of Economics at Penn State University. Mateer digitizes his lectures, which involve a range of interactive learning approaches, and publishes them on his "Teaching Economics with YouTube" (Mateer, 2007) channel. In addition, he encourages students to find, view, and share with others a variety of freely available video clips provided by other YouTube users.	Multi-modal, peer-to-peer and collaborative learning

to navigate and use the overabundance of information available, including the skills required to locate quality sources and assess them for objectivity, reliability, and currency (Windham, 2005; Katz & Macklin, 2007). In a recently published EDUCAUSE Learning Initiative (ELI) white paper, it is recommended that students develop sound information literacy skills in effectively finding, evaluating, and creating information. Additionally, beyond search and retrieval, information is contextualized, analyzed, visualized, and synthesized, which involves complex critical thinking skills (Lorenzo & Dziuban, 2006; Jenkins, 2007). Fortunately, many of the examples presented earlier demonstrate that in combination with appropriate strategies, social software can also serve as levers for such critical thinking and meta-cognitive development (e.g. Sener, 2007b; Lee, et al., 2006).

Furthermore, in fostering learning processes that encourage the production and use of student-generated content, there is still a need for accountability and recognition of authoritative sources of information. As seen in this chapter, content supplied by experts such as teachers and textbook authors is but one of many resources available to assist students in developing knowledge and skills, and may have limitations, particularly if it pre-empts learner exploration and discovery, and active student involvement in the knowledge creation process. At the same time, in their desire to engage in emerging forms of collaborative scholarship and self-expression, students must be made aware of the expectations from the point of view of academic integrity. Practices such as "mix, rip, and burn" raise questions about the importance of originality, and give rise to concerns about copyright, ownership, and intellectual property, which must be carefully addressed by educators and educational institutions. There is also a need for quality assurance mechanisms to maximize the validity and reliability of student-generated content. Moving away from teacher-centered models of evaluation and assessment, the review, editing, and quality assurance of content can be done collaboratively and in partnership with learners, while simultaneously drawing on input from the wider community (i.e. "wisdom of crowds").

A further challenge is that educators may not be fully aware of the potential and range of social software tools, and may need opportunities for professional development to reveal how Web 2.0 applications can support teaching and assessment in meaningful and authentic ways. In addition, teachers who adopt social software tools need to do so not merely to appear conversant with the tools, but to integrate the tools into sound pedagogical strategies in order to add value to existing courses, and facilitate authentic exchange and dialogue with and among students. They must be wary of the fact that they may feel unwelcome in their students' online social networks and communities. Although there may be attempts by teachers to co-opt the technologies students use of communication and entertainment, such attempts may be perceived by students as intrusions into "their space" (Mazer, Murphy, & Simonds, 2007).

CONCLUSION: FUTURE LEARNING LANDSCAPES INFORMED BY PEDAGOGY 2.0 PRINCIPLES

Pedagogy 2.0 offers the potential for transformational shifts in teaching and learning practices, whereby learners can access peers, experts, the wider community, and digital media in ways that enable reflective, self-directed learning. While the adoption of social software tools may provide opportunities to meet the increasingly diverse needs of institutions and learners, they may also be used to support both local communities and wider professional contexts, facilitating both lifelong and life-wide learning.

These next-generation practices provide an opportunity for higher education institutions to look at wider implementation issues around technical infrastructure, but they must also address pedagogical challenges such as the integration of informal learning experiences, the limitations of existing physical and virtual learning environments, and the personalization of learning experiences. There may be a culture shock or skills crisis when "old world" educators are confronted with the expectation of working in unfamiliar environments and scenarios, and with tools with which they lack expertise and confidence. For these reasons, there is a need to make time for talking, awareness raising, and discussion of what pedagogic approaches and tools best target the desired learning outcomes.

In summary, Web 2.0 and social software tools promote autonomy and increased levels of socialization and interactivity, while enabling user-controlled, peer-to-peer knowledge creation and network-based inquiry. There are signs of optimism that existing Pedagogy 2.0 practices, by capitalizing on the three P's of personalization, participation, and productivity, will result in a learning landscape and a diverse range of educational experiences that are socially contextualized, engaging, and community based. However, obstacles and barriers remain. Can teachers, whose traditional frame of reference is formality, understand how informal learning can take place through social networking and beyond the formal spaces of classrooms, libraries, and laboratories? Can they extend these formal spaces to link with dynamic and open communities that are constantly sharing, revising, and creating new ideas? Can academia, with its established legacy of transmissive pedagogy, rise to the challenge and affect the kind of teaching revolution and changes that are both necessary and inevitable in the new age? The goal is to facilitate learning, be less prescriptive, and be open to new media, tools, and strategies, while nurturing innovation and creativity, independent inquiry, and digital literacy skills. This can be achieved by employing the new tools, resources, and opportunities that can leverage what our students do naturally – socialize, network, and collaborate. Overall, for the principles of Pedagogy 2.0 to be realized, institutional and sector-level change is needed to dissolve educational silos and to equip educators with the skills and facilities that make it possible to be responsive to learner needs, while encouraging learners to become active partners in creating educational pathways that will give them the skills and competencies needed to be successful in the networked age.

In describing the wave of social and technological changes affecting higher education, Hilton (2006) uses two competing metaphors to depict the challenges of the Web 2.0 era: "a perfect storm, born from the convergence of numerous disruptive forces … [and] the dawn of a new day, a sunrise rife with opportunities arising from these same disruptive forces" (p. 59). Taking a positive view, the authors of the present chapter believe that change is imminent. Student-driven demand, coupled with a new approach to pedagogy that leverages the flexibilities and creative options of Web 2.0 and social software tools, can and is already beginning to make the teaching and learning process much more dynamic, creative, and generative. As evidenced in Table 2, there is a great deal of innovation and experimentation with social software on an international scale, and many educators are transforming their pedagogy to create learning experiences that are participatory, personalized, and geared to the production of digital knowledge artifacts by learners. Pedagogy 2.0 therefore enables new pathways to learning with peers and connections to the wider community to flourish, and makes active, self-directed, self-managed learning a reality. Clearly, success in the knowledge economy demands that we leverage the educational value of social software tools to promote student-generated content and digital competencies that allow learners to develop their critical thinking, knowledge-building, and creative skills.

KEY TERMS

Architecture of Participation: A term that describes the nature of innovation in the open source movement, whereby individuals can share, create, and amend software, thereby participating in the creation of improved forms of software. This can help turn a good idea, tool, or application into a best-quality product as many users and developers can adapt, change, and improve it.

Collective Intelligence: A form of intelligence that results from the cooperation, collaboration, and/or competition of a large number of individuals. *See also* wisdom of crowds.

Connectivism: A "learning theory for the digital age" developed by George Siemens, based on an analysis of the limitations of behaviourism, cognitivism, and constructivism. It employs a network with nodes and connections as a central metaphor for learning. In this metaphor, a node may be any entity, whether tangible or intangible, that is able to be connected to other nodes, including but not limited to information, data, feelings, and images. Learning is seen as the process of creating connections between nodes to form a network.

E-Portfolio: An electronic collection comprising self-assembled evidence demonstrating a learner's knowledge, skills, and abilities, including learner-generated artifacts in multiple media forms that showcase both the products and processes of learning. e-Portfolios are excellent tools for facilitating students' reflection on their own learning, as well sas serving a variety of purposes in assessment (including recognition of prior learning) within an academic course or program. Lifelong e-Portfolios are also increasingly being used for professional purposes such as certification/accreditation and career advancement (e.g. promotion).

Knowledge Creation Metaphor of Learning: Unlike theories that emphasize learning as knowledge acquisition (the acquisition metaphor) and as participation in a social community (the participation metaphor), this third metaphor foucses on mediated processes of knowledge creation that have become especially important in a knowldge society. This view focuses on mediated processes of knowledge creation that have become especially important in a knowledge society.

Learning Management System: *See* LMS.

LMS: Learning Management System. An integrated suite of software tools designed to manage learning interventions. Commercial examples are Blackboard and WebCT, although many open source alternatives, such as Moodle and Sakai, exist. In addition to the provision of online learning content and activities and the facilitation of online assessment, LMS's typically support a range of administrative functions including learner enrollment, workflow, records management (e.g. reporting of assessment results/outcomes), and resource management (e.g. instructors, facilities, equipment).

Object-Centered Sociality: A term coined by the Finnish sociologist Jyri Engeström to describe the phenomenon whereby shared objects are the means by which people connect to each other to form social relationships and networks. According to this concept, links are created not just between people, but between people and objects, or around objects. Engeström claims that the problem with some social networking services is that they focus solely on people and links, ignoring the objects of affinity that those linked people share. He invokes the concept of "object-centered sociality" to explain how the inclusion of shared objects including but not limited to photos, URLs, and events can enhance online social networking.

Pedagogy 2.0: Digital tools and affordances call for a new conceptualization of teaching that is focused on participation in communities and networks, personalization of learning tasks, and creative production of ideas and knowledge. McLouglin and Lee's concept of Pedagogy 2.0 is a response to this call. It represents a set of approaches and strategies that differs from teaching as a didactic practice of passing on information; instead, it advocates a model of learning in which students are empowered to participate, communicate, and create knowledge, exercising a high level of agency and control over the learning process.

Personal Learning Environment: *See* PLE.

Personal Publishing: A process in which an individual actively produces his/her own content and information and publishes it on the World Wide Web. For example, the maintenance of a personal blog as an online diary is an instance of personal publishing. *See also* user-generated content.

PLE: Personal Learning Environment. A system, application, or suite of applications that assists learners in taking control of and managing their own learning. It represents an alternative approach to the LMS, which by contrast adopts an institution-centric or course-centric view of learning. Key PLE concepts include the blending of formal and informal learning, participation in social networks that transcend institutional boundaries, as well as the use of a range of networking protocols (RSS, peer-to-peer [P2P], Web services) to connect systems, resources, and users within a personally-managed space. *See also* LMS.

Prosumer: A portmanteau formed by contracting word "producer" with the word "consumer," signifying the blurring of the distinction between the two roles in today's knowledge economy.

Student-Generated Content: Content that is produced by students, often for sharing with peers or a wider audience on the Internet, as distinct from instructor-supplied content such as course notes and textbooks. It is arguable that the main benefits to be gained from student-generated content lie in the process of content creation and knowledge construction, as opposed to the end product itself. *See also* user-generated content.

User-Generated Content: A term that refers to Web-based content created by ordinary people or users, e.g. pictures posted on Flickr or encyclopedia entries written in Wikipedia. Such "Read-and-Write" applications are key characteristic of the Web 2.0 movement, which encourages the publishing of one's own content and commenting on or augmenting other people's. It differs from the "Read-Only" model of Web 1.0, in which Web sites were created and maintained by an elite few. *See also* personal publishing.

Wisdom of Crowds: A concept that relates to the aggregation of information in groups and communities of individuals. It recognizes that the innovation, problem-solving, and decision-making capabilities of the group are often superior to that of any single member of the group. The term was used as the title of a book written by James Surowiecki, published in 2004. *See also* collective intelligence.

Chapter 2.3
Electronic Classroom, Electronic Community:
Designing eLearning Environments to Foster Virtual Social Networks and Student Learning

Lisa Harris
RMIT University, Australia

ABSTRACT

The capacity for online learning environments to provide good quality learning experiences for students has been the focus of speculation and debate in the higher education sector from the late 1990s to the present day. In this area, "quality" has become synonymous with engaging students in a learning community. This chapter reports on a qualitative research project designed to explore the significance of community for students studying online. Using three fundamentally different types of online learning environments as case studies, this research explored the relationship between the constructed online learning environment and the development of learning communities or what the author has termed social learning support networks (SLSN). Exploring the common themes to emerge from these three case studies, this research provides new evidence of the benefit of community for students studying online and argues that future online learning environments should be shaped by five key principles designed to foster a sense of social connection between students.

'I pay the schoolmaster, but 'tis the schoolboys that educate my son'.

—Ralph Waldo Emerson (1803-1882)

DOI: 10.4018/978-1-60566-735-5.ch006

INTRODUCTION

Many Australian universities grapple with both interpreting and responding to student engagement data (Coates 2006) and working through the effective use of online learning environments. Creating learning communities or a sense of belonging for students has emerged in the Australian higher education literature as a key goal for those interested in improving the student experience (Coates 2005; McInnis et al 2000). At the same time, many universities are coming to terms with the failure of their investments in eLearning to generate the new revenue streams forecast in the late 1990s, (Zemsky and Massy 2004; Reynoldson and Vibert 2005). This has required them to focus on developing sustainable eLearning policies that try to reconcile the demands of professional development for staff with increasing student demands for courses that are flexibly delivered (Minshull 2004). This chapter reports on research into the significance of community for students studying online and what role the constructed online environment can play in the development of community for students. This is particularly relevant for social work and human service students studying online because much of their education is predicated on the development of good interpersonal communication skills. The use of poorly designed online learning environments for the delivery of social work and human services study programs may well hinder the development of these interpersonal communication skills.

This research is significant because it provides a new way of thinking about "community" for students by showing the importance of community and how it works in both on-campus and online learning environments. But more importantly, it provides a new way of thinking about community that shifts our understanding away from a nebulous, ill-defined idea - to a practical, student-centred idea of community defined as Social Learning Support Networks (SLSN). The research findings indicate that the constructed online environment can facilitate the development of SLSN's for courses delivered fully online if it provides students with what Burbules (2000) calls, a *place* to inhabit. While the evidence for this second finding came from students who were effectively distance learners, it is likely that the elements of the online environment that supported their development of SLSN's are also relevant for the online environment we provide for on-campus students. In this chapter I draw together the common themes from three case studies and detail the significance of this research for future developments of eLearning in higher education by providing five significant challenges to the current design of Course Management Systems (CMS).

THE THREE CASE STUDIES

This research used a multiple-case study approach to explore three different online environments. The first case used a rudimentary web page with email communication and discussion boards. The second, a purpose built Virtual Social Space operating within a Course Management System (WebCT). The third, a text based virtual campus operating in a MOO environment (Multi user dimensions-Object-Oriented).

The first case study took a group of undergraduate social science students who were studying a single course online as part of a three-year on-campus program offered by the School of Social Science and Planning, RMIT University Melbourne, Australia. The online environment in which these students were studying was primitive using only a web page and email, and provided little or no opportunity for the participating students to develop a sense of connection with each other. Students' interactions were teacher driven and focused on course content and assessment activities. The students interviewed in this case were asked to explore their experiences of developing connections with other students both on campus and in the online learning environment they were studying in.

The second case study was a Masters in Information Technology Management program offered from Sheffield University, England. The academics responsible for this program decided to develop a Virtual Social Space (VSS) to act as an umbrella social space running across courses and throughout the program. The VSS provided discussion boards for social interaction, an area for student profiles and program information. Students in this program already displayed a high level of non-content related social discussions within the discussion boards provided in each course module. It was expected that students would use the VSS to further develop these social relationships. However, to the surprise of all concerned, after initial use of this environment, few students returned and no ongoing social contact occurred via the site.

The third case study was a group of students studying an undergraduate, context curriculum course offered by the School of Psychology, RMIT University, Melbourne, Australia. These context curriculum courses are offered to students from other faculties in order to provide them with an extra-discipline experience. As such, the students are from a wide variety of faculties and disciplines and are generally not known to each other. This course, *Personal Identity and Community in Cyberspace,* operated within a text based virtual environment of a Multi user dimensions-Object-Oriented (MOO). This environment provided students with a virtual environment that attempted to replicate a campus. A MOO is a real time, three-dimensional, text based virtual environment that provides users with both a sense of location and a sense of identity. A MOO replicates the real world by having separate spaces (rooms, buildings, etc) in which conversations and interactions can occur privately. A user literally moves between rooms and encounters others as they walk through the spaces. Creating the spatial distinctions between rooms is very important because it parallels aspects of the real world, for example when people in a room are talking, people in an adjacent room cannot see them or hear them unless they come into the room. One can choose to join someone in another room by either being transferred to the space (via a @join command) or you can choose to walk through the various gardens, corridors and stairways until you get to the room - bumping into others on the way. As Clodius (1994) suggests, the MOO creates a sense of place through location ‘The sense of “being” somewhere is reinforced by the illusion of moving through spaces - one types “north”, the description of the room changes, the objects in the room are different, and different options exist’ (para. 24). A virtual campus, the RMIT Tokyo Building was developed in the saMOOrai MOO. This MOO provided a virtual representation of Tokyo and surrounding countryside.

Data was gathered from each of these cases using a variety of methods including in-depth interviews, qualitative surveys and 13 weeks of ethnographic observations in the MOO. Over 50 students participated across the three cases. Data was analysed and key themes developed using the qualitative software computer program NVivo.

KEY THEMES

There are four major themes to emerge from the three cases and each influenced a student’s capacity or willingness to develop community. They are:

- *Community,* in the form of Social Learning Support Networks, was identified as a critical factor in supporting student’s learning in each case.
- *Work-life-study balance* - Students choosing to study online usually have significant demands outside of their study including family, work, recreational and social commitments. The development of Social

Learning Support Networks had to be integrated into their life as a student.

- *Modelling behaviour* - Understanding how to *be* online for students was a result of their interactions with others and the environment. University staff played a key role in establishing the culture of how to *be* online.
- *Physical/virtual environment* - turning space into place. The physical and virtual environments played a significant role in providing students with the opportunity to connect with each other and develop Social Learning Support Networks.

In exploring the significance of community for students, these factors emerged as core to understanding the value of community from a student's perspective. This research points to the value of stepping outside the electronic classroom and recognising that for many students, developing support networks is as much about what happens between them as it is about what the teacher either does or designs into the electronic classroom.

SOCIAL LEARNING SUPPORT NETWORKS

–*Arranged marriages vs. having mates: being pushed rather than pulled into connecting with each other.*

Stage one of the research explored definitions of community, trying to get to the heart of why the concept of "community" has been so important in the online learning literature. Interestingly, through the process of research, I have come to understand something fundamentally problematic about the way we theorise "community", and therefore how we try to operationalize it. For the most part in the literature and in many student engagement policy documents (Conrad, 2002; Palloff & Pratt, 2001; Tinto, 2000; The University of Melbourne Teaching and Learning Plan 2006), the term "community" is used in a very "objective" way. It is generally referring to something we should create for the students or that the students should have or be engaged in – because we know it will be good for them! In the interviews for the first case, students from the RMIT University undergraduate social science course often responded to the idea that they needed to be part of a community with a question. Typical of this, one student looked at me rather quizzically when I asked him if he felt part of a community at university. He paused and tentatively responded *'You mean like, have I got any friends!'*(Harris 2007, p. 209). I suspect community has become something we either do *to* people or it is represented as some utopian dream. This binary either results in people wanting to avoid it or else never feeling like they are quite part of it. It is worth exploring this binary because it shapes student's notions of what it means to be part of a community.

When we are "doing" community "to" people it is often represented by a deficit model, as if the people we want to be part of community suffer a lack of capacity (Frank and Smith 2006), that is there is a problem, and a bit of "community" will fix it. Typical scenarios go something like this. It is said that there has been a "break down" in community when young people in an area are rioting; community development workers are employed to improve 'troubled' housing estates, or people 'with problems' (for example drug users, the mentally ill or young people at risk of suicide) require support. In this deficit model, being someone who "needs" community equals being someone who has a problem or worse, is lonely. A student from the second case, reflecting on the Virtual Social Space (VSS), comments as if he is an outsider on a space he desperately does not want to be associated with:

The VSS as a social space is akin to sitting alone in a bar with no atmosphere drinking diet Tango *and, just before you leave, jot a cryptic message to say that you have been there on a post it note and stick it on the fruit machine. (a bit sad really) (Harris, 2007, p. 216)*

There is nothing in his reflections that might hold the slightest hope that he could get something positive out of such a space. Sticking the post-it note on the fruit machine is the desperate act of a lonely person – but it is not what he did or wanted to do. Everything about his reflection points to a resistance about the very idea of the space. Conrad (2002) suggests the desire to engage students in learning communities can result in teachers designing activities where "learners are pushed, not pulled, into a community framework, somewhat like an arranged marriage" and that doing this often results in "conscious restraint on the parts of learners in contributing to community" (p.4). Students from all three cases confirmed Conrad's point, with only two students from the first case mentioning that one of the ways they made connections with fellow students was through collaborative activities in an on-campus class. I am sure, that at some level this is not an accurate reflection, and that all the students, at some point, developed connections with other students via their engagement in class. The interesting thing however is that the students did not own those connections as their own. The connections they owned were those they made in spaces outside of the classroom. Importantly, for many students with quite established networks, they still did not identify as part of a community when the term was used without further explanation or clarification.

I suspect this was possibly because when students hear the term community they overlay a concept of community that represents some long-past utopian dream that has been important to the history of the social sciences (Toennies 1963). This dream is a representation of community that is outside of most peoples lived experience (Bauman 2001). Contemporary students are all too familiar with idealised stories of political campus life in the 1960s and 1970s – told by academics in their fifties who drift nostalgically back to the days of student activism, free love, drug use, no fees and seemingly no consequences for not passing your exams! It is unclear if this was ever an accurate representation of the student community life. Utopian ideals rarely are accurate. There is little wonder that students today do not identify their experience of university life as "feeling part of a community" if this is the kind of image of community that they are thinking about. Several students from across the three cases, at some point in our preliminary discussions regarding participating in this research, talked about their experience of university life as not being as good as X – "X" being what I call the X factor. For one student the X factor was her husband's university experience 20 years ago, for another it was a mate at a sandstone university. For another it was a friend studying in the U.S. and for another it was a student in the same school but in a different program. It may well be that these friends and relatives did have a better experience of university community life, but it is also possible, as Bauman (2001) argues, that the ideal of community is seemly never within our grasp. Student's resistance to identifying with the term community had a profound effect on this research. During the initial call for participants for the first case, a number of students commented that when they heard that the research was about community, they did not respond because they felt they did not know anything about community. It was from this point on I started to talk about the research in terms of understanding the connections students made with each other.

When community was put in these more subjective, practical and concrete terms it became a question. That question pointed to issues like – *what support do I get from my connection with fellow students, or what support do I give to someone I study with?* Students had no problem identifying the value this type of connection provided for their studies and why they would attempt, where possible, to create these connections. In each case students identified an understanding of how a social network of associations with peers might be of practical benefit. They provided their own examples of these types of relationships working within their lives. They could spell out how these relationships developed and existed. They could also detail how these relationships supported their learning, and they could say how these relationships were active inside and outside of the classroom. Students did not always talk about these connections in terms of strong friendships. For some they were more like “acquaintance-ships” that could be reliably called upon for assistance. These relationships represented an individual student’s network of support that existed outside of the constructed learning space and often extended beyond the duration of a single course. I define these as Social Learning Support Networks (SLSN) partially to distinguish them from both the intensity of a “friendship”, with its sense of longevity and intimacy, as well as from the less reliable concept of an “acquaintance”, with its sense of transience and lack of obligation to assist another.

The use of the term “Social” in SLSN, denotes these relationships as connections that exist outside of the designed learning space but are also social in that they are defined by people coming together (as opposed to learning support resources students might find on a university web site for example). And importantly, SLSN includes the term “Learning” because this dimension was critical for students. Students valued SLSN’s and put energy into creating and maintaining connections with others over time because they understood the importance of these connections during times of study stress, and importantly, that these personal networks actually assisted them in achieving their learning objectives. This was important for undergraduate students, but postgraduate students especially made the point that the choice to study was a choice to redirect resources - time, money and personal energy, from some other aspect of their lives.

WORK-LIFE-STUDY BALANCE

- I work hard and late, I have studies to do and somewhere fit in a social life. This schedule does not leave time to engage in VSS-ing (Sheffield student from 2nd case)

Students participating in this research clearly identified that juggling their study with other parts of their lives was stressful and affected the way they developed connections with each other. This research makes it clear how study is just one part of a multifaceted identity for students. While the depth of this feeling was very strong for the postgraduate students from Sheffield, the undergraduate students from the first case also confirmed that most students who choose to study online, do so in order to be able to fit their studies in with other parts of their life. Palloff and Pratt (2003) characterise the virtual student as someone who “tends to be older, working, and involved with family activities and the community” adding that “The convenience factor is what draws these students to the online environment, because it allows them the time for other equally important aspects of their lives” (p.113). The students in this research certainly reflected Palloff and Pratt’s profile of an online student. For the students in the first two cases, nothing in their constructed online environment facilitated their engagement with one another in the same way as the physical campus did for on-campus students, or the way the MOO did for students in the third case.

In the third case I did not explicitly set out to explore this work/life/study balance. However, students often commented in their daily interactions in the MOO on the pressures of fitting everything in. Interestingly, some students from the third case were able to integrate the time they spent in the MOO with their work life. Some worked in jobs that allowed them to have the MOO running in a background window on their computer. They organised for a pop-up message to hit their screen if someone else logged into the MOO and would click over to the MOO window and say "hello" to whoever had logged in. Spender (1995) and Turkle (1997) have pointed to multitasking as an emerging capability linked to the use of technology like windows-based computers, both in the practice of having multiple applications open on a computer as well as in terms of people's capacity to effectively be engaged in a number of different tasks at one time. This, in effect, allowed them to be in two places at once. These students tended to be the more active participants in the MOO in general but their behaviour also had the unintended consequences of making them available to offer support to fellow students in a "just in time" manner. In the MOO, the timeliness of this support facilitated the development of SLSN's and balanced out the study pressures associated with managing work, home life and study.

Students in the MOO started to establish patterns of online behaviour that colleagues could rely on for support *when* they needed it. These patterns included various practices: some students usually logged into the MOO and hung around the night before an assignment was due; certain students logged on at about 8pm most nights; and one or two students could usually be found in the MOO during the day. These patterns of behaviour and the synchronous nature of the MOO supported students in integrating their study period with other aspects of their lives in two ways. Firstly, the quality of the SLSN's they had developed with each other and the culture of the online environment meant they could confidently seek support from each other. Secondly, the knowledge of their colleague's availability in the MOO allowed students to seek support at common times of study stress. The students in the MOO developed SLSN's that were integrated into their lives as students but existed outside of the defined learning activities in their course.

The students from the first two case studies believed these connections were important but said they did not have either the time or the desire for contributing to a contrived online community. While wanting and valuing the connections between students that resulted in the development of learning support networks, the capacity to build these connections needed to be integrated into their learning processes and/or the learning environment, and modelled by those familiar with the space. In effect, as the literature on community development has suggested (Campfens 1997; Ife 1995), someone needed to take a leadership role in the online environment and model the type of behaviour that could then set the groundwork for students to develop SLSN's.

MODELLING BEHAVIOUR

It was significant that the students in case study one, from the RMIT Social Science program, talked about not knowing how to *be* in the online environment. Knowing how to *be* online is a mixture of both being familiar with the environment, and feeling a sense of presence from others in the space. For many students in this first case, there was uncertainty at a number of levels. They were uncertain about how formal they should be. There was a need for them to both familiarise themselves with the online medium, while at the same time, to understand the permanence of text in online spaces like discussion boards. They looked for clues from other students and from the teaching staff about how much of their personal life they should bring into the online environment, and how "academic" they should be in their contributions. In effect, the entire online environment represented an online classroom space in which their every comment remained permanently on show (for the life of the course). Students from all three cases talked about feeling nervous when going online to make contributions and waiting for others to have their say first, so they could follow their lead. This level of anxiety certainly had an effect on student's willingness to engage online.

However, there was some evidence from the students in case study one that teaching staff could reduce some of this anxiety by modelling the type of behaviour expected in the environment. A tutor from one version of the course started to model a very relaxed style of engagement with students. He did this by commenting in the discussion forums about his personal life and bringing his offline experiences into the discussions. Some of his students said this helped by reducing their sense of anxiety about contributing to the discussions and it provides evidence confirming the importance of teaching staff modelling the type of interactions and engagement they want from their students (Salmon 2001). Most of these students had very little experience in the online classroom and for many there was no sense of how to *be*. They had not developed an online voice or sense of identity in this environment.

The design of the Virtual Social Space that the students in the Sheffield University course encountered tried to reduce their anxiety by having the social environment completely separate from the prescribed learning environment. The Virtual Social Space was built in a separate online environment altogether. The project was designed to allow students to own this space through their management of it. However, knowing how to *be* and achieving a sense of social presence, a sense that the space was a lived place - was not modelled by anyone. Not only was this an unfamiliar environment for students, but activity in the space was not being driven or modelled by teaching staff. There were no course related learning activities in the space and it was not integrated into the students' online learning environment. The experiences of students from the first and second case studies confirms Salmon's (2001) arguments for the modelling of behaviour by teaching staff in what she defines as the "online socialization" stage of an online course (pp. 28-30). Salmon (2001) argues 'When participants feel "at home" with the online culture, and reasonably comfortable with the technology, they move on to contributing' (p. 29). There was little evidence in either the first or second case study of the online environment supporting students to feel "at home" and, as such, there was little online interaction between students that could be defined as social.

This was in contrast with the environment created within the MOO where students learnt how to *be* via their initial interactions with teaching and technical staff, and then through their daily interactions with each other. They developed the confidence and capacity to develop an online voice and a sense of identity. This environment brought together the elements lacking in the other two cases. Namely, the teaching and technical staff modelled the type of behaviour that encouraged casual, friendly, informal contact, and students inhabited the space in a way that ensured that it became a lived space, a place where a student knew they could go to catch up with another student.

This type of casual, just-in-time type of engagement was important in the development of SLSN's because it offered students a "place" they could drop into "without prejudice." Although students were required to log into the MOO for three group conferences, online behaviour outside of these conferences was not monitored or moderated (Salmon, 2001) by teaching staff at any other time. As such this meant that in logging into the MOO they were not publicly committed in their intent. This is similar to when a student comes onto campus. They may be intending to go to the library, they might be going to class, they might be meeting up with friends, they might be attending a counselling service or they might not have a clear intent – they are just coming onto campus as part of their life as a student. In a sense, the MOO provided a similar environment to this. Students could check who was logged on before logging in and some just logged on and went straight to one of the study orientated spaces (galleries or seminar rooms) to complete a task. Others just hung out in their dorm rooms while others wandered around the MOO space, exploring student's contributions to the notice boards or heading off on a virtual train to explore the MOO's virtual representation of Tokyo. Regardless, a MOO etiquette was established that ensured students always greeted each other on entry to the MOO. Teaching and technical staff spent a number of hours each day during the first two weeks of semester in the MOO, and students quickly recognised they could call on staff for assistance with technical issues and questions related to the course. Students developed clear communication processes that allowed them to ask for help in a casual way because of the behavioural etiquette established in the first few weeks. Evidence of the effectiveness of this modelled behaviour started to appear early in the course when some students started to organise to meet at arranged times so they could help each other with technical aspects of operating in the MOO. The MOO was both a familiar and foreign environment for most students. Although spaces had familiar labels, students had to gain technical skills as well as work through their relationships with each other to complete content related tasks. The modelling of behaviour initially by teaching and technical staff, and later between the students, not only reinforced a constructivist approach, it created the opportunity for informal "chat" which became one of the factors for people "getting to know each other" and the development of SLSN's. The environment supported them in this because of the patterns of engagement they had developed with each other.

PHYSICAL/VIRTUAL ENVIRONMENTS: PURPOSEFULLY TURNING SPACE INTO PLACE

The most significant theme to emerge from this research is the relationship between the environment and the development of Social Learning Support Networks. While the literature reviewed for this research related the development of community for students with the learning activities designed by teaching staff, there was no evidence in the literature of the need to understand the relationship between student's engagement with each other outside of the formal learning activities and the vital role the environment played in supporting the development of these relationships. This requires a more holistic understanding of the *environment* to include not just the activities designed in classrooms, nor just the constructed physical or virtual environment students study in, but to understand how students move and engage with each other in those areas not defined as classrooms.

For all three cases, students illustrated the significance of SLSN's and the effect the environment they encountered had on them developing connections with each other. Although students from the first case did not engage socially with each other online, they clearly illustrated how the physical campus environment supported the incidental contact between them that provided the foundations for the development of their SLSN's. Students from the second case went to great effort to ensure they spent social time with most of their colleagues around the on-campus workshop days held each semester, specifically because they understood the value of developing supportive relationships with others; and yet they did not use the virtual space provided online to facilitate these social connections. However, the most compelling evidence for the importance of the relationship between the constructed online environment and the development of SLSN's comes from the third case.

The MOO environment provided students who had no other opportunity to engage with each other, with the capacity to develop SLSN's. This is because the constructed environment of the MOO contained the key elements students required to transform an online space into a lived place - a place they could inhabit by creating things, engage in defined learning activities, play in, and importantly, a place students went to for support in times of study stress.

The idea that the design of the online environment can facilitate the development of community is certainly not new, nor is the idea that people will strive to create support networks using whatever means at their disposal. In 1993, Rheingold argued this in his seminal book *Virtual Community: Homesteading on the Electronic Frontier*:

My direct observation of online behaviour around the world over the last ten years have led me to conclude that whenever computer mediated communication technology becomes available to people anywhere, they inevitably build virtual communities with it, just as micro-organisms inevitably create colonies (Rheingold 1993, p. 6).

This research provides evidence to support the work of those interested in the development of online communities in an educational context and who recognise that the design of the online environment has a relationship to the sustainability of the connections students make with each other. Unlike most Course Management System based online learning environments, the MOO provided the type of environment that supported students' engagement with each other for a few simple reasons. As well as providing an environment that contained the defined learning activities and specified learning spaces (classrooms), it also provided a campus-like environment based on concepts that were familiar to students. This environment provided the capacity for synchronous contact that was not monitored (and therefore represented private space) and the students had the capacity to create objects that enabled them to extend a sense of social presence and their own personality into the MOO. These factors, together with the modelling of a "relaxed and supportive" behavioural etiquette or culture in the MOO by teaching and technical staff, ensured students made sustainable connections with each other that supported their learning.

The behaviour of the students in the MOO confirms the work of Prasolova-Forland and Divitini (2002). They have argued for the use of appropriate spatial metaphors to inform the design of online learning environments. Their work recognises the vital interplay of the spatial arrangements and incidental contact in the development of connections for learners in a way that was confirmed by the students in case study one when they talked about "bumping" into each other, and by the behaviour of students I observed in the MOO. According to Prasolova-Forland and Divitini (2002):

Communication plays a key role in keeping a community alive. Particularly important is the communication that is triggered by casual encounters. This communication is reported to be essential for knowledge sharing and strengthening the ties among community members. The communication is dependent on spatial arrangements, e.g. proximity of desks in a laboratory and attendance in the same classroom. A student that is not physically present in the "territory" of the community cannot take part in this communication. (pp. 259 - 260).

Importantly, Prasolova-Forland and Divitini discuss the implications of using different metaphors in the design and labelling of online environments. They make the distinction between labels that describe real spaces verses those that describe the intended purpose of the space. Key to their argument is the idea that the use of appropriate design metaphors, such as buildings and campuses, creates online environments that are familiar to students. The authors suggest this is in contrast to metaphors that describe the intended purpose of the space (i.e. a discussion board in a Blackboard or WebCT unit) which they suggest focuses 'on the information itself, not the person behind it', arguing that in these environments there is a need 'to strengthen the social aspect in such a system' (Prasolova-Forland and Divitini 2002, p. 262). Focusing on the person behind the information exchange requires an engagement with the environment using a more holistic understanding of the whole online space. It requires a shift in focus, moving beyond the electronic "classroom" to effectively include a student-centred view of a student's online life.

Focusing on a student feeling comfortable in a learning environment requires them to know how to *be* in that environment. This is reflected in Wilson's (1995) work when he talks about the outcome of learning not as "knowing that, know how" or knowing "names for knowledge" but rather as feeling like "we know our way around" in a subject. In advocating for the use of the term "learning environment", Wilson (1995) argues that the use of the metaphor "classroom" invariably starts the conversation from a teacher-led, teacher-centred perspective, as opposed to a learning environment that situates the learner and their experiences in the foreground. The MOO represented starting from this learning environment perspective. It required all involved to negotiate their relationship with both the constructed online environment and each other. In negotiating this relationship by authoring their own identity and social presence, the MOO, as an environment conformed to both Burbule's (2000) understanding of the conditions that mediate the existence of community and Goodyear's (2002) understanding of the learners' need to configure their own "learnplaces." In both these formulations, the learners have licence to act and the capacity to author their own spaces. The construction of the MOO represented this fluidity and the relationship between elements of the online environment and people's behaviour. Students knew how to *be*, and how to use of the environment to develop SLSN's because the environment felt familiar. They could create things and shape their own environment, while others were present in the MOO in ways that facilitated greater engagement. For example students created objects to carry around, authored their own identity via a text-based descriptor of themselves, decorated their own dorm rooms and developed objects for a virtual gallery.

IMPLICATIONS FROM THIS PROJECT FOR FUTURE RESEARCH AND THE DEVELOPMENT OF ELEARNING ENVIRONMENTS

The plague of academic research historically has been its failure to inform practice (Robinson, 1998). Whether research in teaching and learning has been misunderstood, refuted, or simply ignored, the result at the dawn of the new millennium is a mismatch between what we know and what we do. (Brown and Johnson-Shull 2000)

Reflecting on Brown and Johnson-Shull's lament on the failure of academic research to inform practice, it is a little daunting to speculate on the place of a piece of research such as this – one that uses the experiences of students to explore the three distinct fields of "online learning", "community" and "learning environment design" – and to argue for its capacity to inform a new approach to the development of online learning environments. And yet that is precisely the implications of this research. It provides a grounded understanding of the significance of community in the form of Social Learning Support Networks for student learning, and demonstrates that the design of the online learning environment plays a significant role in providing students with an opportunity to build connections and relationships with each other.

Is it right to suggest that all future online learning environments should look something like the MOO used in the third case? The answer to this is simply, no. The development of online learning environments and the use of the Internet in higher education is a rapidly evolving field - as is the technical capability of students - with teaching staff in most fields often lagging somewhat behind, but improving nevertheless. Certainly, we have some examples of graphics-based virtual online educational spaces (such as tappedin.org for K-12 teacher's professional development and projects in SecondLife – a virtual world which will be discussed in detail later). It is fair to suggest these virtual worlds have not really influenced CMS design to date. It is reasonable to argue that this is because the resource issues these environments create, both in terms of the need for broadband Internet access for students, and the technical capacities of teaching staff required to build learning environments in them, are still too great. The MOO was a text-based environment and was very accessible using a dial-up connection and was easy to develop for staff. Further research will be required to understand the changing capacity of the environment and the capacities of those who learn and teach in them. However, a project such as this, that has focused on the human elements of relationship building, our sense of place, and our capacity to know how to be in an environment, has a great deal to offer the field of eLearning particularly when it relates to the education of social work and human services student. The contributions from the students in these three case studies to our understanding of "community" certainly has much to contribute to those engaged in designing tomorrow's eLearning environments. In particular, for the next generation of course management systems, which are the mainstay of most university's commitment to online learning and the typical online environment encountered by social work and human services students.

The individual practice of teachers will always shape the student's learning experience, however, teachers work within the constraints of the learning environments provided in both the on-campus and online worlds. Just as on-campus teaching staff will attempt to move the desks in a room to reshape the learning activity into a more collaborative approach, or struggle to work interactively in large lecture theatres, the vast majority of teaching staff who venture into the online environment use the Course Management System provided by their institution. The findings from this research are a challenge to the designers of CMS to break out of the old paradigm of providing separate electronic classrooms - into creating rich online learning environments. These online learning environments will not only be rich in the various teaching tools educators like to use, but will also be rich in the sense that they take into account the way in which students engage with each other outside the classroom. The following five principles represent challenges from this research for future developers of enterprise-wide online learning environments. These principles bring together the various findings from this research and translate them into core design elements critical for improving the development of SLSN's:

- *Getting together outside the electronic classroom.* Tinto's (2000) research into the benefits of on-campus learning communities found, amongst other things, that members of learning communities developed their own self-supporting groups, they spent more time together outside of the classroom, and did so in ways students reported as supportive. The students' experiences from this research certainly support Tinto's work, but more importantly, their behavior in the MOO is a challenge to us to think outside of the classroom and to provide students with space to inhabit and make their own.
- *Learning environments need to be integrated into the social environment, not the other way round.* To date the development of online learning environments has been split between CMS and content. Effectively, the CMS has shaped the pedagogical approach used by most educators. However, students from these case studies owned and valued the SLSN's they developed outside of the formal learning environment. For students in the MOO and for those in on-campus courses, the learning environment is situated *within* the broader social environment they encountered.
- *Performance anxiety in a text based classroom: students need a space to bounce ideas off each other in their own time.* The

provision of "classroom" only type online spaces limits the opportunities for student to engage with each other and heightens the performance anxiety associated with a written medium. The MOO case study clearly demonstrated that students would take their learning processes outside of the "classrooms" provided and into the halls, dorms and cafes of their virtual university campus or other online sites. These interactions outside the formal learning environment provided them with a safe space to explore their learning with peers.

- *Student identity and social presence: deciding what color shirt to wear that day!* The provision of social spaces with the capacity for extended social presence by a student has both a sense of time and location. The capacity to author their identity and leave their mark on a virtual space transforms it into a *place* that students choose to inhabit.
- *Bumping into each other*. Lastly, the provision of real time (synchronous) opportunities for contact supported the incidental sharing of information between students, which proved to be important in the development of trust relationships and the building of Social Learning Support Networks.

Although the ideas of integrating working environments into social spaces and the importance of incidental, or what is often termed "chance encounters", is discussed in non-learning orientated online work environments [as detailed in the literature on Teleworking, Computer Supported Co-Operative Work and Collaborative Virtual Environments - see Avon (2001), McGrath and Prinz (2001), Buscher et al (2001), Sonnenwald et al (2001) and Wellman et al (1996)], these five design principles provide a radical departure from the dominant eLearning environments found in most universities. It requires us to reassess both how students use online environments and how we conceptualise the boundaries of the online environments we provide for students. The understanding of human interaction and the development of SLSN's from this research contributes to four emerging areas of research and thinking on eLearning, namely: understanding the learning principles designed in successful online computer games; the growth of identity based online communities related to university student life; the development of student portals by many universities; and the use of virtual environments (such as SecondLife) in higher education. While there are certainly commercial drivers involved with some of these projects (facebook.com for example), arguably their success or failure relates to their capacity to start from a student-centred approach and to understand what happens for students as they engage with the online environment.

It is clear that the success of online gaming environments in teaching complex concepts and context related knowledge to players is of interest to the academic community. Authors such as James Gee have started to explore these issues in publications such as *What video games have to teach us about learning and literacy* (2004). At the same time, authors such as Chen (2006) and others have started to explore the value of immersive and non-immersive virtual reality learning environments. Others are exploring Massively Multiplayer Online Games (MMOGs) to understand the education and engagement principles within them (Young et al 2006). Certainly, the remarkable growth of Facebook.com (a website designed for university students to create their own profile) relies on students wanting to make connections with each other and creating a web presence for themselves. In April 2006, Facebook.com reportedly had over seven million users and was worth more than \$1.30 Billion US (Kushner 2006). By 2007 the site had grown exponentially, with a reported seventeen million users (Robbins 2007a). The acceptance by students of sites like Facebook, has caused some authors to challenge educators to abandon their university CMS altogether and use social networking sites (such as Facebook) to deliver their courses:

Getting tired of the Learning Management System on your campus? Ever look to see how infrequently your students actually log in to see their assignments etc? Let me tell you, it's pretty darn infrequently. So why not create a course site on a social network where they already live? (Robbins 2007b, para. 1)

Trying to understand where students of the future will "live" online will be significant in the medium-to-long term as we move towards a more integrated idea of online life. However, the more short-term areas of interest, likely to directly effect the development of CMS, is the work being done by many universities in developing student portals, and the use of online environments such as SecondLife by more and more educators.

Many Australian universities have developed student portals in an attempt to provide 'more complete, holistic online environments for students and staff by converging a number of technologies' (Kennedy et al 2002, p. 24). A student portal attempts to provide an electronic entry point for students from which all the online services a student will use are available. This password protected environment includes everything from library access, to the course management system, student administration and student supports – usually with some capacity for students to provide some identity information about themselves which fellow students can access. While there has been the development of portals designed to improve student literacy skills (Hiscock and Marriott 2003), and other portals designed to improve critical aspects of the student's experience, such as transition (Nelson et al 2005), more universities are now looking towards portals as a way of providing a seamless administrative, communication and learning environment for students. While there is evidence of extensive use of these facilities (with sites like My.monash reporting 95% of students accessing the portal on a weekly basis (Kennedy et al 2002), there is little evidence appearing in the literature on the capacity of these environments to support the development of community for students in the form of SLSN's. This may be because this type of research is underway but just not reported yet or, more worryingly, that there are assumptions that the high usage of these environments will automatically translate to students developing communities. While most Australian universities work on their student portals, many educators, particularly in the US, Europe and UK are starting to explore virtual environments such as SecondLife.

SecondLife, developed in 2003 by the Linden Corporation, is evolving into a rich virtual world capable of sustaining its own economy and developing its own culture. The use of SecondLife for education has been supported by the Linden Corporation but has, until recently, been characterised mainly by individual academics venturing into the environment to teach individual courses (Kirriemuir 2007). The SecondLife environment has similar characteristics to that of the MOO used in this research and, as such, it should provide students with similar opportunities to develop SLSN's. Many higher education institutions are starting to commit resources into SecondLife, develop their own islands, replicate their campuses and run courses "in-world" - a term used to describe being logged in to a virtual world. These institutions have included universities such as Harvard University, New York University, Stanford University (SimTeach 2007) and Oxford University (Kirriemuir 2007). There is also significant research occurring in SecondLife with a view to understanding how the environment might be used in higher education. Kirriemuir (2007) details several projects including: work by Krotoski exploring social network; work by Childs on the learners' experience; work from the University of Portsmouth examining the strengths and weaknesses of virtual environments; and work by Imperial College London comparing two groups of students' experiences – one completing a module SecondLife and the other in WebCT. Recent research is also making the links between educators experience in MOO environments and what implication this might have for the use of SecondLife for tertiary education (Mazar and Nolan 2008)

Certainly many of the institutions building campuses within SecondLife are including the type of social spaces in which students are likely to "bump" into each other, and there is some evidence of 'students commenting on the confidence given them by the environment and how this has helped them as learners' (Kirriemuir, 2007, p. 22). However, there is no evidence of any universities choosing to move from their Course Management Systems fully into SecondLife. This is not unreasonable given that the high-level computer graphics and bandwidth requirements for SecondLife will continue to pose a barrier for many universities outside of the U.S., both for content development and student access. While academic staff can learn the SecondLife programming language and create the learning environments relevant to their course, this requires a significant commitment on the part of the academic and is likely to remain another barrier to the broad adoption of this environment without significant institutional support.

In a sense this is the "tough" question for universities. Build their own integrated online environment including administrative function, learning spaces (both virtual-immersive and CMS like), library resources and social environments - providing them with clear risk management of issues such as copyright and branding. Or choose a third-party environment, not just a third-party application such as BlackBoard run on their own servers, but a whole environment – which will inextricably link their online presence with the branding of the third-party provider and provide all the future-proofing issues universities have face when deciding to move from one CMS to another. While the findings from this research do not provide any clear direction on this question, the five design principles outlined will play an important part in the success of any future online learning environment's capacity to foster a sense of social connection for students.

CONCLUSION

While there is still significant debate about the quality of online learning in universities, it is clear that eLearning and the use of the online environment to support students in their studies will continue to be a dominant factor in university life – including for social work and human services students. While the last decade has seen the almost universal adoption of Course Management Systems by universities, the decades to come are likely to see new developments in online learning environments that will attempt to integrate the student's zeal for products like Facebook, with the richness of virtual environments such as SecondLife, while still proving the security and risk management associated with CMS. The findings from this research will contribute to this new environment.

This qualitative research project used three case studies to explore tertiary students' thoughts and expectations about community in the online environment. Evidence from the first case study suggested there was a need to explore the relationship between the constructed online learning environment and the development of learning communities or what I have termed Social Learning Support Networks. To explore this issue further, the project was expanded and subsequent cases were chosen that included fundamentally different types of online learning environments.

This research had two significant results. Firstly, students not only confirmed popular educational theories on the value of learning communities, but also described how this form of social connection might practically benefit their learning. Secondly, this research found that certain forms of synchronous online environments provided enhanced opportunities for students to form social connections that supported their learning.

These results have provided new evidence of the benefit of social connection, or what many term "community", for students studying online and have been translated into five key design principles. I have argued that future online learning environments should be shaped by these five key design principles to foster a greater sense of social connection between students and to aid in the development of Social Learning Support Networks. Emerson understood the overriding power and currency of the connections students make with each other and the subsequent shaping of their learning experiences. I think it is fair to say, that over a hundred years later, we are still working through how we translate the power of what "schoolboys" (and schoolgirls) have relied on for centuries – "having a mate to call on!" - into a vibrant, sustainable university eLearning environment. This research, while important for all students, is of particular significance for the design of online learning environments social work and human services students encounter. These students are often required to work on the development of interpersonal communication skills as part of their professional development and clearly an online environment, which fosters the development of Social Learning Support Networks, also provides them with the opportunity to develop these skills.

Chapter 2.4
A Methodology for Integrating the Social Web Environment in Software Engineering Education

Pankaj Kamthan
Concordia University, Canada

ABSTRACT

The aim of this article is a technological revitalization of software engineering education from human and social perspectives. It adopts a systematic approach towards integrating the Social Web environment (including technologies and applications based on those technologies) in software engineering education, both inside and outside the classroom. To that regard, a feasibility-sensitive methodology for incorporating the Social Web environment in software engineering education that supports a heterogeneous combination of objectivism and constructivism is proposed and explored. The potential prospects of such integration and related concerns are illustrated by practical examples. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

In the last decade, the discipline of software engineering has gained increasing significance in computer science and engineering education. It is evident that software engineering education (SEE) needs to be sensitive to the variations and evolution of the social and technical environment around it. In particular, any changes in the information technology (IT) environment need to be reflected in SEE, if it leads to viable opportunities and demonstrated benefits. Indeed, there have been calls for a reform of SEE in which technology is given a prominent place (Frailey, 1998; Kamthan, 2008; Shaw, 2000).

The Social Web, or as it is more commonly referred to by the pseudonym Web 2.0 (O'Reilly, 2005), is the perceived evolution of the Web in a direction that is driven by 'collective intelligence', realized by IT, and characterized by user participation, openness, and network effects. For the sake of this article, the Social Web *environment* includes Social Web technologies, applications based on those technologies, and tools for managing both. The focus of this article is to assess the implications of the Social Web environment as it pertains to logistical and pedagogical issues arising in teaching and learning of software engineering, including interaction between teachers and students, and between students.

The rest of the article is organized as follows. First, the background necessary for later discussion is provided and related work is presented. This is followed by a proposal for a methodology (labeled as SW4SE2 henceforth) that aims for a systematic introduction of the Social Web environment in SEE, both inside and outside the classroom. The prospects of SW4SE2 are illustrated using practical examples. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND AND RELATED WORK

There is a need to foster a social environment in software engineering at several different levels and is increasingly being seen as significant to SEE (Layman et al., 2005). The software process environments, with the client and user involvement, have become increasingly collaborative, of which agile methodologies and Open Source Software (OSS) ecosystems are exemplars.

The human aspect and indeed the social aspect of software engineering trickle down to process workflows. It has long been recognized that requirements elicitation is a social process (Macaulay, 1993). The crucial design decisions, such as selection and application of architectural styles or patterns, often depend upon mutual cooperation. The success of Pair Programming, one of the core practices of Extreme Programming (XP) (Beck & Andres, 2005), intimately depends on the acknowledgement of its social nature (Chong & Hurlbutt, 2007).

However, the technological infrastructure enabling the social component of software engineering has taken time to get established. In the 1970s, the environment to support the social aspect of software engineering was not mature, and in the 1980s, the environment was largely limited to the use of electronic mail (e-mail). It was the 1990s, particularly the ascent of the Web, that opened new vistas for people that were non-proximal to communicate in a variety of ways on a global scale.

The three primary factors that can be attributed to bringing the vision of the Social Web to a mainstream realization are: (1) the enablement of a many-to-many communication paradigm in which people are primary, technology is secondary, and the Web is merely a broker, (2) the maturation of the underlying technological infrastructure and the availability of its implementations as open source, and (3) the awareness and large-scale participation by the public at-large.

There have been relatively few initiatives so far for integrating the Social Web environment in education. The uses of Wiki for teaching software engineering have been reported (Decker et al., 2006; Decker et al., 2007; Gotel et al., 2007; Parker & Chao, 2007). However, the correspondence to any teaching strategy or learning theory is unclear. A learning process based on the Socialization, Externalization, Combination, Internalization (SECI) model of knowledge management that uses Social Web technologies has been suggested (Chatti et al., 2007). However, the treatment is largely peripheral and one-sided: the precise advantages of Social Web towards teaching and learning are not given and the corresponding limitations have not been pointed out. This is one of the motivations for this article. The limitations of conventional computer-supported collaborative learning (CSCL) are pointed out and, via the introduction of an application, namely eLogbook, the usefulness of next generation of social software in engineering education has been demonstrated (Gillet et al., 2008). However, the treatment of Social Web technologies in it is largely one-sided, and eLogbook is not yet mature and its relationship to other Social Web applications is unclear.

INTEGRATING THE SOCIAL WEB ENVIRONEMENT IN SOFTWARE ENGINEERING EDUCATION

SW4SE2 is a specialization of IT4SE2 (Kamthan, 2008), a methodology for integrating IT in SEE. It consists of a nonlinear and non-mutually exclusive sequence of steps as shown in Table 1.

In order to be practical, it is imperative that the steps 1–3 of SW4SE2 given in Table 1 be feasible. It is expected that this is part of the overall instructional design and institutional resource management policy. These steps are stated at a high-level and could be granularized further if necessary. For example, a step for evaluation could be added to SW4SE2.

Step One: Deciding the Scope of Software Engineering Knowledge

The initial step in realizing SW4SE2 is a characterization of software engineering knowledge embedded in the curriculum.

The software engineering topics could correspond to the knowledge areas of 'standards' of software engineering knowledge, namely the Guide to the Software Engineering Body of Knowledge (SWEBOK) and the Software Engineering Education Knowledge (SEEK). It is likely that the selection of the topics may be influenced by their correspondence to the software engineering state-of-the-art; their technological necessity and technological reacheability for the purpose of communication; and their relevance to future careers of students, including industrial significance.

Step Two: Adopting a Learning Theory and a Teaching Strategy

The two theories of learning on which pedagogical strategies are being modeled today are *objectivism* and *constructivism* (Smith & Ragan, 1999). From an objectivist view, knowledge is external to an individual (and therefore objective), and therefore learning involves a "transfer of knowledge" from the instructor to the learner. From a constructivist view, knowledge is not external to an individual, and therefore learning involves constructing one's own knowledge from one's own experiences. Constructivism has been broadly classified into the categories of individual, radical, and social. In particular, social constructivism is especially relevant to the context of this article. In recent years, constructivism has received attention in SEE (Hadjerrouit, 2005).

There has been much debate over the years in the educational community on the virtues and drawbacks of objectivism and constructivism; however, there are signs of reconciliation (Cronjé, 2006). Indeed, for the sake of this article, the two views are seen as *complementary* rather than competing and, in certain cases, non-mutually exclusive rather than conflicting.

A teaching approach (strategy) must be sensitive to the theories of learning that have been adopted and currently in practice but should not be

Table 1. A feasibility-sensitive methodology for integrating Social Web environment in software engineering education

1. Deciding the Scope of Software Engineering Knowledge 2. Adopting a Learning Theory and a Teaching Strategy 3. Selecting and Applying Suitable Social Web Technologies/ Applications to Software Engineering Educational Activities	Feasibility

constrained by any one of them. A classroom use of Social Web technologies/applications in SEE could be more objectivist than constructivist where the educator plays the role of an "instructor." This could, for example, entail preparing Social Web technologies/applications-based lesson plans and lectures, and encouraging questions from students on a timely basis without severely interrupting the flow of the lectures. The teacher may also have to exercise some degree of discipline in the role of a "manager" outside the classroom) such as by moderating a course Wiki) where it is necessary to maintain a level of decorum.

A project use of Social Web technologies/applications in SEE could be more socially constructivist than objectivist where the educator plays the role of a "guide." This could, for example, entail providing a balance between discipline and flexibility to the students in carrying out a software project with minimal guidance and timely feedback by the educator as and when needed: the crucial aspect being that the students play the primary role and the educator plays the secondary role.

Table 3 summarizes the possible interactions in a typical SEE setting. It also forms the basis for step 3.

Table 2. A mapping between activities in SEE and corresponding Social Web technologies

Activity	Social Web Technology/Application
Syndication	News Feed (RSS, Atom)
Classroom Demonstrations, Audio/Video Interviews	Mashup, Podcast, Shared Presentation (YouTube)
Core Lecture Material, Supplementary Course Material	Collaborative Note Taking (NoteMesh), Folksnomy, Wiki, Social Bookmarking (del.icio.us, Google Bookmarks, Yahoo! Bookmarks)
Asynchronous and Synchronous Communication, Discussion	Blog, Mailing List, News Group (Yahoo! Groups, Google Groups), Podcast
Researching for Assignment or Software Project	Collaborative Annotation (Google Notebook, Microsoft OneNote, NoteScribe)
Scheduling	Web Calendar (Google Calendar)
Brainstorming	Mind Map (bubbl.us)
Development of Software Process Artifacts	Collaborative Read/Write Application (Wiki, Google Docs)
Management of Software Source Files	Collaborative Source File Sharing (SourceForge)

Table 3. A mapping between the types of possible interaction, communication, and educational contexts

Interaction Type	Communication Type	Educational Context
Teacher–Student	Synchronous	Inside Classroom: Lecture
	Asynchronous	Outside Classroom: Assessment Mode (Assignment, Project), Support
Student–Student	Asynchronous	Outside Classroom: Assessment Mode (Assignment, Project)

Step Three: Selecting and Applying Suitable Social Web Technologies/Applications to Software Engineering Educational Activities

Table 2 highlights the relationship between common types of activities manifesting from student–student or teacher–student interactions in SEE and Social Web technologies. It is not meant to be exhaustive. For a given educational context, there may be more than one applicable Social Web technologies, and they may not necessarily be equally suitable.

The following criteria could be used for selection of a Social Web technology/application: (1) nature of information (such as sensory modality) being communicated, (2) alignment with teaching and learning goals, (3) considerations for openness (proprietary versus non-proprietary), (4) maturity (stability), and (5) feasibility (availability and cost-effectiveness). The criteria are minimal and non-mutually exclusive. An objective third-party review of a candidate technology can also help in making the decision for adoption.

EXAMPLES OF INTEGRATING SOCIAL WEB TECHNOLOGIES AND APPLICATIONS IN SOFTWARE ENGINEERING EDUCATION

As evident from Tables 2 and 3, the Social Web lends various opportunities for communicating. A sample of these is considered next.

Collaborative Learning

For the sake of this article, collaborative learning is a social interaction that involving a community of teachers and students that acquire and/or share experience or knowledge. In an objectivist approach to SEE, lectures and tutorials are still the norm where a teacher (or a teaching assistant) often makes use of black/white board or overhead projector for delivery. It is (at theoretically) expected that each student will attend all of these lectures and tutorials from beginning to the end, and be attentive all the time during the session.

However, in practice, this need not be the case. The author has come across dedicated students who for one reason or another had to come in late, had to leave early, or for reasons of fatigue or otherwise, missed the essence of the session. A partial solution is to make the slides available for download, however, at times, there is implicit knowledge being communicated by the teacher that is not always made explicit. In such cases, students could benefit from their peers. NoteMesh is a Social Web application that allows students in the same courses to share notes with each other as well as edit each others notes. Its motto is 'collaborate to graduate.'

For the reason of time constraints or otherwise, the introduction of a topic during a lecture or tutorial is often relatively 'local' and from a single viewpoint. However, during assignments or tests, the students are expected to see the 'big picture.' Using the notion of folksonomy or social tagging (Smith, 2008), the students could associate other relationships with the lecture as they see fit. For example, phrases from past lecture(s) or the textbook could be candidates for tags.

A collection of tags can lead to the formation of a tag cloud. A tag cloud is set of related tags with associated weights that represent frequency of use of each tag. The frequency of use of each tag within a tag cloud is illustrated by visual cues such as distinct font color and size. Figure 1 shows a tag cloud for the BREADCRUMBS pattern (Ballard, 2007) used in the design of a variety of software applications.

It should be noted that folksonomy (as opposed to taxonomy) is an uncontrolled vocabulary, and the lack of terminological control can have linguistic implications due to synonymy, homonymy, and polysemy. It is also not automatic that all tags that are created by the students may be relevant to the context. For example, a tag labeled as ‘bread’ or ‘crumbs’ is not related to the BREADCRUMBS pattern in the context discussed above.

Syndication

Every so often a teacher needs to keep the students informed of the latest developments, including critical announcements, related to the course. However, individually informing each student of the developments is inconvenient for a teacher; arbitrarily visiting the course Web Site is somewhat unsystematic and time consuming for a student.

The subscription to periodically refreshable news feeds via syndication helps ameliorate this issue. Syndication is a type of metadata implemented in form of channels that the students can subscribe to. There are a variety of syndication technologies of which Really Simply Syndication (RSS) and Atom are beginning to find broad support in conventional user agents and news feed readers. For example, the following RSS markup fragment represents news for a specific day from a single channel:

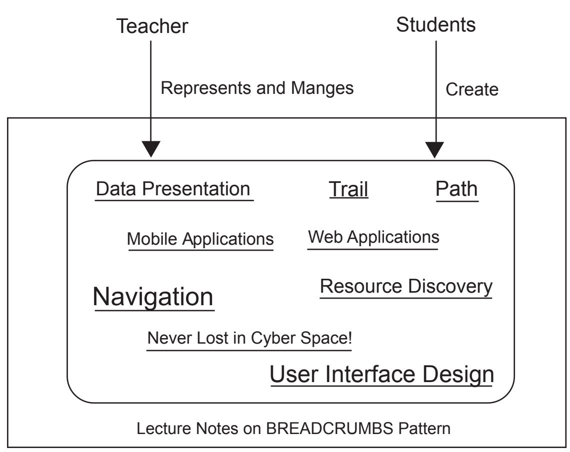
```
<?xml version="1.0"?>
<rss version="2.0">
<channel>
<title>Software Design Course Channel</title>
<link>http://www.see.ca/</link>
<description>
This is a news channel for software design.
</description>
<item>
<title>News for January 15, 2008</title>
<link>http://www.see.ca/2008/01/15/</link>
<description>
A new presentation is available as a podcast.
</description>
</item>
</channel>
</rss>
```

It could, for instance, be stored in a file named `course.rss` and linked from a place that channel readers could readily discover.

Collaborative Researching

The Social Web can be an indispensable source for students researching for information for assignments, or during the realization of a software project. There are Social Web applications like

Figure 1. A tag cloud embedded in the lecture notes on the BREADCRUMBS pattern



Google Notebook, Microsoft OneNote, and NoteScribe that allow one to attach notes to and clip text, graphics, and links during researching. These ‘notebooks’ can be saved, and can subsequently be used for collaboration and sharing with others. The annotations associated with the resources found during researching can take various useful forms including comments on the relevance of the resource to the specifics of the software project, individual perceptions of the quality of the resource, reminders for comparing them with other resources, and so on.

Bookmarking has traditionally been one of the most common ways of remembering the resources of interest visited while browsing on the Web. However, these bookmarks reside on the user’s computer and are not accessible by other devices (and therefore are not shareable). Social bookmarking goes beyond traditional bookmarking and enables management (for example, storage, organization, search, and sharing) of bookmarks residing remotely at third-party services. There are several social bookmarking services in use today including del.icio.us and Google Bookmarks. By unifying their knowledge base, social bookmarking can help both teachers and students to collaborate and share their links to resources.

Social Scheduling

To be able to communicate in person is a critical component in SEE. For example, a team working on a software project has to often schedule a face-to-face meeting with each other or with the teacher (and/or the teaching assistant playing the role of a client). Often, a critical component to education is communication in person. To realize that, a team working on a software project has to often schedule a face-to-face meeting with each other or with the teacher (and/or the teaching assistant). In general, it can be difficult to manage a schedule that is agreeable and flexible to all. Furthermore, seeking consensus can become increasingly difficult as the number of persons involved increases.

The use of Social Web applications that facilitate calendar sharing (such as the Google Calendar) can reduce some of the tedium involved in scheduling a meeting agenda. These applications move the focus away from one person (say, meeting chair) being in-charge of gauging others’ preferences via several bi-directional contacts to each person interacting with the calendar to seek an optimal solution. Furthermore, these applications offer other conveniences such as being reachable at any time of a day, access to the latest schedule, privacy by access to restricted/registered users, and so on.

Brainstorming

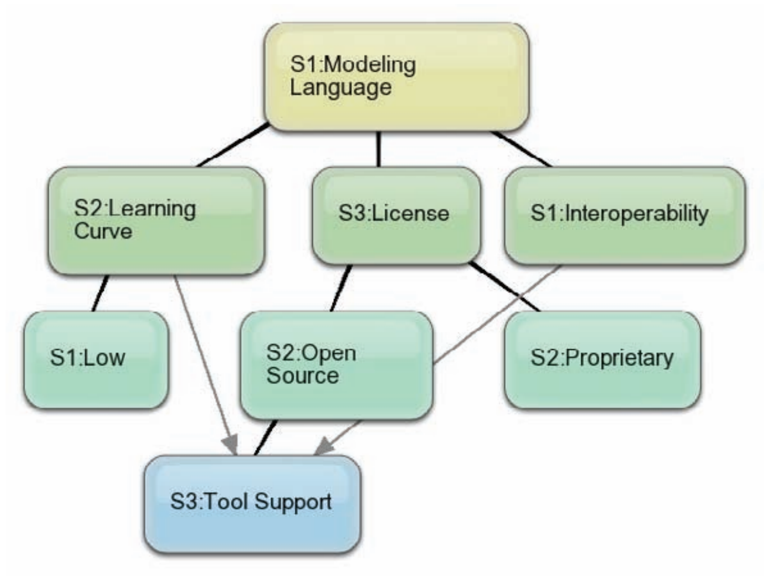
In a collaborative approach to discussing an assignment or the details of a software project, students often engage in brainstorming. One way to brainstorm is through visualization, and mind mapping is a graphically-oriented approach to realize it. A mind map is a diagram that represents goals, tasks, or other concepts linked to and arranged radially around a central theme or an idea. It is used to generate, visualize, and organize ideas, and as an aid to understanding, problem solving, and decision making. The students can share these mind maps over the Web and, depending on the permissions, read and/or edit others’ maps.

Figure 2 illustrates a snapshot in time (work in progress) of a mind map using bubbl.us. In it, three students, namely S1, S2, and S3 are in a brainstorming session on the feasibility of a proposed modeling language. The ‘bubbles’ reflect respective inputs by students.

Collaborative Modeling and Prototyping

The activities of conceptual modeling and prototyping are critical to the success of software projects. They are becoming increasing common in

Figure 2. An example of a partial mind map reflecting a brainstorming session on the viability of a modeling language



SEE (Cowling, 2005), particularly in model-driven approach to software development and interaction design, respectively. The task of creating a large and complex model may need to be decomposed, where parts of it would be created by different students. For example, a conceptual model such as a domain model or a use case model being created by one student could benefit from informal inspections and feedback by another.

Figures 3 and 4 illustrate snapshots of Gliffy, a Social Web application that allows collaboration and sharing of diagrams. Gliffy appears to have a low learning curve and supports version control. However, it has limited capabilities compared to its desktop counterparts like Microsoft Visio or IBM Rational Rose XDE. For example, the support for the Unified Modeling Language (UML) is partial and it is not possible for users to extend a given template.

Collaborative Authoring

The Social Web presents a suitable environment for collaborative authoring of software process artifacts using various means including Google Docs and Wiki.

Google Docs is a Social Web application that provides capability to create word processing documents, spreadsheets, and presentations, as well as there import and export in various commonly-used formats. It also allows real-time collaboration and sharing of these resources using the Web. However, Google Docs has yet to completely replace a conventional office suite. The support is limited to certain user agents and there are currently physical limits on files sizes and designated storage space that may be constraining.

The concept of Wiki was invented in the mid-1990s as a group communication utility. It allowed open editing of information as well as the organization of the contributions and, with various enhancements, continues to serve well in that vein. There are several, opens source flavors of Wiki available today addressing different target groups and organizational needs. Most flavors of Wiki, including MediaWiki and TinyWiki, can be easily acquired, installed, and administered under commonly-deployed computing platforms (Ebersbach, Glaser, & Heigl, 2006).

There are various uses of a Wiki in a software engineering course. A Wiki can be used both by teachers for the course and by students for the course project.

Teacher Uses of Wiki

A teacher could administer a Wiki as means for the electronic entry point for the course (namely, the "Home Page"), as a placeholder for threaded discussions, or as a place for an evolving list of course-related frequently asked questions (FAQ) that is shareable by all. The teacher could also invite students to provide open feedback (anonymous or otherwise) on the progression of the course, including comments and suggestions for improvement. Once the course has ended, the accumulated feedback can be useful in a course retrospective, which may lead to improvements in teaching.

Even if administering a Wiki is not an option, course material pertaining to the lectures could be placed on the Web and Wiki could be used to supplement them. For example, as shown in Figure 5, key topics and terms in a classroom lesson could point to resources from the projects of the Wikipedia Foundation (such as Wikibooks, Wikipedia, Wiktionary, and so on). This enables

Figure 3. The construction in progress of a domain model for a file system showing four concepts and four relationships

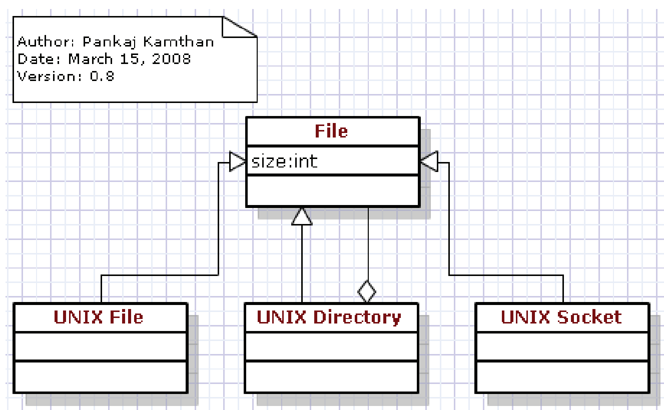


Figure 4. The construction in progress of a low fidelity prototype showing eight user interface elements

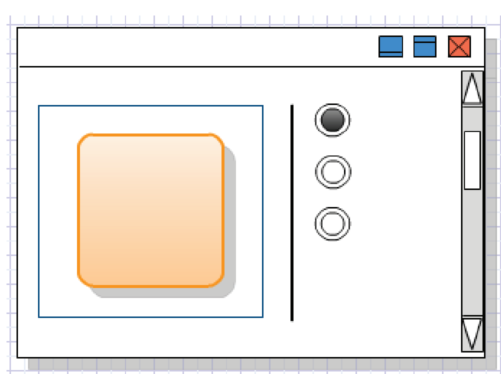

Figure 5. A classroom lesson on object-oriented design using external resources in the Wiki environment

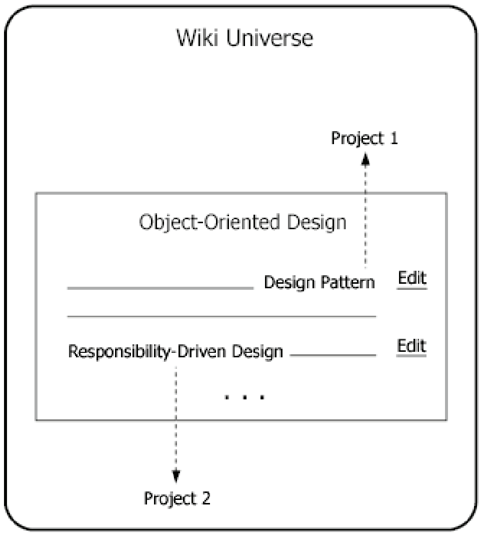

teachers to demonstrate to the students that the discipline of software engineering is not 'closed' (in form of books) and allows teachers to present the course material at different levels of abstraction; that is, highlighting the details on the topic at hand, while suppressing ancillary topics or sub-topics.

Student Uses of Wiki

A team of students could also run its own Wiki specific to course project and limited to its members (and perhaps to the teacher and to the teaching assistants). This has numerous benefits including negotiation of use cases and requirements, centralized availability, ease of modifiability, and traceability of project artifacts such as conceptual models, data dictionary, glossary, and software process documents.

A common problem in software projects is that the details of actually carrying out the process often remain suppressed. However, this implicit knowledge is critical for future projects, particularly those in the same or a similar domain. The versioning and feedback information in software documents based on a Wiki helps make some of the *experience* of the team members in carrying out the process *explicit*. This experience, including triumphs and tribulations, is relevant to social constructivism and can be useful in a project retrospective.

The disadvantages of a Wiki are that student participation is not guaranteed and, while some students may be extrovert in nature and prolific writers, others may not. They are also known for impertinent information and discussions that have morphed into endless debates. Therefore, some form of monitoring and control, perhaps initiated by the teacher, is essential.

Software Engineering is 'Living'

The fact that software engineering is still a young, constantly evolving discipline is not always apparent to undergraduate students. Furthermore, once published, textbooks attempt to merely communicate static knowledge. The teachers who wish to communicate new developments to students are faced with the dilemma of keeping the focus on the core software engineering knowledge while still being able to inject occasional spikes of novelty in their lectures that are within the scope of the curriculum.

Utilities such as Google Trends could be used (Rech, 2007a) by teachers to convey some of the dynamism and excitement of the discipline of software engineering. As an example, based on Google Trends (with the query string q=Agile+Development), Figure 6 shows that in the last few years, the adoption of agile development has been on the rise around the world.

It should, however, be noted that Google Trends is limited by the nature of query formulations expressed in a natural language. For example, searching for 'RDD' on Google Trends yield several irrelevant results, and for the 'Responsibility-Driven Design' (for which the data set was low) there were no results at all. It also turns out that this behavior is not unique to RDD.

From Participants to Innovators and Metaphysical Implications

The Social Web lends a unique opportunity to computer science and software engineering students. As shown in Figure 7, there is a symbiotic relationship between the Social Web technologies/applications and SEE. By participating in the Social Web, the students can become co-producers of information. Moreover, with an appropriate software project, they can even become innovators of Social Web applications. Thus, the students can not only benefit from the Social Web but can also help create technologies/applications that can benefit others in the future. An educational setting provides a starting point towards that goal.

Indeed, some of these applications could be a computer-aided software engineering (CASE) tools themselves. For example, course projects that can potentially make this synergy explicit while still being within the conventional SEE curriculum could involve making minor/major improvements to the core of an open source Social Web application like Wiki to serve as a platform for software process workflows, integrating two or more open source Social Web applications, transitioning a 'legacy' application to a Social Web application while preserving the original functionality, and so on.

There are metaphysical, especially holistic, implications to the synergy between the Social Web and SEE. The benefits of crosspollination can only be optimally realized if the focus of the students carrying out the aforementioned course projects goes beyond the treatment of technical issues pertaining to technologies/applications. The students must be made cognizant of the fact that technologies/applications are not the end, not the means to the end itself and must provide verifiable value to users. In other words, the human and social aspects of the course projects are (at least) as significant as the technical issues.

Figure 6. A snapshot of the adoption of agile development

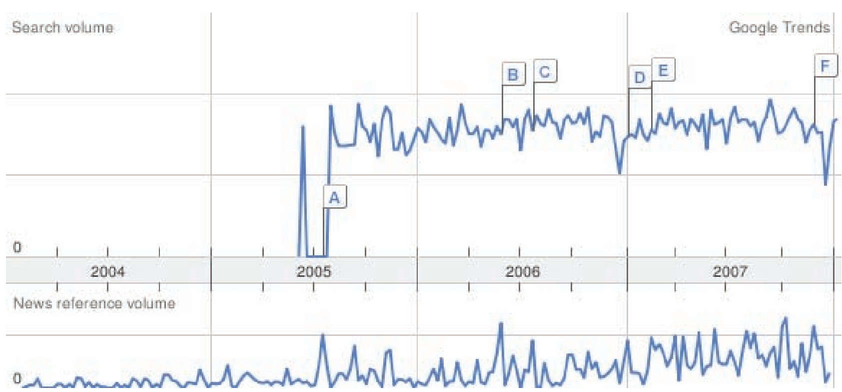

Figure 7. The synergy of mutual benefit between the Social Web technologies/applications and SEE

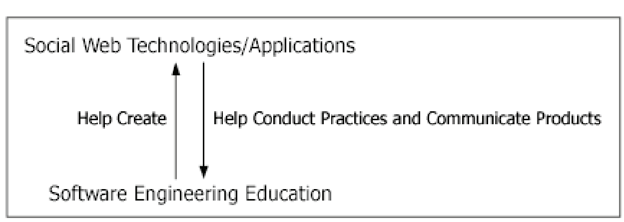


Guidelines for Adoption of Social Web Technologies/Applications in Software Engineering Education

It is known that teachers can face various obstacles in enabling an environment for e-learning at Universities. The following set of guidelines that may help prospective teachers in making an informed decision towards integrating Social Web technologies/applications in software engineering-related courses:

- **Administration:** It is needless to say that the teachers must be aware of the current policies of the institution pertaining to (1) legal and privacy issues regarding students, and (2) security issues regarding information and computing infrastructure. In order to build a learning 'culture' acquiescent to new technologies/applications, it can also be useful to keep the administration (such as the department Chair or the Dean) abreast of any new endeavors, and periodically inform them of successes as well as failures.
- **Students:** The students should be a 'first-class' participants in any integration efforts. In particular, they should be (1) informed of any 'social experiments' being pursued as part of the course, (2) made aware of their rights and responsibilities that comes with flexibility of Social Web technologies/applications, and (3) introduced to the ethical issues in software engineering before they embark on a software project.
- **Infrastructure:** The introduction of Social Web technologies/applications could be incremental. Indeed, it may be useful to initially (1) select technologies/applications that originate from authoritative sources, are relatively stable, and in which the teacher does not have to relinquish control completely, and (2) the presence of technologies/applications is not apparent to students (that is, technologies/applications are transparent to and do not interfere with the learning goals). Then, based on a retrospective, the use of technologies/applications can be scaled appropriately.

DIRECTIONS FOR FUTURE RESEARCH

The work presented in this article can be extended in a few different directions, which are briefly discussed next.

Evaluating the Effectiveness of SW4SE2

It is still early to predict the outcome of the Social Web phenomenon in general and its impact on SEE in particular. To that regard, further evaluation based on surveys of actual teaching experience, and distillation of the experiences in form of 'best practices' could be useful.

The introduction of a new technology/application in education is susceptible to indirections. For example, a sustained integration of Social Web technologies/applications in SEE needs to address quality-related concerns that can arise. In particular, an assessment of the impact on the credibility of information emanating from relaxation of control (from teacher's viewpoint) and emergence of privacy issues (from student's viewpoint) is of research interest.

In the context of global software development, it has been experienced (Gotel et al., 2007) that not all students may have the same exposure to Social Web technologies/applications and as a consequence or otherwise may perceive such technologies to be peripheral rather than essential. In such cases, the significance of communication may need to be reinforced, perhaps with examples of software project successes and failures due to communication.

The use of Social Web applications can be demanding. The hardware and software demands of Social Web applications on both server-side and client-side can not be ignored. For example, the mashups in which aggregation of information takes place on the client-side expect hardware and software capabilities that a consumer may not have or the file sizes of podcasts that are not streamed but are available only as download could be prohibitive to those on low bandwidth. In general, 'Rich Internet Applications' of the Social Web are resource-intensive. To that regard, an investigation into associated cost estimation is of interest.

It is evident that SW4SE2 will change as both software engineering and Social Web evolve. For example, the underlying philosophy of agile methodologies makes them more perceptive to the adoption of Social Web as the communication medium, and a verification of this hypothesis in actual software projects could be useful. Furthermore, Web Services are important to a number of Social Web applications such as mashups, and their impact on the SEE curricula in general and SW4SE2 in particular could also be worth investigating.

Implications of the Social Web in Pattern-Assisted Software Engineering Education

In many cases, any teaching initiative could be viewed as a collection of one or more {problem–solution} pairs that occur in specific contexts. Since education has a long history of lessons learnt from both successes and failures, it is likely that these pairs are not entirely novel. The conceptually reusable experiential knowledge embedded in these pairs, if described appropriately, could be useful in the practice of SEE.

In its simplest form, a pattern is an empirically proven solution to a recurring problem in a given context (Buschmann, Henney, & Schmidt, 2007). The reliance on patterns garnered from past experience and expertise is important for any endeavor, including SEE. For novice teachers, *pedagogical patterns* (Bennedsen & Eriksen, 2006) can serve as a source of guidance and/or reference.

There are limited reports of actual use of pedagogical patterns in SEE (Seffah & Grogono, 2002). However, a pedagogical-pattern-assisted approach can be worthwhile, if appropriately realized. Therefore, an assessment of software engineering teaching based on pedagogical patterns that uses Social Web technologies/applications for realization of the solutions recommended by the patterns could be of interest. This dynamic is shown in Figure 8.

It should however be noted that, in general, such an approach would need to take into account several factors including availability of suitable pedagogical patterns that can sufficiently 'map' learning activities, the selection of pedagogical patterns based on their alignment with the adopted teaching strategy, and clearly identified value to students.

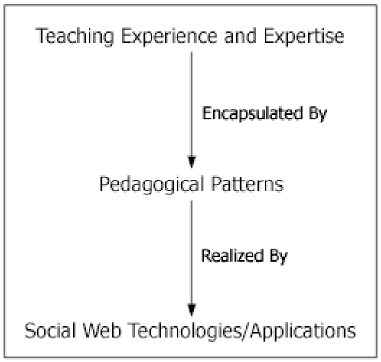
CONCLUSION

The challenges facing the practice of software engineering today are as much technical as they are social in nature. The social and organic aspects of software engineering not only need to be acknowledged by teachers but also made explicit to the students in a feasible manner.

The Social Web provides an avenue for both teachers and students to communicate both inside and outside the classroom. It can open new vistas for teachers as well as stimulate students to become 'first-class' participants in-charge of their own learning.

In conclusion, an adoption of the Social Web may require a re-examination of the current software engineering culture at the institution, both at administrative and at the educational level. The technologies/applications underlying the Social Web can be disruptive: they require change and, in some cases, radical departure from conventional approaches to which not all

Figure 8. The confluence of software engineering teaching, pedagogical patterns, and the Social Web



may be a willing participant. Furthermore, for a long-term sustainability of integrating Social Web technologies/applications in SEE, the likelihood for any technological determinism must be minimized and, as with any other investment, the benefits alongside the associated costs must be kept in perspective.

Chapter 2.5
Ambient Pedagogies, Meaningful Learning and Social Software

American University of Nigeria, Nigeria

ABSTRACT

This chapter will present a new approach to designing learning interactions and experiences that reconciles relatively stable learning processes with relatively new digital practices in the context of social software and Web 2.0. It will begin with a brief position on current educational articulations of social software before offering some theoretical pointers and methodological perspectives for research and development in this area. The authors will then explain how an ongoing initiative in advanced learning design has developed notions of "ambient learning design" and "experience design" to address these issues and describe a new methodology for developing digital tools that incorporate these concepts. This approach is exemplified through ongoing work within an initiative in Digital Dialogue Games and the InterLoc tool that realises them. Finally, the implications this work has for future trends in designing for inclusive, highly communicative and engaging learning interactions and practices for the digital age are discussed.

DOI: 10.4018/978-1-60566-208-4.ch027

INTRODUCTION

One of the problems with recent educational articulations of social software and Web 2.0 is the misalignment of social practices that are ostensibly oriented towards and motivated by 'interest' with those that are oriented towards and motivated by 'learning'. This has been demonstrated in many ongoing projects, such as those supported by the UK JISC (Joint Information Systems Committee), although there is little mature research in this area as yet. Whilst these purposes and the practices they entail are not mutually exclusive, they often involve different processes of meaning making. In learning situations there is usually a defined or identifiable context, that may be organised or emergent, which involves some management, structure or scaffolding. This operates as an ‘interaction narrative’, and is usually required to promote suitable sorts of thinking, collaborative meaning making and content assimilation and generation that corresponds to learning. In other words, whilst specific practices such as personal content creation and expression, communication, media sharing, multimodal dialogue and social networking are relevant to communities of interest and learning, these will usually be orchestrated differently in both. And furthermore, understanding these differences is important if we want to harmonise interest driven informal learning with more formal learning activities, given that all these activities are now increasingly performed within the same digital landscape. So a question we are tackling in this Chapter is: What forms of contextualisation and support are needed with more open and social software to stimulate, catalyse and realise meaning making that corresponds with attested notions of learning through social interaction and dialogue?

Based on substantial previous work emphasising the centrality of dialogue in learning (e.g. Vygotsky, 1978; Mercer, 2000; Ravenscroft, 2001, Wegerif, 2007) and particularly in the context of promoting productive conceptual change (e.g. Hartley, 1998; Ravenscroft and Pilkington, 2000) we hold that a key component in social networking and communication for learning will be the quality, educational efficacy and general value of the dialogue and media-rich interaction between digital interlocutors. Indeed, it may be the case that the degree of learning that occurs with open and social software corresponds to the quality of the multimodal dialogues that are being performed. But how can we design for these inclusive and valuable multimodal learning dialogues? Or more generally: how can we embrace and exploit the opportunities offered by open digital technologies to support contemporary approaches to dialogue, thinking and meaning making in ways that support new and relevant learning practices? When we start to unpack these questions we have to address some additional emphases that characterise contemporary digital practices, such as participation and collaboration, and the production of shared and yet more provisional knowledge representations.

The remainder of this Chapter will present theoretical pointers, a research and development perspective, and a specific approach and methodology to design that aims to address these questions. This work is based on the notion that we will typically need to introduce some appropriate organisation and structure to direct learning whilst ‘working with’ students developing digital literacies. Or for learning we will usually need some pedagogically derived and ‘managed openness’ to support meaningful learning practices We will then show how this approach is realised through an ongoing initiative in Digital Dialogue Games.

BACKGROUND

Before launching into contemporary approaches to designing learning interaction for the digital age it is useful to consider what fundamental learning processes and practices at which we are looking to emphasise and foster meaningful learning experiences. In considering this challenge Ravenscroft, Wegerif and Hartley (2007) have recently argued for a re-conceptualisation of ‘learning dialogue’ through developing and synthesising notions of dialectic and dialogic. Their arguments that are relevant to this article are summarised below.

Dialectic and Learning

The dialectic that was used by Socrates (470-399 BC) during what has become known as 'the Socratic method' is one of the earliest recorded educational approaches, which is also receiving considerable attention in contemporary education through computer-mediated tutorial approaches used by Bjork (2001). Hegel (1770-1831) turned dialectic into a more abstract notion of a dynamic logic proceeding from thesis to antithesis and then synthesis. Hegel's approach rested on a coherence theory of truth, where the truth relies not on a single proposition but a whole system of propositions, and only within this complete system can contradictions be recognised and falsity removed. Similarly, the process of synthesis preserves the rational and removes the irrational but then also provides another thesis that can become the subject of the same triadic process, and so on. So for Hegel, although "The true is the whole", this is a developing whole that develops through contradiction. Applying Hegel's dialectic Marx argued that culture and consciousness arise as 'tools' in the dialectic interaction between humans and nature. Vygotsky took this as a model of how an individual consciousness is formed through the internalisation of tools. So Vygotsky's (1978) theory of the development of higher mental processes can remain a foundation and inspiration for approaches to technology enhanced learning that emphasise collaborative, argumentative and reflective discourses, along the lines that have been emphasised by Mercer (2000), Ravenscroft (2001, 2004) and Wertsch (1991). However, we now need to take full account of the mediational power offered by new and evolving digital tools and semiotic systems.

Dialogic and Learning

Bakhtin (1986), a contemporary of Vygotsky, argued that dialectic had become over formalised and we needed to return to real dialogues because logic itself has no meaning, holding that it is only the clash of different voices that gives meaning. So he opposed what he called 'Hegel's monological dialectic' with his notion of dialogic that refered to the interanimation of real voices where there is no necessary 'overcoming' or 'synthesis' (Wegerif, 1999). Following Wertsch the socio-cultural approach has tended not to recognise this and combine together two notions of mediation, Vygotskys account of mediation by tools including words as sign-tools (dialectic) and Bakhtin's account of mediation by the voices and perspectives of others (dialogic). While mediation by tools is not incompatible with mediation by the perspective of the other person and both happen in education, it is important to point out that these are different kinds of mediation, that can be conceived as different dimensions, or features, of the dialogue process. For each participant in a dialogue the voice of the other is an outside perspective that includes them within it. The boundary between subjects is not therefore a demarcation line, or an external link between self and other, but an inclusive 'space' within which self and other mutually construct and re-construct each other. So, as emphasised by Wegerif (2006), a dialogic approach to learning considers that the main mechanism for learning is taking the perspective of another in a dialogue, where the dialogue is an end to be valued in itself as perhaps the most important goal of education. Recently, Wegerif (2007) has argued powerfully for this perspective to 'expand the spaces of learning' through digital technologies and emphasised that it's not just the use of explicit reasoning but the ability to change one's mind and see things from a new perspective that is essential for learning.

Dialectic or Dialogic? Relative Dimensions for Learning Dialogue and Meaning Making

Ravenscroft, Wegerif and Hartley (2007) also questioned the relationship between these two characterisations of dialogue. Do they work together or in opposition? The work of Ravenscroft and his colleagues in designing dialogue games for conceptual change in science (e.g. Ravenscroft & Hartley, 1996; Ravenscroft & Pilkington, 2000; Ravenscroft & Matheson, 2004) has shown that an argumentative and dialectical approach was needed for a student and tutor to achieve a synthesis around a correct conceptual understanding of the physics of motion. In contrast Wegerif (2006) has argued and demonstrated that in some circumstances, especially when dealing with younger children and those with emotional and behavioural problems, a more dialogic approach, with its emphasis on 'taking the perspective of another' is more important than progression towards some sort of synthesis around a common understanding. So considering their previous work collectively, they argued that dialectic and dialogic are two relative dimensions that are not in opposition, as they focus on different yet equally important features of the dialogue process relevant to learning. Dialectic emphasises the epistemic and cognitive dimensions of learning that are realised through social processes that occur when an appropriate dialogic state is established. Dialogic emphasises emotional and interpersonal dimensions, or the sort of 'relationships' and 'intersubjective orientations' (Habermas, 1991) that enable the spaces where learning can happen. These are a complementary emphasis. The desire to reason to progress towards a rational synthesis does not have to override the need to understand others, and likewise, the desire to understand others does not have to override that pragmatic need to reach a rational consensus that links to purposeful action in a context. The two will always interplay and vary in emphasis based on what is wanted from a learning situation.

"To paraphrase Kant (Kant, 1781/1982, A 51/B75): dialectic without dialogic is blind (as in machine cognition), dialogic relations without dialectic is empty of content (as in the mother child couple): it is through their union that new shared understandings can arise." Ravenscroft, Wegerif and Hartley (2007), p 47

Contemporary Contexts for Learning

An essential point that is entailed by the argument made above is that through social and more open technologies we are creating new spaces and contexts which have the potential for dialectic and dialogic learning through new and developing digital literacies. These contexts can often be conceived as 'democratic spaces' that are either generated or populated by the users, whose relationships mediate learning as much as the processes and tools that are in play. These contexts are clearly creating new forms of intersubjective orientations where learning can happen, that are shaped through open participation, collaboration, multimodal language, the provisionality of representations and could potentially contribute, generally, to a more 'democratic epistemology'. So drawing together the relations we have introduced in connection with dialogue, thinking and the potentially empowering role of social software - our position is similar to that of Friere (2001).

"To think correctly implies the existence of subjects whose thinking is mediated by objects that provoke and modify the thinking subject. Thinking correctly is, in other words, not an isolated act or something to draw in isolation but an act of communication…For this reason, a correct way of thinking is dialogical not polemical." (Friere, 2001, p 42-43)

So in embracing these new (social software) contexts and possibilities, our position also aligns with what tends to be called 'egalitarian dialogue', which foregrounds the assessment of contributions in terms of the validity of the arguments presented rather than according to any power positions of those who advocate them. The remainder of this article will attempt to demonstrate how we can design to support well attested and fundamental approaches to thinking, learning and meaning making through exploiting learners developing digital literacies and practices. Where a key question is: how can we create or support, through design, the pedagogical contexts that realise contemporary forms of learning and digital meaning making? A first step in this process is identifying a suitable research and development perspective that is capable of working in harmony with the rapid evolutions in technologies and related practices that typify the digital age.

DESIGN-BASED RESEARCH FOR CONTEMPORARY LEARNING INTERACTION AND PRACTICE

A central tenet of design-based research, relevant to the work described in the rest of this article, is:

The challenge of design-based research is in flexibly developing research trajectories that meet our dual goals of refining locally valuable innovations and developing more globally usable knowledge for the field. (Design Based Research Collective, Educational Researcher, 2003, p.7).

In the context of the work described in the rest of this article, the locally valuable innovations we will consider are digital dialogue games (Ravenscroft and McAlister, 2006a, Ravenscroft, 2007) and the InterLoc (Collaborative Interaction through scaffolding Locutions) tools that implement them (Ravenscroft & McAlister, 2006b, Ravenscroft, Sagar and Baur, 2007). The latter of these is described and discussed later. More generic insights about the dialogue processes required for learning and conceptual development have been provided through discourse analysis and dialogue modelling methods that are embodied by these tools or led to their development, along with the evaluations of the delivered designs (e.g. Ravenscroft 2000; Ravenscroft and Matheson, 2002; McAlister, Ravenscroft and Scanlon, 2004b; Ravenscroft, McAlister & Baur, 2006).

But a key additional argument for adopting design-based research in our digital age is that it can allow us to fully articulate the role of technology as a mediating tool for social and intellectual development, rather than seeing technology as the organisational 'means' to deliver traditional learning. Given the increasingly pervasive nature of technology, an approach which considers design-based research within a sociocultural scientific frame (e.g. Vygotsky, 1978; Wertsch, 1991; Engestrom, 1987) is particularly powerful for investigating and promoting contemporary learning. This stance emphasises the mediating role of technological tools and social relationships that these tools may operate within or give rise to in the context of contemporary learning practices. So this perspective is particularly relevant to the development of dialogue and social software and the ways these are articulated within the learning landscape.

Following this approach and building on their discourse analysis work (e.g. Pilkington, 1999) Ravenscroft and Pilkington (2000) developed the methodology of "investigation by design" (hereafter IBD) to investigate educational dialogue and design models that support reasoned discourse leading to conceptual change and development. This method combines discourse analysis and other dialogue game techniques (e.g. Levin and Moore, 1977; MacKenzie, 1979; Walton, 1984) to specify models that can be implemented as digital tools. These game designs and tools are developed through modelling key social and pragmatic level features of effective dialogue interaction, such as the roles of the interlocutors (e.g. learning manager, facilitator, player), the ground rules for commitment and turn-taking, and the type of speech-acts (Searle, 1969) that may be performed (e.g. assertion, question, challenge). The dialogue games that are developed, whilst sharing the same categories of features (e.g. pre-defined goals, numbers of players, roles, moves and rules, etc.) are distinctive in terms of the actual configurations of these features. They are also different in terms of the particular learning problems they address (e.g. critical, creative or exploratory dialogue) and the learning processes they support whilst retaining certain 'family resemblances' (Wittgenstein, 1953). The methodology has been successfully used to design a number of digital dialogue game tools (e.g. DIALAB, CoLLeGE, CLARISSA, AcademicTalk and InterLoc) that, along with a more detailed explanation of the IBD and dialogue game approach, are given in Ravenscroft (2007). This educationally and socially derived definition and articulation of games is justified in some detail and contrasted with 'video-game' approaches (e.g. Prensky, 2001; Gee, 2003) in Ravenscroft and McAlister (2006a), and our conception of dialogue games is illustrated in some detail later in this Chapter, in the sections that demonstrate how our InterLoc tool realises them. This technology creates contexts and process-oriented learning designs to support and scaffold collective inquiry, critical thinking and collaborative argumentation through the orchestration of social games that are performed synchronously amongst small groups (of 4 – 8 students). These environments are inclusive and personalised, and yet, also provide structuring and scaffolding, through pre-defined features and rules of interaction - that follow well-established pedagogical frameworks derived from sociocultural and dialogue theory that were referred to earlier. This and earlier dialogue game tools, such as AcademicTalk, have been used and evaluated in a range of Higher Education contexts, from ODL to campus-based institutions (e.g. see Ravenscroft, 2007 for a review).

The latest tools have been produced through a refinement of the IBD methodology. This has involved introducing new concepts of 'ambient pedagogy' (realised through ambient learning designs) and 'experience design' whilst also considering recent research into more personalised approaches to learning design that are suitable for the technology enabled learner (Ravenscroft and Cook, 2007) and their widespread use of social software. So the IBD approach has been extended to support the design of contemporary learning practices that are suitable for social, inclusive and participative approaches within the social software and Web 2.0 landscape. In essence, this has represented an elaboration of pedagogical process design into a more experiential pedagogical practice and context design. However, to signal any potential misconceptions, note that our approach to design needs to be considered within a broader frame than the existing family of social software and conceptions of Web 2.0. Our emphasis on designing highly inclusive, social and collaborative learning is intended to harmonise with developing digital literacies in the context of social software rather than being predicated upon their specific aims and functionality, that can be quite narrow (e.g. based around social networking and media sharing). To clarify this position we will demonstrate how this perspective and methodology is being applied within our ongoing multi-partner dialogue game initiative (see www.interloc.org). This 'serious gaming' approach is inclusive, social and collaborative, and yet focussed on the fundamental need to structure and scaffold learning dialogues that support types of thinking and meaning making that are relevant within the digital landscape and conveyed through the production of a 'collaborative text'. These texts (see Figures 2 and 3 later) are more formal than records of unstructured Chat or dialogue that is typical in conferencing software, and yet are less formal – in terms of textual representation - than a typical wiki or blog, and they are significant in that they capture 'live thinking'. So they can provide unique intermediary representations between collaborative thinking and thoughtful writing. Our approach is also motivated by research that has highlighted the difficulty of supporting truly engaging, critical and reasoned learning dialogue (McAlister, Ravenscroft and Scanlon, 2004a,) combined with the potential of new technologies to help remedy this (e.g. Wegerif, 2007). Note also that this approach does not deny the value of social software as platforms for generating and sharing diverse ideas and media. It instead, attempts to harmonise with these practices and yet manage and coordinate them along pedagogical lines in ways that lead to more focussed and coherent interaction and meaning making that aligns with learning. In a sense, the current dialogue game approach is a way of generating and capturing thinking on the net in ways that realise and satisfy accepted ambitions for learning that also 'sits with' more informal and media driven digital practices with social software.

Ambient Pedagogy and Experience Design

In succinct terms: ambient pedagogy holds that the structure or scaffolding supporting the learning interaction is 'behind the scenes' and yet also implicit in the digital practice that is supported; and, 'experience design' emphasises that the learning occurs through the production of an experiential context, in contrast to foregrounding the management of instruction and pedagogical or learning design. Of course we are not saying that we should literally aim to directly design experiences, instead the term is meant to be interpreted more circumspectly, as 'design that aims to give rise to a particular type of learning experience', that bears some significant similarities with other, typically less formal activities with social software.

Our initial design principles that represent this approach are:

1. Realise digital naturalism: Build on and integrate with developing social software and practices that are familiar to learners, so their educational interaction 'feels like' a natural digital practice.
2. Consider proximal practices: Support highly social, communicative, relevant and engaging experiences that are in harmony with learners' commonplace informal digital behaviour.
3. Emphasise semi-formal activities that reconcile organisational and personal activities and requirements (or constrain interaction for a purpose).
4. Provide flexible, open and yet configurable experiences, or 'managed and structured openness'.
5. Make the complex simple: Design interfaces that incorporate narrative and contingent features, so users only experience the interactions and contexts that are relevant to them. In other words, do not expose the full complexities of the machine, but instead emphasise the experiences that functionalities give rise to.

Note that this approach should not be considered as a simple 'layer above' conventional notions of learning design, but instead considered as a philosophy incorporated into the learning and interaction design process. The following sections demonstrate how these principles are articulated through a design based research initiative in digital dialogue games for learning.

DIGITAL DIALOGUE GAMES: A DESIGN-BASED APPROACH TO DIGITAL LEARNING DIALOGUE

Our Dialogue Game approach has proven efficacy for a range of learning problems and contexts, as documented in a range of research projects over the past ten years that are summarised in Ravenscroft (2007). It is currently realised through the Open Source tool, called InterLoc that realises the dialogue games through creating and organising a suitable learning context and mediating learning processes through supporting a structured practice and a unique method of collaborative text production. This approach has been supported through three successive multi-partner projects over the past three years (see www.interloc.org). The current project that is supported by the UK JISC and has partners at London Metropolitan University, UK Open University, Universities of Exeter and Teesside and, Queen Mary (University of London).

InterLoc3: Attractive, Inclusive and Reusable Learning Dialogues

Our current dialogue game technology, Interloc3, embodies the need to reconcile learners developing digital literacies with the well-established requirements for reasoned and purposeful dialogue. Specifically, through incorporating the notions of 'ambient pedagogy' and 'experience design' we have provided a managed and yet attractive and inclusive learning context and experience that provides a structured, collaborative and engaging learning practice. This practice, in turn, allows learners to incorporate media and generate text and content that are relevant and valuable through linking their digital dialogue to their thinking and the production of collaborative and personalised texts or knowledge assets. So this practice aims to link learners interest-driven, and typically media-centric behaviours, to more learning-driven dialogue and textual practices. There is also the incorporation of multimodal and multimedia aspects into learning interactions to further enrich the learning experience.

In brief, InterLoc3 is Web-technology with low barriers to participation that is easily used and deployed to address relatively generic learning problems and opportunities. So it is pedagogically inclusive and technically pervasive1. In the pedagogical sense, it is inclusive because its ease of operation means that virtually any learner or tutor is capable of using it to support digital learning dialogues and linking these to related learning and pedagogical practices. In the technical sense, it is pervasive because it is easily deployed, is cross platform, and is flexible and extensible. The way that these features are operationalised in the InterLoc3 design and the practices it supports are given later, after briefly describing the technical model that implements them.

Technical Model and Realisation

To address these requirements (above) in the context of a distributed and collaborative application involved the development of a new methodology involving four related layers:

1. Client-server architecture, based on Jabber messaging protocol (sophisticated Open Source messaging protocol);
2. JAVA application programming (for sophisticated learning and interaction design);
3. HTML interface (for a natural and attractive user-experience);
4. Client deployed through Web-start technology (for flexible and robust deployment, e.g. from within institutional infrastructures).

Further details of how the design is technically realised is given in Ravenscroft, Sagar and Baur (2007a). Adopting this development approach and methodology allowed us to develop a sophisticated Web-technology that is easily deployed and feels like a typical 'Web experience'. The design was derived, ostensibly, from two different and yet typical Web-experiences; the first being the use of the Web in the normal sense of the word - such as Web browsing, social networking etc., and the second based on the use of Instant Messaging applications.

The way in which the interface design has taken into account the experience most Web users have with Instant Messaging applications (IM software) is shown in Figures 1 and 3. Users who are familiar with applications like MSN, Yahoo and Skype find using InterLoc extremely easy since the interaction builds on these experiences. As an example, IM users expect to be presented with a simple login page which requires the input of usernames and passwords before gaining access and being presented with content. While logged in, users expect to view the status (online/offline) of their friends (other users) and to be able to communicate informally with them (InterLoc provides an informal chat feature to support this aspect). Also, the layout of the dialogue window (the main venue where the communication between participants is taking place) has typical layout where an upper part is used to present the communication that's taking place (the actual contributions) and a lower part allows the player to enter their contributions to the discussion. InterLoc3 was designed to take into account such subtle layout and design familiarity with 'similar' applications to accommodate the realisation of its design. This allows new users to quickly learn the 'interaction basics' that allow them to increase the sophistication of their dialogue game practices in a cumulative way.

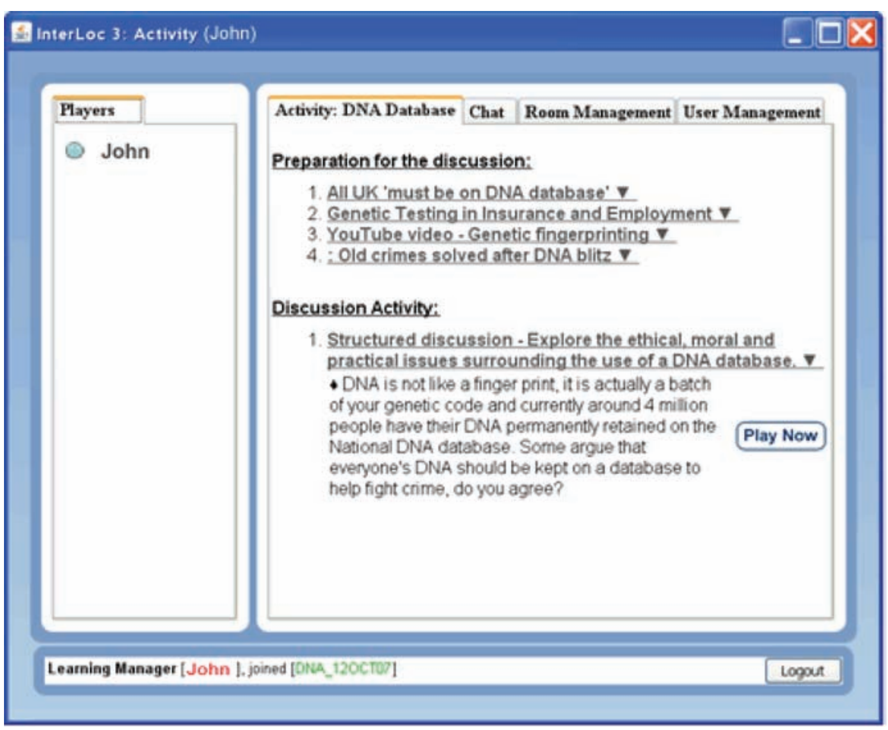
InterLoc3: Interface Design for Organising and Playing the Dialogue Games

Essentially, through following the methodology above InterLoc3 incorporates the same proven pedagogy as previous dialogue game tools (e.g. Interloc1, see Ravenscroft and McAlister 2006b), but has re-engineered this into the Web-technology that realises ambient pedagogy and experience design, so it is more pervasive, intuitive and attractive than previous designs that made their learning design more explicit. Put simply, InterLoc3 makes its complex learning and interaction designs look and feel simple.

Roles and Setting the Learning Context

Users of InterLoc are assigned one of three roles, namely Learning Manager, Facilitator or

Figure 1. The activity screen



Player. The Learning Manager, who is usually a tutor, takes the initiative to set the context for the dialogue games through assigning the roles, selecting any preparatory materials, deciding on a specific dialogue game and setting a question, or questions, that seed the game. Once the users login - using the username and password that has been assigned to them - they are presented with the interfaces that reflect the rights for their role and the functionality that is specific to their role. So for the players - logging in takes them to a realisation of the context and (ambient) learning design that has been set up for them. This is typically a number of preparation materials and media along with the particular dialogue game that has been selected or configured for them. This demonstrates how InterLoc provides the means to realise flexible, open and yet configurable learning experiences.

A user with a Facilitator role sees the same interfaces presented to players in addition to being able to broadcast a message to all players to manage the synchronous game. Figure 1 shows an Activity screen for a discussion topic about using and storing DNA. Here John is a Learning Manager because he has access to Room Management and User Management in addition to having Activity and Chat screens – that are available to all user roles

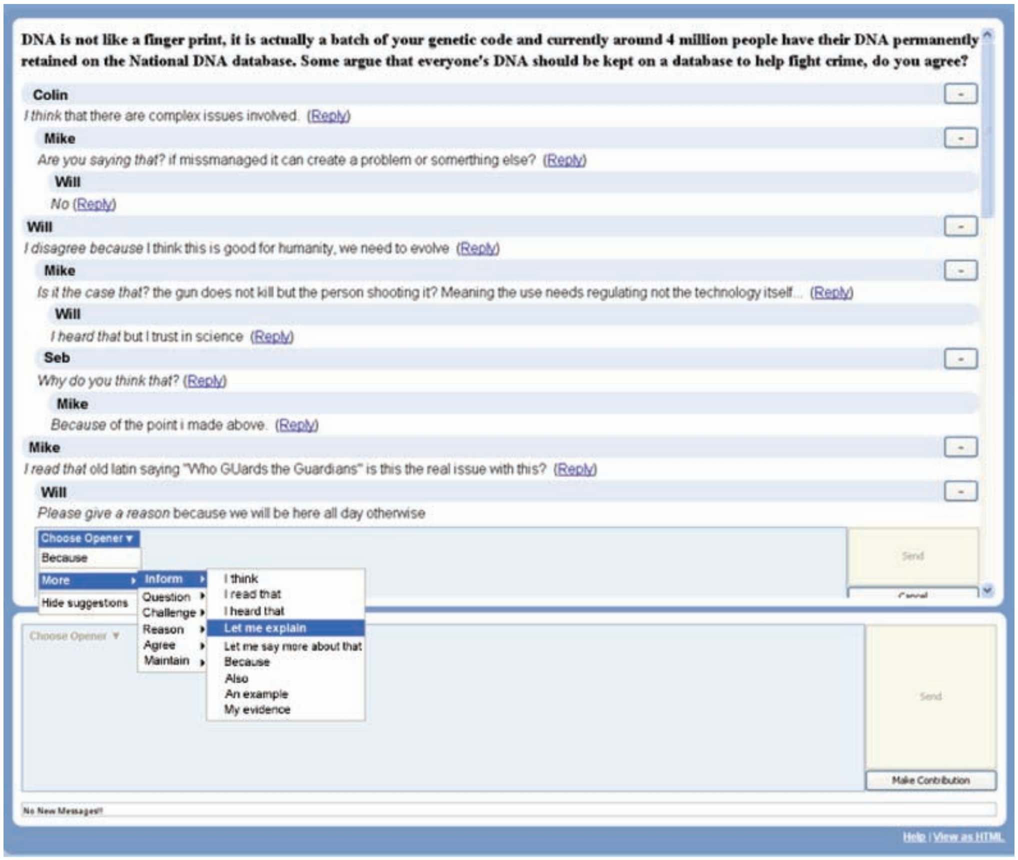
The above example shows how the contextual aspects of the ambient pedagogy are set through linking the preparation tasks to a suitable dialogue game. This activity uses four preparation tasks associated with the topic of DNA testing, but the Learning Manager could use more or less depending on the preparation requirements. Most dialogue games require such preparation, to give the learners sufficient prior knowledge and understanding, or grounding, to perform an engaging and meaningful dialogue game. The second part of the screen displays the actual question, which seeds this dialogue game entered through selecting the “Play Now” button. Typically players will perform the preparation asynchronously, in advance of the scheduled game activity, in their own time. The bottom window pane displays the participant’s role and status.

Playing the Dialogue Game

The interface in Figure 2 shows how each player performs the dialogue game. They can either Contribute to the current state of the developing dialogue through selecting “Make Contribution” or Reply to a specific previous contribution by selecting “Reply”. Contributing to the dialogue places a response at the bottom of the display and Replying indents the responses below the specific contribution that is replied to - in a threaded way. This model contains affordances that achieve a balance of ‘keeping the dialogue moving forward’ whilst allowing reflective asides and specific responses to previous contributions. So players need to distinguish whether they are “Contributing” to the developing dialogue (using the large reply bar at the bottom), typically responding to the latest ‘state of the dialogue’, or replying to a specific previous contribution (by selecting “Reply” next to each contribution). Also, all contributions or replies are made using the pre-defined Move categories (Inform, Question, Challenge etc.) and the specific locution openers (“I think…”, “I disagree because…”, “Let me elaborate…” etc.) that have to be used to perform the dialogue. Similarly, rules about the legitimate and logical responding openers, based on the specific Openers that are replied to, are offered selectively - but these can be overridden to select the full range of options through selecting “More”. For example Figure 2 shows a player called Seb2 deciding to access the full range of moves and openers through selecting “More” instead of using “Because…” - which is the prompted response to the “Please give a reason…” opener.

This interface shows how the adoption of html, CSS and common design colours and idioms (e.g. threading, menu operation and expansion boxes) ensures the dialogue game experience is attrac-

Figure 2. The Interloc3 Interface: Realising ambient pedagogy and experience design



tive and 'feels like' a typical and intuitive Web experience and realises our principles of 'Realise digital naturalism'. Similarly, it operationalises the principle of 'Consider proximal practices' through supporting a style of interaction that builds on students experiences with technologies like MSN and Skype.

Figure 2 also shows how the structuring and scaffolding works. It shows Seb replying to a previous contribution by Will – who has requested a reason for a position offered by Mike. So Seb has responded to Will's Challenging move of "Please give a reason…" using an Informing move "Let me explain…" and is about to enter the content of his response. Even this brief excerpt, which was taken from a user-test performed during a work shop with members of the Learning Technology Research Institute (LTRI), most of whom were using InterLoc for the first time, demonstrates coherent reasoned dialogue about using DNA technology.

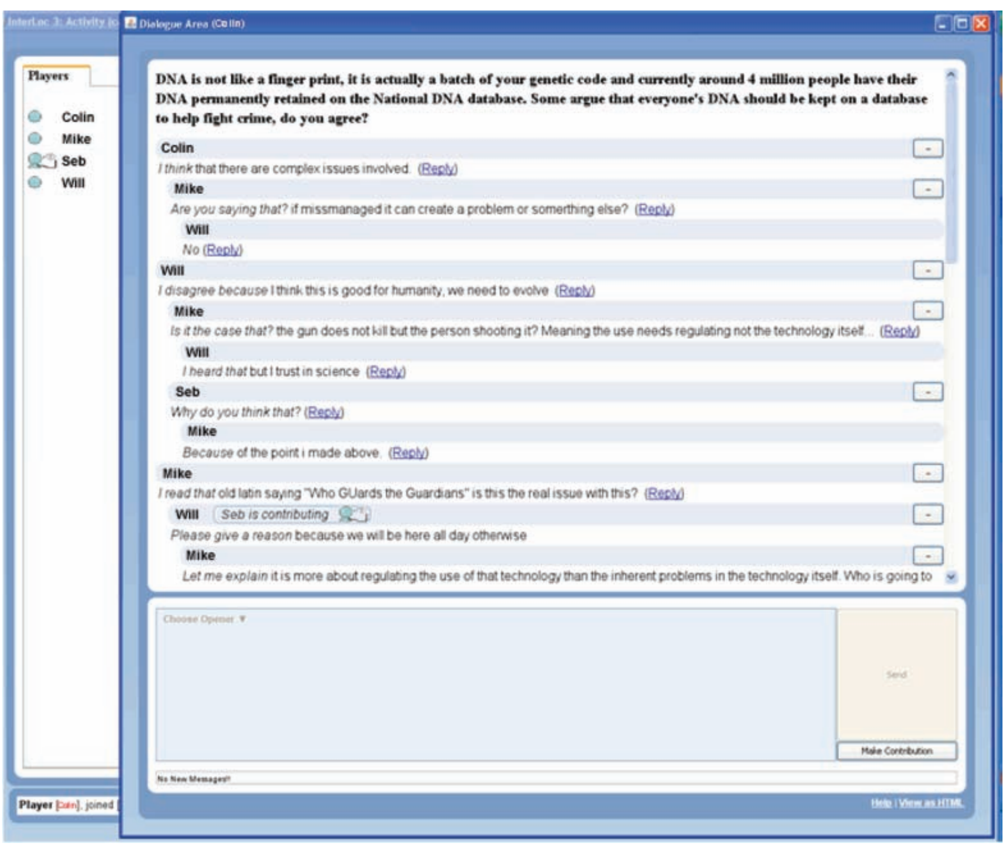
This activity started with all players watching a video about Genetic fingerprinting on YouTube, which was the third preparation activity listed in Figure 1. Figure 2 shows how the question that seeds the dialogue game is bolded and located at the top of the screen. This interchange shows how in addition to the Challenge described above the dialogue game approach supports features such as a clarification requests - "Are you saying that?…", reasoned disagreements - "I disagree because…", various probing questions – "Is it the case that?…", "Why do you think that?…", and referring to evidence – "I read that…". So it should also be clear how this learning and interaction design is semi-formal in nature, in that is supports a scholarly practice that is realised in an engaging way and linked to the types of digital assets that students may frequently use for either informal or formal learning.

Turn-Taking and 'Listening'

To ensure the dialogues remain coherent a turn-taking model is employed, that is shown in Figure 3, which allows each player to 'hold the floor' whilst making a response, which is automatically signalled to the other players, 'blocks out' other responses to the same contribution and generally allows the dialogue to be logically and coherently displayed and managed. So this feature is a good exemplification of our principle of 'Make the complex simple', as without it we would have confusing dialogues and a confusing representation of them. This also means that players don't 'rush' to make their contributions, and instead observe and 'listen' to the developing dialogue. If any player holds the turn for too long (e.g. more than 90 seconds) they are prompted to Contribute or Cancel, and of course players can always attend to another contribution if the specific one they wanted to reply to is in the process of being responded to by another player.

So the turn-taking and awareness features ensure logically (i.e. reasoned) and sequentially coherent dialogue is performed and sequential incoherence (e.g. that is experienced with chat) is avoided. This leads to a more considered, reflective and thoughtful dialogue. Note that problems of sequential and semantic incoherence that are

Figure 3. Turn-taking and listening



addressed by the InterLoc design are significant problems in virtually all other tools that support synchronous communication. In contrast this mechanism realises a balance between fairly managed dialogue and a 'pace of interaction' that leads to thoughtful and yet 'forward moving' dialogue. In Figure 3 we can see what Colin and the other players observe when Seb is making the response referred to in Figure 2. which 'locks out' the Contribution input field for the selected reply for all players of the game until he has finished.

To summarise the interchange in Figure 2 and 3, which although brief, demonstrates how collaborative arguments, and texts, are developed through InterLoc. Colin initiates the dialogue (about storing and using DNA) using "I think…" to assert that there are complex issues involved. Mike replies to this using "Are you saying that…" to probe what these complex issues might be, which Will then disagrees with by saying "No". Will then contributes using "I disagree because…" to explain he's in favour of using DNA technology because it shows 'evolution in humanity'. Mike then replies to this using "Is it the case that…" to question and suggest that its not the technology itself but the people using it that need regulating. Will replies to this with "I heard that…" to acknowledge Mike's point but affirm his own position. Seb then contributes using "Why do you think that…" to question the points made by Mike, who refers him to previous contributions and uses "I read that…" to elaborate his position in terms of "Who GUards the Guardians". This stimulates Will to reply to Mike's contribution, using "Please give a reason…" to press Mike to clarify his position, who then does so using "Let me explain…". A number of previous papers (McAlister, Ravenscroft and Scanlon, 2004a; Ravenscroft and McAlister, 2006a, 2006b) give a considerable number of longer and more varied dialogue game interactions along with their analysis and evaluation.

Saving, Replaying and Reusing the Dialogues

As the content of the dialogue games can be saved as a html file – it forms a valuable learning resource that contains a collaborative, structured and semi-formal textual argument. This may be used as personal notes, the pre-cursor to an essay or assessment exercise, or as content that could be posted to another forum, a blog or a wiki. The html format can de replayed using a standard text to speech translator, such as the one freely available with the Opera browser. This provides an accessible 'replay' facility that can be performed after the dialogue games so that players can decide whether to further manipulate or edit the generated content. Of course, this replay facility could be performed via a Web-enabled mobile phone. This flexibility, across platform, device and modality also demonstrates our principles of 'Realise digital naturalism' and 'Consider proximal practices'.

Amending the Pre-Defined Dialogue Games

Note that all the textual contents contained in the Menus that realise the dialogue games are read in from xml files and so can be easily edited and amended, to provide flexible configuration of the ambient learning design. So the Learning Manager can choose to modify particular Move categories, alter the wording of the Openers or alter some of the rules of the interaction in ways they think will fit their pedagogical purposes. Ongoing work with early adopters is making this process easier, through the development of a dialogue game editing tool.

Ongoing Evaluation of InterLoc3 and Preliminary Findings

There are currently ongoing implementations and evaluations of InterLoc3 across four HE Institutions, involving a range of courses and hundreds of students, so at the moment we can only report some early findings from London Metropolitan University, where the dialogue game approach was initially adopted and used by two tutors and 53 students studying software engineering within the Department of Computing. This total number of students was divided into twelve groups based at two campuses, which accounted for approx 75% of the total cohort of students studying this module.

The course leader set up the dialogue game activities covering pre-examination questions in ‘formal methods for specification’ and specifically included two reading tasks for student preparation. So in this context the aim was to ‘get the students thinking, working and revising’. Two researchers from the project and the course tutor (who are co-authors of this article) observed the student groups, as these initial trials were performed in a computing lab. In a de-briefing interview within a month of these sessions the tutor made the following comments that give a flavour of the anticipated impact of InterLoc and what the student experience might be:

“But with Interloc, what’s different is once students engage with it they realise it’s different and they have to think about what they are doing and that is the difference. They are not just uploading things or downloading things they have to read something and understand whatever they have read. And while they are within the InterLoc sessions they realise that they need to think about what they’ve got to do before they do it. “

“The main thing is that they are thinking while they are within InterLoc. The thinking that they are doing is slightly different from their normal thinking. In as much as they are thinking about other people within the group: everybody’s thinking about what each other’s thinking, about what’s going on, which is very, very important. So it’s almost like meta-thinking activity.”

One clear finding from these initial studies was that the introduction of this innovation requires more contextualisation than originally anticipated, precisely because it is a practice that as the quotes above indicate, whilst clearly beneficial and important, is not typical of the ‘instruction and assessment’ nature of conventional teaching. So the dialogue game activities need careful introduction in terms of the direct and indirect benefits they offer, in terms of improving students understanding of a topic, generating suitable content to support related learning activities and, providing the means for them to develop and practice fundamental skills of critical thinking and collective inquiry. Also, the process of ‘question-setting’ performed by the Learning Manager to seed the dialogue games cannot be underestimated and needs careful thought. In brief, although InterLoc3 is so far being successfully deployed and adopted in this exemplar context, it has to be conceived of holistically, as a practice that needs to be contextualised within a wider pedagogical and technological context, and ideally built into the broader learning designs (e.g. courses).

FUTURE TRENDS

Interestingly, it was over twenty years ago that we were promised a revolutionary cyber-reality, most famously characterised by William Gibson’s (1984) Neuromancer. Then both Scientists and Science Fiction writers predicted the spread of an all-encompassing cyberspace that would tear apart our conventional notions of reality, replacing them with a virtual reality that would drastically change the way we learn, think and behave. But as far as our work and the explosion in social software has shown it has not happened in this way. The work reported in this article suggests that we are not creating a new landscape for ‘e-learning’ or ‘learning in cyberspace’, but instead we are supporting hyper-interactions that are fundamentally human. In this sense the internet is a landscape that provides the technologies that can catalyse, scaffold and amplify learning processes and re-shape learning practices. So contemporary learning will inevitably involve the close interplay of minds, machines and practices.

Hyper-Interactions for Learning

Our work that has been reported in this article demonstrates how specially designed tools, such as InterLoc, support the sort of collaborative thinking and collective inquiry, through blending dialectical and dialogic dialogue, in ways that are virtually impossible to achieve in more naturalistic ways. Studies of our dialogue games have demonstrated how they: empower learners to engage in 'thinking conversations'; scaffold the development of dialogue and reasoning skills; and, promote inclusive and fairly balanced dialogue practices. Also in some of our studies the students frequently commented that these dialogue games were better than face-to-face dialogues for a number reasons, and especially because some were particularly enthusiastic about being given a 'voice' in critical discussions in ways that overcame significant emotional and social barriers that they had previously experienced. So this clearly demonstrates what we have called 'hyper-interactions for learning', where the technological mediation enables the sort of relationships, dialogue and thinking to be developed and realised that could not have been, or would be very difficult to achieve, without this specialised social software.

CONCLUSION

We accept that the ideas, approach and technologies that are reported in this article, along with the synthesis we attempt, are somewhat ambitious. But they represent a serious attempt to reconcile 'classical' learning practices, such as the development of thinking, reasoning and discussion skills, with the opportunities offered by more open, inclusive and social software - and the developing digital practices that these support. It is early days in this initiative, as the educational and epistemological implications that are entailed by emerging digital practices with social software have arisen very much 'from under the radar', and so academic institutions are trying hard to assimilate their significance. Implicit in the argument that has been developed in this Chapter is a call, through design, to re-focus on fundamentals of learning, through reclaiming notions like 'thinking', 'meaning making', 'understanding' and 'collaborative inquiry'. It is strange that when compared with a lot of the current terminology of learning technology, that has tended to be dominated by somewhat mechanistic and content-centric terms like 'managed learning environments', 'delivering learning', 'content repositories' and such like these more fundamental terms seem somewhat fanciful and alien. But it's also reassuring that when we think of designing future learning practices through embracing more open and social software we have the opportunity to focus on these fundamental human processes.This can be achieved through setting up or promoting new contexts, conditions and catalysts for meaningful learning, as an alternative to using technology to emphasise more sophisticated ways to 'teach'.

ACKNOWLEDGMENT

The authors are very grateful to the many colleagues who have significantly contributed to this line of work. In particular, all members of the Dialogue Game project teams at London Metropolitan University, UK Open University, Exeter University, Oxford University, Queen Mary (University of London), University of Teesside and Bolton University, see www.interloc.org. Recent work on InterLoc tool has been carried out with the support of the UK Joint Information Systems Committee (JISC) "Capital Programme". The content of this paper does not necessarily reflect

the position of the JISC, nor does it involve any responsibility on the part of the JISC.

KEY TERMS

Advanced Learning Design: This is an approach to learning design which accepts that contemporary learning is becoming more personalised, social and emergent - rather than the outcome of highly structured and pre-planned institutional practices

Ambient Pedagogy: An approach to pedagogy and learning design that foregrounds the experiences that are produced through the realisation of the pedagogy, that is present but 'behind the scenes', in a learning situation. So this contrasts with approaches that focus on and externalise the structural complexities of the learning design. Instead, here there is a deliberate effort to render the complexities of learning designs into accessible learning practices that are performed 'naturally'

Dialectic: An approach to dialogue which holds that knowledge and understanding develops through 'rational argument' and 'reasoned inquiry', with an emphasis on the clarification of meaning

Dialogic: An approach to dialogue which holds that knowledge and understanding develops in a dynamic and relational way, through a process that involves the continuous development of descriptions, or re-descriptions, that arise from being able to 'adopt the perspective of another' in a dialogue

Digital Dialogue Games for Learning: A well attested approach to learning through dialogue that is organised and managed according to computer-mediated social games (such as InterLoc above) that are performed synchronously amongst small groups.

InterLoc: A 'state of the art' Web-technology that implements digital dialogue games for reasoned dialogue, collaborative inquiry and learning

Investigation by Design (IBD): A methodology for investigating and modelling educational dialogue in ways that: identify and examine the dialogue features and processes that are in play and provides specifications that can be implemented as digital tools

Meaningful Learning: An approach to learning which emphasises the human social and cognitive processes that are in play, such as 'thinking', 'meaning making', 'understanding' and 'collaborative inquiry', and articulates the value of knowledge representations in these terms. So this term foregrounds the processes that give rise to the, usually collaborative, development of knowledge and understanding, in contrast to approaches that locate meaning and knowledge ostensibly within media and content

ENDNOTES

1. Note that here we use the term 'pervasive' to give recognition to the fact that this technology can be used on any Web-enabled platform and from within institutional infrastructures, which currently is not common for an application with InterLoc's level of complexity.
2. Note that the actual names have been anonymised but the gender retained.

Chapter 2.6
A Social Framework for Software Architectural Design

Yves Wautelet
Université Catholique de Louvain, Belgium

ABSTRACT

Information systems are deeply linked to human activities. Unfortunately, development methodologies have been traditionally inspired by programming concepts and not by organizational and enterprise ones. This leads to ontological and semantic gaps between the systems and their environments. The adoption of Multi-Agent Systems (MAS) helps to reduce these gaps by offering modeling tools based on organizational concepts (actors, agents, goals, objectives, responsibilities, social dependencies, etc.) as fundamentals to conceive systems through a development process. Socio-technical design is concerned with the direct involvement of users in software design. To this respect the DesCARTES framework presented in this paper offers three main contributions: 1) the use of agents modeled according to organizational concepts, 2) the use of social patterns in software design that better match with users' organization structures, and 3) the inclusion in an iterative development methodology that involves the user intensively in software development.

If you think good architecture is expensive, try bad architecture.

—Brian Foote and Joseph Yoder

1. INTRODUCTION

Information systems are deeply linked to human activities. Unfortunately, development methodologies have been traditionally inspired by programming concepts and not by organizational and enterprise ones. This leads to ontological and semantic gaps between the systems and their environments. The adoption of Multi-Agent Systems (MAS) helps to reduce these gaps by offering modeling tools based on organizational concepts (actors, agents, goals, objectives, responsibilities, social dependencies, etc.) as fundamentals to conceive systems through all development process. Moreover, software development is becoming increasingly complex. Stakeholder expectations are ever more demanding, while development times are supposed to be shorter. Project managers, analysts and software developers need adequate processes to model the organizational context, capture requirements and build efficient and flexible software systems. Those methodologies have to cover the whole life cycle (Kruchten, 2003) of the project while reducing risk as much as possible, offer tools to manage the complexity of human organizations and provide features to develop applications in a correct way.

At the architectural design level, an important technique that helps handle software construction and documentation complexity is the reuse of development experience and know-how. Styles and patterns have become an attractive approach to reusing architectural design knowledge. Architectural styles are intellectually manageable abstractions of system structure that describe how system components interact and work together (Shaw & Garlan, 1996). Design patterns describe a problem commonly found in software designs and prescribe a flexible solution for the problem, so as to ease the reuse of that solution. This solution is repeatedly applied from one design to the next, producing design structures that look quite similar across different applications (Gamma, Helm, Johnson, & Vlissides, 1995).

Taking real-world social structures as metaphors, the DesCARTES[1] (Faulkner, Kolp, Coyette & Do, 2004) framework proposes a set of generic architectural structures (Kolp, Giorgini & Mylopoulos, 2001). It, as well as i*, Tropos and SPEM, is supported by the DesCARTES tool (Kolp & Wautelet, 2007). The aim is to offer and validate a software architectural design process specifically for agent-based systems:

- At the architectural level, organizational styles inspired from organization theory and strategic alliances are used to design the overall MAS architecture. Styles from organization theory describe the internal structure and design of the MAS architecture, while styles from strategic alliances model the cooperation of independent architectural organizational entities that pursue shared goals.
- At the detailed design level, social design patterns drawn from research on cooperative and distributed architectures, offer a more microscopic view of the social MAS architecture description. They define the agents and the social dependencies that are necessary for the achievement of agent goals.

The paper uses a running example to illustrate our approach: E-Media is a typical business-to-consumer application supporting the following features:

- An on-line web interface allows customers to examine the items in the *E-Media* catalogue, and place orders;
- Customers can search the on-line store by either browsing the catalogue or querying the item database. An online search engine allows customers to search title, author/artist and description fields trough keywords or full-text search;
- Internet communications are supported;
- On-line financial transactions including credit card and anonymity are protected;
- All web information (e.g., product and customer turnover, sales average, …) of strategic importance is recorded for monthly or on-demand statistical analysis;
- Based on this statistical and strategic information, the system permanently manages and adapts the stock, pricing and promotions policy. For example, for each product, the system can decide to increase or decrease stocks or profit margins. It can also adapt the customer on-line interface with new product promotions.

The chapter is organized as follows. Section 2 describes the main contributions of the framework to socio-technical design. The objectives of each discipline as well as the workflow and artifacts used as input or output are described.

Section 3 overviews architectural organizational styles, details one of them, the structure-in-5, and applies it to design the architecture of the e-business application. Section 4 presents the social design patterns, details one of them, the broker, and applies them to design in details part of the e-business application. Section 5 overviews the agent oriented e-business system implementation. Section 6 overviews related work. Finally, Section 7 concludes the paper.

2. TOWARDS A SOCIO-TECHNICAL DESIGN ORIENTED DEVELOPMENT FRAMEWORK

Socio-technical design is an under development discipline in which contributions are coming from different aspects of literature. We claim that the development framework proposed in this chapter contributes to the development of socio-technical design on different levels.

Indeed, following (Scacchi, 2004), *socio-technical design is concerned with advocacy of the direct participation of end-users in the information system design process*, furthermore the paper highlights the system environment as being a part of it. The software process described in this chapter contributes to the development of socio-technical approaches in three distinct ways.

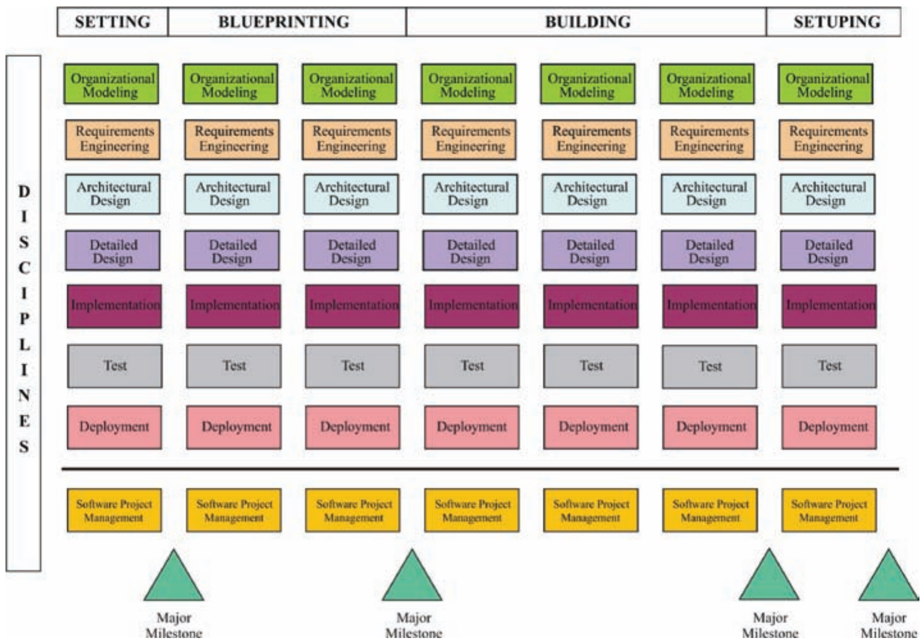
First of all, the use of the agent oriented paradigm allows modeling concepts and techniques in accordance to the reality of human organizations. Indeed, when developing multi-agent systems (MAS) the system being modeled can be represented by using organizational concepts (actors, agents, goals, objectives, responsibilities, social dependencies, etc.) as fundamentals to conceive systems through all development process. Moreover, the i* approach (Yu, 1995) included in our framework proposal allows one to model the actors inside and outside the system as well as their collaborations in terms of goals, tasks, resources or softgoals.

Secondly, by the use of social patterns into software design, some human organizational structures are directly used/mapped into software design which emphasizes even more the benefits from using MAS conceptualization into a socio-technical approach.

Finally, the process presented into this paper is part of a broader (iterative) development methodology called I-Tropos (Wautelet, 2008). Figure 1 offers a two dimensional view of the I-Tropos process: it shows the disciplines and the four different phases to which they belong. This methodology is by essence iterative so that users are intensively involved into the system development; their participation, feedbacks as well as environmental evolutions/changes are directly incorporated into the development process. Such a process leads to a better user involvement and the development of software product with a higher perceived quality. Software users, enterprise workers, other project stakeholders and their environment are thus centric in our approach; this is perfectly in accordance with the principles of socio-technical design. This makes our approach different of a traditional software engineering one based on the activities performed by professionals designed to build a set of solution-driven development artifacts. Due to a lack of space we cannot document the complete I-Tropos software process in this chapter, the interested reader can refer to (Wautelet, Kolp & Achbany, 2006; Wautelet, 2008) for such a documentation using the Software Process Engineering Metamodel (Object Management Group, 2007) concepts.

The case study developed in this chapter, e-media, is interesting from the socio-technical design point of view since it has involved intensively into the development a large number of users having various profiles (the social system) and other physical devices (the technical system). A broader illustration of the framework also pointing the advantages of iterative development on a coking plant production management system development is available in (Wautelet, 2008).

Figure 1. The I-Tropos process: Iterative perspective



The latest case study is also very illustrative of socio-technical design especially onto the technical system in which various machines behaving as agents are involved.

3. ARCHITECTURAL DESIGN WITH ORGANIZATIONAL STYLES

System architectural design has been the focus of considerable research during the last fifteen years that has produced well-established architectural styles and frameworks for evaluating their effectiveness with respect to particular software qualities (Bass, Clements, & Kazman, R., 1998). Examples of styles are pipes-and-filters, event-based, layered, control loops and the like (Shaw & Garlan, 1996). Examples of software qualities include maintainability, modifiability, portability etc (Kruchten, 2003). We are interested in developing a suitable set of architectural styles for multi-agent software systems. Since the fundamental concepts of a Multi-Agent System (MAS) are intentional and social, rather than implementation-oriented, we turn to theories which study social structures for motivation and insights. But, what kind of social theory should we turn to? There are theories that study group psychology, communities (virtual or otherwise) and social networks. Such theories study social structure as an emergent property of a social context. Instead, we are interested in social structures that result from a design process. For this, we turn for guidance, in DesCARTES, to organizational theories, namely ***Organization Theory*** and *Strategic Alliances*. Organizational Theory (e.g., Mintzberg, 1992; Scott, 1998; Yoshino & Srinivasa Rangan, 1995) describe the internal structure and design of an organization, while Strategic Alliances (e.g., Dussauge & Garrette, 1999; Morabito, Sack & Bhate, 1999; Segil, 1996) model the strategic cooperation of independent organizational stakeholders who pursue a set of shared goals.

3.1 Organizational Theory

"*An organization is a consciously coordinated social entity, with a relatively identifiable boundary, that functions on a relatively continuous basis to achieve a common goal or a set of goals"* (Morabito, Sack & Bhate, 1999). Organization theory is the discipline that studies both structure and design in such social entities. Structure deals with the descriptive aspects while design refers to the prescriptive aspects of a social entity. Organization theory describes how practical organizations are actually structured, offers suggestions on how new ones can be constructed, and how old ones can change to improve effectiveness. To this end, schools of organization theory have proposed models patterns to try to find and formalize recurring organizational structures and behaviors.

In the following, we briefly present organizational styles identified in Organization Theory. The structure-in-5 will be studied in detail in Section 3.3.

The Structure-in-5 style. An organization can be considered an aggregate of five sub-structures, as proposed in (Mintzberg, 1992). At the base level sits the *Operational Core* which carries out the basic tasks and procedures directly linked to the production of products and services (acquisition of inputs, transformation of inputs into outputs, distribution of outputs). At the top lies the *Strategic Apex* which makes executive decisions ensuring that the organization fulfils its mission in an effective way and defines the overall strategy of the organization in its environment. The *Middle Line* establishes a hierarchy of authority between the Strategic Apex and the Operational Core. It consists of managers responsible for supervising and coordinating the activities of the Operational Core. The *Technostructure* and the *Support* are separated from the main line of authority and influence the operating core only indirectly. The Technostructure serves the organization by making the work of others more effective, typically by standardizing work processes, outputs, and skills. It is also in charge of applying analytical procedures to adapt the organization to its operational environment. The Support provides specialized services, at various levels of the hierarchy, outside the basic operating workflow (e.g., legal counsel, R&D, payroll, cafeteria).

The pyramid style is the well-know hierarchical authority structure. Actors at lower levels depend on those at higher levels. The crucial mechanism is the direct supervision from the Apex. Managers and supervisors at intermediate levels only route strategic decisions and authority from the Apex to the operating (low) level. They can coordinate behaviors or take decisions by their own, but only at a local level.

The chain of values merges, backward or forward, several actors engaged in achieving or realizing related goals or tasks at different stages of a supply or production process. Participants, who act as intermediaries, add value at each step of the chain. For instance, for the domain of goods distribution, providers are expected to supply quality products, wholesalers are responsible for ensuring their massive exposure, while retailers take care of the direct delivery to the consumers.

The matrix style proposes a multiple command structure: vertical and horizontal channels of information and authority operate simultaneously. The principle of unity of command is set aside, and competing bases of authority are allowed to jointly govern the workflow. The vertical lines are typically those of functional departments that operate as "home bases" for all participants, the horizontal lines represents project groups or geographical areas where managers combine and coordinate the services of the functional specialists around particular projects or areas.

The auction style involves competitively mechanisms, and actors behave as if they were taking part in an auction. An auctioneer actor runs the show, advertises the auction issued by the auction issuer, receives bids from bidder actors and ensures communication and feedback with the auction issuer who is responsible for issuing the bidding.

3.2. Strategic Alliances

A strategic alliance links specific facets of two or more organizations. At its core, this structure is a trading partnership that enhances the effectiveness of the competitive strategies of the participant organizations by providing for the mutually beneficial trade of technologies, skills, or products based upon them. An alliance can take a variety of forms, ranging from arm's-length contracts to joint ventures, from multinational corporations to university spin-offs, from franchises to equity arrangements. Varied interpretations of the term exist, but a strategic alliance can be defined as possessing simultaneously the following three necessary and sufficient characteristics:

- The two or more organizations that unite to pursue a set of agreed upon goals remain independent subsequent to the formation of the alliance;
- The partner organizations share the benefits of the alliances and control over the performance of assigned tasks;
- The partner organizations contribute on a continuing basis in one or more key strategic areas, e.g., technology, products, and so forth.

In the following, we briefly present organizational styles identified in Strategic Alliances.

The joint venture style involves agreement between two or more intra-industry partners to obtain the benefits of larger scale, partial investment and lower maintenance costs. A specific joint management actor coordinates tasks and manages the sharing of resources between partner actors. Each partner can manage and control itself on a local dimension and interact directly with other partners to exchange resources, such as data and knowledge. However, the strategic operation and coordination of such an organization, and its actors on a global dimension, are only ensured by the joint management actor in which the original actors possess equity participations.

The arm's-length style implies agreements between independent and competitive, but partner actors. Partners keep their autonomy and independence but act and put their resources and knowledge together to accomplish precise common goals. No authority is lost, or delegated from one collaborator to another.

The hierarchical contracting style identifies coordinating mechanisms that combine arm's-length agreement features with aspects of pyramidal authority. Coordination mechanisms developed for arm's-length (independent) characteristics involve a variety of negotiators, mediators and observers at different levels handling conditional clauses to monitor and manage possible contingencies, negotiate and resolve conflicts and finally deliberate and take decisions. Hierarchical relationships, from the executive apex to the arm's-length contractors restrict autonomy and underlie a cooperative venture between the parties.

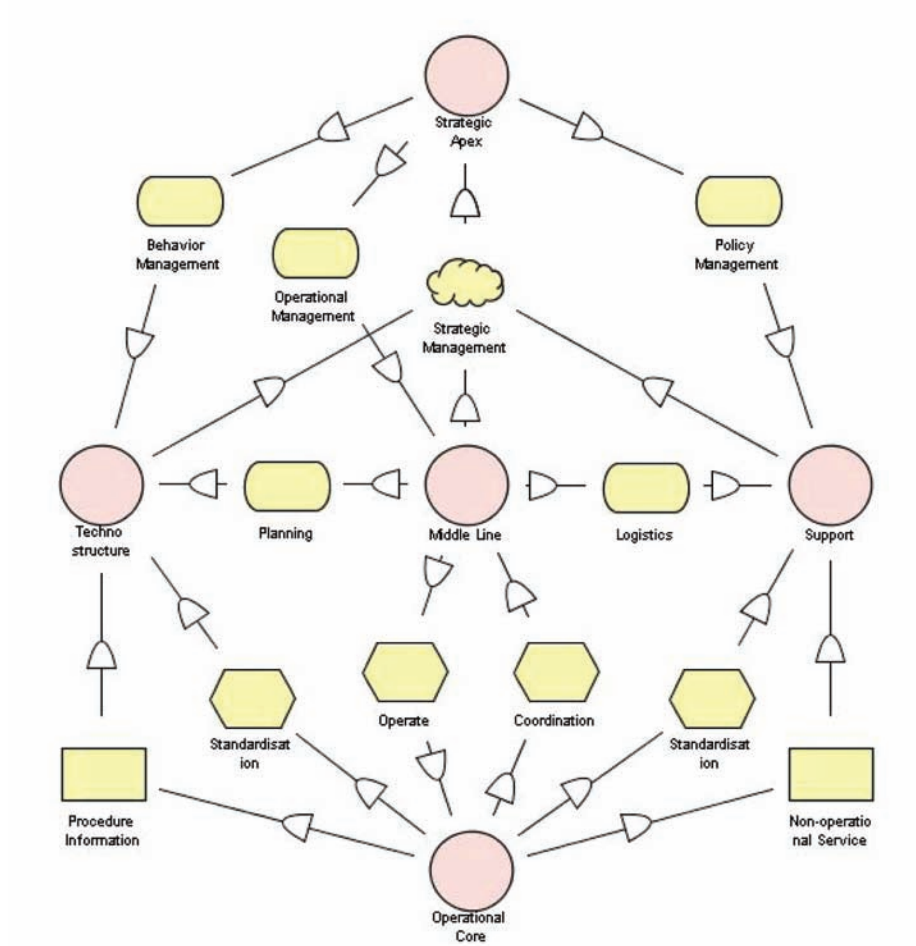
The co-optation style involves the incorporation of representatives of external systems into the decision-making or advisory structure and behavior of an initiating organization. By co-opting representatives of external systems, organizations are, in effect, trading confidentiality and authority for resource, knowledge assets and support. The initiating system has to come to terms with the contractors for what is being done on its behalf; and each co-optated actor has to reconcile and adjust its own views with the policy of the system it has to communicate.

3.3. An Organizational Style in Detail

Figure 2 details the structure-in-5 style using the *i** framework. As said, i* diagrams in this chapter are drawn with DesCARTES.

The Technostructure, Middle Agency and Support actors depend on the Apex for strategic man-

Figure 2. The Structure-in-5 style

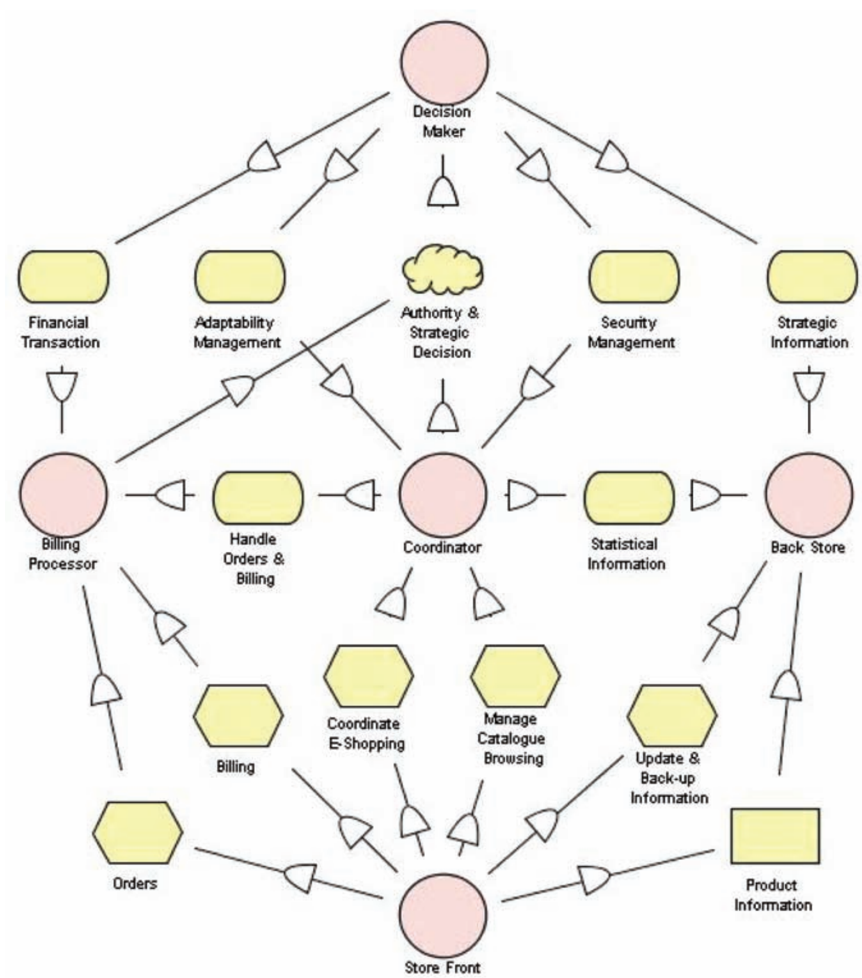


agement. Since the goal Strategic Management does not have a precise description, it is represented as a softgoal (cloudy shape). The Middle Agency depends on the Technostructure and Support respectively through goal dependencies Control and Logistics represented as oval-shaped icons. The Operational Core is related to the Technostructure and Support actors through the Standardize task dependency and the Non-operational Service resource dependency, respectively.

A number of constraints can also be applied to supplement the basic style:

- The dependencies between the Strategic Apex as depender and the Technostructure, Middle Line and Support as dependees must be of type goal;
- A softgoal dependency models the strategic dependence of the Technostructure, Middle Line and Support on the Strategic Apex;
- The relationships between the Middle Line and Technostructure and Support must be of goal dependencies;
- The Operational Core relies on the Technostructure and Support through task and resource dependencies;

Figure 3. The E-Media architecture following the structure-in-5 style



- Only task dependencies are allowed between the Middle Line (as depender or dependee) and the Operational Core (as dependee or depender).

3.4. Applying Organizational Styles

Figure 3 models the agent-oriented architecture for E-Media following the structure-in-5 style.

The Store Front plays the role of the structure-in-5's Operational Core. It interacts with customers and provides them with a usable front-end web application for consulting, searching and shopping media items.

The Back Store constitutes the structure- in-5's Support component. It manages the product database and communicates to the Store Front relevant product information. It stores and backs up all web information about customers, products and sales to be able to produce statistical information (e.g., analyses, average charts and turnover reports). Such kind of information is computed either for a predefined product (when the Coordinator asks it) or on a monthly basis for every product. Based on this monthly statistical information, it provides also the Decision Maker with strategic information (e.g., sales increase or decrease, performance charts, best sales, sales prevision, …).

The Billing Processor plays the role of the structure-in-5's Technostructure in handling customer orders and bills. To this end, it provides the customer with on-line shopping cart capabilities. It also ensures the secure management of financial transactions for the Decision Maker. Finally, it handles, under the responsibility of the Coordinator component, stock orders to avoid shortages or congestions.

As the structure-in-5's Middle Agency, the Coordinator assumes the central position of the architecture. It is responsible to implements strategic decisions for the Decision Maker (Strategic Apex). It supervises and coordinates the activities of the Billing Processor (initiating the stock and pricing policy), the Front Store (adapting the front end interface with new promotions and recommendations) and the Back Store.

3.5. Selecting an Architecture

Software quality attributes (i.e., non-functional requirements describing how well the system accomplishes its functions) relevant for multi-agent systems have been studied in (Kolp, Giorgini, & Mylopoulos, 2001). These are, for instance: predictability, security, adaptability, coordinability, cooperativity, competitivity, availability fallibility-tolerance, modularity, aggregability.

Three of them (adaptability, security, availability) have been identified as particularly strategic for e-business systems (Do, Faulkner, & Kolp, 2003). Due to the lack of space, we will only focus on these three qualities for the structure-in-5 style and refer the author to the bibliography for the other attributes and other styles.

Adaptability deals with the way the system can be designed using generic mechanisms to allow web pages to be dynamically changed. It also concerns the catalogue update for inventory consistency.

The structure-in-5 separates independently each typical component of the E-Media architecture isolating them from each other and allowing dynamic manipulation.

Security. Clients, exposed to the internet are, like servers, at risk when using Web applications. It is possible for web browsers and application servers to download or upload content and programs that could open up the client system to crackers and automated agents. JavaScript, Java applets, ActiveX controls, and plug-ins represent a certain risk to the system and the information it manages. Equally important are the procedures checking the consistency of data transactions.

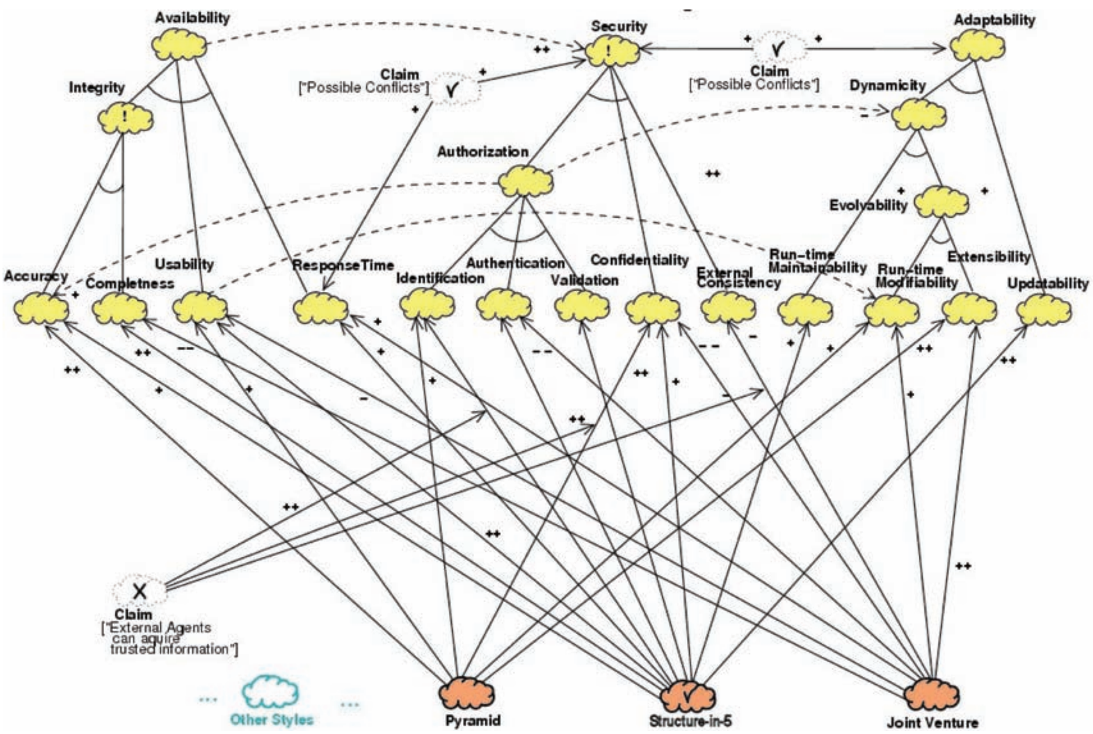
In the structure-in-5, checks and control mechanisms can be integrated at different levels assuming redundancy from different perspectives. Contrary to the classical layered architecture (Shaw & Garlan, 1996), checks and controls are not restricted to adjacent levels. Besides, since the structure-in-5 permits the designer to separate process (Store Front, Billing Processor and Back Store) from control (Decision Maker and Monitor), security and consistency of these two hierarchies can also be verified independently.

Availability. Network communication may not be very reliable, causing sporadic loss of the server. There are data integrity concerns with the capability of the e-business system to do what needs to be done, as quickly and efficiently as possible in particular with the ability of the system to respond in time to client requests for its services.

The structure-in-5 architecture make agents more tolerant to network availability problems by differentiating process from control. Besides, higher levels are more abstract than lower levels: lower levels only involve resources and task dependencies while higher ones propose intentional (goals and softgoals) relationships.

To cope with software quality attributes and select the architecture of the system, we go through a means-ends analysis using the non-functional requirements (NFRs) framework (Chung, Nixon, Yu & Mylopoulos, 2000). In the

Figure 4. Selecting an architecture



NFR framework, software quality attributes are called non-functional requirements represented as softgoals (cloudy shapes). The analysis involves refining these softgoals to sub-goals that are more specific and more precise and then evaluating alternative architectural styles against them, as shown in Figure 4. The styles are represented as operationalized softgoals (saying, roughly, "make the architecture of the new system pyramid-/joint venture-/co-optation-based,…"). Design rationale is represented by claim softgoals drawn as dashed clouds. These can represent contextual information (such as priorities) to be considered and properly rejected into the decision making process. Exclamation marks (! and !!) are used to mark priority softgoals. A check-mark "✓" indicates a fulfilled softgoal, while a cross "×" labels an unfulfillable one.

In Figure 4, Adaptability is AND-decomposed into Dynamicity and Updatability. For our e-commerce example, dynamicity should deal with the way the system can be designed using generic mechanisms to allow web pages and user interfaces to be dynamically and easily changed. Indeed, information content and layout need to be frequently refreshed to give correct information to customers or simply be fashionable for marketing reasons. Frameworks like Active Server Pages (ASP), Server Side Includes (SSI) to create dynamic pages make this attribute easier to achieve. Updatability should be strategically important for the viability of the application, the stock management and the business itself since *E-Media* administrators have to very regularly update the catalogue for inventory consistency.

Availability is decomposed into Usability, Integrity and Response Time. Network communication may not be very reliable causing sporadic loss of the server. There should be data integrity concerns with the capability of the e-business system to do what needs to be done, as quickly and efficiently as possible: in particular with the ability of the system to respond in time to client requests for its services. It is also important to provide the customer with a usable application, i.e., comprehensible at first glimpse, intuitive and ergonomic. Equally strategic to usability concerns is the portability of the application across browser implementations and the quality of the interface.

Security has been decomposed into Authorization, Confidentiality *and* External Consistency.

Eventually, the analysis shown in Figure 4 allows us to choose the structure-in-5 architectural style for our e-commerce example (the operationalized attribute is marked with a "✓"). More details about the selection and non-functional requirements decomposition process as well as evaluation and comparison of the styles with respect to architectural criteria can be found in (Castro, Kolp, & Mylopoulos, 2002; Kolp, Giorgini & Mylopoulos, 2001).

4. DETAILED DESIGN WITH SOCIAL PATTERNS

The organizational abstraction sketched during the architectural design discipline gives information about the system architecture to be: every time an organizational style is applied, it allows to easily pointing up, to the designer, the required organizational agents.

Next step in MAS architectural design requires detailing and relating identified (organizational) agents to more specific ones in order to proceed with the agent behavior characterization. Namely, each agent in Figure 3 is much closer to the real world system actor behavior than software agent behavior that we consequently aim to achieve. Consequently, once the organizational architectural reflection has figured out the MAS global structure in terms of actors and their intentional relationships, a deepener analysis is required to detail the agent behaviors and their interdependencies necessary to accomplish their roles in the software organization.

To effectively deal with this objective, design patterns are used to describe a problem commonly found in software designs and prescribe a flexible solution for the problem, so as to ease the reuse of that solution. In DesCARTES, we adopt social patterns (Do, 2005) that are design patterns focusing on social and intentional aspects that are recurrent in multi-agent or cooperative systems. Similarly to organizational styles, social patterns are generic structures that define how (a small number of) agents are interacting together in order to fulfill their obligations.

DesCARTES classifies social patterns in two categories. The Pair patterns describe direct interactions between negotiating agents. The Mediation patterns feature intermediate agents that help other agents reach agreement about an exchange of services. These patterns are then applied to design in detail the E-Media application.

4.1. Pair Patterns

The **Booking** pattern involves a client and a number of service providers. The client issues a request to book some resource from a service provider. The provider can accept the request, deny it, or propose to place the client on a waiting list, until the requested resource becomes available when some other client cancels a reservation.

The **Subscription** pattern involves a yellow-page agent and a number of service providers. The providers advertise their services by subscribing to the yellow pages. A provider that no longer wishes to be advertised can request to be unsubscribed.

The **Call-For-Proposals** pattern involves a client and a number of service providers. The client issues a call for proposals for a service to all service providers and then accepts proposals that offer the service for a specified cost. The client selects one service provider to supply the service.

The **Bidding** pattern involves a client and a number of service providers. The client organizes and leads the bidding process, and receives proposals. At each iteration, the client publishes the current bid; it can accept an offer, raise the bid, or cancel the process.

4.2 Mediation Patterns

In the **Monitor** pattern, subscribers register for receiving, from a monitor agent, notifications of changes of state in some subjects of their interest. The monitor accepts subscriptions, requests information from the subjects of interest, and alerts subscribers accordingly.

In the **Broker** pattern, the broker agent is an arbiter and intermediary that requests services from providers to satisfy the request of clients.

In the **Matchmaker** pattern, a matchmaker agent locates a provider for a given service requested by a client, and then lets the client interact directly with the provider, unlike brokers, who handle all interactions between clients and providers.

In the **Mediator** pattern, a mediator agent coordinates the cooperation of performer agents to satisfy the request of a client agent. While a matchmaker simply matches providers with clients, a mediator encapsulates interactions and maintains models of the capabilities of initiators and performers over time.

The **Wrapper** pattern incorporates a legacy system into a multi-agent system. A wrapper agent interfaces system agents with the legacy system (source) by acting as a translator. This ensures that communication protocols are respected and the legacy system remains decoupled from the rest of the agent system.

More details about the evaluation and comparison of the styles with respect to architectural criteria can be found in (Do, 2005).

4.3 A Social Pattern in Detail

Figure 5 details the Broker social pattern in *i**.

It is considered as a combination of (1) a Subscription pattern (shown enclosed within dashed boundary (a)), that allows service providers to subscribe their services to the Broker agent and where the Broker agent plays the role of yellow-page agent, (2) one of the other pair patterns—Booking, Call-for-Proposals, or Bidding—whereby the Broker agent requests and receives services from service providers (in Figure 5, it is a Call-for-Proposals pattern, shown enclosed within dotted boundary (b)), and (3) interaction between broker and the client: the Broker agent depends on the client for sending a service request and the client depends on the Broker agent to forward the service.

Figure 6 depicts the Broker pattern components. For brevity, each construct described earlier is illustrated only through one component.

Broker is one of the three agents composing the Broker pattern. It has plans such as QuerySPAvailability, SendServiceRequestDecision, etc. When there is no ambiguity, by convention, the plan name is the same as the name of the service that it operationalizes. The private belief SPProvidedService is used to store the service type that each service provider can provide. This belief is declared as private since the broker is the only agent that can manipulate it. The ServiceType belief stores the information about types of services provided by service providers and is declared as global since its must be known both by the service provider and the broker agent.

The constructor method allows the programmer to give a name to a broker agent when created. This method may call other methods, for example loadBR(), to initialize agent beliefs.

SendServiceRequestDecision is one of the Broker pattern plans the broker uses to answer the client: the BRRefusalSent event is sent when the answer is negative, BRAcceptanceSent when the broker has found some service provider(s)

Figure 5. The broker pattern in i*

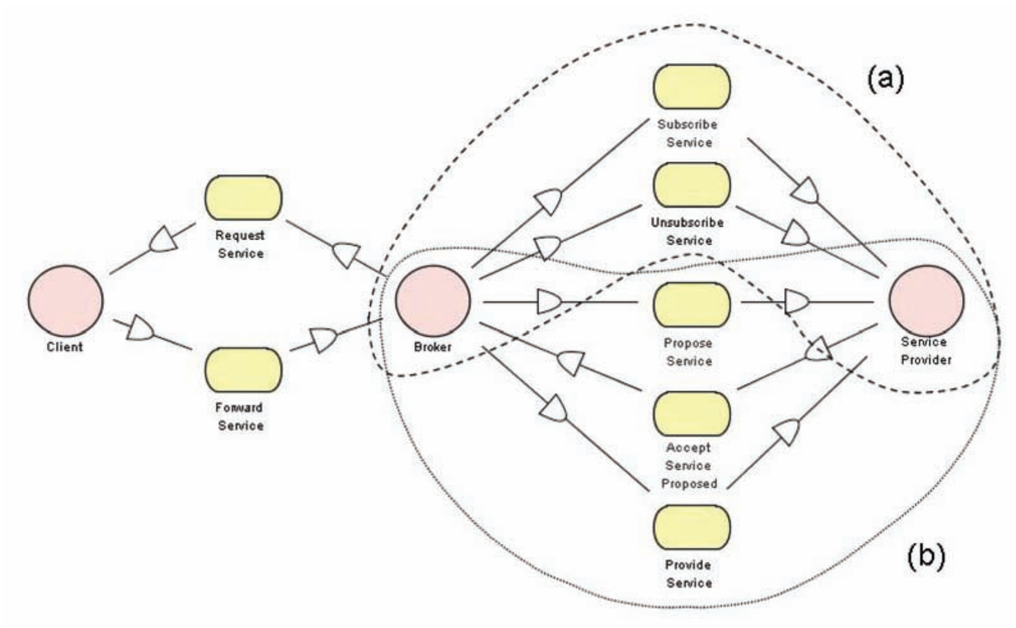


Figure 6. Structural diagram: Some components of the broker pattern

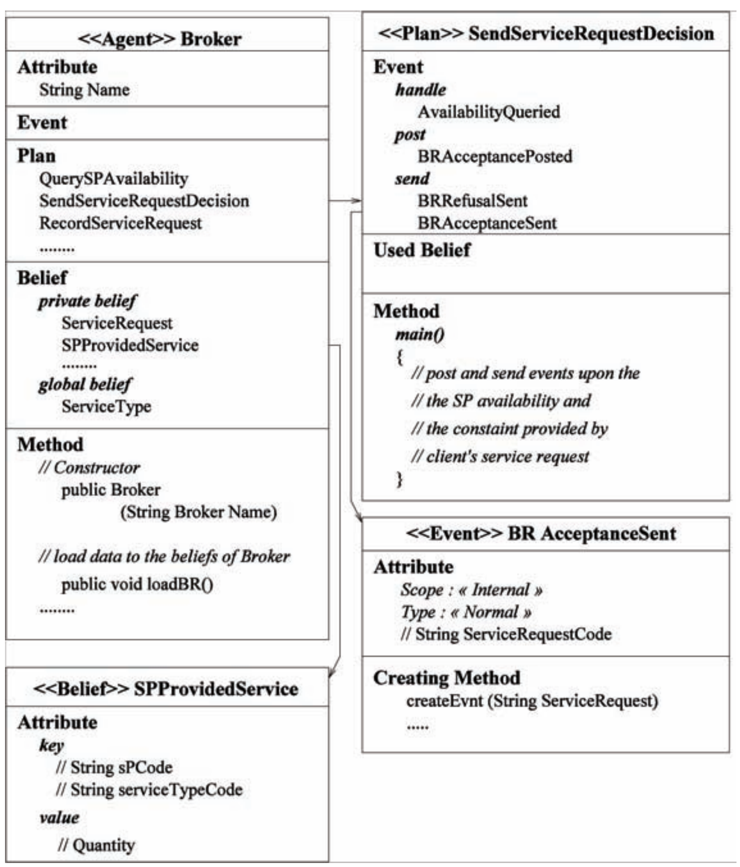

Figure 7. Interaction diagram for the broker pattern

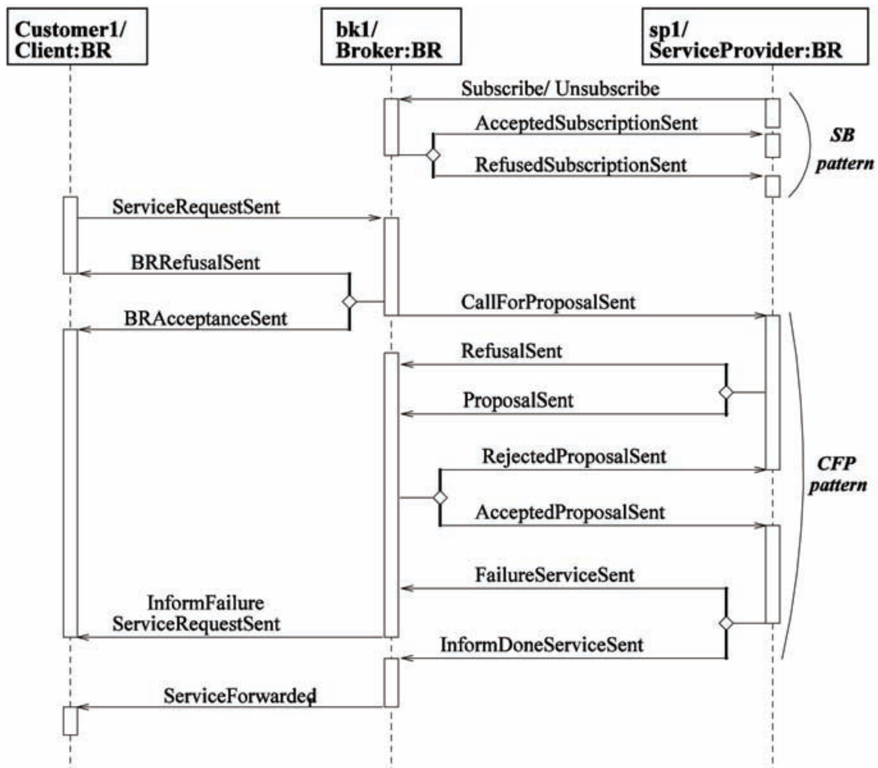

that may provide the service requested by the client. In the latter case, the plan also posts the BRAcceptancePosted event to invoke the process of recording the client's service request and the process of 'call for proposals' between the broker and the services providers. The SendServiceRequestDecision plan is executed when the AvailabilityQueried event (containing the information about the availability of the service provider to realize the client's request) occurs.

SPProvidedService is one of the broker's beliefs used to store the services provided by the service providers. The service provider code sPCode and the service type code serviceTypeCode form the belief key. The corresponding quantity attribute is declared as a value field.

Figure 7 shows a sequence diagram for the Broker pattern. The client (customer1) sends a service request (ServiceRequestSent) containing the characteristics of the service it wishes to obtain from the broker. The broker may alternatively answer with a denial (BRRefusalSent) or a acceptance (BRAcceptanceSent).

BRAcceptanceSent is an event that is sent to inform the client that its request is accepted.

In the case of an acceptance, the broker sends a call for proposal to the registered service providers (CallForProposalSent). The call for proposal (CFP) pattern is then applied to model the interaction between the broker and the service providers. The service provider either fails or achieves the requested service. The broker then informs the client about this result by sending a InformFailureServiceRequestSent or a ServiceForwarded, respectively.

The communication dimension of the subscription pattern (SB) is given at the top-right and the communication dimension of the call-for- proposals pattern (CFP) is given at the bottom-right part of Figure 7. The communication specific for the broker pattern is given in the left part of the figure.

We omit the dynamic dimension of the Subscription and the CFP patterns, and only present in Figure 8 the activity diagram specific to the Broker pattern. It models the flow of control from the emission of a service request sent by the client to the reception by the same client of the realized service result sent by the broker. Three swimlanes, one for each agent of the Broker pattern, compose the diagram. In this pattern, the FindBroker service is either operationalized by the FindBR or the FindBRWithMM plans (the client finds a broker based on its own knowledge or via a matchmaker).

4.4. Applying Social Patterns

Figure 9 shows a possible use of the patterns for the Store Front component of the e-business system of Figure 3. In particular, it shows how to realize the dependencies Manage catalogue browsing, Update Information and Product Information from the point of view of the Store Front. The Store Front and the dependencies are decomposed into a combination of social patterns (Kolp, Giorgini & Mylopoulos, 2002) involving agents, pattern agents, subgoals and subtasks.

The booking pattern is applied between the Shopping Cart and the Information Broker to reserve available items. The broker pattern is applied to the Information Broker, which satisfies the Shopping Cart's requests of information by accessing the Product Database. The Source Matchmaker applies the matchmaker pattern to locate the appropriate source for the Information Broker, and the monitor pattern is used to check any possible change in the Product Database. Finally, the mediator pattern is applied to dispatch the interactions between the Information Broker, the

Figure 8. Dynamic diagram: Broker

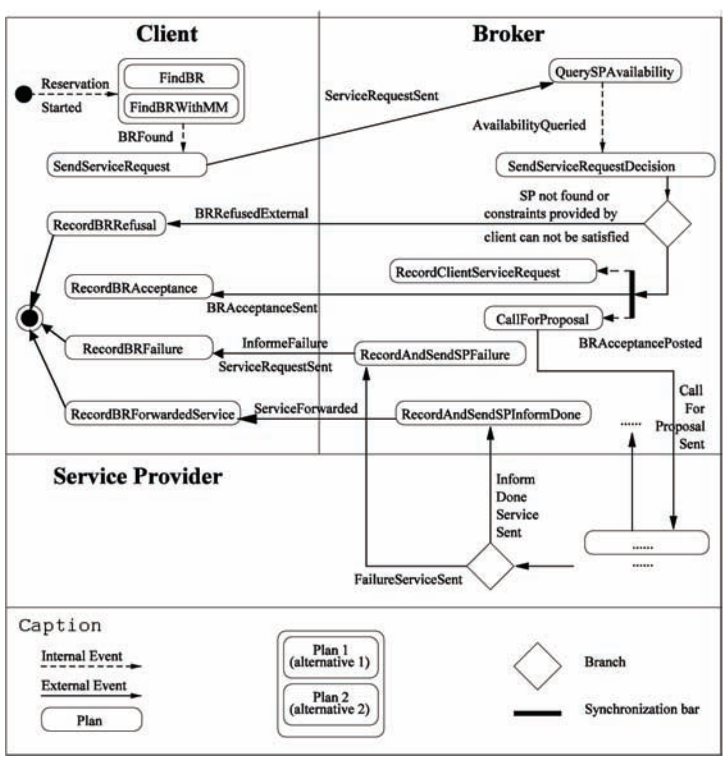

Figure 9. Decomposing the Store Front with Social Patterns

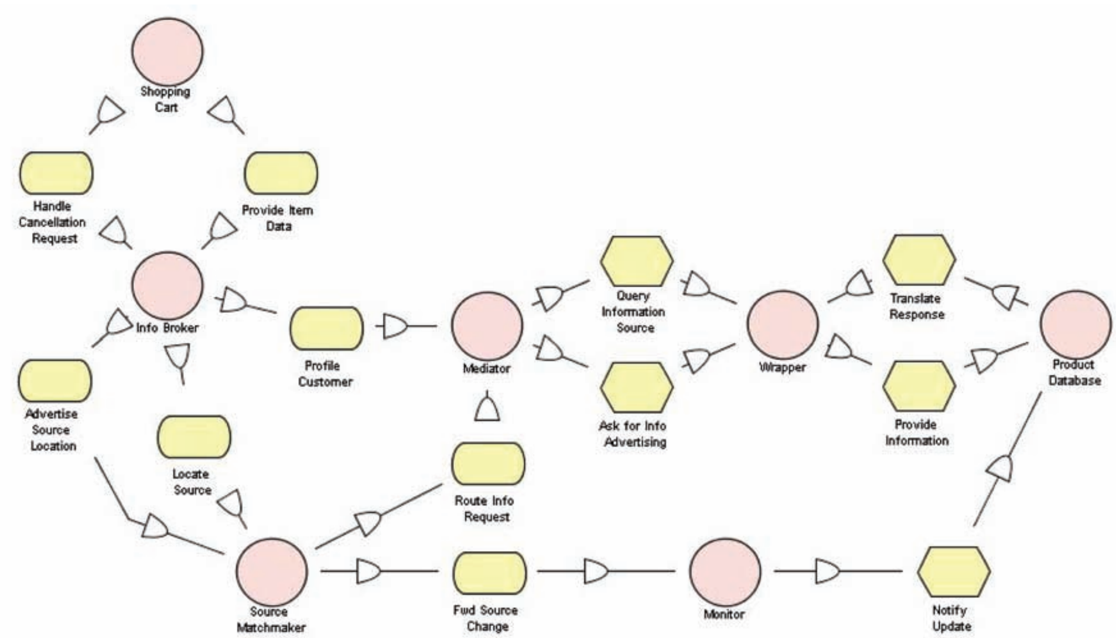


Source Matchmaker, and the Wrapper, while the wrapper pattern makes the interaction between the Information Broker and the Product Database.

5. IMPLEMENTATION

We briefly describe in this section the E-Media system itself by focusing on the role of the *agents* and how they interact. The implementation has been derived from the architectural design explained previously. It has been realized on the JACK agent-oriented development environment (Agent Software, 2007).

When a user gets connected to E-Media, the Front-Store is instantiated and displays the interface depicted on Figure 10. It allows the new coming user to register on the web-site (1). The information provided by the users is handled by the Back-Store which checks the validity (2). Once this has been done, the users can perform purchases on E-Media by adding product to the shopping cart (4). The shopping cart is managed by the Billing-Processor. At any moment during the session the user can use the navigation-bar (3) to switch from one to another section. Promotions (5) and the top 5 best sales (6) are part of the strategic behaviour. The promotion policies are initiated by the Decision-Maker from the strategic information provided by the BackStore. The Coordinator chooses the best promotions and adapts the promotion interface. The coordinator acts in the same way with the best sales, the Back-Store computes the five best sellers and the coordinator is in charge of updating the Front-Store interface.

Figure 11 describes the Store-Front interface when the "DVD" button of the navigation-bar is activated. To start a search the users must fill one or several fields from the search engine (1). The Front-Store sends the query parameters to the Back Store which provides the results to the Front-Store (2). At any moment during the session, if the user clicks on a product (best seller, query result, shopping cart…) a request is sent to Back-Store to provide more information on this product (3).

Figure 10. E-Media main interface

The E-Media administrator has also the possibility of consulting information computed by the various agents. For instance Figure 12 gives indications on the Billing-Processor. The administrator can either displays the current stock for each product or the orders that have been sent for a certain period.

Particularly for the broker pattern implementation, Figure 13 shows the remote administration tool for the information broker described in Figure 2. The customer sends a service request to the broker asking for buying or selling DVDs. He chooses which DVDs to sell or buy, selects the corresponding DVD titles, the quantity and the deadline (the time-out before which the broker has to realize the requested service). When receiving the customer's request, the broker interacts with the media shops. The interactions between the broker and the media shops are shown in the bottom-right corner of the figure.

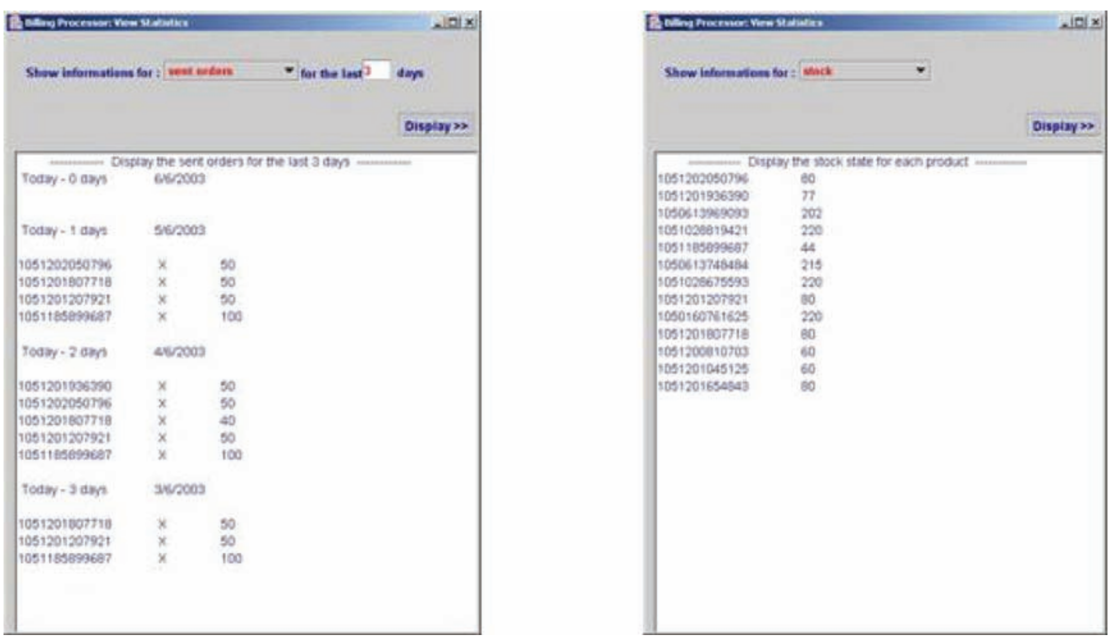
6. RELATED WORK

Literature on MAS offers many contributions on using social concepts to design MAS. Fox (1981) has introduced the idea that using such metaphors can be useful to *describe* the organization of distributed systems. Our motivation is different: we focus on how to use organizational and social concepts to effectively *design* multi-agent architecture and how to apply them in a software engineering perspective while Fox studies organizations as an emergence of social behavior.

Computational methods have been used to better understand the fundamental principles of structuring MAS (Lesser, 1999) based on an organizational perspective. Although they can be extremely useful for detailed design (modeling sophisticated capabilities, alternative methods, activity-related effects, and complex interactions), they are not suitable for architectural design, where more abstract concepts, such as actor, goal and strategic dependencies are needed.

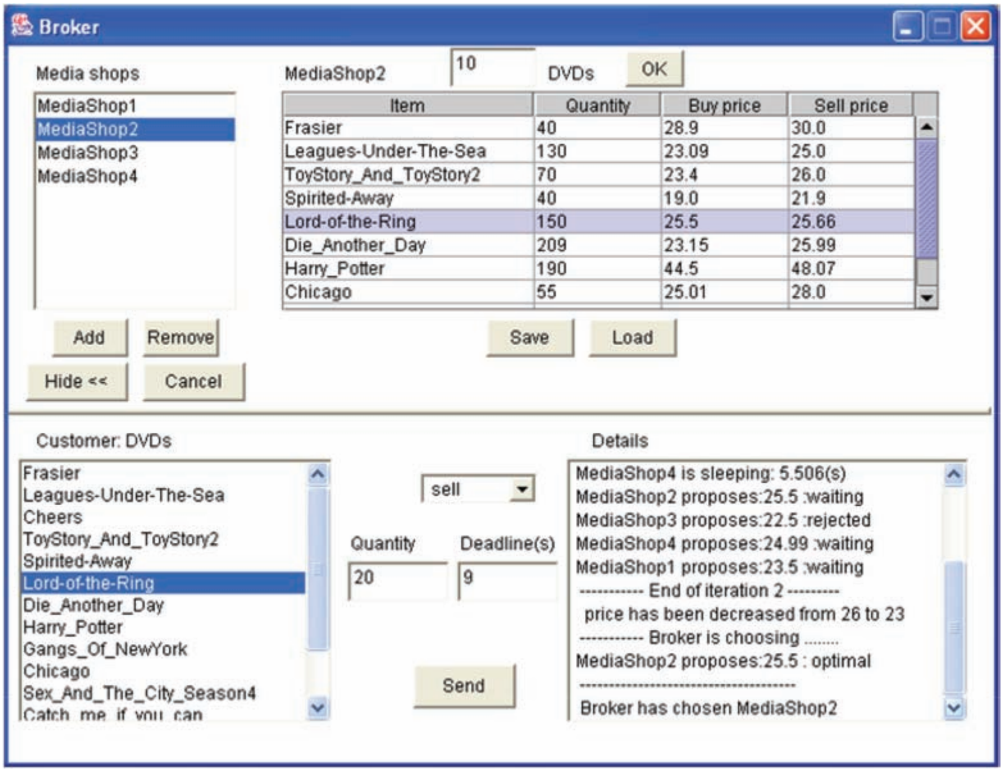
Figure 11. E-Media main interface, DVD section

Figure 12. Statistics on stock and sent-orders



Other research work on multi-agent systems offers contributions on using social concepts such as agent (or agency), group, role, goals, tasks, relationships (or dependencies) to model and design system architectures. Aalaadin (Ferber & Gutknecht, 1998) uses such concepts to

Figure 13. The Information Broker of E-Media



model the organizational structure of multi-agent systems. Different types of organizational behavioral requirement patterns have been defined and formalized. Similarly, in the Gaia methodology (Wooldridge, Jennings & Kinny, 2000), role and interaction models are used for analyzing the understanding of the system and its structure. The main difference with our approach is that in both Gaia and Aalaadin, the organization description does not include the goals associated to the agents.

On a design patterns perspective, the proposals of agent patterns (see e.g., Do, Kolp & Faulkner, 2005) are not intended to be used at a design level, but during implementation when low-level issues like agent communication or information gathering are addressed.

7. CONCLUSION

Agent-Oriented modeling and design is an engineering discipline still under development. But the interest of this recent software paradigm comes from that it can better meet the increasing complexity and flexibility required to develop software built in open and distributed environments while deeply embedded in social and human activities. Nevertheless, the emergence of a new approach requires time to be absorbed by the software community and market. Indeed, it needs standardization, productivity gains, proven efficiency on huge and complex user-interactive software development projects, well-designed development frameworks, etc. to review its standards.

Architectural design for MAS has not yet received the attention object-oriented architectures have had during the past decade. Collection of well-understood architectural styles and patterns exist but for object-oriented rather than agent-oriented systems.

Considering the social intrinsic nature of MAS, this chapter has proposed a social-driven framework to design architectures for such systems. The framework considers MAS architectures at two social levels: Organizational architectural styles constitute a macro level; at a micro level it focuses on the notion of social design patterns.

In particular we have detailed and adapted the structure-in-5, a well-understood organizational style used by organization theorists and the Broker social design pattern viewed as a combination of several other social patterns.

The chapter has proposed a validation of the framework: it has been applied to develop E-Media, an e-business platform implemented on the JACK agent development environment.

KEY TERMS

DesCARTES: Design CASE Tool for Agent-Oriented Repositories, Techniques, Environments and Systems (DesCARTES) is a framework proposes a set of generic architectural structures. It is also constituted of the DesCARTES Architect, a CASE Tool for the edition of i* and other Tropos diagrams.

Tropos: Tropos is a novel methodology for building agent-oriented software systems. Tropos is based on two key ideas. First, the notion of agent and all related mentalistic notions (for instance goals and plans) are used in all phases of software development, from early analysis down to the actual implementation. Second, Tropos covers also the very early phases of requirements analysis, thus allowing for a deeper understanding of the environment where the software must operate, and of the kind of interactions that should occur between software and human agents.

Architectural Design: The objective of Architectural Design is to organize the dependencies between the various sub-actors identified in the previous phases in order to meet functional and non-functional requirements of the system.

Detailed Design: in Detailed Design the behavior of each architectural component is defined in further detail. This discipline is concerned with the specification of the agent micro level taking into account the implementation platforms. The objective is to perform a design that will map directly to the code.

Chapter 2.7
From Pragmatism to Interaction Design:
A Sociotechnical Design Space

Anders I. Mørch
University of Oslo, Norway

ABSTRACT

This article presents an approach to interaction design that is inspired by sociotechnical systems (STS) and grounded in sociocultural theory. The focus is on the early phases of the design process and in particular how theoretical ideas can stimulate design. It starts by surveying key works in theory-based design in HCI and CSCW. The notion of 'externalized design' of buildings has been adopted as a framework for how to incorporate conceptual (non-computational) artifacts in user interfaces. The framework is applied to the retrospective analysis of an interactive system developed by the author (Janus). The system was stimulated by the notion of reflection-in-action. A three-staged process provides gradual steps for translating reflection-in-action into a concrete user interface: 1) selection, 2) appropriation, and 3) translation. The article ends by discussing strengths and limitations of the approach, and identifies directions for further work. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

This article introduces sociotechnical interaction design (STID), which integrates human-computer interface (HCI) design and the socio-cultural approach to research (Wertsch, 1991). Sociotechnical system (STS) design is interpreted to mean the integration of social and technical components by the application of social science theories to interaction design. STID is a method to express sociocultural ideas in interaction design, and to enhance communication of significant ideas of the past to students of today. This interest of mine was prompted by a retrospective analysis of two interactive systems I have been involved in designing over a number of years, one of which is presented in this article. These systems were inspired by ideas of Pragmatism, a branch of early American social science that began in the late 19th century and is associated with the works of Charles S. Pierce, William James, John Dewey, George Herbert Mead (Rosenthal, Hausman & Anderson, 1999), and their followers like Donald Schön (Schön, 1983; 1987), among others. Pragmatism is applied research and continuous to be relevant to contemporary problems phased by society. It is also interdisciplinary, a perspective on research shared by many scholars today. For instance many of the early contributors were associated with several disciplines like philosophy, psychology, sociology, education, and urban design. Within each discipline and their intersections, they developed far-reaching insights, many of which are relevant to contemporary problems studied in these fields. It is beyond the scope of this article to go into the details of that work here (but I return to one theory later in the article).

The critical reader educated in interaction design might object to my use of theoretical ideas that originated in the pre-web era, and are not directly related to the knowledge-based society we live in today. At present, there are new forms of communication and information-sharing emerging, which extends face-to-face (f2f) interaction, as well as new tools to reflect online behavior. Some of this work will have the effect of rendering communities more transparent than they have been in the past, which may require new theories and models to be made. However, it does not mean that social science has to be reinvented. Human nature is still the main component of social interaction. An implication of this is that many of the significant theories developed by the American Pragmatists are highly relevant today. This is manifest in the application of these thinkers' and their followers' ideas to the problems society is facing today. An example is Dewey and Mead's ideas on education (Barnes, 2002; Schön, 1987).

Pragmatism has implications for practical action, collaboration, learning and design. In particular I claim the ideas contain insights that are useful to interaction designers in HCI, Computer Supported Cooperative Work (CSCW), and Computer Supported Collaborative Learning (CSCL). The claim is put forward as a worked out example in this article.

On the other hand, socio-technical systems (or STS) originated in an effort to study organization design by recognizing the importance of interaction between people and technology in the workplace. STS researchers study the various forms of interrelatedness of social and technical sub-systems. The term STS was coined in the 1960s by Fred Emery and Eric Trist, who were working as consultants at the Tavistock Institute in London. They have evolved the approach over many years, and together with colleagues made important contributions to multidisciplinary studies in organizations, e.g., (Bostrom & Heinen, 1977; Mumford, 2006; Trist, 1981/2004) and participatory design, e.g. (Nygaard, 1986). For example, Bostrom and Heinen identified what conditions caused information systems design of its time to fail and suggested to reframe the conditions in terms of STS to create a better fit between the technical and the social sub-systems (Bostrom & Heinen, 1977). STS was also influential (albeit in a different way) on the early work in participatory design (Schuler & Namioka 1993), in particular on Kristen Nygaard and his colleagues in Scandinavia. He contributed to STS by developing a conceptual framework for collaborative design of information systems for developers and users to work together (Nygaard, 1986).

Socio-technical systems are interpreted in the continuation of participatory design and extended to mean the evolutionary creation of web-based collaboration environments with a focus on the interaction between social and technical components (Ye & Fischer, 2007). Furthermore, the interaction between social and technical components is interpreted to mean the application of social science theories to interaction design. In particular how theories from the applied social sciences (American pragmatism) can inform the design of technical tools (Mørch, 2007). Furthermore, this article understands STS as a "design space," bounded by source (theory) domain and target (technical systems) domain, within which artifacts are "transformed" by appropriation and translation. This is reflected in the subtitle of the article. Appropriation is the adoption of ideas from the source domain into the target domain (Dittrich et al., 2005), and translation is the step-by-step work to "move" an object through the space, from the inception of a theoretical idea in the theory domain to a concrete instantiation in the technical domain in the form of a Graphical User Interface (GUI).

Summary. By socio-technical interaction design we mean the appropriation of ideas from the applied social sciences to stimulate and guide (with affordances and constraints) interaction design and to communicate the ideas through interaction with the resulting designs.

The following issues guide the work reported here:

- What support and triggers are needed during the early (creative) phases of design before designers start to think in terms of usability and technical (software) objects? What lessons can be learned from other fields of creative design when it comes to early design work?
- How can we trace the development of abstract objects (theoretical ideas) into concrete (interaction) objects in terms of evolutionary design and user participation?

The rest of the article is organized as follows. It starts by giving a survey of theory-based design in HCI and CSCW. Next, it presents the design process behind an award-winning chair in the Nordic design tradition to provide an example of creative appropriation in the early phases of the design process. This is followed by an example of 'externalized design,' a technique from post-modern architecture, which provides a model for how to incorporate external (non computational) objects into user interfaces. Based on this, a socio-technical framework is developed that breaks the first part of the design process into three stages (selection, appropriation, translation). This framework is applied to the analyses of an interactive system (Janus). The analysis reveals strengths and limitations of the approach. Finally, lessons learned and directions for further work are discussed.

THEORY-BASED DESIGN

Theory-based design (TBD) of interactive systems is a design approach first proposed in HCI, e.g. (Card, Moran & Newell, 1983). The basic idea is that a theory, theoretical idea, conceptual model or a set of related concepts provides the starting point for a design process. What makes this controversial (and challenging) is that the theory should originate in a field outside of computer science, most notably cognitive science (the source of inspiration of early HCI), or the social sciences, which is more common today with the advent of new theoretical frameworks like Activity theory (Kaptelinin & Nardi, 2006). The phrase theory-informed design is sometimes used instead of theory-based design. I do not make a distinction between the two phrases here. The survey below focuses on two seminal contributions in HCI and CSCW: design principles for user interfaces and design process of the Coordinator system.

Design Principles for User Interfaces

The term theory-based design in HCI can be traced to work done at CMU and the University of Colorado in the mid 1980s. Polson and Lewis (Polson & Lewis, 1990) proposed a design based on psychological theories and cognitive models.

The goal was to build a formal theory of exploratory learning that could assist in the design of easy-to-use interfaces. From the theory, they derived a list of design principles they could use to design user interfaces (Lewis, et al., 1990). Four of the seven design principles derived from this theory are:

- Make the repertoire of available actions salient.
- Provide an obvious way to undo actions.
- Offer few alternatives (to prevent wrong moves).
- Model tasks that require as few choices as possible. (Lewis et al., 1990)

The success of these and related design principles have been useful for specific platforms. For example, Apple Computer and IBM created guidelines along these lines for supporting user interfaces within their GUI frameworks. These guidelines tended to be either very general and open-ended like those used in IBM's 1984 Olympic Message System (Gould et al., 1987), or, like the Macintosh Human Interface Guidelines (Apple Computer, 1987), they gave very detailed specifications for how to select (GUI) components, how components should look on the screen, and what behavior they should exhibit in applications. Critics at that time considered these design principles severely limited in scope and a passing fad in terms of impact, favoring consistency over creativity and exploration (Grudin, 1989).

When looking back at the evolution of the field, the design principles movement in HCI gradually turned into research on evaluation criteria. The application of Polson and Lewis' work is a good example of this. Their frequently cited cognitive walkthrough methodology is an evaluation technique rather than a design method, and it was developed on the basis of the above-mentioned theory and corresponding design principles (Lewis et al., 1990). Another influential evaluation technique for user interfaces is heuristic evaluation. This can also be traced to the design principles developed in the late 1980s (Norman, 1988).

Strengths and limitations of design principles to support design of user interfaces are as follows:

- Strength: Design principles work best for specific platforms and GUI frameworks when the action space is large and there are expectations that user interfaces are consistent with respect to given standards and conventions.
- Limitation: The same set of design principles could be derived from multiple sources, each of seemingly legitimate origin, e.g., psychological theories, empirical findings (user needs), and informed guessing based on design experience. The importance of theory to support design was not adequately demonstrated.

Another approach to theory-based design is represented by the design of The Coordinator, a messaging system known for bringing theory-based design to CSCW. It addresses some of the limitations of the design principles approach.

The Coordinator

One challenge (as well as strength) in theory-based design is to connect two separate domains of discourse (theory domain and technical solutions domain) without "mechanically mapping" elements from one domain into the other (Carroll & Kellogg, 1989). The design space should be kept open to encourage multiple paths to solution. The Coordinator system (Winograd, 1987) is arguably the best-known early system in this tradition. It has theoretical roots in speech act theory, which is a theoretical framework for the study of human communication proposed by Searle (Searle, 1975).

Speech acts are operationalized in the Coordinator system in the form of templates (sentence openers) for managing the different stages of communication (generating, transmitting, storing, retrieving, and displaying messages). The user interface supports this by providing menus for selecting what actions the user may take at any point in a conversation. In many ways it resembles email structured according to message types. For example, the menus for responding to requests include the items: acknowledge, promise, counter-offer, decline, and report-completion (Winograd, 1987).

Ordinary email does not support message categorization in the way the Coordinator does. Some critics say that by requiring explicit structuring of a phenomenon that in the outset is subtle (i.e. transition between illocutionary acts), the Coordinator changes the nature of communication (Suchman, 1994). Proponents reply that Searle's conversation structure can instead be found inside the body of text messages (i.e. reveal the conversation structure at a different level of abstraction, for example, separated by punctuation and spacing). An advantage of the Coordinator over ordinary email is that it allows message recipients to view the conversation structure when browsing previous messages. Communication situations relying on visualization of complex conversation can benefit from this approach. However, the upfront cost of breaking a complex conversation into conversation chunks may not be worthwhile when considering all factors, because those who benefit are not those who do the work. Previous studies have shown that such a dilemma is likely to cause a system to fail or gradually be subverted (Ludvigsen & Mørch, 2003).

Strengths and limitations of the "conversation model" approach to design of collaboration systems are as follows:

- Strength: Several successful collaboration systems in CSCW and Computer Supported Collaborative Learning (CSCL) have been designed based on this model, using templates and sentence openers to organize online conversation.
- Limitation: Task-specific collaboration (e.g., student communication in web-based forums) is highly determined by situation-specific constraints. Predefined conversation types might be in the way because they do not (and cannot) take these constraints into account. As a consequence they do not make sense to some students (Ludvigsen & Mørch, 2003).

EXTERNALIZED DESIGN

The rationale for theory-based design (i.e. why TBD is important) has not been emphasized in the past work, and the stages passed through when translating theoretical ideas into concrete designs (theory adaptation) was not identified, discussed, or problematized. Furthermore, situational constraints were not brought into the environment. In the remainder of the article we address these issues by developing a model of theory-based design based on creative practices associated with two design fields that interaction design can be compared with: furniture design and building architecture (Alexander, et al., 1977; Ehn, 1999; Hooper, 1986; Norman, 1988).

Furniture Design

The design process of chairs is characterized by integrating creativity with utility. Utility (usability, usefulness, and domain-specific needs) is as important to furniture designers as it is to interaction designers. For example, a chair that is uncomfortable will not be used, but one that is comfortable will be. More importantly, and as result of the abundance of comfortable chairs in the world, furniture designers have to bring innovation into their designs to succeed in competition with fellow designers. The Nordic designer Olav Eldøy explained the role of creativity as the first and most important step of the following three-step design process (simplified for illustration):

Figure 1. Peel chair (2002). Orange peels falling to the ground inspired this design

Figure 2. Portland Building (1982). Reflections of elements in the local surrounding are embodied in the façade

- Find a recognizable idea that can be expressed in physical form.
- Balance creativity against utility when building prototypes.
- Provide a construction that affords production and export.

All phases were essential in the design of his award winning Peel chair. The inspiration for this chair was orange peels falling to the ground (Figure 1). This turned out to be a realizable idea. The result can be judged by the degree of resemblance between idea and physical form and color. On the other hand, finding a recognizable idea that can be expressed in computational form is not commonly associated with interaction design. However, there is no intrinsic reason why it should not also be applicable here. Another example of the same phenomenon is described in the next section by distinguishing notions of inner and outer language.

Postmodern Architecture

Postmodernism architecture is associated with architects such as Michael Graves (Patton, 2004; Wheeler, 1982). One of the buildings he is known for is the Portland Building in Oregon, USA (Figure 2). This building was one of a few that instantly became an icon for postmodern architecture. It is distinguished from the nearby buildings by external decoration and small cubic windows. The effect of this is a mix of modernism with older styles in an overall avant-garde design. Graves contrasted it with modernist architecture in the following way:

> While any architectural language, to be built, will always exist within the technical realm, it is important to keep the technical expression parallel to an equal and complementary expression of ritual and symbol. It could be argued that the Modern Movement did this; it expressed the symbol of the machine, and therefore practiced cultural symbolism. But in this case, the machine is retroactive, for the machine itself is a utility. So this symbol is not an external allusion, but rather a second, internalized reading. A significant architecture must incorporate both internal and external expressions. The external language, which engages inventions of culture at large, is rooted in a figurative, associational and anthropomorphic attitude. (Wheeler, 1982, p. 11)

The Portland building makes a distinction between external (artistic, symbolic) and internal (technical) expression. The "external language" he refers to consists of reflections of elements in the local surroundings, which are literally embodied in the building's façade. It consists of symbols professionals can relate to (e.g., small cubic windows on a light-colored background makes one think of the Bauhaus, whereas the blue ribbons have an artistic or non-functional association).

The combination of expressions from a non-technical (external) language with the concrete material of the building forms the hallmark of the postmodern approach to architectural design. The two kinds of languages (internal and external) have direct implications for user interface design. A user interface is defined by internal languages (program + design patterns) as well as an external language (interaction design), although the latter is often not thought of as such. However, from the point of view of theory-based design, one can think of this in terms of two domains of discourse: one associated with the technical system and the other with socio-cultural theories. It is the expression of the latter into the former that can be seen as equivalent to the externalized design of buildings.

TRANSLATIONAL APPROACH TO THEORY-BASED DESIGN

In order to adopt externalized design for interactive systems, the following working hypothesis is made. In the same way as nature, site and symbolic association have inspired architects and materialized in the built environment (physical objects); theoretical ideas, concepts, and abstract notions ought to provide the same kind of inspiration for interaction designers (computational objects). This claim is based on the following differences between computational and physical objects:

- Computational objects like software components are abstract compared to physical objects like chairs (Kramer, 2007). For example software components are defined in terms of program code in addition to being

interactive objects on a computer screen.
- Theoretical ideas and conceptual models have been important to the success of many innovative user interfaces (see Section on TBD).

A socio-technical conceptual framework is presented below. It adopts the "architectural model" presented above and was further inspired by the retrospective analysis Carroll and Kellogg (1989) performed to identify the "myriad of claims and their interrelations" embodied in the Training Wheels and HyperCard interfaces to determine how the claims were given coherence by being codified in software. The authors used the term psychological claim to refer to elements in the "source domain," which in our work is replaced by theoretical idea. A socio-technical approach puts more emphasis on cultural tools (Wertsch, 1991) and conceptual artifacts (Bereiter, 2002) than on cognitive artifacts (Carroll, 1991; Norman, 1988). In spite of this, cognitive artifacts have been important in understanding the design of interactive systems, and re-conceptualizing them in terms of cultural artifacts will bring a social dimension to that line of work.

The following stages define gradual translation and serve as intermediate abstractions for talking about the early (creative design) stages of interaction design:

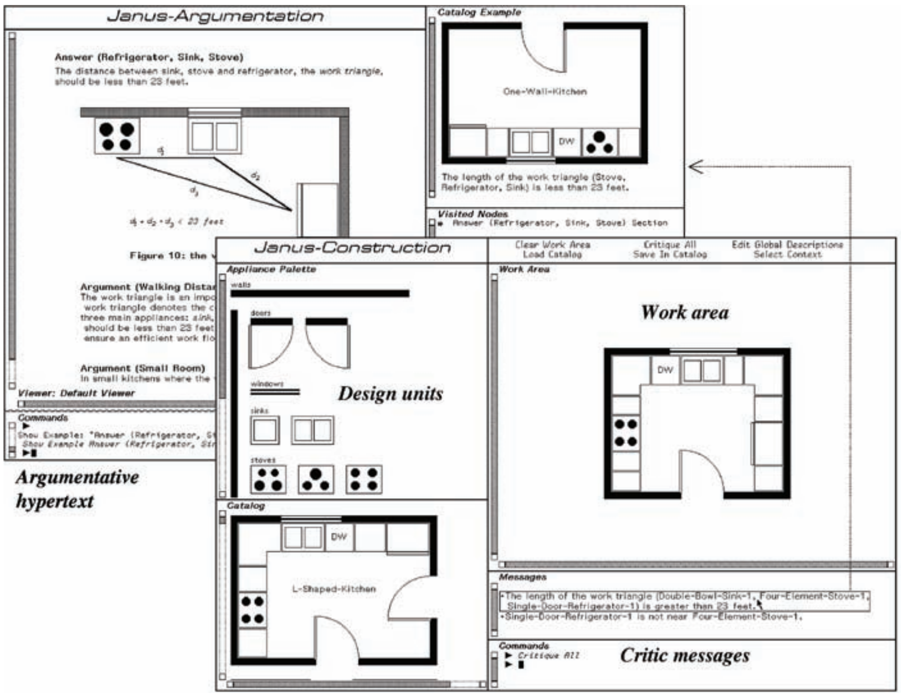
- **Selection:** Any source of inspiration one wishes to explore for the purpose of realization into physical (computational) form. A criterion for selection is to be able to communicate the idea to others (designers and users). However, there are no intrinsic reasons for prohibiting certain ideas. In the work presented here, selection is associated with theories, chosen from a domain outside computation and cognition (social science).
- **Appropriation:** From a socio-cultural point of view, appropriation has been defined as "the process of taking something that belongs to others and making it one's own" (Wertsch, 1991, p. 53). According to Wertsch the path to appropriation is not always straight and smooth, but sometimes involves tension between what we appropriate and the way we use it within a particular context. Appropriation is the act of breaking down an idea so that it will stand out in a contemporary design context, and restructuring the elements to make a concrete design possible without distorting the conceptual integrity.
- **Translation:** This is arguably the most critical step, as it is the most revealing. It involves turning appropriated material into concrete design. An example is the translation of a conceptual artifact (e.g., key words or tags) into a physical or computational artifact (e.g., GUI objects). There are multiple ways of accomplishing this, some better than others. To avoid 'Kitsch design' (poor translation, misunderstanding of original idea), evaluation criteria for assessing the quality of a translated idea are necessary.

In the remainder of this article this conceptual framework is applied to analyze the theory adaptation stages of the design process of a software application in order to illustrate the translational approach with a concrete example.

RETROSPECTIVE ANALYSIS

The system presented below has developed over a number of years and have been written about in the literature, but it has not been profiled in terms of sociotechnical interaction design. The theoretical idea that inspired Janus was reflection-in-action (Schön, 1983).

Figure 3. Janus provides computer support for action and reflection with "back talk" triggered by critic messages



Reflection-In-Action and Janus

The Janus system (Fischer, McCall & Morch, 1989; Fischer et al., 1991; McCall, Fischer & Morch, 1990) is a design environment for kitchen design. It was inspired by Donald Schön's concept of reflection-in-action (Schön, 1983). The end result was the integration of two sub-systems (for construction and argumentation support) with a design critiquing system.

Selection. Reflection-in-action (Schön, 1983; 1987) can be described as "thinking on our feet." Schön has examined this largely unarticulated, improvisational process in a study of practitioners in a variety of professional domains to identify how they explore design spaces and "communicate" with the domain materials for inspiration. It involves looking to our experiences, connecting with our feelings, and attending to our working theories. It entails building new understandings in the present, and based on these understandings to inform our actions in new situations. From this perspective, the knowledge inherent in practice is to be understood as artful doing. In Schön's own words:

In a good process of design, this conversation with the situation is reflective. In answer to the situation's back talk, the designer reflects-in-action on the construction of the problem, the strategies of action, or the model of the phenomena, which have been implicit in his moves. (1983, p. 79)

Appropriation. Schön was primarily interested in developing a descriptive account of design activities, illustrating and explaining what designers do, identifying the importance of human collaboration in this process, and arguing for educational changes on this basis (Schön, 1987). Therefore, his ideas do not lend themselves to operationalization in an interactive system design. His concepts must be further interpreted and broken down into manageable chunks before they can be experimented with in terms of computer support.

We considered "action" and "reflection" as the basic activities of a reflective practitioner and to form the basic components of computer support for reflection-in-action. For reflection support to be part of reflection-in-action, however, it needs to be brought to the designers' attention during the "action present," and to provide answers to the situation's "back talk." In this respect, Schön's notions of "action present" and "back talk," intimately connected to reflection-in-action, have been interpreted to mean automated feedback from the work area the designer is interacting with immediately after an operation on a design has occurred. This is analogous to how a human design critic stands behind the shoulder of a student in a design studio and gives feedback on work in progress.

Translation. Janus consists of two separate interfaces, one supporting action (construction) and the other supporting reflection (argumentation), as seen in Figure 3. During construction, designers select "design units" from the palette and place them into the "work area." The critiquing component links construction and argumentation. Critics provide automated feedback, "critique messages," as shown in the lower right part of Figure 3 (Janus Construction), and they operationalize Schön's notion of "back talk." The "back talk" of the situation depicted in the right screen image in Figure 3 tells the designer that the 'work triangle' is greater than 23 feet. This may trigger reflection on how to incorporate a design recommendation into the design currently under development. The left screen image of the Figure shows the argumentation interface. It is an early hypertext system based on the IBIS design methodology (McCall, 1991). It is structured as issues, answers, and arguments, and represents the design rationale behind kitchen planning principles, and in this case shows a discussion of the various pros and cons of the work-triangle concept.

Table 1 summarizes the appropriation and translation of the theoretical idea reflection-in-action (Schön, 1983) into a concrete interaction design (Janus interface).

Strengths and limitations of the translational (sociotechnical) approach to interaction design are as follows:

- Strength: Identifies theory appropriation as the first stage of the lifecycle of an interactive system before conventional design-time (usability, technical) and use-time (empirical evaluation) activities begin. This is a stage where "amateur computer scientists" such as end-user developers in a user organization can participate. It requires knowledge of two domains of discourse (theory domain and technical systems domain). It does not preclude or disturb any of the conventional approaches to interactive systems design such as user requirements, prototyping, and user testing.
- Limitation: There are examples of externalized design of buildings that have been criticized for incorporating external expressions that are not considered successful design elements, ranging from surface cosmetics with little impact on design to Kitsch (poor translation, misunderstanding of original

Table 1. Translation table for Janus: a three-staged process

Stage	Janus
Selection (motivating idea)	Reflection-in-action (Schön, 1983)
Appropriation (defining the design context)	Action, reflection, action-present, back-talk
Translation (interaction objects; user interface configuration)	Work area, design units, critic messages, argumentative hypertext (see Fig. 3)

idea), which for theory-informed interaction designs might mean unrecognizable ideas and little impact on design. Successful results require belief in the approach, developing several examples, and proficiency in two domains of discourse, all of which are demanding.

GENERAL DISCUSSION AND DIRECTIONS FOR FURTHER WORK

The issues raised in the beginning of this article were:

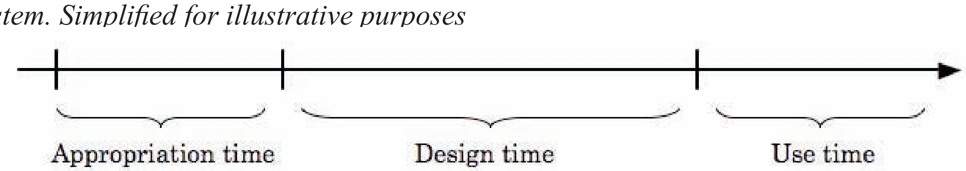
- What support and triggers are needed during the early (creative) phases of design before designers start to think in terms of usability and technical (software) objects? What lessons can be learned from other fields of creative design when it comes to early design work?
- How can we trace the development of abstract objects (theoretical ideas) into concrete (interaction) objects in terms of evolutionary design and user participation?

Related to the first part of the first question is the open issue as to what extent should there be selection criteria for choosing theory/idea to be appropriated in the first place. I have not advocated selection criteria in this article, only to strive for the goal of being able to instantiate and communicate personally meaningful ideas to others (designers and users). Another criterion is motivation: To select an idea that you believe is important to understand and put into a concrete form (other than writing) for others to learn about. A third criterion is quality of outcome. What are the measures and metrics that can help to assure the end product is of a certain quality, and if any of these can be associated with a selected theory domain. The notion of critiquing system can be useful here. Critics can be associated with theoretical perspectives of various source domains and can provide feedback on the application of the theoretical ideas to a technical systems domain.

When it comes to the second part of the first question I have taken inspiration from and made extensive use of examples from design of chairs and buildings, in particular the post-modern movements that made a distinction between external and internal languages of design. The main lessons to be drawn from this is a process that starts with an act of creation ("find a recognizable idea that can be expressed in physical form", "reflections of elements in the local surrounding") that is not commonly associated with interaction design, and which can be explained by the stage "appropriation time", in order to distinguish it from the more established lifecycle stages "design time" and "use time" (when lifecycle is grouped into two: design activity and use activity). This relationship is displayed in Figure 4.

Furthermore, a claim was made by analogy that theoretical ideas relate to interaction design in the same was as nature, building site and symbolic association relate to post-modern architecture (as illustrated by the designs in Figures 1 & 2). The rationale for this claim is that the internal building blocks of the two domains of creative designs differ: computational objects are the material

Figure 4. "Appropriation time" as the first stage in the design process of a theoretically inspired interactive system. Simplified for illustrative purposes



of interaction design, whereas physical objects are the material of chairs and buildings, and the former is more abstract than the latter. This claim and rationale remains is currently a hypothesis that needs to be further developed and tested in subsequent work.

Related to the second question (evolutionary design), I have explored the integration of two kinds of artifacts that belong in disparate worlds. In terms of the philosopher Karl Popper, they are World 3 (conceptual artifacts, ideas) and World 1 (physical and computational artifacts). I have shown how one can move from World 3 to World 1, expressing the abstract ideas of the former world in the material of the latter. This should be thought of as a form of externalization (Kaptelinin & Nardi, 2006). Another of our long-term goals is to understand the transition from World 1 (external expressions) to World 2 (mental representations), which can provide a model for internalization and learning. Whether or not there is a connection from the work presented here (W3 → W1) toward that end (W1→ W2) is an open issue for further research.

When the second question is addressed from the point of view of user participation, the approach proposed can be compared with related (socio-technical) approaches in HCI and participatory design (PD), including contextual design (Holtzblatt, 2001) and user participation in system development (Nygaard, 1986). Whereas many researchers in HCI have taken inspiration from methods originating in the social science in order to improve the design (usability and usefulness) of interactive systems they have had varying degree of success when it comes to integrating technical and social components. Many times the process will stop halfway and not be able to reach to software engineering without starting the process all over, or it has a too ambitious goal at the outset regarding the expectations of user participation. For example, Holtzblatt (Holtzblatt, 2001) makes use of a range of techniques to involve users in the design process. These techniques have many features in common with PD techniques (paper prototyping, informal work models, story boards, diagrams, mock-ups, use cases, etc.). On the other hand, it is difficult to trace the influence of these techniques when analyzing the final results, and often the design process of PD ends with diagrams and conceptual models, but uncompleted systems. Nygaard's (1986) approach to integrate PD and system development attempted to create a comprehensive organization-inspired model of object-oriented systems together with end users. That puts high demands on voluntary user participation. In this work I have a much less ambitious goal because I do not address the entire system, only the user interface, since it is the component that is most intimately involved with end users. The long-term goal of our approach is to make the GUI resemble and be traceable (as an account) back to a set of theoretical ideas associated with a non-technical source domain (social science is the domain explored here). Whether or not this has been achieved in the current work is up to the users (and readers) to judge. As a final note it should be mentioned that I do not imply that other components of an interactive system (beyond the user interface) should be excluded from the sociotechnical approach to design. For examples many researchers in HCI, CSCW, and CSCL consider use contexts and user activities as key to understanding what should be designed. On the other end, software engineers are often more concerned with the internal components of a system. To the extent these components (external and internal) define links to the human computer interface component (i.e. can be made accessible to end users while interacting with a system) they may also benefit from theory informed design according to the approach proposed in this article.

Open issues for further investigation include:

- The translational approach and the design principles approach have many similarities. For example, educational technology developers have treated a concept like "scaffolding" as a design principle in instructional design, which has evolved from a theory in educational psychology. Does that mean that the translational approach should provide intermediate stages in the form of design principles as a normative adaptation of an idea rather than starting directly with the original idea (e.g., reflection in action)?

- Complex ideas like reflection-in-action offer affordances and constraints for design (as well as motivation), and the analyses show that the final design of Janus (user interface components, configuration and functionality) could be traced back to the idea of reflection-in-action. Can similar or better results be achieved if other developers were asked to do the same exercise, i.e. starting with the same basic idea and express it in different interaction designs? My tentative answer is that these designs will be variations of a common theme already established.
- To retrospectively analyze other interactive systems and concrete designs to identify how they display elements and configuration that can be traced back to ideas originating in domains outside of interaction design.
- To appropriate theoretical ideas in the design of interactive systems and other types of concrete artifacts in order to find out what (if any) difference it makes to usability, utility, and educational value. Will it increase or decrease usability and/or utility of the systems? Will it be able to communicate the underlying ideas to new users?

ACKNOWLEDGMENT

The author thanks Gerhard Fischer and Raymond McCall at University of Colorado, Boulder who contributed to the design of Janus and suggested Donald Schön's concept of reflection-in-action as inspiration. Colleagues and students at InterMedia, University of Oslo provided constructive feedback on previous versions of this article. The writing of the article has been supported financially by the Knowledge Practices Laboratory (KP-Lab) project, European Information Society Technologies (IST) 6th framework program, contract no. 27490.

Chapter 2.8
The 'Social Experience Factory' and the Fabrics of Collaboration in Virtual Communities of Practice

Demosthenes Akoumianakis
Technological Education Institution of Crete, Greece

ABSTRACT

This chapter proposes and discusses the "social" experience factory (SEF). The SEF provides a general model and architecture supporting information-based product assembly by cross-organization communities of practice using interactive toolkits and practice-specific technologies. In terms of engineering ground, the SEF builds on two prevalent research tracks, namely experience-based and reuse-oriented proposals for the management of virtual assets and automated software assembly as conceived and facilitated by recent advances on software factories. Our account of the SEF focuses on functions facilitating electronic squads (i.e., cross-organization virtual community management) and workflows (i.e., practice management) which collectively define the scope of collaboration using the SEF. Further technical details on operational aspects of the SEF as deployed in the tourism sector to facilitate vacation package assembly are presented in Chapter XXI in this volume.

DOI: 10.4018/978-1-60566-340-1.ch006

INTRODUCTION

Over the years, increasingly mature ICT infrastructures and novel software platforms and tools either general purpose or domain-specific, have established new grounds for augmenting human intellect across a variety of application domains and engineering disciplines. Amongst the primary beneficiaries are enterprises which face new opportunities for innovation, through novel means of production and customer-relationship management models. This is particularly evident in information-based industries whose products are non-material (intangible) and knowledge is central to gaining competitive advantage. In such domains, new product development is progressively dependent upon the capability to manage virtual (knowledge-based) assets through inter- or intra-organizational virtual partnerships.

In this chapter our objective is to describe a technical framework for appropriating the benefits of virtual networking to assemble new information-based products and services from shared virtual assets. We refer to this framework as the 'social' experience factory (SEF) to highlight three characteristic properties. Firstly, the 'social' qualification is derived from the SEF's orientation to provide support for the articulation of shared practices devised to establish a social protocol of cooperation between (otherwise autonomous) members of communities of practice. We are interested in communities of practice formed by representative knowledge workers engaged in virtual partnerships whose mission is to build and support a 'collective' information-based product. In this context, product assembly is conceived of as a *social practice* framed in designated workflows as much as in *social interaction*—considered as informal exchanges—concerning expression of opinion, commenting, reflecting upon and critiquing aspects of the product being developed – expressed electronically through dedicated tools.

Secondly, the primitive knowledge-based assets of the SEF are in the form of codified *experience* stored and manipulated in shared and reusable repositories (or data stores). These experiences include software product specifications (typically encoded as XML product families), visual domain-specific vocabularies for visualizing the product and its evolution, as well as reusable components for executing statements of the visual vocabulary.

Thirdly, the production process is highly automated, implying a *factory* setup whereby final products are assembled as instances of a corresponding product line/family. To this effect dedicated software plug-ins are needed to undertake the required transformation of an abstract model into a concrete offering matching the requirements and expectations of the intended customer base.

In the remaining of the chapter we provide insights to the theoretical roots and rationale of the SEF as well as its functional and structural underpinnings as established in the context of recent research and development work. We also review on-going efforts to provide supporting software tools for enacting a variety of software engineering processes within a deployed SEF, thus establishing an effective operational model for collaboration in cross-organization communities of practice.

THEORETICAL LINKS AND STATE OF PRACTICE

The SEF in its basic form constitutes a reference model for a mature virtual enterprise in which new product development is the collaborative outcome of virtual partnerships operating as communities of practice. The qualification 'mature' to the virtual enterprise is used to designate the SEF's commitment towards continuous improvement of engineering practices to achieve high quality through mass customization and adaptations. In terms of theoretical ground, the SEF links with recent works on virtual organizations and cross-organization communities of practice. As for its engineering base, the SEF builds upon recent developments on software product assembly and in particular the notion of software factories so as to attain the goal of mass customization through adaptation. In the following we provide a brief review of relevant recent works in these research fields emphasizing how the SEF expands some of the prevalent conceptions.

Virtual Partnerships and Cross-Organization Communities of Practice

In a recent article Ripeanu et al. (2008) define virtual organizations as '… flexible networks of independent, globally distributed entities (individuals or institutions) that share knowledge and resources and work toward a common goal…'.

Typically, the set of shared resources may range from computing power and storage to elements as diverse as data sets, analysis tools, and instruments. There are various connotations and operational models for virtual organizations (for a review see Travica, 2005), including the virtual corporation (Davidow and Malone, 1992), the virtual alliance (Strader et al., 1998), virtual teams (Lipnack and Stamps, 1997; Powell et al., 2004), as well as a variety of studies reflecting upon alternative structures, behaviours and capability for innovation (Jarvenpaa et al., 1998; Vartiainen et al., 2001; Lethbridge et al., 2001; Dustdar & Gall, 2003).

Moreover, recent works indicate both the promises and the challenges confronting enterprises seeking to attain inter-organizational virtual networking in a variety of industries. Representative examples include software development (Scacchi et al., 2006), business travel management (Sigala, 2007; Cardoso and Lange, 2007; Stockdale and Borovicka, 2006), the ship construction industry (Kern and Kersten, 2007), global inter-firm product development (Jin and Hong, 2007), the automobile industry (Schultz and Pucher, 2003; Wenger et al. 2002), etc. The common theme in all these efforts is the intention to appropriate the benefits of novel organizational and technical infrastructures to integrate virtual resources so as to fabricate the required degree and intensity of collaborative practice. To this effect, a variety of methods have emerged with some being explicitly focused on and targeted to capitalizing upon new technologies for knowledge creation during new product development. In a recent study, Hoegl and Schulze (2005) provide convincing evidence of the value of 14 such methods as experienced by 94 new product development projects. The authors admit that a criterion for selecting and studying candidate methods was that they should be well known and widely used (p. 264). As a result, some recent developments such as software factories (Greenfield and Short, 2004), community-based innovation (Fuller et al., 2006) and user toolkits for innovation (von Hippel, 2001; von Hippel and Katz, 2002; Franke and Piller, 2004) were not explicitly addressed.

Our current effort links with virtual organizations established to promote multi-sector collaborations and end user involvement for new product development. A multi-sector collaboration is a partnership formed by representatives of at least two sectors (non-profit, private, and public organizations and community members) to solve problems that impact the whole virtual enterprise. In cases that collaborations are sought for to facilitate new product development, end users' involvement is known to provide a source for incremental innovation (von Hippel, 1988). Recently, the literature on the management of innovation has proposed concepts such as toolkits for user innovation and design (Thomke and von Hippel, 2002; von Hippel, 2001), user design (Dahan and Hauser, 2002) and community-based innovation (Fuller et al., 2006), providing convincing evidence of the value resulting from setting up and maintaining inter-organizational partnerships as virtual communities involving end users, engaging in the practice of new product development. The idea is that creative users manipulate a domain-specific toolkit to devise virtual prototypes of new products which can then be appropriated by the manufacturing partners. This type of set-up is characterized by sense of community amongst the members which is maintained by the members' improved capacity to exercise control and influence the development of a product with high anticipated added value. In turn, this added value motivates both the end users' contributions as well as the member's commitment of resources towards realizing a common goal.

For the purposes of the SEF, the notion of a user toolkit (von Hippel, 2001) is generalized to the concept of practice-specific toolkit, used by members of a virtual community for engaging in the practice the community is about. This makes explicit the link between the SEF and the concept of virtual communities of practice (Wenger, 1998;

Wenger and Snyder, 2000) and in particular the type fostering cross-organization partnerships formed as cross-sector coalitions to attain a specific mission. Cross-organization virtual communities of practice, although less studied and understood, do exist in engineering domains such as open source software development (Scacchi et al., 2006) and scientific practice communities (Foster and Kesselman, 1998). Despite this, the vast majority of empirical works report virtual communities of practice setup and operated in single organizations either public or private (Juriado and Gustafsson, 2007). The more demanding problem of community formation across organizational boundaries – either through inter-organizational partnerships or external communities of practices – is seldom addressed (Dewhurst and Cegarra Navarro, 2004). The complexity of this challenge in terms of organizational and technological set up is explored in a recent study by Kern and Kersten (2007) where the authors investigate technologies for Internet-based inter-organizational product development and identify the problems involved in designing the partnership interaction.

Genres of Supporting Tools

General-Purpose Community Management Tools

The tools supporting cross-organization virtual communities of practice fall into different genres, with the vast majority aimed to fostering the social construction of knowledge (Erickson and Kellogg, 2001). Examples include virtual prototyping suites (Franke & Piller, 2004), tools for idea exploration (Erickson et al., 1999), tools for organizational memory management (Ackerman, 1998; Ackerman and Palen, 1996; Hackbarth and Grover, 1999), collaboratories (Olson and Olson, 2000), Grids (Foster and Kesselman, 1998), as well as tools for information sharing such as electronic mailing lists, or listservs, MOOs, Blogs, Wikis, etc. Typically, tools such as the above almost exclusively focus on managing what organisations know (Davenport and Prusak 2000), rather than what organizations should know (Lueg, 2003). Although the latter is widely acknowledged as a potential source of innovation and a drive for improvement, managing what an organization needs to (but does not yet) know remains a challenge and turns out to be a difficult undertaking. Market research indicates that companies do invest on monitoring on-line discussions aiming to find out what is being said about a company and its products using tools such as eWatch, CyberAlert and IntelliSeek. Moreover, there is also evidence indicating that companies are often not prepared to deal with potential criticism expressed in these forums (Lueg, 2001; MacInnes, 2006). Whatever the case, however, the key question is how such findings are translated into new knowledge and experience.

Another common characteristic of the vast majority of tools, which limits their uptake in the context of cross-organization virtual communities of practice, relates to the type, range and scope of the practice elements supported. Establishing a common ground on what constitutes practice in a virtual community of practice is far from trivial. In general, practices emerge from accumulated wisdom or rules of thumb. Shared practices represent the collective wisdom or repertoire of resources accepted and used widely by practitioners of a domain of discourse towards a goal (Wenger, 1998). In their recent analysis of information infrastructures for distributed collective practices, Turner et al. (2006) offer two alternative interpretations of what may be accounted as practice. The first frames distributed collective practicing in the context of the social interactions taking place between members of a virtual team or a community of practice. The authors' conclusion is that this view on practicing suggests that '… designing infrastructures for supporting on-going collective practices lies in better understanding the dynamics of interacting at a distance – not in the sense of being physically distant as opposed to being co-located in close proximity, but distance in the sense of being emotionally challenged by the position taken by another and requiring breathing room in order to be able to continue to perform independently in a capable manner (p. 105)…'. Nevertheless, this is not the only valid view upon practicing. An alternative is to frame collective practices in shared processes, the artifacts and the tools used for manipulating the artifacts. Turner et al. (2006) acknowledge this view upon practicing and declare that it is more challenging but also less studied in the literature. Indeed our reading of the relevant literature reveals that very few of the efforts reported claim convincingly that the systems studied provide a 'place' for engaging in the practice the community is about.

In the case of the SEF, such an encompassing interpretation of practice is more relevant as it allows distinguishing between organization-specific practices and community-oriented (or social) practices. The former type includes 'local' practices employed and used by an organization to plan and execute own business activities. These practices are grounded on the organization's context of work and may be embedded in dedicated technological tools (i.e., enterprise databases, intranet) and local procedures. The second type, namely community-oriented (or social) practices represent the accepted medium (i.e., processes, tools and artifacts) through which different organizations joining the virtual partnership engage in the practice the community is about. This type of practicing is shared and constitutes the 'social' protocol for participating in the virtual space of the community of practice. de Souza and Preece (2004) refer to these practices collectively as sociability implying the means through which members participate and contribute in the virtual community.

Software Factories as Practice-Specific Toolkits

In contrast to community management which is served by a variety of tools, practice-specific toolkits are rare and less studied. For information-based products, an emerging virtuality which holds the potential to catalyze the development of powerful domain-specific practice toolkits is the notion of a software factory (Cusumano, 1989; Fernstrom et al., 1992; Aaen et al., 1997). In the software engineering literature, software factories are known for quite some time now and there have been various proposals. We are primarily interested in proposals which address the factory support environment (i.e., the computerized support components of a software factory), rather than its institutional character, as well as proposals for factory setups supporting communicating and enacting software engineering activities. In this context, the literature describes various proposals with the most prominent focusing on software assembly lines (Greenfield and Short, 2004) and software process improvement (Basili, et al., 1993).

Software assembly lines concentrate of establishing patterns, frameworks and models and integrating them into software schemas and domain-specific design languages so as to build software form components. Generally speaking, a software factory of this type is installed to extend an organization's development environment, adding guidance-related tools and resources. For example, a software factory might include design patterns, reusable code and solution templates that make it easier to start a new application. Furthermore, it might provide wizards and design guidance throughout the entire development cycle. The basic premise of a software factory is that architects customize the various code recipes that are available with a software factory and then they can redeploy the customized software factory to development teams. This gives architects a practical mechanism for distributing their own guidance to developers.

In contrast, Basili introduced the notion of the experience factory as a pathway towards software process improvement relying heavily upon reuse and deployment of previous codified experiences (Basili, et al., 1993). The experience factory denotes an institutional setup intended to support development teams to appropriate the benefits of empirical evidence and previous project experience. Even for small organizations, large amounts of information can be built up over the years comprising expertise, project data, lessons learned, quality models, etc. For such information to be usable, it needs to be modelled, structured, generalized, and stored in a reusable form in order to allow the effective retrieval of relevant artefacts (Cubranic et al., 2004). A continuous build-up of knowledge requires a suitable organizational structure and appropriate tools. Basili introduced the notion of the experience factory (Basili, 1993) as an institutional concept comprising three distinct components, namely the software development organization, the experience organization and a support organization separate from the other two components. The task of the support organization is to carefully package, document and certify (where applicable) software artefacts. In the original formulation of the experience factory, Basili did not prescribe a particular role for technology or the type of tools needed to support the operation of an experience factory. However, in subsequent publications several examples of codified and packaged experiences have been described as well as the ingredients of the underlying technological set-up (Basili et al., 2001; Seaman et al., 2003).

The SEF and the Management of Collective Practices

In light of the above, the present work aims to contribute to the debate regarding the engineering ground and the type of tools needed to facilitate cross-organization virtual communities and management of collaborative community practices in information-based industries. A key theme in this context is what constitutes 'practice' in a cross-organization virtual community of practice and how such practices can be technologically mediated, shared and capitalized upon to foster new high quality information-based products and services. Our understanding of the efforts reported in the relevant literature is that they characterize virtual communities of practice through constructs which represent valid connotations for online communities of interest or action, rather than virtual communities of practice. The underlying difference is that in virtual communities of practice, the elements of 'practice' are embodied as much (if not more) into shared processes, tools and artifacts, as into social interaction and information sharing. Consequently, interpersonal interaction in the form of feedback, among the members is necessary but not sufficient. Feedthrough becomes equally important (if not more critical) and amounts to shared responsibility and exercising influence on the work of peers. In this view, the systems needed to form, maintain and sustain the virtual community of practice should provide a 'place' for engaging in the practice the community is about.

In our recent work, we are experimenting with a model for knowledge and experience management, which is motivated by Basili's experience factory (Basili, 1993), although it fosters an alternative perspective with regards to both the building components (constituents) and the activities being undertaken. We refer to this model as the 'social' experience factory (SEF) and it aims to address a number of specific objectives briefly summarised below.

The SEF's Objectives and the Products Assembled within its Scope

The SEF seeks to provide the basic model for appropriating the benefits of virtual networking in information-based industries whose products are non-material (intangible) and knowledge is central to gaining competitive advantage. To this effect, it aims to setup and operate a 'virtual' software factory tuned to managing and reusing shared assets, tools and domain-specific software components. This requires an orientation towards implementing assembly lines rather than programming-intensive production lines. Consequently, our primary objective is to describe a domain-independent archetype of a virtual organisation in which domain-specific elements and practices are realised by dedicated tools (such as domain-specific design languages, model building components, visual manifestation of artefacts and sound XML-based protocols) to assemble information-based products.

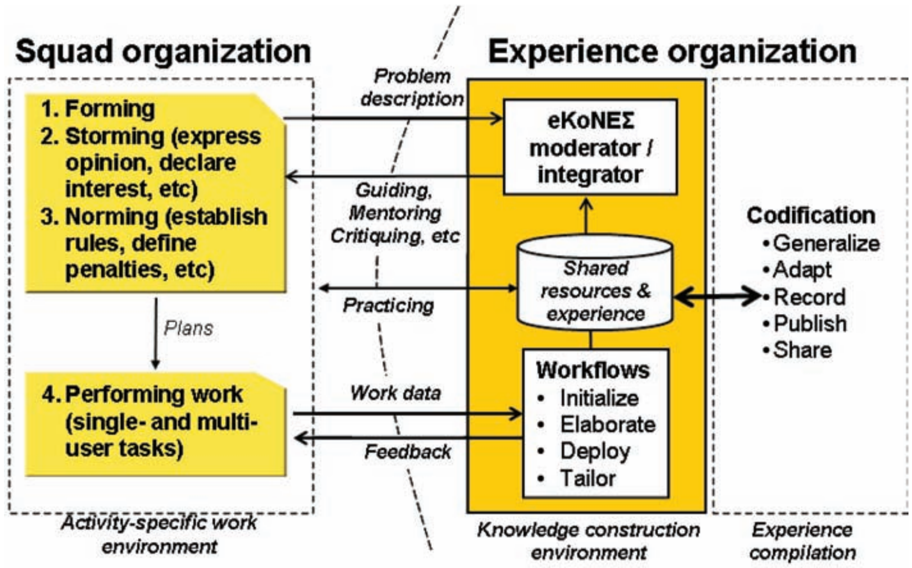
Products assembled within the scope of the SEF have designated characteristics. First of all, they are intangible, information-based artefacts i.e., the end user does not actually experience the end product at the time of purchase, while purchasing behaviour is determined by the information available. Secondly, they are user- or circumstance-driven in the sense that the rationale for building the product is either induced by customers or found in purely circumstantial factors such as foreseen or unforeseen events taking place in the wider social environment of the virtual enterprise – hence the need for adaptation and mass customization for such products to meet varying requirements and preferences. Thirdly, they are fabricated (or assembled) in a moderated fashion by virtual teams using a flexible assembly line (i.e., practice-specific toolkit) and a product family specification. Fourthly, such products have a 'local' character (i.e., they are regionally bound and can be assembled and offered by locals), and short life cycles. Finally, these products cannot be effectively and efficiently developed by anyone member of the virtual partnership alone. Instead, they require collective contribution which makes them orthogonal to other products and services offered by members of the virtual partnership. Consequently, assembling and packaging such services (on-demand) amounts to articulating distributed collective practices so as to yield added-value for all parties concerned including the end user. As these products are the result of collaboration between members in a virtual partnership, they are owned by the coalition for as long as the product / service is offered. To realize these objectives the SEF is organized in distinct and separate constituents, which can be considered from a functional and structural view. We will review first the functional archetype of the SEF and in a subsequent section we will discuss the structural view which relates to the SEF's assembly line.

The SEF's Functional View: Constituents and Archetype

The functional archetype of the SEF, which is depicted in Figure 1, shares common ground with Basili's Experience Factory, although it is distinctively different in terms of organization and processes. As shown, it is structured around two distinct and separate constituents, namely the squad organization and the experience organization. The rationale for this separation of functions is to be found in the type, range and scope of tasks allocated to each constituent. Specifically, the SEF implements an activity-specific work environment referred to as 'squad organisation' and a separate knowledge construction and experience compilation organization referred to as the 'experience organization'. Parallels are to be drawn between the software development organization and the experience organization in the original formulation of the experience factory and our notions of squad and experience organizations respectively. However, the processes being executed by the two constituents are different from those in Basili's experience factory.

The squad organization encapsulates the distinct lifecycle stages followed by collaborating teams / virtual partnerships as they attain joint goals. On the other hand, the experience

Figure 1. Archetype of the 'social' experience factory



organisation encapsulates two sub-components the knowledge construction environment and the experience codification. A virtual partnership or squad is formed across the two constituents and comprises members from different sectors of the industry and at least one moderator from the experience organization. The virtual and cross-organization nature of such partnerships necessitates that community practices are encapsulated into computer-mediated tools and workflows to allow incremental and collaborative construction of artefacts. Thus, a normative objective of the SEF is to provide the grounds for a platform enabling rich collaborative interactions between members of virtual groups.

The Squad Organization and Lifecycle

Squads are cross-neighborhood coalitions (virtual teams) tasked to attain common goals by aggregating and negotiating primitive resources (i.e., neighbourhood assets). Neighbourhoods are virtual communities with topical/thematic interest, a collective memory and cultural vocabulary. For instance, neighbourhoods in the tourism sector include transport, accommodation, cultural heritage communities, etc. Each neighbourhood sets up own rules of engagement which determine participation and acceptable social behaviour within the neighbourhood. As these neighbourhoods exist virtually, rules are embedded into processes covering registration and access rights, acceptance of new members, rules for acceptable behaviour, security, privacy, freedom of speech/act and moderation.

Squads are formed to carry out a designated mission, thus they are mission-specific. The mission may vary depending on the domain of application (i.e., tourism, learning or construction). The SEF is functionally organised in such a way so as to support the social interactions taking place between collaborating group members. In this context, social interactions imply exchanges taking place between group members and being dependent on the group's lifecycle stage and level of stability. Such exchanges differ as the group progresses from formation, to storming (i.e., getting to know each other), norming (i.e., resolving conflicts and reaching agreement) and performing towards the common goal (Tuckman, 1965).

The second reason for the 'social' qualification (of the SEF) is that the above distinct stages in the group's lifecycle are explicitly supported (by dedicated tools) and characterize the design of the SEF. In other words, the SEF assumes that group work entails attainment of distinct goals during the forming, storming, norming and performing stages. Throughout these stages, an experience function / organization compiles experiences by monitoring, analyzing and consolidating persistent outcomes of a group's collaborative exchanges. In the following we provide a detailed account of the squad organization function of the SEF as currently supported in the eKoNEΣ pilot in the area of tourism.

Once formed, squads follow distinct stages to reach their ultimate target (see Figure 1). Initial formation is determined by the mission's requirements (or primitive services required) and the assets of neighbourhood members as declared during electronic registration to neighbourhoods. Each squad comprises one moderator and several participants joining forces to address a problem (i.e., develop a vacation package). The moderator designates the type of input required and establishes a pace of working. In due time, a squad may change in form and structure depending on contextual and circumstantial factors (i.e., a member may be temporarily unavailable or unwilling to commit further resources). This means that at any time, a member can opt out from a squad only through an explicit request for withdrawal. Nevertheless, dynamic formation seldom ensures stabilization and effective performance. Instead, empirical evidence suggests that group stabilization is strongly correlated with the group's ability to effectively move from the initial forming and storming stages into norming and performing. In other words, the group's level of stabilization increases as the group progressively moves from forming (i.e., trying out activities, expression of opinions), to storming (i.e., resolving conflicts) and into norming (i.e., enfolding group coherence, setting group objectives) and performing (i.e., carrying out activities towards the group's mission). The SEF provides explicit tools for moderators to manage squads as they move from formation to performance. These tools are transparent to squad members and utilize data posted / exchanged through the SEF's shared collaborative message board.

The Experience Organization

The experience management organization of the SEF is broadly defined in terms of three sub-constituents namely a distinct role (i.e., moderators), a collection of domain-specific workflows and the persistent experience data store. As indicated in Figure 1 these constitute components of the knowledge construction environment which mediates and interacts both with the squad operational settings (i.e., activity-specific work environment) and the experience compilation component. The important issue to be highlighted is that in contrast to the squad organisation, which is flexible and independent of organisational model, the experience organization assumes a centralized institutional setting with designated roles and functions.

At the core of the SEF's experience management organization is a domain-specific ontology, which serves as the main knowledge and experience-modelling repository. In the context of our current work, we are using Protégé (http://protege.stanford.edu/) to build the ontology for the pilot application domains where the SEF is deployed. The design philosophy of the ontology is as follows. Member organizations are registered in neighbourhoods. Each neighbourhood maintains its own social policies and rules of engagement. Neighbourhoods are specialized into sub-classes depicting structure of the neighbourhood and custom member offerings. Shared resources deposited by members are of two types namely primitiveServices and packages. A primitiveService is a neighbourhood specific activity (i.e., accommodation). Packages are built by assembling instances of primitiveServices and are negotiated by squads.

They represent resources, which do not pre-exist but rather are compiled by members to facilitate an articulated demand. However, the process of assembling them and negotiating their details is distinct and totally different than conventional practices. Specifically, an instance of Package is derived from the archetype of a package family, in a similar fashion as a product inherits properties of a product line. Thus assembling a package involves incremental tailoring of properties of a family of packages. Each package is owned by the squad contributing to the package. Moreover, all deliberations made by squad members leading to the package are persistent and can be traced.

The moderating role is responsible for (a) organizing, leading, mentoring and facilitating the group's virtual activities (b) extracting information from, updating and mining the shared experience data store and (c) codifying successful practices and experience by generalizing, adapting, recording, publishing and sharing artefacts. The moderator is mandatory and there can be no squad without at least one moderator. This role involves active engagement in a range of social interactions and knowledge-based tasks. Social interaction entails monitoring, guiding, facilitating, mentoring and critiquing squads as they move from formation to performing. On the other hand, the knowledge-based tasks involve manipulation of the 'soft' components of the experience organization (i.e., visual models, templates, evidence, etc). Accordingly, the moderator's work may be seen as a complex undertaking with a dual responsibility. The first responsibility is acting as a competence centre or an experience broker mediating between the virtual assets of the community of practice and the active squads. In this capacity the moderator offers advice on problem solving strategy, tools, and best practices, based on existing experiences. The second responsibility of the moderator is acting as a silent critic to mine the data generated by a squad as it works to accomplish its set targets and to codify these data in the form of persistent new knowledge. These responsibilities are further detailed in the next section where operational details of the SEF are described.

The second important constituent in the experience organization is the domain-specific component in the knowledge construction environment, which designates the distinct workflow stages (i.e., initiation, elaboration, deployment and tailoring) characterising the fidelity of the artefacts produced (see Figure 1). The initiation workflow is the responsibility of the moderator and aims to define the squad's mission. The mission is typically a product specification derived from a corresponding product family. Each product family includes mandatory fields to be defined in the initiation workflow (i.e., assignment of a name, indication of resources required such as type of neighbourhood resources and duration). In effect, this task amounts to creating a new instance under the abstract product family. This instance will incrementally be transformed to a concrete offering. Once the instance of the product family is defined a corresponding squad is initially formed as a coalition of all members offering the resources required by the product.

The elaboration workflow requires a stable squad. A squad is stable if for every neighbourhood resource declared in the initiation phase there is at least one, ideally more, committed members. During elaboration, and prior to expressing commitment or withdrawal, squad members seek to populate the designated product with all possible or alternative offerings. Their contributions may range from requests for clarifications to designation of specific parameters of the product, such as pricing of services, discount policies, temporal constraints of a service and other product-specific details. These exchanges are persistent and result in updates in the product's model or the introduction of pending issues requiring agreement. In case of conflicts between the squad members or unresolved issues, the moderator launches a virtual meeting in the form of a synchronous session. This is an innovative component of the current version of the software as it supports typical groupware functions (i.e., object sharing, floor control) as well as role-based access to and various collaborative practices over the shared objects. Notably, throughout such exchanges the object of collaboration (i.e., a graphical version of the product) remains fully synchronized, using a powerful object replication model. At the end of the elaboration phase, a new product has been populated including a variety of possible options to be selected by end users.

In the deployment stage the product has been agreed and becomes an active resource through the portal available for review and refinement. This entails selection and authoring of one or more template layouts so as to facilitate the product's multi-platform presentation (e.g., desktop using Java or HTML, PDA or a cellular phone). In case an existing template layout does not suffice, then a new one can be created and stored as a reusable component in the experience data store. A dedicated software component undertakes to provide the container for deployed products and to allow exploration by users. Moreover, through an asynchronous notification mechanism, all end users who have registered their interest in the product are informed and prompted to consider making a personalized reservation.

Personalization / tailoring is the stage where end users (i.e., prospective customers) are exposed to the product and adapt it so as to reflect own preferences. Product adaptation entails making choices from the variety of alternatives encapsulated in the deployed product, thus specifying a customised instance within a product family. For instance, users may select a particular feature from the range supported. Since the product is fully populated, end users can access it through a variety of devices including desktop computers, mobile devices or other network attachable terminals using the suitable templates. It is also worth mentioning that during tailoring users can engage in a variety of social interactions commonly found in on-line communities. For instance, prospective buyers of a product are presented with the feedback provided by persons who have already bought a similar product in the past. Also during tailoring, customers are presented with information on patterns of tailoring which have emerged. Finally, customers are also encouraged to provide ratings and write reviews for services offered and products obtained.

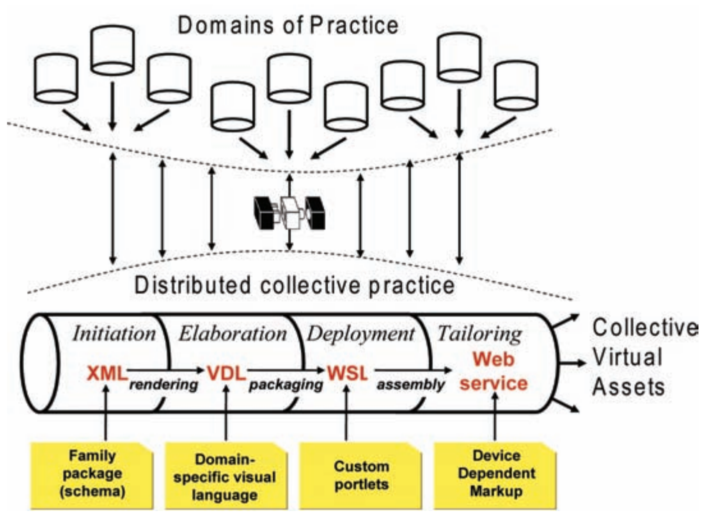
The SEF's Structural View: The Assembly Line

Having described the primitive constituents of the SEF, we now turn to some operational details and in particular the issue of assembling products initiated, elaborated and deployed using the SEF. Our aim is to provide a general description of an assembly line which makes use of concepts such as domain-specific design languages and software factories to automatically compile an information-based product. Such an assembly line has been fully implemented for building vacation packages in the context of the eKoNEΣ project (see Chapter XXI for further details). We will not repeat such details here. Instead, we will try to sketch the engineering ground supporting the SEF's operation.

A structural view for the workflow component in the SEF's experience organization is depicted in Figure 2 highlighting the four workflows which collectively establish the process through which virtual assets are manipulated as distributed collective practice as well as the basic technologies involved. These technologies are embedded into an interoperable software suite which provides the operational context of the SEF. It is worth noticing that this assembly line is located within the experience organization of the SEF to convey that it is transparent to the members of the community of practice. In other words, the community of practice through dedicated tools feeds these workflows without the members' knowing of the involved stages.

Attempting to further characterize the ingredients of such an assembly line we can derive the

Figure 2. Overview of the assembly line

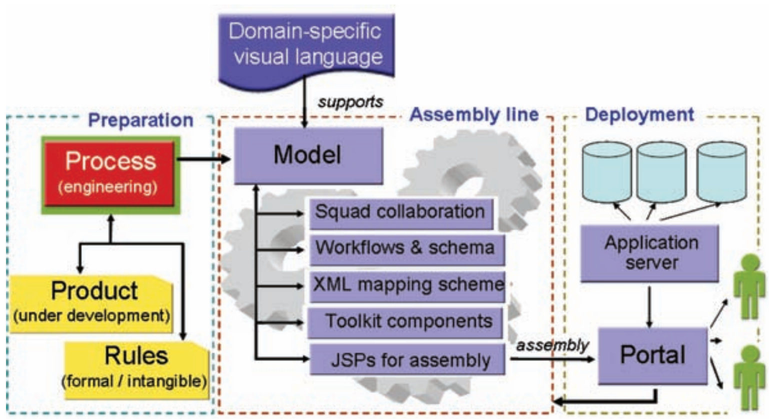


software schema specification which is needed to facilitate interoperability across workflows and enactment of distributed collective practices. This is shown in Figure 3 which bundles the key elements identified in Figure 2 into a concise software schema specification. As shown, the assembly line intertwines with two logical constituents annotated as the preparation and deployment. The preparation constituent is responsible for determining process-related aspects involved in the assembly of a particular type of artefact. On the other hand, the deployment constituent delivers the results of the assembly line to the wider environment of the community. For the purposes of the present work, we will assume that this amounts to deploying assembled artefacts in a portlet context of a community portal.

The assembly line operates on a domain-specific product line specification which characterizes products assembled within the scope of the assembly line. This model is populated by different types of tools devised to facilitate squad collaboration and workflow management so as to derive an instance of a product under a product line specification (or a product family). These tools include general purpose collaboration software (i.e., collaborative message boards, virtual meeting tools, synchronous communication, etc) and practice-specific toolkits supporting the designated distributed collective practice. The practice-specific toolkit provides the community medium through which electronic squads contribute to the development of new products and services within the scope of the assembly line. As the basic user roles in an electronic squad are two, namely the moderator and the squad member, the practice-specific toolkit encapsulates both these roles and offers appropriate functionality in each case.

The key idea behind the above conceptual foundation is that the product is assembled in its entirety from XML. This is illustrated in Figure 4 which describes a relevant extract of a vacation package family and the corresponding XML segments. Both these constitute elements of pre-packaged experience codified in the SEF prior to the initiation of a squad. For purposes of simplicity we have intentionally omitted details of the package family description which are not needed for the present discussion. As shown, the package is considered as a hierarchical structure comprising activities taking place within a day. Such containment hierarchies can be extended to depict alternative application domains. Activities represent instances of neighbourhood services and

Figure 3. Components of the assembly line



can be interrelated. Currently, four activity operators can be used to designate activity relationships, namely *overlap* for activities belonging to different neighbourhoods and having partial temporal execution, *sequence* for serial activities following one after the other, *parallel* for activities belonging to different neighbourhoods and having exactly the same duration and start/end points, *containment* for activities belonging to the same neighbourhood and having partial temporal overlap.

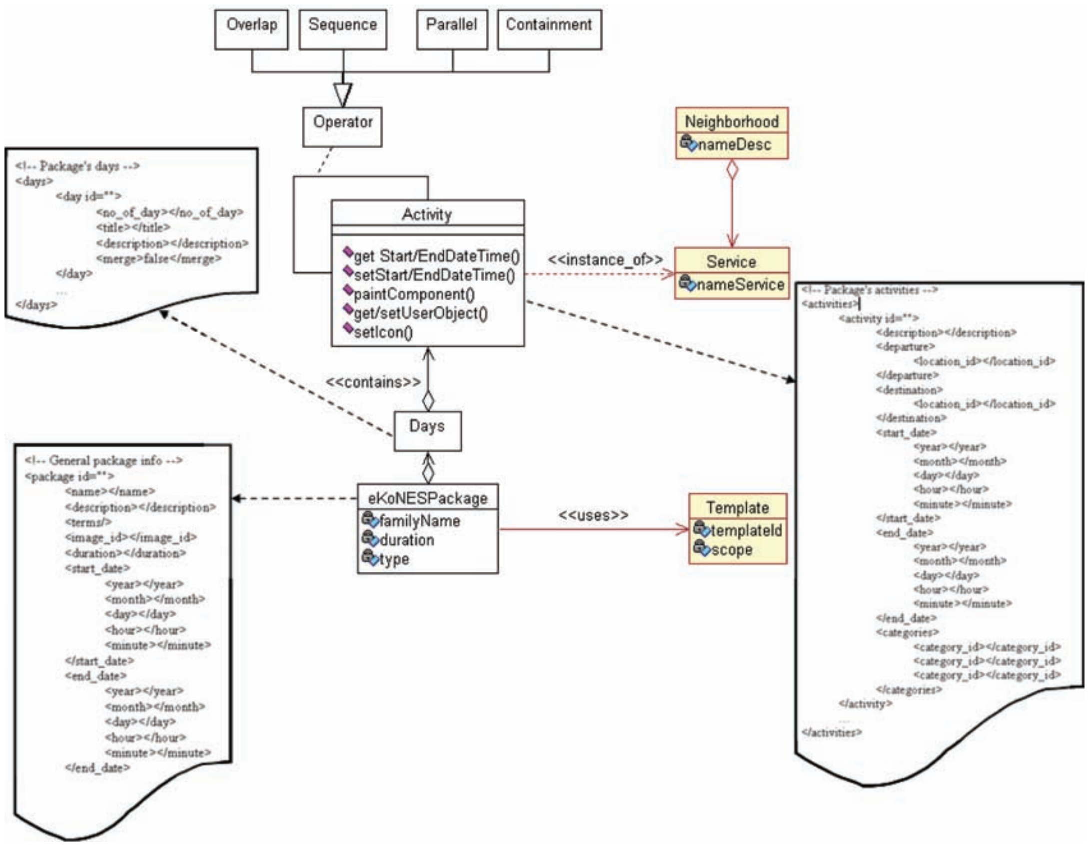
The result of such an assembly line is a concrete product manifested as a collective outcome available for review and manipulation. For our vacation package example, this signals an automatic update of a custom container which undertakes to assemble the components of the new package automatically and publish it either as device-dependent mark-up or in any other form deemed suitable. In all cases, the assembled package includes clear indication of the tailoring that the user can undertake to reflect a customer's detailed requirements and preferences.

DISCUSSION: SEF AND THE DESIGN OF TOOLS FOR VCOP

The SEF promotes a knowledge management model which is built around one generic and one domain-specific component. The generic component is the squad organization, comprising distinct stages in the lifecycle of social groups, while the experience organization is by intention domain-specific. Nevertheless, there are elements and components of the experience organization which may easily be reused, extended and applied to other domains. One issue deliberately not addressed in our discussion so far relates to the technological foundations and engineering base of the SEF. Although our current perspective and thinking on this is documented elsewhere (see Akoumianakis et al., 2007; Akoumianakis et al., 2008; Chapter XXI in this volume), we chose not to make explicit link with the concept of the SEF, as it may be supported through different means and tools. Therefore, in this section, our intention is to provide a critical discussion of the implications raised by the SEF on software tools for virtual communities of practice. Expressed in a different way, our aim is to highlight the SEF's requirements as related to software platforms for managing distributed collective practices (Turner et al., 2006)

Over the years a wide range of technologies have emerged to facilitate collaborative tasks and social interactions in community settings. Bos et al. (2007) provide a classification highlighting tools for ontology engineering (Cragin and Shankar,

Figure 4. Class model of a package family



2006), scientific data repositories and collaboratories (Chin and Lansing, 2004), organizational memories (Ackerman and Halverson, 2004), digital libraries (van House, 2003), community networks (Schuler, 1996; Kavanaugh et al., 2005), recommendation systems (Reichling et al., 2007), etc. Despite the plethora of tools very few efforts have studied the integration of such tools in unified architectures (or information infrastructures) for managing distributed collective practices (Turner et al., 2006). This is not surprising as such a task is both complex and demanding, while several research issues need resolution before a consolidated information infrastructure for distributed collective practices can be conceived. Our work offers insight to this as the SEF constitutes one approach to building technologies for practice. Specifically, we consider that software platforms for communities of practice, such as the SEF, require two separate but interoperable software components, one devoted to community management (i.e., discovering, building and maintaining community) and one devoted to the management of the practice the community is about. From these two, it is the practice management component which is of interest to the current discussion, as it is less studied and understood. To gain some insight, it is perhaps useful to briefly consider what practice is and how off-line practice is influenced and intertwined with on-line practice in different application domains.

On-Line vs. Off-Line Practices

Although it is far from straight forward to define the term 'practice', we will adopt the view that practices represent the collective wisdom, rules of thumb and common ground (i.e., processes, tools and artefacts) characterizing a community, whether professional such as accounting, medicine, landscape engineering, etc., or otherwise. In our account of the term, we also consider that in cross-organizational virtual communities of practice, practice is manifested as on-line or off-line practice, with the two frequently being strongly intertwined. On-line practices are computer-mediated and subsume technology for their enactment, processing and transmission elements of practice. The literature offers a variety of empirical evidence regarding the type of on-line practices prevailing across different application domains such as free and open source software projects (Scacchi, 2005; Scacchi et al., 2006), new product development (von Hippel and Katz, 2002, Franke and Shah, 2001, Franke and Piller, 2004), the automobile and airspace industries (Schultz et al. 2003; Wenger et al. 2002), etc.

In some of these examples practice is solely bound and bundled in the social interactions taking place between the members of the community. It is this social interaction which influences and determines intertwining on-line and off-line practice. In such cases, on-line practice is manifested through the design of tools for engaging in social interactions. Nevertheless, there are application domains, in which practice may be framed in the process, tools and artefacts being produced as well as in social interactions. The implication is that tools for social interaction do not suffice, but instead, practice-specific toolkits are needed for the members of the community to engage in the designated practice. These more involved situations require special components (such as domain-specific visual languages, workflow engines, assembly lines, virtual prototyping toolkits, custom groupware, 'socially' designed user interfaces, community data mining) for manifesting practices, as well as models for codifying knowledge and experience. We use the term new virtuality (Winograd, 1996) to designate the new context offered by these tools for manifesting on-line practice. Thus, new virtualities result in variations in practice codification, enactment and processing, and frequently in totally new (and innovative) practices. Framing practice in this way has implications on the communityware infrastructure. Specifically, mere support for social interaction does not suffice, while the design of the communityware is much more demanding and sensitive to a range of issues. Some of them are elaborated below.

Community Workflows vs. Workflow Engines

Typically, practice domains such as architecture, engineering and software design, are distinctly characterized by workflows, visual languages, domain-specific vocabularies and social semiotics. Even within the same domain of practice some of these tools may evolve and change. For instance, in software design object-orientation brought about a totally different design language (methodology, guidelines, visual languages, etc) than the more traditional structured systems analysis. In tourism, Semantic-Web technologies have begun to change both the traditional workflows and models of cooperation and work; for example dynamic package technologies (Cardoso and Lange, 2007) have changed the way in which tourist packages are compiled, marketed and traded. Similarly, scientific digital libraries have totally altered the practice of preparing, submitting, processing and publishing scientific works. In all these cases, the difference is brought about from the digital medium and the new virtuality being established by software mediating the institution of the underlying practices. Moreover, in all these cases, the computer-mediated environment encapsulates different workflows, practice vocabularies and artefacts. We can therefore conclude that *'infrastructures for cultivated virtual communities of practice should be designed so as to support designated* *workflows encapsulating the community's shared wisdom of practice'*.

Such workflows should prescribe how the community reaches collective outcomes and how distributed collective practices are instituted. In other words, they should depict stages in an evolutionary continuum of joint activities resulting in a collective outcome. For instance, Figure 5 depicts possible workflows through which a vacation package is assembled from a vacation package family. As shown, each stage involves several actions on behalf of the vacation package development team (squad), with some of them being manifested through on-line practices (agreed and shared by all) and others being off-line (local, individualistic or custom) practice. The collective outcome, namely an assembled vacation package, is constituted by the entirety of on-line and off-line practices, which means that the team accomplishes its mission only if the vacation package is deployed and tailored so as to become a concrete offering available to potential customers. This example emphasizes two key points:

- Supporting community workflows amounts to designing to facilitate an effective intertwining between on-line and off-line practices, and
- The social role of practitioners who are embedded in an institution of on-line (shared and agreed) and off-line (relatively autonomous) practices.

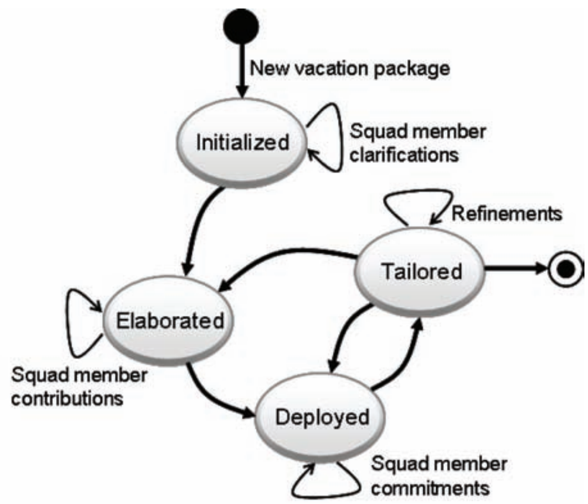
Distributed Collective Practice Toolkits vs. Groupware

The next relevant issue relates to the practice vocabulary articulated in community workflows and how this vocabulary is structured, manifested and processed so as to support distributed collective practices. Traditionally, groupware technologies have emphasized the technical aspects of asynchronous and synchronous collaboration focusing on casual interaction systems such as *instant messengers* (Nardi et al., 2000) where participants carry out communications-oriented tasks, *virtual worlds*, including MUDs, chat rooms, on-line games (Bartle, 2004) where people meet other inhabitants of the virtual world, participate in joint activities and manipulate visual artefacts that comprise the virtual world, *media spaces* (Mackay, 1999) where physical offices and public spaces are linked through networks of audio and video, thus allowing members to easily see who is around and what they are doing. More recent efforts make use of screen sharing technology (Kimberly et al., 2006) to address the limited support for activity and artefact awareness of conventional groupware systems.

One major issue which stands out very promptly in all these efforts, and which is vital for collaboration in communities of practice, relates to the type, range and scope of the artefacts of collaboration, as these constitute elements of the practice-oriented vocabulary. The vast majority of existing works concentrate on conventional artefacts such as documents, communication transcripts and media (i.e. video, audio, images), assuming implicitly that practice is bundled to the social interactions taking place between community members. However, as already pointed out, this is only one view of what practice is about. The alternative view is to frame practice as an institution of processes, tools and artefacts. This view, though less popular in the literature, is the most challenging and useful in the context of communities of practice.

The SEF, as presented so far, supports the latter view. Specifically, it is claimed that designing collaborative practices entails (a) defining the core elements of a suitable practice-specific design language, typically codified as graphical models or notations, integrity constraints, guidelines, and operations on models, and (b) devising mechanisms for computer-mediated collaborative manipulation and execution of valid statements (or artefacts) of this language. Collectively, the design language and its execution environment constitute the *toolkit*

Figure 5. Stages in a vacation package assembly



for managing distributed collective practices. As enactment and reconstruction of collaborative practice is the sole objective of such a toolkit issues such sharing, mutual awareness (conceived of as comprising social awareness, action awareness, workspace awareness and situation awareness), coordinative tasks, asynchronous and synchronous session management, etc., should lie at the core of its design.

Social Community Mining vs. Data Management

Social community mining refers to the process of exploiting the community's knowledge, discovering patterns, codifying reusable experiences and improving practice in a community of practice. There are two issues of particular interest in the context of our current work. The first is extracting patterns and codifying reusable experience. The second relates to applying data mining to discover social networks and 'hidden' or emergent communities. To some extent the two issues are interrelated in the sense that identification of a 'hidden' or emergent community will inevitably result in the consolidation of new patterns and work experiences. However, for the purposes of this discussion, we will address them separately since they constitute subject matters of distinct research communities.

Identifying 'hidden' communities reveals periodic or permanent clusters or cliques formed dynamically as a result of exchanges between members of a social network. For instance, consider the scenario where a community of practice is formed by representatives of a regional tourism industry to assemble vacation packages comprising accommodation, transportation, food and beverage, etc. In such a situation two types of cliques may occur. The first may be a repeatedly recurring clustering between members from different neighbourhoods. For instance, elderly may be consistently choosing bed & breakfast accommodation, public transportation, and two meals from food and beverage while business travelers may favor luxury hotel accommodation, private transportation and no food and beverage. Being able to discover such tendencies (i.e., 'hidden' communities designated or implied by choice of neighbourhood members) or recurring patterns in purchasing behaviours is useful for targeting marketing strategies and building profile-based vacation packages. The second type of clique may designate cross-neighbourhood coalitions (i.e., specific members of a neighborhood that tend to be associated with specific members of another neighborhood). For instance taverns near by a historical site may be more popular than taverns farther away. In this case, the clique amounts to a community within the community with possible negative implications. Indeed, there may be effects such as community desegregation (i.e., establishment of new neighbourhoods), which in turn, may damage the community's stability, coherence and members' trust.

The second relevant application of social mining is for extracting patterns and codifying them as reusable experience. This is a knowledge management and experience building activity aiming to increase the competencies and the capacity for differentiation of a virtual organization. In the context of virtual communities of practice in tourism, such experience building is critical for sustaining an acceptable level of stability between the community members. Moreover, it turns out that it is the presence or absence and periodic refinement and endorsement of community participation policies and rules, which determine both structural and behavioural aspects of the community. To build, maintain and assure endorsement of such rules requires experience and access to community's memoir of interactions. A typical example is the negotiation between customers and providers of a vacation package. Frequently, providers of the same type of service, such as accommodation, in a vacation package including accommodation, transport and visit to local cultural heritage, develop antagonistic behaviours manifested as discounts or last minute offers. Such behaviours may damage the community's stability leading to providers opting out, internal clustering of members, etc. To avoid such negative implications, the community should impose rules of participation and acceptable behaviour. These rules may govern registration and access, acceptance of new members, rules of acceptable behaviour, security, privacy and freedom of speech/act. Moreover, they should be extracted by intelligently manipulating persistent data reflecting each member's behaviour, and negotiated and agreed upon before coming to effect. It turns out, therefore, that moderating such communities is not only about managing access to shared collaborative resources but more importantly a knowledge-based and experience-building task.

SUMMARY AND CONCLUSION

In this chapter, an attempt was made to describe the notion of a social experience factory and how it is substantiated in the context of virtual communities of practice. Our treatment was rather general and abstract. However, the reader may find further details of the SEF and how it was deployed in a pilot application in the tourism sector in Chapter XXI in this volume. The SEF, as presented here, provides a conceptual model and an engineering method for tightly coupling social activities performed in the course of team formation, storming, norming and performing with collaborative workflows such as initiation, elaboration, deployment and tailoring of information-based products.

The SEF has now been used in the area of tourism, which is the main pilot application in which the concept is being validated, but also in other engineering domains through small-scale case studies. These case studies serve a two-fold purpose in the context of the present work. Firstly, they contribute to the verification of the basic operational model of the SEF as described in Figure 1, both in terms of squad lifecycle stages and package development workflows. Secondly, they unfold commonalities which can be generalized across application domains, abstracted to form reusable components and codified to become shared experience through the SEF.

The main contributions of the SEF to the literature on virtual communities of practice can be summarized as follows. First of all, the SEF provides a frame of reference and a guide for building software tools to support knowledge-based virtual communities of practice in their efforts to construct information-based products by assembling components and reusing experience. As such, it is not only concerned with computer-mediated communication, but instead, it seeks to provide a place for engaging in the practice the community is about. Secondly, the SEF emphasizes the social aspects of collaborative practicing, in the sense that it links explicitly practice-related outcomes to evolutionary stages of a virtual team's lifecycle. In other words, the outcome of a virtual team is intertwined with the team's level of stability. Thus, a mission is complete only when the team engages in certain performative practices of a designated workflow. Thirdly, the SEF adopts a model-based approach to establish the fabrics for collaboration. This approach integrates several technological tools to allow role-based access to shared artefacts, adaptable interactive manifestation of domain-specific objects and model editing. Finally, the SEF implements a factory-oriented model for assembling resources into new packages. Such packages are information-based services assembled from components rather than constructed from scratch. Moreover, they represent added value both for the end users (prospective customers) and the coalition members (participating organizations), since no single member of the latter could offer the package cost effectively.

KEY TERMS

Codified Practice: Elements of a practice embedded in processes, tools and artifacts.

Distributed Collective Practice: Activities executed by electronic squads and relating to the enactment of virtual practices leading to the achievement of a collaborative mission / task.

Electronic Squad: A moderated cross-organization / neighborhood coalition (virtual community of practice) tasked to attain a common mission by aggregating and negotiating primitive resources (i.e., neighborhood assets).

Social Experience Factory: A software engineering setup aimed to provide the computer-mediated environment for managing moderated electronic squads in their engagement in distributed collective practices.

Chapter 2.9
Information Systems Development:
Understanding User Participation as a Social Network

Angela Mattia
Virginia Commonwealth University, USA

Heinz Roland Weistroffer
Virginia Commonwealth University, USA

ABSTRACT

Conventional wisdom has it that user participation in information systems development (ISD) is essential for systems success. Though the significance of user participation to systems success has been much discussed in the literature, results from empirical studies are inconsistent and suggest, that perhaps new avenues need to be explored. One approach may be viewing user participation as a social network that is, looking at the emergence of social structures and their technological expressions during the user participation process. In this chapter, a framework is presented that organizes user participation approaches that emerge from the different worldviews existing within organizations. This user participation approach (UPA) framework is used as the structure for the systematic arrangement of user participation approaches into a fourfold taxonomy based on extrinsic information attributed to them in the literature. In addition, a categorical analysis and social network analysis (SNA) are used to map and visualize the relationships between analyst and users, thus providing a conceptual and visual representation of the relational structures.

DOI: 10.4018/978-1-60566-344-9.ch005

INTRODUCTION

A critical factor in successful information systems (IS) development is generally assumed to be user participation. Interestingly enough, empirical studies have been unable to conclusively link user participation to systems success. Indeed, attempts to organize and synthesize past empirical studies on user participation have resulted in conflicting results (Cavaye, 1995; Hwang & Thorn, 1999; Olson & Ives, 1981). This may not be totally surprising, due to the dynamic nature of organizations (Doherty & King, 2005) and the inability to capture many of the *everyday* social interactions that occur as users participate. Everyday user participation may or may not be public and therefore has been difficult to assess in the past.

However, in today's world, online communication is becoming an increasingly important part of how users participate in information systems development (ISD). Project participants go online to look for information, keep in touch with co-workers and other professional contacts, conduct business, talk about the project, track progress, discuss new developments, and look for answers to problems. Most of these interactions leave behind records of some sort of social interaction: exchanged email messages, discussion forums, instant messaging (IM) logs, newsgroup postings, blog entries, wikis, etc. Hidden in these growing archives of interactions are useful social patterns that, if more easily recognized and understood, could greatly improve the outcome of an ISD project. This chapter looks at how social interaction may be visualized and how such representations may help organizations understand the mediated environments they inhabit, the worldviews they exhibit, and the relationships of these factors to information systems outcome or success. Indeed, information visualization offers a method of observing the unobservable (Shneiderman, 1998).

The Internet has produced a new way to identify "social networks". Indeed, these networks support social interaction and user participation on an unprecedented scale. Social networks are changing the user participation context, as millions of people around the world come together in online public spaces and exchange ideas, ask questions, and comment on daily life events. Indeed, individuals and organizations are *evolving* in their interactions as they recognize and learn to appreciate how they can stay in touch by e-mail or in online discussion forums with hundreds of people all over the globe. These social networks, which may be public or private, are about collaboration and empowerment for individuals, organizations, and societies (Shneiderman, 2002). They leave behind copious evidence of the evolving social networks and the *revolutionary* ways users are participating. Yet, this evidence is largely undefined and thus so far has been unusable in the context of ISD user participation research. The objective of the current research is to provide a framework that will facilitate visualizing the cues and patterns that are present in social networks, in order to help users, analysts, managers, and other stakeholders participating in ISD, better understand the worldviews they exhibit and their relationship to systems outcomes.

In a sense, we undertake making the intangible aspects of user participation in ISD tangible. In doing so, an issue to contemplate is whether the process of "how users participate" is evolutionary, or are we experiencing a *revolution* with respect to "how users participate?" Disclosing the worldviews and patterns of "how users participate" may help illuminate these issues and others about user participation in ISD. Indeed, it may be a step towards conclusively showing a link between user participation and system success.

This chapter is organized as follows. After providing and discussing some basic terminology, we present and extend the *user participation approach (UPA)* framework (Mattia and Weistroffer, 2008) and justify its use as a means to better understand user participation as a social network. Based on a survey of the literature, we provide and summarize a categorization of user participation approaches using the UPA framework. The chapter concludes with a discussion on how the proposed framework can be better understood as a social network.

THE USER PARTICIPATION APPROACH FRAMEWORK

Basically, this research involves extracting, analyzing, and categorizing information retrieved from available data. The concept of organizing data for better comprehension is not new, and indeed, has an extensive history in the user participation literature (Cavaye, 1995; Hwang & Thorn, 1999; Olson & Ives, 1981; Ware, 2000). What is different in our research is the *what*, *how*, and *why* in organizing, analyzing, and understanding user participation during ISD, viewed as a social network.

Definitions of Terms

User participation has been discussed in the literature from many theoretical perspectives, but attempts at organizing and synthesizing the literature have proven difficult. First, to properly organize the user participation process in ISD we must define several ambiguous terms. Barki and Hartwick (1989) suggest that the term *user participation* should be used "when referring to the set of operations and activities in the systems development process that users participate in", and the term *user involvement* "should be used to refer to a subjective psychological state which influences user perceptions of the system."

Development-related activities performed by users during ISD include activities that may pertain to either the management of the ISD project or to the analysis, design, and implementation of the system itself (Cavaye, 1995). Therefore, participation reflects what specific behaviors are performed, how many of these behaviors are performed, and how often they are performed. These behaviors can be measured by asking users to indicate the extent to which they have participated in specific assignments, activities, and tasks (Hartwick & Barki, 2001).

Due to the diverse use of the terms user participation and user involvement, the term *user engagement* has emerged, referring to either user participation or user involvement or both (Hwang & Thorn, 1999). In addition, recent research also looks at *user attitudes* as a separate term and defines it as affective or evaluative judgment (e.g., good or bad) towards an object or behavior (Barki & Hartwick, 1989). Simply said, it is a psychological state that reflects the user's feelings about IS. This is important because recent research has suggested that user participation, user involvement, and user attitude exert different impacts on system outcomes. Indeed, a circular relationship is suggested (Lin & Shao, 2000), because when user's perform participatory activities, they can help users get more involved, which may improve the user's attitude and make them feel more satisfied with the IS.

A *social network* is defined in this research as a social structure consisting of nodes (which are generally individuals or organizations) that are tied by one or more specific worldviews. Consequentially, persistent data to be investigated and visualized need to be collected from different social networks. Thus, these collections of data deal with user participants and with the spaces and the people they encounter during ISD. Rather than visualizing information systems as a technological phenomenon, we are visualizing the social fabric of the user participation process: the relationship between the roles of analysts and users. User roles in this research are sub-classified as user (in the narrow sense), stakeholder, and manager. This role distinctness is necessary to more accurately model the attributes and relationships of the worldview in which the user role exists. Thus the role of a user (in the wider sense) is flexible; it may range in its definition as solely using the system, to designing and managing the user participation process. We are visualizing the ordinary activities of analyst and users participating in ISD and their worldviews that have an impact on these activities. In so doing, we are not limiting this research to one kind of environment, but instead, explore a variety of online spaces and social networks. Every ISD project is fundamentally different from every other, dealing with different social networks, and online architectures. This approach allows us to explore how social networks may affect distinct user and organizational worldviews, synchronous and asynchronous user participant environments, conversation-based and artifact-based ISD communities. Consequently, this research shows how a user's worldview and social networks can impact user participation in ISD and the resulting system outcomes.

The Proposed Framework

Typically in academic research, a research question is first identified, and then ways are investigated to explore and answer this question. In contrast, creators of social networks often begin with, first, the purpose they are interested in pursuing and, second, the raw dimensions present in the data. To these two parameters, the work presented here adds a third one: empirical findings from information systems research and a variety of social science research – ranging from sociology and psychology to communication research. Whenever possible, the choice of which dimensions to visualize in this research has been guided by the theories and empirical results from these fields. Communication research in particular, can be of great value to designers of social networks because they highlight the kinds of cues users of online spaces utilize as they interact. These studies spell out some of the inner workings of social processes such as online impression formation and the impact that different cues have on interpersonal communications processes (Carroll, 2002). Furthermore, this research explores social network analysis as one analytic approach to better understand user participation.

Adapted from Cavaye (1995) and Mattia and Weistroffer (2008), Figure 1 depicts the various dimensions that have been used in previous user participation research, but extends the model by synthesizing numerous other ideas put forward in the literature, including the four paradigms of information systems development proposed by Hirschheim and Klein (1989). This user participation approach (UPA) framework is designed to present a more complete visualization of a complex phenomenon that is frequently marked by gradual changes through a series of states. In addition, this extension will help organize existing research findings and continue the cumulative research tradition on user participation.

Burrell and Morgan (Burrell & Morgan, 1979) use epistemological assumptions (how you obtain knowledge) and ontological assumptions (your social and technical worldview) to yield two dimensions: a subjectivist-objectivist dimension and an order-conflict dimension. The subjectivist position seeks to understand the basis of human life by exploring the depths of the subjective experience of individuals.

The main concern is with understanding the way in which an individual creates, modifies, and interprets the world. The objectivist position applies models and methods resulting from the natural sciences to the study of human affairs. The objectivist thinks of the social world as being the same as the natural world (Burrell & Morgan, 1979). The conflict-order dimension is described as where an order or integrationist worldview emphasizes a social world characterized by order, stability, integration, consensus, and functional coordination. The conflict or coercion worldview emphasizes change, conflict, disintegration, and coercion (Burrell & Morgan, 1979). The dimensions are offered as a theoretical schema for analyzing organizational theory.

Following Burrell and Morgan (1979), Hirschheim and Klein (1989) map the dimensions onto one another to yield the four paradigms of information systems development. These four paradigms are sets of assumptions about ISD which reflect different worldviews about the physical and social world (Hirschheim & Klein, 1989; Hirschheim, Klein, & Lyytinen, 1995). Different worldviews tend to be reflected in different theories. Indeed, all approaches are located in a frame of reference (worldview) of one kind or another. Iivari, Hirschheim and Klein (2001) extended this line of research by supplying a four-tiered framework for classifying and understanding ISD approaches and methodologies that have been proposed in the literature. The UPA framework proposed in this chapter is a frame of reference for the user participation process in ISD. This provides a comprehensive schema for analysis of user participation outcomes (issues and problems) within ISD and in particular, the user participation domain.

The UPA framework recognizes contingencies, which refer to the variables that enable or inhibit user participation. Intervening mechanisms are included to illustrate that the system outcome may have variables that moderate the user participation effect (Cavaye, 1995). It is important to recognize these, so that the user participation process is viewed in the context of the larger picture.

Categorical Analysis of the User Participation Process

A categorical analysis of the user participation process is used to analyze the UPAs in the context of *information system development approaches (ISDA)*. First, we classify and map the list of user participation items into different process model elements. In a similar manner we characterize the ISDAs. Finally, heuristics are used to investigate how the approaches translate into manager, analyst, stakeholder, and user actions. In this study, this analysis technique helps clarify the story that the UPA tells us. In addition, we use the UPA framework and social network analysis to infer from the whole ISD structure to the user participation part; from organizational structure to individual user participant; from behavior to worldview. Consequentially, this allows us to study whole social networks, all the ties containing specific relations in the defined user participation population, and the personal social networks of user participants and the ties that specific users have, such as their *individual communities*.

A categorical analysis of the user participation process produces four generalized categories. Each category consists of typical classes of behavior that follow from the assumptions of a particular worldview. The worldviews that the ISDAs are derived from are archetypes that represent highly simplified but paramount conceptions.

Elements of the Categorical Analysis:

- The definition of the UPA indicates the overarching concept explicitly defined in the approach.
- The definition of the ISDA indicates the worldview concept explicitly defined in the approach.
- The *management rationale* indicates which justifications are provided for the use of the approach and specific goals that managers should pursue.
- Social *relationships* exemplify the established leadership in the user participation process.
- An *episode* is a set of participatory activities.
- Users, managers, stakeholders, and analysts form social networks that have encounters. It is important to note that encounters mark the beginning and end of an episode, i.e. they separate episodes.
- The heuristics indicate how the participatory activities and the UPA are related. The four main view elements are organization, practice, requirements, and functionality.

The worldviews are arranged in groups (categorized) according to the relationship identified in the UPA framework. Therefore, the categorical analysis provides us with a cognitive map (Table 1) that conceptualizes the attributes, whereby nodes (actors) or individuals can be distinguished.

Social Network Analysis of the User Participation Process

The general form of this analysis views the user participation process as a social network that emerges from the UPA chosen. Actors (nodes) participate in social systems; therefore social network analysis is used to make the relation-

Table 1.

User Participation Approach (UPA) Taxonomy		
Worldview	**I. The analyst as the user participation leader**	**II. The analyst as a facilitator**
UPA:	User participation as a rational process in a social network.	User participation as a sense making process in a social network.
Worldview:	Functionalism (objective-order) focuses mostly on technical change.	Social relativism (subjective-order) focuses on social interaction.
ISDA:	Typically these approaches to ISD share a number of common features that drive interpretations and actions. Examples: Structured, information modeling, decision support system, socio-technical design, object-oriented.	Interactionist, soft systems methodology, professional work practice.
Management rationale:	The ideal of profit maximization.	None are apparent. As the social worldview is continuously changing, no particular, rationale can be provided to 'explain' the user participation state.
Social Network:	Management, the analyst and users.	Users and the analyst.
Social Relationships:	Analyst-led.	Equivocation.
Episode's Guiding Principles:	Information systems are developed to support rational, organizational operation and effective and efficient project management.	Information systems development creates new meaning.
Heuristic:	This UPA is technical in nature and significantly focused on the requirements element. Functionality, practice, and organizational elements follow in its analyst-led, technical to social focus. Significant emphasis on design and requirements model a worldview that turns a system into a useful tool for management to achieve its goals.	Interrogative activities that enable debate. This UPA focuses on social interaction and thus, is significantly focused on the functionality element. Through interaction, objectives emerge and become legitimate by continuously developing or adding functionality to the information system. The technical communicator role, with its increased emphasis on listening to users and advocating their needs and desires, also can be used to increase and enhance communication during the user participation process and reduce the pain of these changes.
Worldview	**III. The user as the user participation manager in a social network.**	**IV. The analyst and stakeholders as partners in a social network.**
UPA:	User participation as a process of empowerment.	User participation as an equal opportunity process.
Worldview:	Radical structuralism (objective-conflict) focuses on radical change.	Neohumanism (subjective-conflict) focuses on social change.
ISDA:	Participation supports democracy at work and quality of work. Example: Trade unionist.	Models communicative action in organizations. Example: Speech act-based.
Management rationale:	The ideal of an evolution from capitalist market economy to a collectively planned and managed economy. This evolution empowers users to meet their own needs.	The ideal of emancipation. Information systems should lead to freedom from all unwarranted constraints and compulsions (e.g., distorted communication) toward a state of well-being for all.
Social Network:	Management and the analyst.	Stakeholders and the analyst.
Social Relationships:	User-led.	Joint system development.
Episode's Guiding Principles:	Information systems are developed to support managerial control because management is the user.	Information systems are developed to remove distorting influences and other barriers.
Heuristic:	This UPA focuses on radical changes that allow users to meet their own needs (User-friendly ISD tools) thus, is significantly focused on the practice element. Craftsmanship and productivity are thought to improve when the users' daily practices are enhanced.	This UPA is social in nature and significantly focused on the organizational element. Practice, functionality, and the requirements elements follow in its social to technical focus. Significant emphasis on organizational design and adaptation should lead to an ideal environment for joint system development.

ships between actors explicit. The theoretical and methodological focus of social network analysis is identifying, measuring, and testing hypotheses about the structural forms and relations among actors, making this type of analysis well suited for use with the UPA framework, in contrast to factor research which has an individualistic and variable-centric focus (Knoke & Yang, 2008) (see Figure 1). Basic units of analysis are relations (ties). Other measures of social network structure include range, density, centrality, groups, and positions (for a review, see (Wasserman & Faust, 1994)).

As a point of departure we offer the following research question: *What enables certain groups of users participating in ISD to contribute to system success?* A traditional approach to this question has been to focus on the analysts and their ability to manage the process of user participation. This is because analysts have traditionally played a pivotal role in designing and coordinating collective actions. This traditional (objective) leader-centered worldview has provided valuable insights into the relationship between leadership and group performance. Today, user led approaches exist that are also consistent with an objective, leader-centered worldview. All of these objective, leader-centered worldviews assume that there is only one leader in a group, and view leadership as an exclusively top-down process between one leader and the other users (Figure 2).

A newer, more subjective approach to managing the user participation process is to have multiple leaders. This approach has proven effective because groups often have more than one leader. Even when there is a formally assigned analyst or user as the group leader, other, informal, leaders may emerge. Users often choose informal leaders of their own, leaders who are separate from the analyst designated as leader by the organization. The subjective, multiple-leader worldviews assume that there is a need for more than one leader in a group. These worldviews view leadership as an emergent process between multiple leaders and the other users (Figure 3).

Basic units of analysis here are relations (ties) measured by visualizing formal social structures of the type “reports to”.

Figure 1. User participation approach (UPA) framework

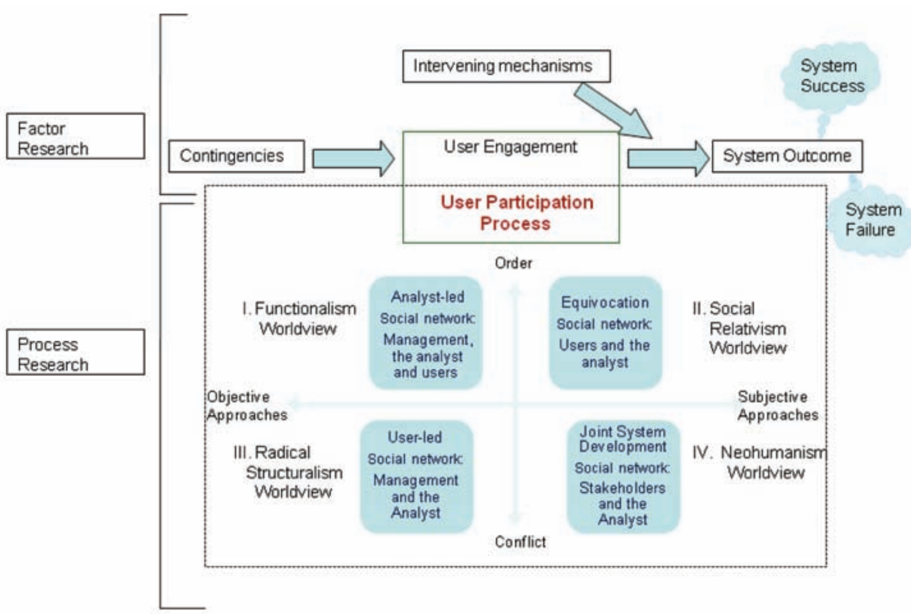

Figure 2. Objective, leader-centered social network

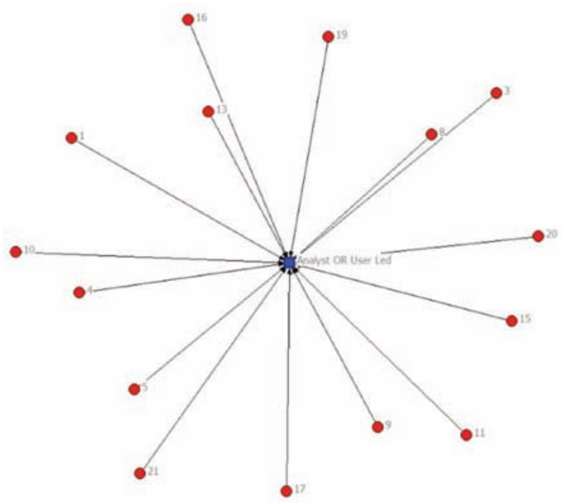

Figure 3. Subjective, emergent-leader social network

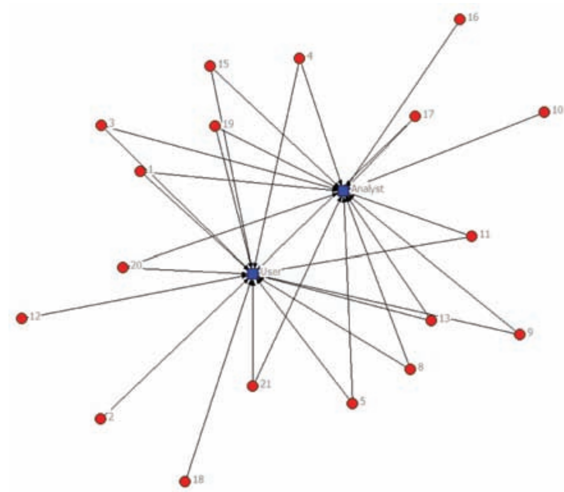

The purpose of this section was to give a brief explanation and a corresponding visualization of the social relations indentified in the categorical analysis. We have briefly outlined how social network analysis can enhance the research agenda set forth in the UPA framework. User Participation during ISD until now has remained mostly untouched by social network analysis. In all four worldviews of the UPA framework, we argue that the network perspective combined with the categorical analysis has the potential to supply a cross-level analysis, generally incorporating more macro-level constructs (such as management rationale) into micro-level research (such as user participation leadership). As we continue to analyze user participation during ISD using the UPA framework, we expect social network analysis to supply many more interesting explanations about the user participation process.

CONCLUSION

The research-in-progress reported in this chapter is focused on organizing and analyzing user participation by viewing it as a social network. Though people are quite adept in participating in social networks in new and ever-more detailed and persistent ways, they often lack the ability to see the relationship in intelligible, useful, and business oriented ways. And yet, it is clear that the use of social networks can be an important source of information about the people that create them and the worldviews they exhibit. Worldviews play a critical role in determining the way problems are solved, organizations are run, and the degree to which individuals succeed in achieving their goals. Existing social networks supply persistent datasets on how users participate, and a social network analysis may present the cues and patterns that allow us to better understand the relationship of user participation in ISD to systems outcomes. In addition, visual representations of social networks help us understand the dataset and convey the results of the analysis. Social network analysis tools can change the layout, colors, size and many other elements of the social network representation. Indeed, a picture can say a thousand words.

The refinement of the categorical analysis on user participation leads to a more organized taxonomy and therefore a more useful understanding of a user's worldview and the user participation approaches most congruent to the worldview identified. The next logical step is to analyze the social networks and the ties that bind them as a source of persistent data on user participation. This will open new avenues of making tangible what is now obscured and intangible. In addition, social networks should be investigated as a new (evolutionary or revolutionary) approach that managers, analysts, users, and stakeholders can utilize in accordance with the appropriate worldview that they exhibit. As simple as this approach may sound, it is a clear departure from how user participation in ISD has traditionally occurred. Most user participation during ISD is disconnected from the organizational and individual worldviews and the social networks available to the participants. By categorizing user participation approaches according to validated aspects of each worldview and exploring social network structures, this research expands our knowledge of how visualizations of the user participation social network can be used and what impact these UPAs have on systems outcome.

Chapter 2.10
A Framework for Integrating the Social Web Environment in Pattern Engineering

Pankaj Kamthan
Concordia University, Canada

ABSTRACT

In the last decade, patterns have emerged as a notable problem-solving approach in various disciplines. This paper aims to address the communication requirements of the elements of pattern engineering (namely, actors, activities, and artifacts) in general and the pattern realization process in particular. To that regard, a theoretical framework using the Social Web as the medium is proposed and its implications are explored. The prospects of using the Social Web are analyzed by means of practical scenarios and concrete examples. The concerns of using the Social Web related to cost to actors, decentralization and distribution of control, and semiotic quality of representations of patterns are highlighted. The directions for future research including the use of patterns for Social Web applications, and the potential of the confluence of the Social Web and the Semantic Web for communicating the elements of pattern engineering, are briefly explored. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

The reliance on the knowledge garnered from past experience and expertise is important for any creative endeavor. A pattern is one such type of conceptually reusable knowledge (Buschmann, Henney, & Schmidt, 2007b). From their origins in urban planning and architecture in the 1970s (Alexander, Ishikawa, & Silverstein, 1977; Alexander, 1979), followed by object-oriented software design in the late 1980s and the early 1990s (Gamma et al., 1995), patterns have found applications in various domains of interest (Rising, 2000; Henninger & Corrêa, 2007). For novices, patterns are means of guidance; for experts, they are means of reference. The use of patterns has, for example, enabled the construction of high-quality distributed software architectures (Buschmann, Henney, & Schmidt, 2007a), electronic commerce applications (Kamthan & Pai, 2008), mobile interaction design (Ballard, 2007), secure systems software (Schumacher et al., 2006), use case models (Kamthan, 2009), and Web Applications (Kamthan, 2008), to name a few.

The human-centric nature of patterns has been known for some time (Coplien, 1996; Schumacher et al., 2006). For its broad acceptance and use, the knowledge in form of patterns needs to be explicably communicated to its actors.

The Social Web, or as it is more commonly referred to by the pseudonym Web 2.0 (O'Reilly, 2005; White, 2007), is the perceived evolution of the Web in a direction that is driven by 'collective intelligence' (Engelbart, 1995), realized by information technology, and characterized by user participation, openness, and network effects. The purpose of this paper is to assess the viability of the Social Web environment in serving as an ecosystem for many-to-many asynchronous and synchronous communication of the elements of pattern engineering in general and the pattern realization process in particular. For the sake of this paper, the Social Web *environment* includes Social Web technologies, applications based on those technologies, and tools for managing both.

The rest of the paper is organized as follows. The background and related work necessary for the discussion that follows is first outlined. This is followed by introduction of a theoretical framework for communicating the elements of pattern engineering via the Social Web (namely, SW4PE) that includes identifying and classifying actors of patterns, a model for the pattern realization process, and communication requirements for pattern engineering. Then, a detailed analysis of the prospects and concerns of using the Social Web for communicating the elements of pattern engineering along different dimensions is carried out. In particular, the role of 'collective intelligence' and of the technologies/applications underlying the Social Web including blogs, folksonomy, mashups, microformats, podcasting, social bookmarking, social networking, and Wikis, is highlighted. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND AND RELATED WORK

This section presents a synopsis of terminology specific to patterns and a perspective of related work. In particular, limitations of the current media towards communicating the elements of pattern engineering are highlighted.

A Terminological Overview of the Pattern Space

There is currently no standard or a reference model for terminology related to patterns. Therefore, for the definition of the members in the *pattern space*, this section relies on selected publications (Appleton, 1997; Meszaros & Doble, 1998; Buschmann, Henney, & Schmidt, 2007b) that can be considered as authoritative.

A *pattern* is defined as an empirically proven solution to a recurring problem that occurs in a particular context. There are several possible views of a pattern. From a structural viewpoint, a pattern is typically described using an ordered list of elements that are labeled as (pattern) name, author, context, problem, forces, solution, examples, and related patterns. At times, the labels may vary across community, and other (optional) elements, such as those related to *metadata*, may be included to enrich the description.

The name element of a pattern is an evocative, often a noun-phrase, metaphor reflecting the nature of the solution; the author element gives the identity of the pattern author(s); the context element provides the situation or pre-conditions within which the problem occurs; the forces element provides the constraints that are resolved to arrive at a solution; the solution element provides an abstract, general, and reusable solution to the problem and is shown to work in practice via an examples element; and the related patterns element outlines any other pattern(s) to which a pattern is related to in some way. It is this structure that makes patterns more practical in their applicability compared to other expert bodies of knowledge such as principles, guidelines (Wesson & Cowley, 2003), and heuristics.

A pattern is usually referred to by its name. In this paper, the name of a pattern is listed in uppercase in order to distinguish it from the surrounding text.

There are other members in the pattern space closely related to a pattern. An *anti-pattern* is a pattern that suggests a 'negative' solution to a given problem, and occurs when the context of the problem is not understood or the underlying forces are not optimally balanced. A *patlet* is a 'simplified' description of a pattern, providing only a short statement of the problem and solution, and does not include other elements. A *pattern thumbnail* is similar to a patlet except that it is usually accompanied with a picture of the solution. The purpose of both patlet and a pattern thumbnail is to briefly introduce a pattern (without engaging in details) so that a pattern reader can make an informed decision whether or not to read any further. This can be particularly significant when there is a large collection of patterns to select from.

It is rarely the case that a pattern exists in isolation. Indeed, a pattern is often intimately related to other patterns in many different ways. A *pattern language* is a network of patterns that are intimately related to each other by a common goal and collectively solves a larger problem than that possible by any individual pattern. The collection of patterns in a pattern language when taken together forms a 'vocabulary' that can be used by the actors for communication.

A sequential reading through the text of a lengthy pattern language may not be sufficient to gain an overall picture that is necessary for its understanding and subsequent use. A compact graphical representation can be useful in such a case. For a given pattern language, a *pattern language map* is a visual presentation of patterns and their relationships.

A *pattern management system* (PMS) is an interactive software system with responsibilities that include archiving a selected collection of patterns that could evolve (added, deleted, or modified), facilitating the discovery of those patterns via navigation or searching, and rendering those patterns on a user agent. For example, a PMS could be based on a client-server environment of the Web (Kamthan, 2008).

A *pattern realization process* (PRP) is a collection of activities and their interrelationships for specifying a pattern. The activities themselves can either be individual or social.

Finally, *pattern engineering* (PE) is a systematic and disciplined approach to the definition, subsequent use and maintenance, and interface to humans, machines, and other entities of knowledge of a member of the pattern space within the given constraints of available resources. A PRP is a part of PE.

Medium for Communicating the Elements of Pattern Engineering and the Human/Social Factors

Every means of communication requires a medium. From 1970s to about mid-1990s, patterns were essentially restricted to print medium like commercial-only books or event proceedings. According to an empirical study (Henninger & Corrêa, 2007), the print medium continues to dominate as a major channel for publishing patterns.

However, a print medium provides limited opportunities for communication. In particular, it enables only a one-to-many communication paradigm; there is no interaction; information in modalities like animation, audio, video, or three-dimensional graphics can not be communicated; there is notion of presentation, not of representation; a reuse can only be realized through citation or duplication; entities (such as books) are essentially isolated from each other; it is not possible to provide multiple views of the same information (for example, change the level of magnification) or, on-demand, present information at different levels of abstraction; and there is no support for hypertext.

In the past decade or so, the electronic (digital) medium, particularly the distributed environment of the Internet and the Web, has proved to be a useful vehicle for communicating elements of PE in different sensory modalities. The use of electronic mail (e-mail) and Internet Relay Chat (IRC) services, both of which predate the Web, has conventionally been made for communicating asynchronously and synchronously, respectively. As indicated by surveys (Deng, Kemp, & Todd, 2005; Henninger & Corrêa, 2007), mailing lists and newsgroups dedicated to patterns have spawned and various domain-specific portals/repositories for patterns, usually equipped with navigation and search mechanisms, have been established.

However, mailing lists and newsgroups provide limited capabilities for organizing patterns (Manolescu et al., 2007). Furthermore, a conventional repository is limited by one or more of the following issues: it tends to be prescriptive; it still only enables a one-to-many communication paradigm; it usually only provides an author-view of patterns where the role of a reader is that of a mere observer, not a contributor; and, in general, any human or social relationships in PE are not always made explicit. This is prohibitive to the advancement of patterns and could potentially undermine their significance.

To alleviate some of these issues, human and social aspects of the PRP and subsequent deployment, in addition to technical considerations, is necessary. There have been some partial efforts in that direction such as the use of Wikis (Weiss & Birukou, 2007) but an in-depth analysis has not been carried out. This lends one of the motivations for this paper.

A FRAMEWORK FOR COMMUNICATING THE ELEMENTS OF PATTERN ENGINEERING USING THE SOCIAL WEB ENVIRONMENT

This section posits SW4PE, a framework for communicating the elements of PE via the Social Web illustrated in Figure 1. In the forthcoming sections, the actors of patterns are identified and classified, the details of the PRP are specified, the actor-specific requirements for communicating the elements of PE are outlined and, based on these, the prospects/concerns of integrating the Social Web technologies/applications in PE in general and PRP in particular are discussed in detail.

A Model for Actors of Patterns

According to the CLEAR TARGET AUDIENCE pattern (Meszaros & Doble, 1998) and the CONSISTENT “WHO” pattern (Harrison, 2003), the external entities to which a pattern is being communicated need to be recognized. An *actor* is a person who has interest in a pattern for some purpose. Based upon their *roles*, the possible actors of patterns can be identified and classified as follows:

- **Producer:** *Pattern Author* (responsible for authoring a pattern), *Pattern Shepherd* (responsible for inspection and feedback on a pattern), *Pattern Writers’ Workshop Participant* (responsible for inspection and feedback on a pattern), *Pattern Engineer* (responsible for providing means for representation and presentation of a pattern), and *Pattern Administrator* (responsible for maintenance and management of patterns).

- **Consumer:** *Pattern Reader* (target for perceiving a pattern) and *Pattern User* (target for using a pattern).

The actor classification scheme has a few properties. In it, the actors are not necessarily mutually exclusive. For example, there is a generalization-specialization relationship between a pattern reader and a pattern shepherd and the same between a pattern reader and a pattern user; however, the converse in both cases is not necessarily the case. The same person can also take upon different roles, and the same role can be taken upon by different persons. For example, a person casually reading a pattern plays the role of a pattern reader but given the write permission can (at least in part) play the role of a pattern administrator. The Social Web has made the boundaries among actors increasingly fuzzy as a professional pattern consumer can become a voluntary pattern co-producer, or a pattern 'prosumer' (Shuen, 2008).

Remarks

The actor classification scheme can be granularized further if needed. For example, a pattern reader and a pattern user could both be categorized further into *novice* and *expert*, or into *putative*, *potential*, or *future*. Also, pattern user could be labeled as a secondary actor, while all other actors as primary actors.

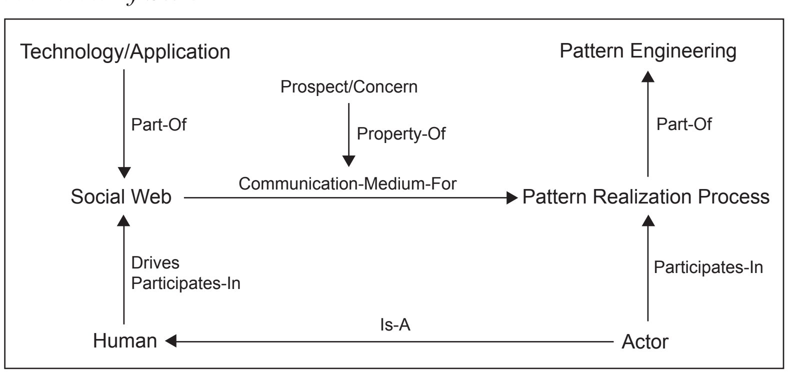
The actor classification scheme can also be extended. For example, a pattern reader could be generalized to a pattern percipient. A means of creating a taxonomy of actors for a general software system is available (Alexander, 2005), the discussion of which is beyond the scope of this paper.

A Model for a Human-Centric and Evolutionary Pattern Realization Process

The PRP is an actor-centric, iterative, and incremental process, the resulting product of which is a pattern. A *workflow* of PRP is a high level organization unit that consists of one or more activities. As shown in Figure 2, there are a number of workflows in PRP, including (1) *planning*, (2) *developing*, (3) *representing and presenting*, (4) *inspecting and revising*, (5) *publishing*, and (6) *maintaining*. These are prefixed by (0) *internalizing knowledge and assessing viability*, which is a prerequisite to the workflows that follow.

[0]. Internalizing Knowledge and Assessing Viability

Figure 1. A high-level view of SW4PE



The two recommended approaches for acquiring internal knowledge are *individual* and *sociological*. In an individual approach, there is a single pattern author who relies on personal experiences *and* extrospections (observations) based on others' experiences; in a sociological approach, there are multiple pattern authors relying on each other's experiences.

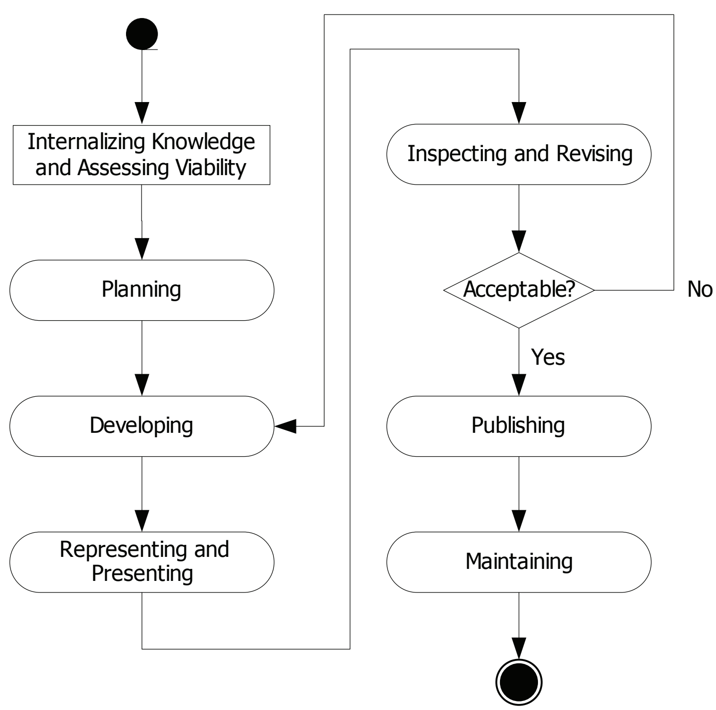
For the sake of discussion, consider the individual approach. It is assumed in this paper that practice involves action (doing). The practice over a period of time by a person of repeatedly solving a problem in some domain leads to experiences. Among other factors, the ensemble of the experiences themselves and of the retrospective after each experience (and perhaps extrospections based on others' experiences), lead to insight. The experiences also lead to acquirement of skill. It is then insight *and* skill together that form expertise. The a posteriori, situated, and experiential knowledge internalized by the person is either implicit or tacit. The person may voluntarily decide to share the implicit knowledge with others. For that, the implicit knowledge needs to be externalized (articulated) to explicit knowledge. At that point, the person takes upon the role of a (potential) pattern author.

Based on the expertise and research of existing pattern base, the pattern author determines the viability of proposing a 'new' pattern (also known as the *proto-pattern*) to the pattern community at-large (including target pattern readers and potential pattern users). As part of this workflow, the pattern author also checks for the existence of patterns that may be similar or variants of the one being proposed. This workflow concludes with a favorable decision to proceed with the definition of a proto-pattern.

[1]. Planning

In order for the PRP to be productive, the definition of the proto-pattern requires appropriate planning by the pattern author(s). The planning

Figure 2. The sequence of workflows in a pattern realization process



needs to include an assessment of the availability of resources including time, effort, expert body of knowledge, and tools. In case of multiple pattern authors, schedules for meetings also need to be decided upon.

There is a cost factor associated with the PRP. In particular, if the pattern author seeks a 'formal' analysis of the proto-pattern, there is cost involved in traveling to the Pattern Languages of Programming (PLoP) 'family' of conferences. There can perhaps also be ancillary cost related to publishing and administering the proto-pattern. The exceptions to this are the voluntary time and effort of the pattern authors and pattern shepherds.

There are a few non-commercial resources at the pattern author's disposal to assist in the PRP. These include expert bodies of knowledge like guidelines (Buschmann, Henney, & Schmidt, 2007b) and patterns (Meszaros & Doble, 1998; Harrison, 2003) for describing patterns, and patterns for shepherding (Harrison, 2000) and Writers' Workshops (Coplien, 2000). There are also tools for representing and presenting the patterns, the discussion of which is delegated to later sections.

[2]. Developing

For the purpose of referencing, the pattern author assigns an evocative name to the proto-pattern. From an analysis of the given information, the pattern author then abstracts the problem and, guided by previous personal experiences and extrospections based on others' experiences from [0], explicitly places the problem in a specific context that reflects the scope of the problem.

Next, a general and (conceptually) reusable solution for the problem needs to be devised. This is achieved via abstraction of instances of the solution from personal experiences and extrospections based on others' experiences from [1]. The solution describes both the process *and* the thing (created by the process). The purpose of the process aspect of the solution is pedagogy. It is likely that the problem has more than one solution, and that each solution has its own advantages and disadvantages. The 'best' solution is chosen based on an optimal balance (or equilibrium) of forces (constraints), which are usually the desirable quality attributes of the solution (Lea, 1994). From an examination of previous work, it appears that the means of achieving this balance are not given.

Since even the best solution is not absolute, the pattern author examines the implications (consequences) of applying the solution. The consequences could include forces that are not entirely resolved as well as new forces that may arise. This may lead to the need for other pattern(s), which is the inception of a pattern language.

The solution proposed by the proto-pattern must be generative (Lea, 1994), that is, it must be demonstrably proven to work. Therefore, based on the 'rule of three' (Meszaros & Doble, 1998), the pattern author elicits three solution instances or examples that best demonstrate the feasibility of the proposed solution. The examples could possibly be from earlier personal experiences and extrospections based on others' experiences from [0]. However, since the proto-pattern is based on empirical knowledge, it is prone to subjectivity. Therefore, to lend some degree of objectivity, these examples should not exclusively be internal, that is, they should not be all from the pattern author's personal experiences. In other words, there must be at least one external example.

Finally, the proto-pattern is placed in its social context. To do that, related patterns (if any) along with their relationships to the proto-pattern are listed.

[3]. Representing and Presenting

In order to become explicit, the information in [2] needs a suitable means of representation. A representation can subsequently be presented in one or more ways, in one or more sensory modalities, to make it perceptible to an actor.

In this workflow, the pattern author selects one of the available means for representing and presenting the proto-pattern (that are made possible by a pattern engineer), keeping the needs of the readership (Meszaros & Doble, 1998; Harrison, 2003) into consideration. The possible means for representing and presenting a proto-pattern can vary across the spectrum of formality (informal, semi-formal, formal), modes (text, graphics), open/closed technology, and so on.

For example, proto-patterns (and even an entire proto-pattern language) may be represented (Kamthan & Pai, 2006a) in the Extensible Markup Language (XML) and, depending on the target device, subsequently presented in one of the profiles of the Extensible HyperText Markup Language (XHTML) that is targeted for the Web or in the Portable Document Format (PDF) that is targeted for printing. This marks the end of the first iteration of the PRP.

[4]. Inspecting and Revising

The proto-pattern may go through an informal inspection (a non-anonymous, highly recommended but optional, review process) to evaluate the characteristics of the proto-pattern.

The prime example of inspection includes submission of the proto-pattern to one of the members of the PLoP 'family' of conferences, which leads to shepherding (which is one-on-one mentoring of the author by another person, namely the pattern shepherd, who is familiar with the underlying domain and is experienced in describing patterns) followed by participation in a Writers' Workshop (which is a face-to-face structured peer review process involving domain experts). The inspection may lead to a few iterations of the proto-pattern and thereby a re-visitation of [2] and [3]. At the end of the inspection, the proto-pattern may reach the candidacy of a pattern.

The pattern author, individually or otherwise as a result of the inspection, may associate a rating reflecting the confidence or maturity level of the pattern. Before publication, the pattern author may also optionally include metadata information related to configuration management, copyright/licensing, and so on, in the description of the pattern.

[5]. Publishing

Up until now, the pattern is limited to internal consumption. In order for the pattern to reach a broader community (beyond the pattern author(s), pattern shepherd, and participants of the Writers' Workshop), it needs to be published in a public environment.

The pattern is published in some (usually print and/or electronic) medium that is deemed reachable to the patterns community. The Web in general and the Social Web in particular is one candidate medium for publication of patterns. For example, a Web Application for patterns could be developed in a systematic manner (Kamthan, 2008) that archives and serves desirable patterns.

[6]. Maintaining

If needed, a pattern administrator carries out corrective and/or adaptive maintenance of pattern(s) on a timely basis. Furthermore, these pattern(s) may also be integrated (into a larger collection) and organized (classified and indexed) in some way. This concludes the conventional PRP from the viewpoint of the pattern producers.

A pattern, once published, does not get 'retired' or 'terminated' (in the sense of hardware or software systems). However, for various reasons, it may lose support and go out of use.

Remarks

A few remarks concerning PRP are in order. From the description of PRP, it is evident that PRP is non-linear and its workflows are not necessarily mutually exclusive. PRP also relies on human creativity and can not be completely automated. In some ways, PRP is similar to agile software development methodologies and open source software development processes but it is not as rigorous or formal. There has traditionally been modest involvement (if any) of the pattern consumers in PRP. This changes significantly by the introduction of the Social Web as a medium in the PRP.

A multidisciplinary, interdisciplinary, and participatory methodology called Identification-Development-Refinement (IDR) for realizing interaction design patterns has been proposed previously (Winters & Mor, 2008). However, IDR does not precisely identify actors or provide details of their involvement, rejects shepherding, and its steps are subsumed by that of PRP.

Actor-Specific Requirements for Communicating the Elements of Pattern Engineering

This section lists computing environment-, domain-, and technology-independent requirements for communicating the elements of PE driven by the needs of the actors. These informally collated requirements are identified by the prefix [PE-CR-n], n = 1, 2, 3, 4, and stated as follows:

- **[PE-CR-1]** It should be possible for a pattern author to readily describe a proto-pattern; it should also be straightforward for a pattern shepherd to readily inspect and provide feedback on it (in proximity as well as remotely). In general, a pattern author and a pattern shepherd should be able to collaborate and share a proto-pattern.
- **[PE-CR-2]** It should be possible for a pattern engineer to provide a means to represent and present proto-patterns.
- **[PE-CR-3]** It should be possible for a pattern administrator to manage (including store, retrieve, process (manipulate, transform), modify, and delete) a collection of patterns with minimal effort.
- **[PE-CR-4]** It should be relatively easy for a pattern reader (and a potential pattern user) to be able to locate, read, and understand a pattern and, with appropriate permissions, be able to distribute the pattern. It should be possible for a pattern reader to contact the pattern author and the pattern administrator.

These requirements serve as a guide for the rest of the paper. The use of qualitative terms in the statements [PE-CR-1] – [PE-CR-4] is intentional: their quantification is possible but is beyond the scope of this paper. In the following, symbols [+PE-CR-n] and [–PE-CR-n], n = 1, 2, 3, 4, are used to respectively denote strong and weak conformance to the corresponding requirement.

Communicating Patterns using the Social Web Environment

The Social Web has recently emerged as a perceived extension of the current Web that fosters ‘collective intelligence’ (Engelbart, 1995) and further decentralization. The notion of the apparent ‘humanization’ and ‘socialization’ of the Web is not new and dates back to the early days of the Web. Indeed, amazon.com and eBay are classical exemplars of consumer participation that introduced product review/recommendation and feedback, respectively. The notion of decentralization also has its predecessor in file sharing via Peer-to-Peer (P2P) computing.

However, it appears that there are three primary factors that have brought the vision of the Social Web to a mainstream realization: (1) it enables a many-to-many communication paradigm; (2) the maturation of the underlying technological infrastructure and the availability of its implementations as open source, and (3) the awareness, followed by immense interest and large-scale participation, by the public in general.

This paper advocates retaining the advantages that the Web offers towards communicating the elements of PE and assessing the viability of the Social Web in extending those advantages. The Social Web provides the medium in which human-to-machine-to-human communication takes place to realize human-to-human communication.

Scope of SW4PE: Open Problems in Patterns—Beyond Information Technology and the Web

There are certain impediments that the actors currently face in their dealings with patterns. In the future, it is theoretically possible that some of the issues, like the existence of a meta-index of repositories (Manolescu et al., 2007) or means for more precise search/retrieval might be addressed and even get resolved by technological means within the realm of the Web and its extensions.

Still, there are other pressing issues, like existence of a coordinating body for patterns, standardization of terminology related to pattern engineering body of knowledge (PEBOK), standardization of representations of patterns, or making all patterns as open/freely available content, that are obstacles to pervasiveness of patterns. These issues naturally constrain SW4PE, and are likely to remain beyond the scope of the Web and its foreseeable extensions.

AN ASSESSMENT OF THE PROSPECTS AND CONCERNS FOR COMMUNICATING THE ELEMENTS OF PATTERN ENGINEERING USING THE SOCIAL WEB ENVIRONMENT

In this section, based on the background set forth in the previous sections, the prospects as well as the concerns in deploying the Social Web are each assessed along certain dimensions.

Prospects for Communicating the Elements of Pattern Engineering via the Social Web

There are certain aspects of patterns that make them a natural fit within the environment of Social Web. In this section, the potential of the Social Web for communicating the elements of PE is explored along the lines of [PE-CR-1] – [PE-CR-4] and, to that regard, specific examples are provided.

Collaborating and Sharing

There is need for collaboration and sharing during the different workflows of the PRP. A pattern reflects *shared* understanding of a domain, and can be viewed as a shared resource or 'commons' (Hess & Ostrom, 2007). In the PRP, the transition of a proto-pattern to the status of a pattern inevitably involves collaboration during shepherding and during Writers' Workshops. Also, a pattern author needs to be cognizant and be sensitive to pattern readers' concerns. The Social Web lends various opportunities for collaboration and sharing, which we consider next.

Collaborative Researching

The Web has become an indispensable source for researching for information, and the same holds for elicitation of domain knowledge (such as elicitation of pattern instances) during the PRP. There are Social Web applications like Google Notebook and Microsoft OneNote that allow one to attach notes to and clip text, graphics, and links during researching. These 'notebooks' can be saved, and can subsequently be used for collaboration and sharing with others. Furthermore, the 'notebooks' in Google Notebook can be exported to Google Docs.

Social Scheduling

A face-to-face meeting, whether it is for sociological approach to elicitation of domain knowledge or for Writers' Workshop, requires scheduling. A schedule that is agreeable to all, particularly as the number of persons involved increases, can become difficult to manage. The use of Social Web applications that facilitate calendar sharing (such as the Google Calendar) can reduce some of the tedium involved in scheduling a meeting agenda.

Brainstorming

Brainstorming is implicit to various activities in the PRP. For example, in a sociological approach to elicitation of domain knowledge, the authors often engage in brainstorming (for collectively organizing their thoughts and recall, for collaborative decision making, and so on). The same idea applies to the dynamics of shepherding.

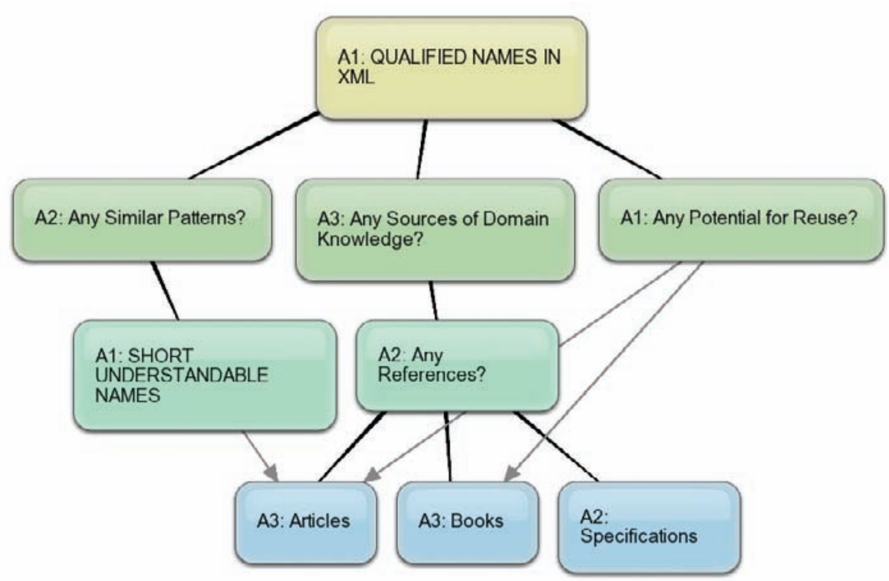
One way to brainstorm is through visualization, and mind mapping is a graphically-oriented approach to realize it. A mind map is a graph where nodes represent sub-ideas (or sub-goals or sub-tasks) at different levels of granularity and vertices represent 'semantic' relationships, all of which are arranged radially around a central idea (or goal or task, respectively). The pattern authors can share these mind maps over the Web and, depending on the permissions, read and/or edit others' maps.

Figure 3 illustrates a snapshot in time (work in progress) of a mind map using the bubbl.us tool (http://www.bubbl.us/). In it, three authors, namely A1, A2, and A3 are in a brainstorming session on the viability of a proposed pattern. The 'bubbles' reflect respective inputs by pattern authors.

Collaborative Authoring

The Social Web presents a suitable environment for collaborative authoring of patterns using various means including Google Docs and Wiki. The concept of Wiki (Leuf & Cunningham, 2001) was invented in the mid-1990s as a group communication utility. It allowed open editing of information

Figure 3. An example of a partial mind map reflecting a brainstorming session on the viability of the 'new' QUALIFIED NAMES IN XML pattern

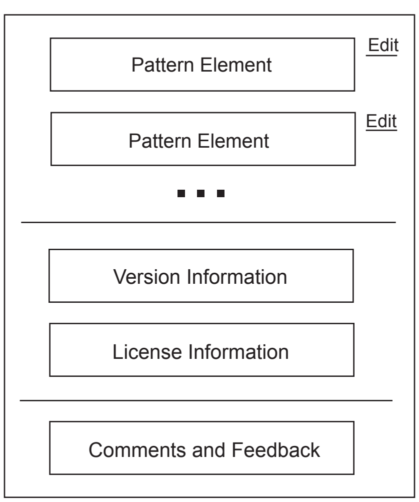


(like patterns) as well as the organization of the contributions and, with various enhancements, continues to serve well in that vein (Weiss & Birukou, 2007). A properly administered Wiki assists pattern authors, pattern shepherds, and pattern readers. Indeed, barring certain reservations, a Wiki environment enables a person to play the dual role of a pattern reader and a pattern administrator.

There are several, opens source flavors of Wiki available today addressing different target groups and organizational needs. Most flavors of Wiki, including MediaWiki and TinyWiki, can be easily acquired, installed, and administered under commonly-deployed computing platforms (Ebersbach, Glaser, & Heigl, 2006). For example, Asynchronous JavaScript and XML (AJAX) Patterns (http://ajaxpatterns.org/) and Perl Design Patterns (http://perldesignpatterns.com/) are collections of patterns based on MediaWiki and TinyWiki, respectively.

Figure 4 presents a simplified view of the description of a pattern within the Wiki environment. The mandatory elements of a pattern can be presented where they can be progressively disclosed (Lieberman, 2007) and edited; the details of history of the document can be automatically highlighted through version information; licensing terms can be made explicit; and pattern reader's feedback can be solicited and included. The figure could, for example, be extended by the addition of a block for the table of contents (in case the document is lengthy).

Figure 4. A glimpse into an abstract, partial view of the description of a pattern within the Wiki environment



It is not absolutely necessary (although it may be relatively easier) to deploy Social Web technologies/applications for realizing collaboration. The conventional technologies/applications that have found success on the Web such as the Personal Hypertext Preprocessor (PHP) can be used to achieve similar effect as a Wiki. For example, a collection of patterns for 'living spaces' (http://architypes.net/patterns.php) is built from collaboration between architects, interior designers, and photographers.

Syndication

Every so often pattern consumers need to keep track of several resources on patterns, including announcements of new patterns or modifications of the existing ones, availability of relevant books or podcasts, and so on. However, individually and somewhat arbitrarily visiting each Web Site of interest can be inconvenient and time consuming. The subscription to periodically refreshable news feeds helps ameliorate this issue.

Syndication is a type of metadata implemented in form of channels that point to relevant resources on a topic that the pattern readers can subscribe to. There are a variety of syndication technologies of which Really Simply Syndication (RSS) and Atom are beginning to find broad support in conventional user agents and news feed readers.

For example, the following RSS markup fragment represents news for a specific day from a single channel:

```
<?xml version="1.0" encoding="UTF-8"?>
<rss version="2.0">
  <channel>
     <title>Pedagogical Patterns Channel</
     title>
    <link>http://www.pattern.ca/</link>
    <description>
     This is a channel for news on patterns
     related to teaching and learning
       in the classroom.
    </description>
    <item>
       <title>News for January 15, 2008</
     title>
   <link>http://www.pattern.ca/2008/01/15/</
     link>
       <description>
        The interview of the author of the
     recently published book titled
       Patterns in the Classroom is avail-
     able as a podcast ...
       </description>
    </item>
  </channel>
</rss>
```

It could, for instance, be stored in a file named `PedagogicalPatterns.rss` and linked from a place that pattern readers could readily discover.

Social Bookmarking

Bookmarking has traditionally been one of the most common ways of remembering the resources of interest visited while browsing on the Web. However, these bookmarks reside on the user's computer and are not accessible by other devices (and therefore are not shareable).

Social bookmarking enables management (for example, storage, organization, search, and sharing) of booksmarks residing remotely at third-party services. By unifying their knowledge base, social bookmarking can help pattern authors and pattern shepherds communicate more effectively during the PRP. By expending modest effort, it can also help pattern consumers share links to resources (including desirable patterns) amid themselves. The notion of social bookmarking was pioneered by itlist.com in the mid-1990s and brought into mainstream around 2003 by del.icio.us. Since then other social bookmarking services like Google Bookmarks have spawned.

Organizing and Social Networking

It was claimed more than a decade ago that "finding patterns is much easier than describing them" (Gamma et al., 1995). On the Web, one could locate a pattern one of the following three ways: (1) directly using the (known) address where a pattern resides, (2) by navigating to the address, or (3) by searching through a collection. However, the rapid growth (Henninger & Corrêa, 2007) of the number of patterns and pattern languages has made the task of locating desirable patterns increasingly challenging for the pattern readers. Still, by participating in the Social Web, the pattern consumers can help one another (and indirectly help the pattern producers) in somewhat easing the task of locating desirable patterns, and folksonomy is one way to do that.

Folksonomy

A suitable organization of patterns is critical for locating desirable patterns. However, the search for a suitable organizing scheme for locating desirable patterns continues to remain a persistent and elusive problem (Hafiz, Adamczyk, & Johnson, 2007).

A crucial aspect of organization is classification. There is no universal scheme for classifying patterns: a pattern placed in one category by its author(s) can reappear as belonging to a different category in a different pattern language by another set of author(s). For example, the MODEL-VIEW-CONTROLLER (MVC) pattern (Buschmann, Henney, & Schmidt, 2007a) can be classified in multiple different ways, including categories that are not envisioned by its original author(s) but are considered relevant by its pattern readers and pattern users. This 'post-publication' faceted classification of a pattern is possible by social annotation, specifically via the notion of folksonomy or social tagging (Smith, 2008).

Folksonomy enables pattern readers to associate with a resource words or phrases that they deem meaningful, relevant, and significant in describing the resource. By doing so, there is an implicit assumption that other (new) pattern readers will share and benefit from this understanding of the resource.

Folksonomy can be realized in several different ways. For instance, the semantics of the XHTML documents can be extended using certain mechanisms within the `div`, `span`, and `class` elements, and `id` and `rel` attributes. Microformats (Allsopp, 2007) are an effort to standardize the conventions for using these extension mechanisms. In XHTML, the attribute-value pair `rel="tag"` can be used to indicate that the resource that has been linked-to acts as a tag for the current context. For example, to tag an XHTML document describing the MVC pattern with 'Distributed Computing,' markup such as `<a href="http://path/to/MVC/" rel="tag">Distributed Computing</a>` could be used.

A collection of tags can lead to the formation of a tag cloud. (There are some resemblances between a tag cloud and the classical Web concepts of image map and site map.) A tag cloud is set of related tags with associated weights that represent frequency of use of each tag. The tags within a tag cloud are usually ordered lexicographically and the frequency of use of each tag is illustrated by visual cues such as distinct font color and size. It is preferable to use a style sheet language such as the Cascading Style Sheets (CSS) for associating presentation semantics with tags.

The 'human element' of the Social Web—as personified by mutual collaboration among the actors in locating desirable patterns through navigation—can be realized in the following manner: by proper organization of tags and representation of weights in a tag cloud, pattern administrators and pattern engineers can help the pattern readers, and by a careful selection of tags, pattern readers can help each other.

Figure 5 shows a tag cloud for the MVC pattern. It can be noted that the tags are not all of the same type: while some are about things, others are about people. For example, Modularity is a software engineering principle; POSA is the acronym for Patterns for Software Architecture; and Trygve Reenskaug is the person who is ascribed for first introducing MVC, and the tag could, for instance, link to a resource that acknowledges this.

The above idea can be extended to tagging a pattern language map that is dynamically-generated and expressed in a vector graphical language such as the Scalable Vector Graphics (SVG).

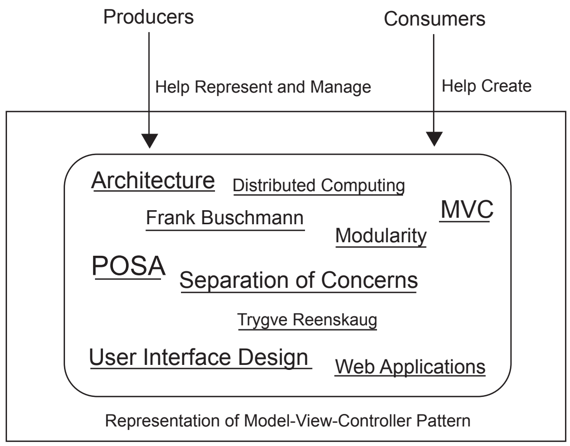
Social Networking

There are plenty of opportunities for social networking (Freeman, 2004) during and after the PRP. A variety of different types of social relationships can exist among the actors including pattern author-to-pattern author, pattern author-to-pattern shepherd, and pattern reader-to-pattern reader that can be made explicit.

The XHTML Friends Network (XFN) is a specification for explicitly indicating social networking relationships using `rel` attribute values in XHTML on blogroll links. For example, XFN values can be added to the `rel` attribute by a pattern author to indicate that John Smith is the shepherd, is a colleague, and is someone the author has met, using the following markup:

```
<ul>
  <li>
    <a href="http://john.smith.ca/"
        rel="colleague met shepherd">John
     Smith</a>
  </li>
</ul>
```

Figure 5. A tag cloud embedded in the abstract representation of the MODEL-VIEW-CONTROLLER pattern



The social networking relationships expressed in XFN could be exploited by programs like bloggers, search engines, or spiders.

Publishing

The authors of patterns and pattern languages publish their work at the end of the process. In doing so, there are several issues involved. The representation and presentation of a published pattern can often be heterogeneous in nature, involving the use of different modes of information (text, graphics, source code, and so on). For instance, the solution of a pattern, particularly that is structurally-oriented, is usually accompanied with a picture illustrating the solution in an abstract manner or of its instances (examples). Any publishing also needs to take into account that some information can be reused and repeated at multiple places, and it needs to evolve independently for an effective maintenance. For example, the picture in a solution may also be a part of a pattern thumbnail. It is also possible that the author may not have complete technical control or legal rights to physically include some of the desirable information but nevertheless still needs to point to it. From a Social Web viewpoint, these considerations, if appropriately carried out, are suitable for a mashup.

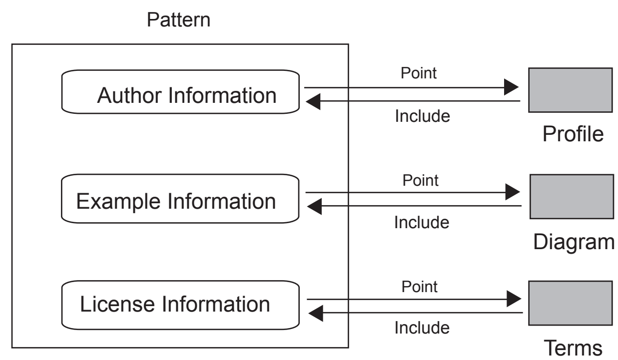
Mashups

A mashup aggregates and reuses information from multiple sources. This is accomplished via some means such as a transclusion (Nelson, 1982), which is an on-demand inclusion of one resource into another via hyperlinking and/or a programmatic mechanism like an Enterprise Mashup Service (EMS), which is a Web Service based on the Service-Oriented Architecture (SOA). It then presents information in a federated manner that is transparent to a pattern reader.

Figure 6 illustrates an abstract construction of a pattern mashup in which author information, picture of an example, and licensing terms are 'transcluded' from external sources.

Both pattern authors and pattern readers (using, say, iGoogle) can benefit from mashups. For example, the description of a user interface pattern could reside on one server and, after receiving appropriate permissions, 'transclude' a picture depicting a solution instance from another server (like that of Flickr). As another example, the author can indicate that the pattern is licensed under the Creative Commons 3.0 Attribution Required License by including the markup `<a href="http://creativecommons.org/licenses/by/3.0/" rel="license">CC by 3.0</a>` in an XHTML document.

Figure 6. A pattern mashup that points to and includes three different external sources



Deliberating, Educating, and Outreaching

It is the responsibility of the pattern authors to make a considerate effort to reach their audience of pattern consumers and, in doing so, use any means available to them. Being able to publish is only one aspect of communicating the elements of PE: it is also indirect, passive, and static, where the human side of patterns is less apparent. The Social Web presents an array of possibilities for direct, active, and dynamic means for communicating the elements of PE through a judicious use of media outlets. In particular, blogging and podcasting are asynchronous and synchronous means of communicating, respectively.

Blogging

A blog is an outlet for anybody to publicly express opinion, in writing, on just about any subject. In side bar of a personal blog, a blogger can provide a list of other blogs (or a blogroll).

There are a few benefits of blogging for the actors of patterns. Blogging gives pattern authors to respond to concerns of pattern consumers in an informal environment, inform others of their scholarly activities related to patterns (like relevant presentations at events), or state their current position about the (mis)use of patterns. For example, for the past few years, Grady Booch has been blogging about issues related to the Handbook for Software Architecture (http://www.booch.com/architecture/), which is one of the largest collections of patterns on software architecture. Blogging also gives pattern readers an opportunity to ask questions, and make their agreements and disagreements known in a public forum. For example, the Software Patterns Blog (http://pattern.ijop.org/) has been used by Mohamed Fayad to express concerns regarding current obstacles to learning and selecting patterns.

Podcasting

Podcasting provides an avenue to the pattern community for education and outreach by means of audio and video. For example, YouTube (http://www.youtube.com/results?search_query=Patterns) provides a platform for authors to post their presentations from events or other forms of media supporting patterns for a general audience without having to provide the service themselves. The pattern readers can provide comments on the videos, rate the videos, and add the videos to their list of social bookmarks.

As another example, the Software Engineering Radio (http://www.se-radio.net/) offers podcasts for interviews on software engineering related topics in general (Rech, 2007) and software patterns in particular. These interviews provide an opportunity for the authors to *converse* about patterns: demonstrate the patterns process by answering questions related to their experience in the domain, including successes and failures; draw attention to the history of patterns they elicited; mention the reasoning behind the selection of a means of representation or choice of examples; and so on.

Table 1. A mapping of activities in PE and concepts/activities associated with the Social Web

Pattern Engineering Activity	Social Web Concept/Activity
• Eliciting Pattern Instances	• Collaborative Researching • Brainstorming
• Assessing the Viability of the Pattern	• Brainstorming
• Eliciting Domain Knowledge (Sociological Approach)	• Social Scheduling
• Locating Expert Body of Knowledge for Authoring a Pattern	• Folksonomy • Social Bookmarking • Syndication
• Selecting Expert Body of Knowledge for Authoring a Pattern	• Brainstorming
• Participating in Writers' Workshop	• Social Scheduling
• Locating the Means for Representing and Presenting Patterns	• Folksonomy • Social Bookmarking • Syndication
• Selecting the Means for Representing and Presenting Patterns	• Brainstorming
• Authoring a Pattern	• Collaborative Authoring
• Assuring the Quality of a Pattern	• Social Web Application
• Representing and Presenting a Pattern	• Mashup • Microformat
• Publishing a Pattern	• Social Web Application
• Shepherding	• Collaborating • Social Networking
• Evaluating the Quality of a Pattern	• Collaborating
• Locating a Pattern	• Folksonomy • Microformat • Social Bookmarking • Syndication
• Reading and Understanding a Pattern	• Folksonomy
• Selecting a Pattern	• Brainstorming
• Using a Pattern	• Blogging • Podcasting
• Reflecting on the Use of a Pattern	• Blogging • Feedback
• Mentoring a Pattern Author, Pattern Reader, or Pattern User	• Blogging • Podcasting • Responding to Feedback
• Maintaining a Pattern	• Social Web Application
• Interfacing a Pattern with Other Entities of Knowledge and Artifacts	• Social Web Application

Table 1 presents a summary of the key activities in PE and supporting concepts/activities corresponding to the Social Web discussed in this section.

Concerns of Communicating the Elements of Pattern Engineering via the Social Web

The integration of patterns within the Social Web is not absolute and has its share of shortcomings. In this section, the scope and limitations of the Social Web for communicating the elements of PE is examined and in doing so specific examples are provided.

Cost to Actors

The issue of cost impacts all actors. The increase in the number of mature, open source implementations of the technologies underlying the Social Web has contributed to control of development costs and thereby to the reduction of entry barrier for aspiring pattern producers. There is still the non-trivial cost of time and effort in learning, especially due to the fact that there is currently no single provider of these implementations and that the interaction (including the user interface functionality) varies tremendously from one application to another.

However, for pattern consumers, the technological infrastructure of the Social Web remains largely exclusive: for optimal operation, it assumes high-speed Internet connection, state-of-the-art operating systems, and latest user agents with up-to-date capabilities on the client-side. This is not all free-of-cost for personal use. In general, 'Rich Internet Applications' of the Social Web are resource-intensive. For example, the mashups in which aggregation of information takes place on the client-side expect hardware and software capabilities that a pattern consumer may not have. As another example, the Software Engineering Radio podcasts are currently not streamed but are available only as download at file sizes that could be prohibitive to those on low bandwidth.

The issue of hardware and network cost is not perennial. If past statistical trends are any indicators, then it is likely to subside with time. The cost of hardware necessary for creating Social Web applications (like computers with fast processor speeds, and large storage space and memory; digital cameras; audio recorders; and so on) has been on decline in the past few years, and reflect a market trend that is expected to continue. The same applies to cost of Internet service. However, it also needs to be noted that the original vision of the Web is yet to be realized: a large segment of the world population does not (still) have access to the Internet in general (Press, 2004) and the Web in particular.

Decentralization and Distribution of Control

The technologies underlying the Social Web can be disruptive: they require change and, in some cases, radical departure from conventional approaches. For instance, the Social Web is not meant for pattern authors working individually in isolation.

Any form of multi-node interaction over a distributed network where a node could be either a human or a machine (like real-time collaboration among author and shepherd, resource sharing, or mashup) creates an indirection. Its success is based on the assumption that it works like a symphony: *all* the nodes involved are available, are in unison, interaction among them is transparent and timely, and so on. The past experience with the Web has shown that the relationship between the probability of success and the number of nodes is not linear (the former can decrease as the latter increases).

The 'transfer' of even some of the traditional control from server-side to client-side has its side-effects that need to be balanced. For example, the exposure of the PRP to the Social Web may lead to a perception by the pattern readers that a pattern is never 'complete' but in a 'perpetual beta' state, which contradicts the characteristic of 'timelessness' (Alexander, 1979) of a pattern. The transfer of control also faces a classical dilemma. For example, moderating feedback by retaining only complimentary messages from pattern consumers or time-delimiting the feedback could be perceived as bias on part of pattern producers, which is against the spirit of openness of the Social Web. In contrast, it is not automatic that all unfiltered feedback driven by 'citizen journalism' or 'user-generated content' contributes to enriching the description of a pattern, and therefore some degree of moderation is necessary.

In spite of several possible uses, the flexibility of blogs and Wikis comes with a price: they are known for 'noise' (including impertinent information), 'casual' writing (due to the presence of phonetic, 1337 style of writing, and frequent spelling and/or grammatical errors), and 'editing wars' (discussions that have morphed into endless debates that put personal interest before that of a pattern reader). These, however, can be attributed to human usage rather than to inherent limitations of the underlying technology. In any case, this impacts the quality of the description of a pattern, and is not favorable to either a pattern administrator ([–PE-CR-3]) or to a pattern reader ([–PE-CR-4]). A partial solution to this issue could be to (1) separation of the description of a pattern as provided by the pattern author from any annotations (which should be clearly labeled and managed as such), and (2) provision of multiple views of a pattern, including the option to suppress any annotations, to a pattern reader.

Folksonomy (as opposed to taxonomy) is an uncontrolled vocabulary, and the lack of terminological control can have linguistic implications due to synonymy, homonymy, and polysemy. In particular, classical issues associated with the natural language use of acronyms can surface. It is not automatic that all tags that are created by pattern consumers may be relevant to the context. For example, MVC has other known expansions like Marriott Vacation Club, the Missouri Valley Conference, and the Motor Vehicle Commission that are irrelevant to the notion of a pattern as discussed in this paper. Similarly, the tag 'Architecture' in the civil engineering sense is not relevant to the MVC pattern. Therefore, once again, to add long-term value, the tags associated with the description of a pattern need to be monitored and moderated.

Semiotic Quality of Representations of Patterns

The theory of semiotics is the field of study of signs in which the communication itself is viewed as interchange of signs. It is known that a pattern can be viewed as a second-order sign of a semiotic system (Buschmann, Henney, & Schmidt, 2007b). It is possible for a sign to have one or more representations.

From a semiotic viewpoint (Stamper, 1992), the quality of the representation of a pattern (and a member of the pattern space in general) can be viewed on six interrelated levels: physical, empirical, syntactic, semantic, pragmatic, and social. This paper focuses on the last two levels. Then, inspired by conventional quality modeling (Fenton & Pfleeger, 1997) and by [PE-CR-1] – [PE-CR-4], pragmatic and social levels can be decomposed further. The desirable pragmatic and social quality attributes of concern to a pattern producer include comprehensibility, legality, and maintainability, while the desirable pragmatic and social quality attributes of concern to a pattern consumer include accessibility, comprehensibility, credibility, performance, readability, reliability, and usability.

The quality of representations of a growing number of patterns and pattern languages on the Web is a concern. In recent years, various accessibility, performance, reliability, and usability issues with patterns and pattern languages made available on the Web have been reported (Dennis & Snow, 2006; Segerståhl & Jokela, 2006; Manolescu et al., 2007). The evaluations (Deng, Kemp, & Todd, 2005) of certain collections of patterns (Gaffar et al., 2003) lead to questions of the credibility of these collections and for which there are no trivial answers.

The technologies/applications underlying the Social Web do not by themselves contribute towards the improvement of many of the aforementioned quality attributes of representations of patterns. In fact, in some cases they can potentially lead to a detriment. For example, let use consider the case of accessibility and legality. The misuse of microformats by overriding the semantics of XHTML attributes or real-time applications based on AJAX that are exclusively visually-driven, mouse-input-only, can be unfavorable to accessibility (Cooper, 2007). The use of fixed fonts and certain colors can make the tags/tag clouds inaccessible to those with certain forms of visual disability. A similar argument holds for podcasts. XFN graphs can become unreadable as the number of nodes and vertices increase. Furthermore, this situation only gets exacerbated with the use of mobile devices to access the Social Web.

The rise of the Social Web has amplified the classical struggle between liberty and legality. The term 'free' in the notion of 'freely sharing' on the Social Web (analogous to the open source movement) stands for freedom. As the same time, the preservation of rights of the creators of digital work is an ongoing challenge in a distributed environment where laws (if any) can vary across jurisdictions, and patterns are no exception. The use of pattern mashups, similar to its predecessors like 'inclining images,' can be open to legal issues related to copyright infringement, irrespective of nature (intentional or inadvertent) of the motive. The issues related to absence of any clear terms of use, or lack of comprehension of misinterpretation of license by an average pattern reader, are yet to be satisfactorily addressed.

Therefore, if the aim is to reach broad, diverse, and global readership, both the pattern producers and the pattern prosumers need to exercise caution towards adopting new, unproven, techniques and technologies in representations of patterns. In particular, as the boundaries between actor classes fade, quality assurance will need to become a *shared* responsibility. In absence of a supervising authority and relying solely on an honor system, this can be admittedly difficult.

DIRECTIONS FOR FUTURE RESEARCH

It is still early to predict the outcome of the Social Web phenomenon in general and its impact on patterns in particular. The work presented in this paper can be extended in a few different directions that are briefly discussed next.

Social Network Analysis of the Pattern Community

The diversity and visibility of participants in public appearances such as events (conferences, meetings, and workshops) in different countries, postings on blogs, mailing lists, and newsgroups, and so on, indicates that the pattern community is thriving. A social network analysis (SNA) of the pattern community, as it continues to grow and morph into a dedicated social network, would be useful.

In particular, quantitative properties of the resulting graph such as centrality, closeness, clustering coefficient, cohesion, density, eigenvector centrality, and radiality, could be analyzed. This could help reveal certain relevant qualitative aspects of the network such as the relationships between actual actors; frequencies of use of specific patterns and pattern languages by certain actors; publications related to patterns and pattern languages recommended by people; demographical use of patterns; new domains of applicability of patterns; and so on.

Using Patterns for Social Web Applications

As shown in Figure 7, there is an apparent *symbiotic* relationship between patterns and the Social Web, one direction of which is explored by SW4PE in this paper.

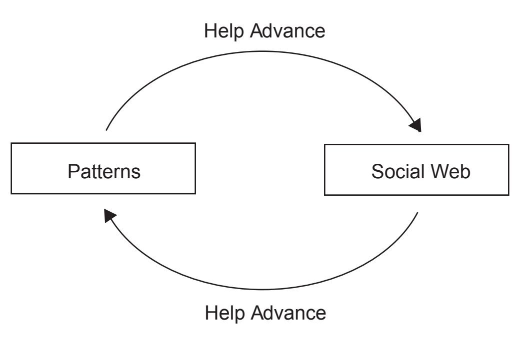
The support for the other direction has been steadily increasing. The User Interface Design Patterns Library (http://ui-patterns.com/) provides, for instance, a TAG pattern and a TAG CLOUD pattern. There are patlets (Decker et al., 2006), patterns, and anti-patterns (Mader, 2008) available for making proper use of Wikis, which in turn could improve the collaboration between patterns authors and pattern readers. There are design patterns for writing new microformats (Allsopp, 2007). There are also patterns available for computer-mediated communication in general (Schümmer & Lukosch, 2007) and for the design of Social Web applications in particular (O'Reilly, 2005) that can assist in the other direction. For example, APPLICATION SHARING, COLLABORATIVE SESSION, SHARED ANNOTATION, SHARED BROWSING, SHARED EDITING, and SHARED FILE REPOSITORY are patterns applicable to the Social Web context. It would be interesting to investigate the impact on the quality of collaboration and the quality of social (groupware) software that make use of these patterns. Finally, the design of Social Web applications typically corresponds to the PUBLISH-SUBSCRIBE architectural pattern.

The Convergence of the Social Web and the Semantic Web: Implications for Patterns

The Semantic Web has recently emerged as another perceived extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning (Hendler, Lassila, & Berners-Lee, 2001). The Social Web efforts and the Semantic Web initiative are not competing but complementing, and need to co-exist. For the sustainability of the architecture of the Web, it is essential that the extensions of the Web evolve harmonically (Shadbolt, Hall, & Berners-Lee, 2006). For a unified view, the Social Web-specific efforts will need to take advantage of formalization (and thereby become more machine-oriented) and the Semantic Web-specific efforts will need to become more human-centric. This can be crucial for a future generation of PMS.

It would therefore be of interest to examine the synergies between the Semantic Web and the Social Web efforts, or as it is more commonly referred to by the pseudonym Web 3.0 (Lassila & Hendler, 2007), from the viewpoint of benefits

Figure 7. The symbiotic relationship between patterns and the Social Web



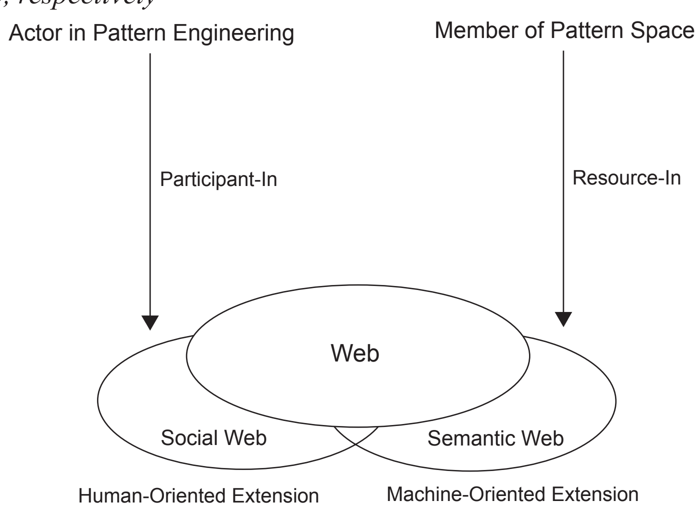
and concerns to patterns. This, as the Figure 8 illustrates, is all the more significant since the actors in PE are participants in the Social Web and the members of the pattern space are resources in the Semantic Web.

Indeed, there are an increasing number of initiatives (Mika, 2007) that belong to the intersection of the Semantic Web and the Social Web, some of which may be relevant to PE. The Friend of a Friend (FOAF) and RELATIONSHIP are both Resource Description Framework (RDF) vocabularies: FOAF is used for expressing metadata about people, and their interests, relationships between them, the things they create, and activities they are involved in; RELATIONSHIP enriches FOAF by extending the types of relationships between people. As an example, the following is a combination of FOAF and RELATIONSHIP markup that represents the Myers-Briggs Type Indicator (MBTI) (Keirsey, 1998) of the shepherd John Smith and the relationship between John Smith and the author Steven Nash:

```
<?xml version="1.0" encoding="UTF-8"?>
<rdf:RDF
    xmlns:rdf="http://www.w3.org/1999/02/22-
     rdf-syntax-ns#"
  xmlns:foaf="http://xmlns.com/foaf/0.1/"
 xmlns:rel="http://purl.org/vocab/relation-
    ship/">
  <foaf:Person>
    <foaf:name>John Smith</foaf:name>
     <foaf:mbox rdf:resource="mailto:john.
    smith@john.smith.ca"/>
          <foaf:myersBriggs>ESTJ</
    foaf:myersBriggs>
    <foaf:knows>
      <foaf:Person>
        <foaf:name>Steven Nash</foaf:name>
      </foaf:Person>
    </foaf:knows>
    <rel:mentorOf>
      <foaf:Person>
        <foaf:name>Steven Nash</foaf:name>
      </foaf:Person>
    </rel:mentorOf>
  </foaf:Person>
</rdf:RDF>
```

The limitations of these vocabularies are evident as they do not represent precise relationships among actors of patterns. For example, the `mentorOf` element is only an approximation to a shepherd.

Figure 8. The actors in PE and the members of the pattern space belong to the human and machine extensions of the Web, respectively



The notion of an ontology perhaps forms one of the most important layers in the Semantic Web architecture. A formal representation of a pattern language as an ontology in the Web Ontology Language (OWL) enables better opportunities for organization and inferencing than that is possible by conventional means (Kamthan & Pai, 2006b). For example, an ontological representation of a pattern language allows making the implicit relationships between patterns explicit, which can complement [3] of PRP. However, the focus in this study is on technical rather than on social aspects. The aforementioned means of social collaboration could be useful towards ontology engineering of patterns, which is conducted in a social context (Gruber, 2004) and requires a considerate human effort to reach a consensus. These ontologies could be enriched by more knowledge about the actors. For example, the Semantically-Interlinked Online Communities (SIOC) Project aims to use Semantic Web technologies to connect people using different (Social) Web applications (like e-mail, blog or Wiki). The SIOC Core Ontology Specification explicitly uses RDF, OWL, and FOAF.

The other possibilities for a confluence between the patterns, the Semantic Web, and the Social Web from a research viewpoint are: a pattern language map in SVG could be generated from an OWL ontology and annotated with pattern reader-oriented tags to make it amenable to the tools for the Social Web; the FOAF – XFN and FOAF – hCard microformat connections from the perspective of an ontology of pattern language could be further exploited; the places where an ontology falls short could be compensated by the creation of a microformat for representation of patterns in XHTML; the implications of Semantic Wikis on communication of patterns from an ontological viewpoint could be examined; and so on.

Patterns on the Mobile Social Web

It would perhaps not be an overstatement to suggest that in the last few years the ability to access the Web via a wireless device has been remarkably successful (Stanoevska-Slabeva, 2003). The potential of mobile access to the Social Web has evidently inspired the notion of Mobile Social Web, or more commonly known by the pseudonym Mobile Web 2.0 (Jaokar, 2006; Golding, 2008).

Due to the inherent constraints of both hardware and software (Tarasewich, 2003), it is unlikely that the Mobile Social Web could ever become 'de facto' environment for communicating the elements of PE. However, it could still serve as a means to facilitate collaboration in the PRP, in particular that of patlets, pattern thumbnails, and small pattern language maps, and for syndication. Further exploration of the interplay between patterns and the Mobile Social Web, particularly from the viewpoint of an extension to Figure 7, would be of interest.

Extending the Scope of SW4PE

The arguments presented in this paper accentuating the prospects versus highlighting the concerns of communicating the elements of PE via the Social Web are not exclusive. They could apply to other members of the pattern space as well as to other similar situations. For instance, as the number of anti-patterns grows, assessing the viability of the Social Web in communicating anti-patterns would be worth investigating.

The world of patterns is not secluded from other entities of knowledge. Indeed, software design patterns are related to (in the sense that they are influenced by or influence), for example, aspects, software engineering principles, Application Programming Interfaces (APIs), and software frameworks (Garzas & Piattini, 2005). The Social Web has potential benefits for these other entities of knowledge that are related to patterns and, in doing, so would benefit patterns indirectly. The same applies to the relationships between software patterns and other reusable software artifacts such as those identified in the Zachman Framework for Enterprise Architecture (Zachman, 1987).

There are various knowledge areas in the Guide to the Software Engineering Body of Knowledge (SWEBOK) and the Software Engineering Education Knowledge (SEEK) that require human-to-human communication. Further studies on topics, such as, integrating Social Web technologies/applications in requirements engineering (Macaulay, 1993), collaborative conceptual modeling, or in a socio-constructivist approach to software engineering education in general and in a collaborative approach to open source course projects in particular (Kamthan, 2007), would also be of research interest.

CONCLUSION

The creation and transfer of knowledge that occurs in PE rests strongly on human-to-human communication. This human-orientation needs to be acknowledged explicitly, and the Social Web provides an open and global environment for doing so.

The Social Web opens new vistas for the actors of patterns and indeed for the PRP itself. It celebrates a critical feasibility issue facing the pattern producers—that the number of pattern producers is less than the number of pattern consumers, and due to practical limitations on resources (in terms of time and effort) to dedicate, can not realistically be expected to explicitly document every possible view of patterns—a resolution to which results from the ‘collective intelligence’ of the pattern consumers. This, however, is not free of cost.

It is likely that by appropriate use of technologies/applications, some of the concerns outlined in this paper can at least be avoided if not entirely eliminated. It should, however, be noted that although certain limitations of the Social Web as it pertains to communication of patterns are transient, others are more fundamental.

The potential benefits of the Social Web can outweigh the costs in the long-term if the expectations are realistic and if an effort is made to address the associated concerns. If the past experience with the use of the Internet and the Web is any indicator, the movement has traditionally been towards flexibility, usability, and universality. The success between the interplay of patterns and the Social Web is likely to depend on these invariant values.

In conclusion, the shared benefits of any socialization for the purpose of communication of patterns can only come to fruition with the *shared* sense of accountability and responsibility on part of all actors. This can come only with coordination between pattern producers and pattern consumers. Therefore, an optimistic but cautious use of the Social Web is an imperative.

ACKNOWLEDGMENT

The author would like to thank the reviewers for their feedback and suggestions for improvement.

Chapter 2.11
A Framework Describing the Relationships among Social Technologies and Social Capital Formation in Electronic Entrepreneurial Networking

Kelly Burke
University of Hawaii at Hilo, USA

Jerry M. Calton
University of Hawaii at Hilo, USA

ABSTRACT

E-commerce technologies—including online exchanges—focus heavily on transaction support. They are designed primarily to reduce transaction costs between suppliers, producers, distributors, and customers. Entrepreneurs however are not likely to realize the full business potential of e-commerce unless the transaction technologies are simultaneously supported by technology-enabled social learning networks used to stimulate the formation of social capital in its three primary manifestations. Toward that end this article argues that a number of Internet-based social technologies (e.g., email, chat, blogs, wikis, podcasts, etc.) can be used more effectively when it is understood that each technology offers different characteristics in support of the formation of different dimensions of social capital. This article presents a conceptual framework describing the capacities of various social technologies for supporting the formation of social capital. A primary thrust of the article is that alignment of a social technology infrastructure with the social capital requirements in entrepreneurial communities will facilitate the formation of electronic learning networks, enabling more collaborative and therefore more successful entrepreneurial communities.

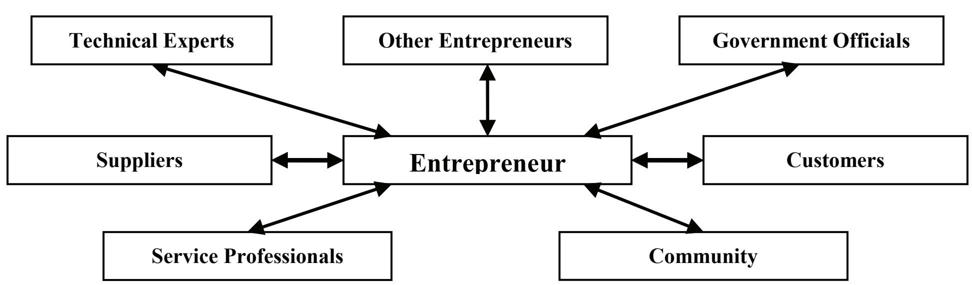
INTRODUCTION

A number of entrepreneurship theorists have suggested that community-based entrepreneurial infrastructures critically influence the development and support of existing, new, and growing small businesses. These infrastructures include: 1) assistance to the owners, 2) physical and monetary resources, 3) information, and 4) knowledge (e.g., Tan, Tan, & Young, 1997; Van de Ven, 1993). Of particular importance in the present study is the development of infrastructures to facilitate information and knowledge acquisition and sharing among entrepreneurs in support of their business objectives (Huysman & Wulf, 2006; Swan, Newell, Scarbrough, & Hislop, 1999). We consider the potential benefits various Internet-based social technologies (such as e-mail, chat/instant messaging, blogs, podcasts, and others) provide to entrepreneurial communities. We are especially interested in the potential role of information technology in facilitating the cogeneration and sharing of tacit knowledge or "know-how" associated with effective utilization of an e-commerce cooperative network. Figure 1 below presents a visual conceptualization of an entrepreneurial information resource environment.

Feedback from recent e-commerce workshops conducted by one of the authors suggests that even among entrepreneurs who currently use some of these technologies in support of business operations, many of them feel the need to learn more about current technologies before adopting them or expanding their use. Understanding the diffusion of information technologies in entrepreneurial communities requires awareness of how the participants come to know about and develop individual as well as shared understandings about these technological opportunities. Research has emphasized the importance of social networks in entrepreneurial development (e.g., Aldrich & Zimmer, 1986). Accordingly, this article takes a social network perspective in discussing technology adoption among participants in an entrepreneurial community.

In fact, the article applies multiple, but related, theoretical perspectives in describing the relationships among social technologies, social capital, and entrepreneurial networks. The framework draws from the following theoretical perspectives: entrepreneurship as a network phenomenon, social capital theory, and small business information systems (SBIS) use. The next section details the theories relied on in generating the framework, with particular attention to the dimensions of social capital. Following that, we describe the network and information requirements associated with each dimension of social capital. We then present the framework describing how the characteristics of various social technologies support each dimension of social capital. In the forth section, the article discusses the implications of the framework as it might be applied in support of social capital formation in an emerging entrepreneurial community. Finally, we conclude

Figure 1. Entrepreneurial information resource environment



with a discussion of issues for future research and conclusions.

BACKGROUND THEORY AND LITERATURE

Entrepreneurship as a Network Phenomenon

The Kauffman Foundation report (2005) notes that much of the entrepreneurship literature has tended to focus on individual attributes and intentions as explanatory factors for entrepreneurial success. The report called for closer attention to entrepreneurship as *organizational experimentation*, defined as "the development and implementation of a novel value-creation and value-capture system" (2005, p. 18). Thus, a network (electronic or otherwise) can be seen as one manifestation of an emergent "entrepreneurial infrastructure" supporting the acquisition and mobilization of resources, particularly new knowledge (Aldrich & Zimmer, 1986; Premaratne, 2002; Tan et al., 1997; Van de Ven, 1993).

Social Capital as a Network Phenomenon

In their study of venture creation, Liao and Welsh (2005) adopt Nahapiet and Ghoshal's (1998) view of social capital, which they define as "the sum of actual and potential resources embedded within, available through, and derived from the networks of relationships possessed by individual entrepreneurs" (2005, p. 348). This article employs Nahapiet and Ghoshal's three dimensions of social capital. Specifically, this article discusses how and why various social technologies support formation of the three types of social capital. The dimensions of social capital are *structural* (the pattern of interactions between actors), *relational* (development of trust and trustfulness), and *cognitive* (development of shared meanings as a basis for cooperation and joint learning).

Small Business Information Systems (SBIS) as a Network Phenomenon

Early research about small business information systems has focused primarily on the adoption of technology as a strategy for improving the internal efficiency of the firm. For example, Bergeron and Raymond (1992) developed a matrix for identifying strategic SBIS opportunities in small businesses, including performance forecasting, electronic data interchange with suppliers, computerized order entry, and marketing database applications, and for supporting such organizational activities as inventory control, receiving, production, accounting, distribution, pricing, and so forth. More recently, however, Levy, Powell, and Yetton (2001) maintain that SBIS have for too long been focused on operational efficiencies and suggest the need for a broader perspective in evaluating the application and success of SBIS. The current article views the value of an e-commerce system as a function of the resulting operating efficiencies in combination with the system's ability to facilitate knowledge acquisition and mobilization via social capital formation.

Communities of Practice as a Network Phenomenon

Steinfield (2004) and Ackerman and Halverson (2004), among others, argue that technology-based knowledge management systems need to incorporate social processes for *embedding* or *contextualizing* information, especially shared tacit/implicit insights about not only *know how*, but also *know who* and *know why*. Huysmann and Wulf (2006) go so far as to argue that electronic networks cannot survive without a corresponding and coexisting social network. Wenger (1998) suggests that members in a *community of practice* learn through participation in that community and that the boundaries of the community are determined by the task(s) the members share in common, the culture, and the history of the community. Members in the community share their understanding and expertise with other members, embedding knowledge in the network for later reuse and reconstruction as a resource in problem solving. Swan et al. (1999) characterize this new approach to knowledge management as a community networking model, envisioning a task-oriented community where knowledge is not so much processed as it is continuously recreated and reconstructed through dynamic, interactive, and social networking activity.

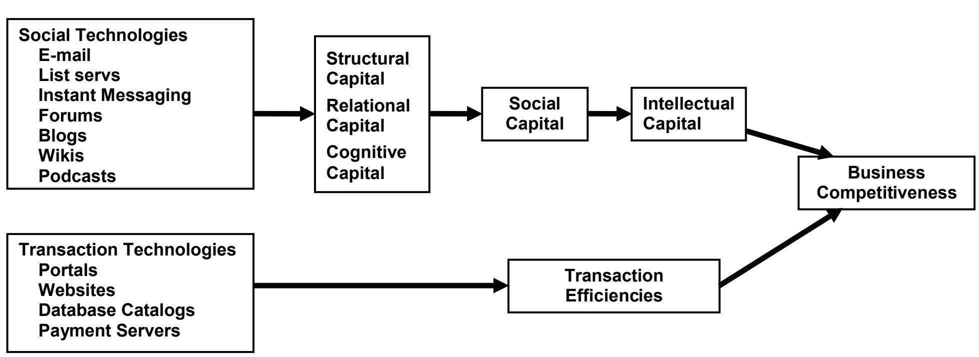
INTEGRATED THEORETICAL FRAMEWORK

The current study describes how characteristics of different social technologies can be seen to support the development of different aspects of social capital, permitting more (or less) effective entrepreneurial learning networks. This article extends the work of De Carolis and Saparito (2006) in arguing that the formation of different elements of social capital within entrepreneurial networks can also contribute to the building of stronger structural and relational ties while leveraging shared knowledge assets, rather than contributing primarily to unrealistic and destructive risk assessments of entrepreneurial opportunities. Such networks suggest the potential for a new business model of internet-based cooperative competition, referred to as coopetition by Brandenburger and Nalebuff (1996). Figure 2 below presents the theoretical model.

Small Business Information Systems (SBIS) Resources

As mentioned earlier, strategic organizational information technology issues have largely been seen from a transaction-based perspective. For example, Bergeron and Raymond (1992) present a matrix of information systems for competitive advantage (ISCAs) which referred to suppliers, competitors, and clients as targets of information used for strategic activities. Similarly, e-commerce has been seen from a transaction perspective. Researchers have described e-commerce business models as business-to-consumer (B2C), business-to-business (B2B), consumer-to-business (C2B), or consumer-to-consumer (C2C). For example, Bailey and Bakos (1997) categorize electronic markets into industrial (B2B) or consumer (B2C). This approach suggests that information management is critical to facilitate transactions between a firm and its buyers and suppliers. The transaction approach draws largely on the transaction cost theory of the firm, developed by organizational economists, such as Williamson (1985), to explain

Figure 2. Relationship among Internet technologies, social capital and business competitiveness



how internalizing market functions can help firms gain competitive cost advantage. E-commerce is used to internalize many types of business functions, including research, purchasing, sales, and distribution, that are often accomplished via intermediaries external to the firm. Focusing on transaction cost reduction, however, overlooks the value of learning from information flows, as well as other critical resources, within a network of associated parties in the business environment, particularly in an emergent, entrepreneurial setting.

A more inclusive view of the business information environment can be helpful in guiding entrepreneurs and other small business managers in implementing their business information strategies. Consider that in larger firms many information resource management functions are internalized. For example, larger firms often have entire departments developing and managing resources such as field and technical expertise (e.g., chemical or environmental advisors), or other business support services (e.g., finance, marketing, etc.). But for smaller businesses, often these resources must be acquired from sources external to the firm. Thus, small business information technology strategies need to find ways to manage and thereby leverage information flows among various external participants, considered as a resource-based (including knowledge) network.

In particular, we call attention to the need for small business information systems to incorporate and enable knowledge management as a dynamic strategic capability, one that may best be developed within an informal social network. Burton-Jones (1999) argues that the knowledge-based strategic benefits of informal small business networks include: (1) integration of tacit knowledge drawn from a variety of internal and external sources as part of an ad hoc problem solving effort; (2) improving the congruence of product-knowledge across the product line by trading surplus knowledge in one product area for new knowledge from network partners to overcome a knowledge deficit in a different area; (3) overcoming uncertainty by learning what it will need to know to remain competitive; (4) addressing timing issues related to overcoming uncertainty; and (5) repairing a "leaky" knowledge asset base by exchanging and mutually protecting shared productive knowledge assets. While the resource network includes the traditional participants, that is, suppliers and customers, it is important to also include in the network other participants in the information environment. For instance, entrepreneurs need to manage interactions and relationships with participants such as professionals offering supporting legal, financial, or other services, government agencies, technical or field experts, fellow entrepreneurs, and even competitors who come to recognize potential mutual benefits of growing markets by sharing product or market information (see again Figure 1). Extending network infrastructure to facilitate information flows among these various parties will significantly expand an entrepreneur's potential resource base, creating those strategic benefits described by Burton-Jones (1999).

The Role of Social Capital in Developing Entrepreneurial Networks

Social capital is required for the formation and mobilization of intellectual capital or knowledge for productive purposes (Nahapiet & Ghoshal, 1998). Social capital develops out of problem-based interactions among participants in a shared cognitive domain or community of practice. The shared problem (e.g., how to acquire and utilize resources needed to generate and sell one's product) triggers a search for ways to manage interdependent relationships between self (the firm) and others (the network). Social capital has the effect of contextualzing (i.e., giving meaning and credence to) resources, and particularly knowledge, within shared network linkages, relationships, and understandings so that these resources can be more effectively mobilized and utilized to achieve complementary objectives. Huysman and Wulf (2006) contrast human capital, which highlights individual ability with social capital, which refers to collective abilities derived from social networks. Social capital typically is expressed in three dimensions: structural, relational, and cognitive (Nahapiet & Ghoshal, 1998). In support of intellectual capital, social capital helps create structural opportunities, a relational motivation to share knowledge, and a cognitive ability to jointly develop and apply shared knowledge to solve problems within a socially embedded context. Social capital is a dynamic asset that will wither and die in the absence of continual social reinvestment by network participants. One result of social capital is that participants see the return value and become committed to developing and sustaining cooperative, nonopportunistic interaction within the community of practice.

Structural capital is the capacity to access and develop information, knowledge, and other resources that are essential to business operations. In practice, structural capital is defined by the patterns of connections or linkages among participants in an entrepreneurial network. These patterns are described by the number (density) and variety (diversity or multiplicity) of connections. Density is a measure of the location and number of ties in a network. Diversity is a measure of the variety of expertise possessed by members of the network. Connections can also be either direct, as in one-to-one exchanges, or indirect, as in broadcast-type interactions. Broadcasting increases density and yields diversity. Granovetter (1973) characterizes "strong ties" as exhibiting more density, being more direct, being low in diversity, and exhibiting high solidarity. In contrast, "weak ties" are more diverse and indirect. Both kinds of ties are important in developing and mobilizing knowledge assets. Strong ties reflect shared insights and commitment to common knowledge; weak ties tend to serve as sources of new information, promoting knowledge acquisition and strategic adaptation.

Where structural capital relates to the patterns of relationships among participants, relational capital is defined more by the affective or emotional quality of the connections themselves. Relational capital concerns the willingness of participants to share information, knowledge, and support based on a converging sense of shared identity (of both self and other) and purpose. As respect and trust increase, the parties will be more likely to share knowledge, especially tacit knowledge.

Finally, cognitive capital is described as those resources that provide shared understandings via mutually accepted representations, interpretations, and systems of meaning among parties to an interaction (Nahapiet & Ghoshal, 1998). In other words, to the extent that people can cognitively connect with each other, they understand the meaning intended by others during communication. Orlikowski and Yates (1994) argue that this sort of sense-making occurs when effective use is made of shared stories, language, and communication regimes. Use of multiple-cue modes of communication can assist in conveying meaning, for instance, when showing a person a photograph of the damage to a plant while describing a plant pathogen. Huysman and Wulf (2006) conclude that media characteristics, for example bandwidth, must be appropriately matched to the communication requirements to support such interaction. When explicit knowledge transfer is required, such as a listing of product prices, an e-mail message or a Web page can suffice. When more complex tacit knowledge needs to be shared, for example when soliciting members' feelings about the trustworthiness of a supplier, more complex forms of interaction (e.g., a telephone conference call) will be more effective.

It is often the case however that none of these three dimensions is sufficient in itself for generating social capital. To gather usable knowledge in one's business network, an entrepreneur must be able to tap into all three forms of social capital.

Structural capital is critical. The entrepreneur must be able to interact easily, and sometimes spontaneously, with people in various areas of expertise: He or she must have a number and variety of network connections. Merely having the opportunity to interact, however, is not sufficient to ensure knowledge sharing and joint learning. One also needs to be able to trust the source of the information before it can be transformed into useful knowledge. Trust allows one to be confident that the provider of the information, and therefore the information itself, is reliable. Trust is the essence of relational capital. Nor is it sufficient to possess just a connection to and trust in the information. It is also critical that both parties to an exchange share similar meanings and understandings about the content as well as the implications for use of the shared information, especially when the interaction is complex, consisting of a series of related and ongoing exchanges. Hence, to generate usable social capital, technology must be designed to support all three aspects of social capital.

Social Technologies in Support of Social Capital Formation

Designing effective infrastructure in support of social capital formation requires matching the characteristics of the social technologies with the network and information requirements inherent in the three forms of social capital. To identify appropriate match-ups, in the next few paragraphs we explain the network/information requirements for each of the forms of capital. The discussion clarifies the relationship of capital requirements to technology characteristics by giving some examples of relevant characteristics for some technologies relative to specific network/information requirements. Following that we present a table that lists a variety of social technologies, the relevant characteristics of each, and its general performance fit for supporting each dimension social capital.

Structural capital relative to a social technology relates to the number of nodes made accessible in a network (density). Also important structurally is the ability of the technology to service connections with participants from varying interest areas (diversity). For instance, list-servs, discussion forums, blogs, and even podcasts tend to coalesce around common topics, and are therefore more homogenous than e-mail, which allows people to target receivers from a variety of interests. Finally, structural capital includes connection directness. Directness refers to whether the information can be directed to an individual or specific group of individuals (as with e-mail and e-mail lists) or if the information is relayed to people indirectly, including people not intentionally targeted by the source. For our purposes, indirectness can include information that is passed along, but we also include situations where information is broadcast, with the sender not knowing who the particular recipients will be.

Relational capital for a social technology relates to how it fosters feelings of trust and shared identity among network participants. Trust is developed through cooperative interactions over time. Thus, the level of *interactivity* supported by a technology will affect the level of trust. Generally, a technology that allows a person to respond to a specific exchange can be said to facilitate interaction more than a technology that allows less responsiveness. Similarly, a technology that permits immediate responses is more interactive than one that tends to delay responses. This notion of interactivity, including responsiveness and delay, as a characteristic of technology is rooted in Media Richness theory (Daft & Lengel, 1986). Accordingly, a technology that permits specific responses and allows for minimal delays between exchanges (e.g., instant messaging) is more interactive than a technology that permits responses but exhibits longer delays (e.g., e-mail), which is in turn more interactive than a technology that permits no response at all (e.g., podcasts). Relational capital also consists of what we term *collectivity*. Nahapiet and Ghoshal (1999) argue that in addition to trust, relational capital also depends on a sense of identity among participants and a sense of belonging to the group, leading to a belief in the benefits brought to its participants. Technologies can be seen in terms of how well they foster group belonging. For example, instant messaging sessions are very limited in the size of the group allowed to participate, while wikis permit participation by very large groups of individuals. We call this characteristic the *collectivity* of the technology.

Cognitive capital consists of the capacity to share multiple languages and vocabularies, or what Nahapiet and Ghoshal (1998) refer to as shared codes. Differing codes may be generated via various modes of communication. For instance, nonverbal communication can be used to enhance the communication of a verbal message. We refer to this characteristic as cue multiplicity, that is, the capacity for a technology to transmit more than one type of communication cue simultaneously. A second component of cognitive capital regards the sharing of narratives (Nahapiet & Ghoshal, 1998). Narratives are stories whose historical context provides meaning to contemporary interactions. In examining technology-related aspects of cognitive capital we appeal to the notion of "personal focus" as posited by the social presence theory (Short, Williams, & Christie, 1976) in conjunction with the speed of responsiveness a technology exhibits, as suggested by the media richness theory (Daft & Lengel, 1986). Richer media carry more types of cues simultaneously, allowing for greater perceived salience by the receiver, a form of personal focus. For example, e-mail allows the sender to target a specific individual while also allowing the attachment of images and graphics. This capacity to convey correspondingly more communication cues results in the potential for a more personally focused and hence more interactive exchange than typically occurs in a blog. The level of contextualization support provided by information technologies has been shown to determine the level of knowledge development in virtual teams (Majchrzak, Malhotra, & John, 2005). Contextualization is provided by offering participants information repositories, identities of contributing members, historical links between contributions, multiplicity of media (e.g., accompanying messages with pictures of the sender), and other sorts of informational enhancements. Thus, the availability of various social technologies can provide different contextualizing opportunities for participants in the network, depending on the participants' needs.

Table 1 illustrates the conceptualization of each technology's capacity to support the formation of social capital. The Internet technologies listed in Table 1 were presented as "conversational technologies" in a discussion by Green and Pearson (2005) of social software and its relationship to the development of strong and weak relational ties.

The forgoing discussion suggests that the physical characteristics of the Internet technologies do not necessarily function as resources in isolation. Rather, they tend to interact, working together to provide different forms of capital. For example, a technology that permits the use of several media (i.e., cue multiplicity) may facilitate shared meanings (cognitive capital), and because of the potential for greater personal focus, can simultaneously facilitate shared trust (relational capital). In other words, technologies and their attendant characteristics work in combination to support various aspects of social capital formation.

It is important to note that, while Table 1 describes specific capacity characteristics exhibited by various social technologies, the reality is that a technology may be appropriated in various ways, some expected and some unexpected. A technology may provide more or less capacity for a specific social capital than described by the current framework, depending on how it is actually used. In practice, the framework should be considered from a contingency perspective. For instance, according to the table, typical one-to-one e-mail

Table 1. The capacities of social technologies for developing social capital

Technology	Dimensions of Social Capital						
	Structural (shared linkages)			Relational (shared trust)		Cognitive (shared meanings)	
	Density	**Diversity**	**Directness**	**Interactivity**	**Collectivity**	**Cue Multiplicity**	**Interaction History**
Email	Low	High	Direct/ Indirect	Med	Low	Med-High	High
List-Servers	Medium	Low	Indirect	Low	Med-High	Medium	Medium
Chat / IM	Low	Low	Direct	Med-High	Low	Med-High	Low
Forums	High	Low-Med	Indirect	Med	High	Med-High	High
Blogs	High	Low-Med	Indirect	Med	High	Med-High	High
Wikis	High	Low	Indirect	Low	High	Low	High
Podcasts	High	Low	Indirect	Low	High	Low	Medium

use exhibits a moderate degree of interactivity and a low degree of collectivity, suggesting that e-mail would normally not be ideal for developing relational trust, which requires high levels of interactivity and collectivity. In some situations, however, e-mail can support greater degrees of interactivity (e.g., when responding immediately to messages received while online) and collectivity (e.g., forwarding messages to a special-interest distribution list). Consequently, in some contexts e-mail can facilitate trust development to some degree. In this respect, Carlson and Zmud (1999) argue that, rather than being fixed in nature, a technology's capacity is really dynamic, and its use can sometimes result in capacity enhancement, what they refer to as *channel expansion*.

In addition to the potential for technologies being used differently in different contexts, it is also possible for a specific characteristic of a technology to result in different outcomes when used in different circumstances. For instance, the model presented here argues a positive relationship between interactivity and trust development: A technology that allows relatively more interactivity (e.g., instant messaging) has the capacity to facilitate trust development more than a less interactive technology. In a highly contentious context, however, more interactivity could allow the exchange of more negative communications. In other words, it is not the technology itself that develops trust; rather it is the way in which the network members use the technology that results in more or less trust being developed.

Aligning Social Technologies to Social Capital Requirements

At this point a brief discussion examining several of the technologies with regard to their capacities for social capital formation might help the reader toward understanding the rationale for the assessments presented in Table 1. *E-mail*: as typically used is one-to-one resulting in low density; allows connections among a variety of participants, rating high in diversity; allows both direct exchanges and, through forwarding, indirect ones; allows pointed responses but with delayed timing, making it moderately interactive; connects one-to-one or small groups making it low in collectivity; allows transmittal of text, images, and even videos resulting in high multiplicity; and finally, by permitting the archiving of exchanges, its historical capacity allows substantial contextualization.
