- **What you post may affect your future.** There is a growing trend for employers to check Google and social networks to gather information about potential candidates. The online persona you create today may be available when you begin your internship or full-time job search or when you apply to professional or graduate school—even if you think you've deleted it. Carefully consider how you want people to perceive you before you give them the chance to misinterpret your profile and pictures.

As Lombardi describes, the career center's approach is "…to warn students that what they post is available for everyone to see so they should make sure they are presenting themselves in a way that won't damage their image. We found that most students are posting pictures and using language that they probably won't want a potential employer to see." She also said that while Duke University does not offer student workshops solely on the topic of online social networking, the topic is integrated into other workshops associated with recruiting, orientation, résumé and cover letters, and interviewing. Or, as she put it, it's discussed "…anytime we have a captive audience."

Lombardi's legal and ethical concern over online social networking centers on the issue of privacy. She cites a NACE Spotlight Online June 2006 article posted on the Duke University career center's Web site, an article showcasing the ethical issues surrounding the privacy of profile pages. The article describes a young man searching for an internship and, wanting to showcase himself in the most positive light; he recognized that many of the photographs and much of the language on his profile jeopardized this. He heeded advice to limit access to his profile. During an interview, he was surprised to be questioned about specific references to his Facebook account and the information posted on it. He did not think this information could be viewed to outsiders because he had limited his privacy settings. The interviewer explained that working for a state agency meant recruiters could access his Facebook account under the rules of the Patriot Act.

While some students vehemently oppose this seeming intrusion, others do not see their peers as victims in these circumstances. College student Lindsey Holder said, "People shouldn't be so naïve as to think that the Internet is private. I don't think people would see any problem with a job candidate not being hired because he has his own public access show that showcases his weekend binges, so why is it any different that he has devoted his own online profile to do the same? I understand that not everything that gets posted, photos in particular, can be controlled, but these businesses are putting their public faces on the line. I think they are entitled to feel confident that their new employees are representing them in the best light."

College student Sarah Powell agrees. "I think that it is a good idea to have employers look at student profiles. If I were an employer, I would not want to hire a student who parties and gets drunk all the time. That to me shows a lack of maturity. If a student does not want certain information seen or revealed to people, then it shouldn't be placed on the Web."

Rights and Responsibilities

Information gleaned from online profiles is not only used by off-campus employers, but extends to on-campus experiential education situations. Lowe Schneider of Hanover College said that she and her staff view Facebook pages when a student applies to be an orientation leader. "Particularly since these students are to be role models in our community, it's important to see what messages are out there," she said.

The ethical and legal issues associated with online social networking are a prevalent theme of discussion among the student life staff at Hanover College. There are First Amendment considerations to ensure students have the freedom to express themselves. But when that expression infringes on the rights and privacy of others, what are the results? Lowe Schneider offered a recent example of when a student posted pictures from a party on his Facebook page, and one of the pictures included a prominent female student leader violating the College's alcohol policy. The student asked her peer to take down the photograph and he refused. "So whose rights are more important here and how does the college judicial system intervene?" Lowe Schneider ponders.

Derek Morgan (personal communication, June 7, 2007) has served as a director of student activities for four years at the Colorado School of Mines. He works with all student organizations, Greek life, orientation programs, student government and campus programming. Several members of his student life staff have personal Facebook accounts and use the accounts to invite students to campus events. The accounts are also used as a vehicle to connect with students, view group pages, and share photographs from recent events. Morgan considers online social networking to be similar to cell phones and e-mail, all valuable mediums to communicate with others. “Online social networks are just another way to efficiently and effectively communicate with each other,” he said. “They are an instant way to communicate.”

Morgan said his school initially had a few Facebook groups such as the Intramural Sports office group and the Outdoor Recreation Center group that are no longer in existence. According to Morgan, a Facebook representative called the School to explain that offices and departments could not have accounts. To comply, the School now simply makes announcements about events through the personal pages of directors and other administrators. A Facebook group that remains active is the Mines Activity Council programming board group for the school. The group administrators update the account weekly, making announcements about upcoming events and submitting pictures from previous events to the group’s 162 members.

Morgan believes online social networking groups can be particularly helpful for first-year students, through the creation of orientation groups, residence hall groups, and other interest groups designed with the first-time student or transferring student in mind. He stated it would be hard to prove retention is positively impacted by online social networking, but noted, “Students that participate in the networks probably feel better about their experience and more involved with their campus community.”

Like Lombardi at Duke University, Morgan sees privacy issues as a concern. “There is the debate whether pictures on Facebook or MySpace can and should be used in disciplinary cases,” he said. “Student groups advertising illegal activities or things that violate school policy could be an issue, like fraternity pages showing pictures of hazing activities or underage drinking.”

Ethically, he sees even more challenges facing student affairs professionals. He raises two important questions: 1) As an advisor of student organizations, how far do I go to make sure all students’ Facebook pages are free of negative pictures and comments? 2) Does the school have an obligation to control content when a student has a page based on his or her enrollment in the school?

Linguistic Fantasy or Reality

Those higher education administrators interviewed for this chapter expressed concern over the issue of privacy and the type of personal information students are divulging on profile pages. After conducting interviews with students, an interesting commonality began to emerge. They too were concerned about privacy, but from a different vantage point. Students are concerned with privacy invasion, but mainly because they fear unseasoned online social networkers will not be able to distinguish between the real person behind the fantasy profile. With more than 100 million profiles on MySpace alone, students are working hard to be bold, unique and stand out in any way possible (Pospisil, 2006). Students see online social networking as their time for play, for fantasy. As college student Lauren Trisler said, “I’m not the same person on my profile as I am in real life.”

College student Danny Pfrank echoed this sentiment and added that he sees online social networking as a stage-specific endeavor. “Facebook and other online social networks always seemed to me as something you do throughout high school and college and then you get rid of as soon as you are in the ‘real world.’”

Perhaps his thinking stems from the fact that many elements of non-professional behavior can be found within the OSN realm. It is not only discussions of drunken debauchery or risqué photographs found within personal profiles. Facebook has a clipart gallery of "gifts" that can be purchased and sent to another member for $1 each. It is a clever concept, with many of the 160-plus gifts seemingly designed with sophomoric humor in mind. Imagine clipart gifts including jock straps, pacifiers, a screw, handcuffs, bikinis, a thong, and a roll of toilet paper.

There are also groups that could make a conservative college or university official cringe. An article in *The Boston Globe* in 2005 (Schweitzer) details students discussing on their Facebook sites their use of marijuana and a desire to have sex with certain university professors, with the group titled *my goal in College is to fuck a professor*. Group names are often created using edgy or offensive language. A ten-minute search of group sites around the nation in June 2007 brought up a unique sampling:

- I Hate When I Cheat off a smart person test and I still Flunk with 468 members
- Hey, President Brogan: WE WANT OUR $577,950 BACK! with 229 members
- B+?! F*ck you, Professor…Just give me the A- with 91 members
- Anti-America with 52 members
- Al Qaeda Terrorist and Anti Liberal Network with 44 members
- ANTI Hilary Clinton for president '08 with 59,873 members
- Actually Mr. Bush, you're an idiot with 3,456 members
- Petition against Professor Stephen Kaufman with 548 members

Whether these groups make a person squirm in discomfort, laugh, or simply be content knowing we live in a society of free expression, a challenge arises when a person is linked to an unintended group based on another affiliation or friend. It is common for students to realize all too late that they are associated with a group without having directly chosen to do so.

Tracy Mitrano, director of IT policy at Cornell University, has written several thoughtful pieces detailing how caution should be exercised when using online social networks. One of these, appropriately titled *Thoughts on* Facebook (Mitrano, 2006), discusses how what may seem appropriately funny as a teenager could be embarrassing or even disastrous as an individual gets older. Her example details a young man proud of his well-endowed anatomy, and how he boasted of this fact in an online chat room.

Years later, after being turned down from a job he really wanted, he found out the reason. The potential employer had found this information on the Internet, and the topic was deemed unprofessional enough to warrant a reason for not selecting the individual for the job. The young man requested the information be removed from the original site, but he was told that it was not possible since a commercial Internet Service Provider (ISP) was the domain of his posted information. It was an issue of caching, which in oversimplified terms is the storage of Web files for later use. Caching, as Mitrano explains, "…means that if you post something on Facebook, let's say for a day or two, just to be funny or to make a point, even if you take it down or change it, it remains accessible to the rest of the world on the Internet anyway (Mitrano, 2006)."

Implications for Administrators

How long all this information will be accessible is anyone's guess, but diffusion theory may help reveal the rate that OSN can be expected to continue its emergence as a critical influencer on students and administrators. This theory helps determine the rate of diffusion of a technological innovation, as well as assists in identifying the variables that may encourage or impede the acceptance or adoption of the technology by a community of people.

Diffusion theory is grounded in the idea that adopters make voluntary decisions to either accept or reject a technological innovation based on the expected benefits from independent use. In IT diffusion it should be noted that the adoption may be encouraged or required by management as opposed to being determined by independent use. This encouragement or mandate may influence whether adoption by a critical mass has been established (Katz & Shapiro, 1986). Achieving critical mass with a community of users is crucial. If critical mass is achieved, the innovation is likely to be universally adopted and, if not, the technology is typically abandoned (Markus, 1987).

Those higher education administrators surveyed for this chapter were in consensus that while they felt a critical mass of prospective students and current students use OSN, how the technology will ultimately be used for recruitment and retention purposes is still evolving. Online social networking may be considered an innovation that has progressed through the stages of diffusion in what is considered an extremely short timeframe as compared to the time most technological innovations move through the process. The stages of diffusion according to the innovation decision process theory (Rogers, 1995) are knowledge, persuasion, decision, implementation, and confirmation, and the stages of IT implementation include initiation, adoption, adaptation, acceptance, routinization, and infusion (Kwon & Zmud, 1987). Online social networking has moved through knowledge to confirmation, and from initiation to infusion, for a critical mass in only a few years. Facebook helped ensure IT diffusion to a critical mass by offering its site to more than just students. Through open enrollment, a domino effect is created so that the site becomes increasingly compelling as more people, and more connections, are made.

Not only are these connections compelling from a social standpoint, but online social networking sites could be one of the most effective ways to engage today's students and to strengthen their bonds to the university in a way that improves enrollment, increases retention, and establishes the foundation for strong and committed alumni relations. With such a new forum, at least in comparison to enrollment and communication strategies that have been utilized for decades, it is important for administrators to consider the issues and implications of using online social networks to communicate. Specifically, college and university administrators should consider:

- Creating strategic plans to communicate with prospective students as well as ongoing correspondence upon admittance. High school students make decisions about what college to attend based on a myriad of factors, including Web sites, campus visits, discipline offerings, cost, location, and friends and family. College and university administrators should not underestimate the power of online social networking sites that promote and highlight campus features. Even more, online social networks can help prospective students feel socially accepted even before participating in a campus visit. As part of a comprehensive e-recruiting campaign, online social networks are a relatively inexpensive and efficient way to communicate.
- Developing workshops on the topic of online social networking. While most everyone involved in academia is used to hearing and reading about safety issues related to OSN, many unexplored areas of this particular form of social media exist. Students can benefit from learning how best to utilize online social networking sites to gain a feel for campus culture. For example, a discussion could occur as to what OSN groups exist to promote weeknight or weekend happenings to help the student feel connected. Offering training or information-based workshops during orientation sessions may be useful, but incorporating them into discussions throughout

the year is ideal. Some students have reported feeling overwhelmed by the amount of time they spend on OSN sites (Currie, 2007), almost as an addiction, and discussions of how to healthily and effectively enjoy OSN may prove valuable.

- Extending these workshops to faculty and administrators. Many faculty and administrators are intimidated by online social networking sites and are unsure of how, if at all, to access and utilize groups and sites. Most online technology discussions revolve around how to impact learning. But the critical examination of "extended learning" outside the classroom should be a topic as well. A panel of faculty and staff can help colleagues brainstorm the social media and academic link, offering definition to an often gray area of what is appropriate. Workshops can also help faculty and administrators gain an appreciation of OSN as a way to reach students about departmental clubs, research or campus-related interests. OSN sites are not designed as educational tools, but they can be immensely effective in communicating to students about academic-related information.
- Writing an official policy. Official policies on online social networking practices are becoming more prevalent at colleges and universities. Cornell University offers an extensive policy, including information about *why* policies, safety measures, and self-responsibility are important. Roger Williams University has an online social networking and blogging policy dedicated to employees. The policy requires employees to consult with their dean for approval before accessing an online social network when using a university e-mail account (Roger Williams University, 2007). For those college and university administrators uncomfortable with an official policy or statement that may infringe or stifle First Amendment rights, it remains a helpful exercise to review other college or university policies. These discussions can be informative and useful as college administrators determine the level, if any, of involvement a campus has with social networks.
- Promoting organizational clubs, organizations, social gatherings or other events through online social networking sites. At Eastern Illinois University, peer educators are finding success in using Facebook to actively encourage the idea of a smoke-free campus (Currie, 2007). Groups at other colleges and universities show a strong online presence through Facebook groups touting minority tolerance and diversity acceptance, residence hall rules, science clubs, and pre-professional associations.
- Targeting special-interest groups such as student-athletes, transfer students or parents. Public relations efforts geared toward niche audiences can be effective but costly. Online social networks make it feasible to reach targeted segments or publics with personalized information, something enrollment experts say is critical in today's highly technological and competitive environment (Noel-Levitz, 2006).
- Coordinating meetings with high school teachers, principals, guidance counselors, students, and university administrators on the subject of OSN. The majority of college attendees enter directly from high school. Collaborative efforts between high school and college administrators can only strengthen understanding of the use, benefits, and concerns of communicating with students in today's high-technology environment. Particularly when it comes to high school-college transition issues, college administrators may benefit greatly by hearing perspectives from others. To be locked away in the proverbial ivory tower implies administrators may be out of touch

and unaware of the needs of Millenials. It behooves all educational administrators to gain a respect and understanding of social media.

CONCLUSION: CONNECTIVITY

This chapter details new findings regarding the use of online social networking sites by college and university administrators. It also presents a compilation of data and information in respect to many of the dominating issues surrounding online social networking, including legal issues, concerns over privacy, and how OSN may prove useful to bereaved college students. As with most topics, there are advantages and disadvantages. Online social networking is no exception. Groups and profiles exist that are fun, interesting, informative, entertaining, clever and repugnant.

Like it or not, communicating via online social networking sites is what millions of young people do each day. A market research study commissioned by MySpace, Isobar and Carat (Never Ending Friending, 2007) found a tie in the top two choices of what 15-34-year-olds would do if they had 15 minutes of time: they would either check out a social networking site or talk on their cell phone.

With approximately 90% participation among U.S. college undergraduate students, Facebook alone is transforming the way younger generations communicate (Ellison, Steinfeld, & Lampe, 2006). Institutions of higher education no longer have the luxury of serving as what Levitz and Noel (2000) refer to as "non-intrusive institutions," passively assuming students will value and be involved in their educational experience. University officials must analyze how best to use online social networks as proactive tools. As part of her College's Early Alert Team, Lowe Schneider views the Facebook pages of students struggling academically or socially. Oftentimes the profiles and postings can help her glean information about the source of the struggle or identify key support systems that might be effective to the individual student.

Most educators and university administrators agree that when student success is not left to chance, when institutions utilize all available tools to assist in encouraging and helping students, is when attrition rates are lowest. The earlier connectivity is established, the more likely a student will feel engaged to a particular college or university, and the more engaged or connected, the better chance the student has of successfully graduating. As Duke University administrator Lombardi said, students seek involvement as soon as they are accepted to a college or university, so participation in specialized online social networking groups helps them develop a community prior to arriving on campus.

Because of this connection, and the growing ethical and legal issues surrounding online social networking sites, many postsecondary institutions are electing to create and maintain their own online social networking architectural systems. Hanover College, Western Illinois University, Wilkes University, and others have campus online social networking systems available to users. The University of Alabama has further extended its networking initiatives to parents of first-year students with the development of *myBama Family Connection* (Santovec, 2006).

If nothing else, college administrators may find it imperative to take an active interest in online social networking sites for the time it is takes away from academic studies. Consider the online social networking group titled *When I Flunk Out of College, It's All* Facebook's Fault.

Chapter 4.16
Social Marketing in Healthcare

Manuel W. Mah
University of Calgary, Canada

ABSTRACT

Social marketing is a way to influence the behaviors of stakeholders in the healthcare system. This chapter will define the traditional transaction marketing concepts of exchange, segmentation, competition, the marketing mix, and audience orientation. Then it will describe the current paradigm shift to relationship marketing with its logic of collaboration and the cocreation of value. Relationship marketing is enhanced by the arrival of Internet-based "social media" such as blogs, file sharing sites, and social networking sites that place creativity and communication channels under "audience" control. These developments in marketing strategy and social software will profoundly affect the next generation of social marketing programs.

DEFINITION AND DOMAIN OF SOCIAL MARKETING

Social marketing is defined as "the use of marketing principles and techniques to influence a target audience to voluntarily accept, reject, modify, or abandon a behavior for the benefit of individuals, groups, or society as a whole" (Kotler, Roberto, & Lee, 2002). In reality, the social marketing field relies on more than mainstream marketing for its theory and practice; it also borrows insights from health education, communications theory, anthropology, and social psychology. Nonetheless, social marketing's primary reliance on commercial sector marketing is beneficial because the latter is "one of the most impactful and constantly evolving forces for social change in the world" (Andreasen, 2006).

The preceding definition of social marketing reveals four motivations of social marketers. First, the focus on a *target audience* (defined below) enhances program effectiveness and efficiency. Second, the goal of changing *behavior* rather than awareness or attitudes differentiates it from education. Third, the desire to advance the welfare of *society* rather than earn profits distinguishes social marketing from its commercial counterpart. Finally, the decision to stimulate v*oluntary* behavior change contrasts with law enforcement.

Education may be characterized as a "libertarian" approach to social change that informs people of the long-term benefits of a behavior but offers no prospect of short-term rewards or punishment

DOI: 10.4018/978-1-60566-356-2.ch041

(Rothschild, 1999). Since education involves neither coercion nor immediate rewards, it maximizes individual human freedom to make behavioral choices. However, an educational approach also creates externalities or costs to other parties who may not have agreed to bear them. For example, individuals who choose to smoke cigarettes may create a health hazard in the form of second-hand smoke for others around them. In contrast to education, law enforcement represents a "paternalistic" approach to social change in which people are coerced to comply through implied threats of punishment. Thus, law enforcement curtails individual freedom in order to reduce externality. In contrast to education and law enforcement, marketing may be viewed as the offering of free choice opportunities with incentives in a competitive environment, the offering of benefits that are so appealing as to be coercive and freedom-limiting, or the offering of behavioral opportunities that satisfy self-interest (Rothschild, 1999).

Social marketing is not the only means to social change, and it may not be the best choice for all social or behavioral issues. For example, marketing is inappropriate when a target audience requires basic education or a change in their values (Andreasen, 2006). On the other hand, marketing excels at addressing the lack of opportunity or ability to adhere to a desired behavior (Rothschild, 1999). Thus, the nature of the social issue dictates whether marketing should be used by itself, as a complement to other strategies, or not at all.

There is growing interest in the application of social marketing to medical education, health promotion, and national health strategy (David & Greer, 2001; McCarthy, 2003; Grier & Bryant, 2005; Hastings & McDermott, 2006). This interest parallels the market reform of healthcare manifested by the arrival of value-based healthcare competition; "pay-for-performance" programs; internet-based patient self-management; and the acceptance of joint responsibility for the production of health by the state, the private sector, the charity sector, and citizens (Porter & Olmsted Teisberg, 2007; Petersen, Woodward, Urech, Daw, & Sookanan, 2006; Forkner-Dunn, 2003; Sowers, French, & Blair-Stevens, 2007). Thus, the present milieu favors the acceptance of marketing solutions to social problems.

The remainder of this chapter will define essential social marketing concepts, describe marketing's evolution from a "transaction" focus to a "relationship" focus, explore the role of information technology, and enumerate social marketing's limitations as a discipline.

CONCEPTUAL FRAMEWORK AND CONCEPTS

Social marketing may be viewed as a management process consisting of three phases: planning and research, strategy design, and implementation and monitoring (Chapman Walsh, Rudd, Moeykens, & Moloney, 1993; Andreasen, 2006). In the planning and research phase, marketers specify the program's behavioral objectives and performance indicators. Then they conduct research to identify the target audience, analyze the competition, designate the marketing mix, and examine the target audience's preferred communication channels. In the strategy design phase, marketers develop the marketing mix and communication methods, and pretest their concepts and messages for comprehensibility and acceptability with a sample of the target audience. In the implementation and monitoring phase, products or services are delivered to the target audience, messages are communicated, and performance indicators are monitored. If performance is deemed unsatisfactory, further research is conducted so that the program can be revised and implemented again in iterative cycles of improvement. The components of the social marketing process are explicated below.

Once the behavioral objectives are specified, marketers select the group of people who will be engaged in the social change program. *Audience* *segmentation* is the activity of conducting research to characterize and divide a large, heterogeneous group into smaller, homogeneous groups called market segments on the basis of geographic, demographic, psychographic, and/or behavioral variables (Kotler et al., 2002). Marketers then evaluate, prioritize, and select one or more market segments to be the program's *target audience*. Social marketing programs do not focus on heterogeneous groups because the members of such groups are likely to differ in the factors that affect behavioral adoption. A program designed to address heterogeneous needs would be complex, expensive, and prone to failure. A segmentation and targeting strategy enhances the effectiveness and efficiency of a marketing program by narrowing the scope to the needs of one or a few homogeneous groups; this is desirable because the resources available to conduct marketing programs in the social context are typically fewer than those that are available in the commercial one.

Another early step in the social marketing process is an assessment of the *competition*. In commercial marketing, competition refers to alternative brands of products or services that can be purchased by the consumer. But in the social context, competition is defined as the existing behaviors that people do not want to give up, alternative new behaviors that people prefer over the behavior that marketers want to promote, or organizations and individuals who disseminate messages that oppose the desired behavior (Kotler et al., 2002). Social marketers analyze the benefits and costs of competing behaviors so that they can design or choose a desired behavior that has greater benefits and/or lower costs and/or is more socially acceptable than the competition. However, unlike the commercial context in which the offerings can be continually improved over time, it is an unfortunate reality in the social context that social marketers are often "stuck" offering unmodifiable solutions that may be less attractive than the competition. In such situations, marketers may seek to persuade the target audience that the competition has fewer benefits and/or more costs than the desired behavior. Another tactic is to enhance the benefits of a desired behavior by offering financial and/or non-financial incentives and rewards to adoptees (Deshpande, Rothschild, & Brooks, 2004).

Marketing programs operate on the premise of *exchange theory,* which posits that individuals act out of self-interest and voluntarily engage in economic activities when they derive value from them. Value occurs when the perceived benefits of a transaction equal or outweigh its costs. (Kotler et al., 2002; Rothschild, 1999). In commercial marketing, the pursuit of self-interest by the target audience is openly acknowledged, but in social marketing, target audiences are often asked to adopt behaviors that appear to contradict the self-interest present in their current behaviors (Rothschild). Hence, the creation of exchanges in the social marketing context is more challenging than in the commercial one. Nonetheless, a social marketing program should seek to increase the benefits of a desired behavior and decrease its perceived costs because adherence increases when self-interest can be discerned.

The *marketing mix* is the customary strategy for designing an exchange and is composed of the "four Ps" of product, price, place, and promotion. The *product* is a package of benefits that meets the needs or desires of the target audience. A social marketing product may be characterized as having three levels: the core product which refers to the societal benefit of the desired behavior, the actual product which refers to the desired behavior itself, and the augmented product which refers to the tangible objects and services that support behavior adoption (Kotler et al., 2002). An example of these product levels is provided by hand hygiene promotion programs in healthcare settings. The core product is the prevention of communicable disease transmission, the actual product is hand hygiene adherence, and the augmented product is the provision of antiseptic hand rub that enables hand hygiene behavior to be convenient and accessible.

To develop a product, social marketers research the target audience to learn what problems it wishes to solve and what benefits it desires. These findings are then used to design the product, which can either be a physical object or a service that confers the desired benefits and solutions. Benefits can be tangible entities such as cash rewards or gifts, or intangible entities such as satisfaction, enhanced self-esteem, or social approval. Benefits are also classified as direct (immediate) or indirect (non-immediate); direct benefits are considered to be more powerful motivators of behavior adoption than indirect ones. For example, smoking cessation that is packaged with the remote benefit of reducing lung cancer occurrence is not as attractive as cessation packaged with the immediate benefits of higher energy levels, more disposable income, odor-free clothing, and enhanced self-esteem. Obviously, it is advantageous for social marketers to offer benefits and solutions that are more desirable than those offered by the competition.

Price is the total cost accrued by the target audience when it adopts the product. Costs may be monetary (prices charged for objects or services) or non-monetary (loss of time or pleasure, physical discomfort, or psychological risks such as social embarrassment) (Kotler et al., 2002). In the commercial context, monetary costs predominate, while in the social context, non-monetary costs usually equal or exceed monetary costs in importance. Social marketers reduce or minimize adoption costs so that the desired behavior receives widespread adoption. Furthermore, analogous to the product concept, marketers should seek to outperform the competition in reducing the costs of behavior adoption.

Place is the location and time at which products and services are acquired and the desired behavior is performed (Kotler et al., 2002). Commercial marketers address place with "channels of distribution" (Strand, Rothschild, & Nevin, 2004). Channels are networked organizations or processes that deliver products and services to target audiences so as to enhance their benefits and reduce their costs. In commercial marketing, it may be difficult for businesses to differentiate themselves from their competition solely on the basis of a product's qualities (for example, different brands of coffee are still essentially coffee), so the channel of distribution (for example, a coffee shop) delivers not only the product but additional benefits (for example, pleasant music and aromas, a meeting place, wireless internet access) that create a total experience that is valuable to the consumer. In the social context, consideration of place leads social marketers to enhance convenience by offering closer locations, extended service hours, and product or service availability at the point of decision making (Kotler et al.). Adding convenience enhances a product's perceived benefits and reduces its perceived costs.

Promotion is communication about a product's value and availability that persuades the target audience to make a purchase. In the social marketing context, purchase equates with adopting the behavior. There is a popular misconception that promotion or advertising is marketing's predominant activity. In fact, promotion is the culmination of a multifaceted process of selecting a target audience, analyzing the competition, and designing an attractive exchange. Thus, social marketers promote not ideas but the prospect of gaining value.

Promotion involves the development of a communications strategy, the selection of communications channels, the design of messages, and the achievement of adequate message exposure intensity (Kotler et al., 2002). Research has shown that health promotion messages are more effective when they are framed in terms of gains rather than losses. For example, asking people to undergo medical screening tests to improve their health is more attractive than asking them to undergo these tests to prevent suffering or death from disease (Rothman & Salovey, 1997). Social marketers are also aware that a high level of exposure to behavior messages accomplished by repetition through diverse communication channels is more likely to change behavior than low levels of exposure (Hornik, 2002). The salutary effect of intensive exposure has been attributed to the enhancement of learning, the perception that a behavior is a social expectation, and the stimulation of discussion about the behavior in the target audience.

The preceding marketing activities presuppose an *audience orientation* in which the audience's needs and desires drive the design and implementation of the marketing program. Social marketers believe that voluntary behavior adoption is more likely to occur when the target audience has a say in the decisions that affect them. In practical terms, an audience orientation requires marketers to conduct *audience research* throughout the course of a social marketing program. As stated earlier, *formative research* is performed at the planning and research phase of a social marketing program to inform the segmentation of the audience, the analysis of the competition, the development of the marketing mix, and the selection of communication channels. Formative research helps marketers to understand what they might offer based on the audience's perceptions about benefits and costs, sources of social influence, knowledge, skills, current levels of adherence, and competing behaviors (Andreasen, 2006). A second kind of research called *pretesting* reveals whether key elements of the marketing intervention will be acceptable to a sample of the target audience. A third kind of research known as *monitoring* tracks the progress of the intervention with repeated measurements of performance indicators. Finally, *evaluation* research assesses whether a program has met its original objectives.

The customary audience research tools of social marketers are interviews with key informants, focus groups, and systematic surveys. However, "human factors research" methods employed by industrial design firms have recently captured the attention of social marketers. (Brunner, Waugh, & Kretschmar, 2007). Relying on a combination of interviews and ethnographic methods, designers seek to uncover the "latent needs and emotional triggers" of the audience by listening to stories of product usage and observing behaviors in the everyday environment. Observation is informative because members of the target audience may be unaware of their needs or unable to verbalize them. Observation can also unveil contradictions between what people say and do. The experiences of "extreme users" or nonusers of products and services are also valuable because these individuals amplify the concerns of average users and reveal interesting phenomena such as environmental cues that prompt behavior, thoughtless acts that accompany behavior, and adaptations of existing products. The preceding insights are synthesized into a "customer experience" that guides the design of solutions.

A final aspect of social marketing programs is the application of behavioral and social theories and models (Lefebvre, 2000). Social marketers rely on theories and models to learn from previous knowledge, to simplify the complexity of human behavior, and to make decisions about marketing activities (Hastings, 2007; Lefebvre). However, theories and models should not be applied thoughtlessly and must be appropriate to the context. Examples of theories or models that are relevant to social marketing include Exchange Theory, the Health Belief Model, the Transtheoretical model, and the Diffusion of Innnovations Model.

PARADIGM SHIFT IN MARKETING

The process described in the previous section is a "goods-centered" view of marketing that may be termed *transaction marketing* (Gronroos, 1994). This kind of marketing relies heavily upon the economic exchange concept and emphasizes the management of the marketing mix as the key determinant of profitability or program success. In the transaction paradigm, manufactured physical objects are considered to embed technical solutions or other forms of value, and are exchanged in short-term transactions with an anonymous body of potential consumers or adopters. This paradigm has dominated the logic of marketing since the 1960s, and retains a strong presence in some academic circles. However, confidence in this paradigm has been eroded by its inability to provide insights and managerial rationales for industrial marketing, services marketing, and customer relationship economics.

In the 1980s, marketing scholars began to challenge the transaction paradigm with a "service-centered" perspective called *relationship marketing* which emphasizes service provision, the co-creation of value, and relationships (Vargo & Lusch, 2004). *Service* provision refers to the application of specialized knowledge and skills to create benefits. *Value* is "defined by and co-created with the consumer rather than embedded in output." *Relationship* implies a long-term, continuous process of collaborating with customers, learning from them, and meeting their needs and aspirations. The desired outcomes of relationship marketing are customer satisfaction, trust, and commitment; and the desired reward is sustainable competitive advantage.

Although the relationship marketing approach does not preclude the offer of a tangible product to customers or audiences, it is the quality of the interactions in the relationship rather than the product itself that is the major source of value. Thus, the goal of relationship marketing is to "... establish, maintain, and enhance relationships with customers and other partners...so that the objectives of the parties involved are met. This is achieved by a mutual exchange and fulfillment of promises" (Gronroos, 1994). Long-term relationships empower customers or audiences to become active participants in the creation of value, and give them access to technological, knowledge-related, or social benefits. Relationships benefit companies or organizations by lowering marketing costs (long-range planning is easier and more economical because customers are stable and defined), increasing word-of-mouth advertising, lowering price sensitivity (customers are willing to pay a higher cost for service benefits), and stimulating up-selling (selling more product or service) and cross-selling (selling other products and services) (Hastings, 2003).

Social marketers need the broader perspective afforded by relationship marketing because their offerings are generally less attractive and demand a higher level of commitment than commercial sector offerings (Hastings, 2003). However, the increasing prominence of relationship marketing does not necessitate abandonment of transaction marketing or the exchange concept: "the existence of a market relation is the foundation of exchange not a substitute for it." (Gronroos, 1994). Nonetheless, relationship marketing is a different approach than transaction marketing, and the two may be viewed as opposing extremes on a strategy continuum. A prudent manager must assess whether a behavioral issue is predominantly transactional (requiring a "one-time" purchase) or relational (requiring "repeat purchases" on a long-term basis) in order to apply the marketing strategy that maximizes results.

THE ROLE OF INFORMATION TECHNOLOGY

Information technology plays an important role in social marketing programs. In the past, social marketers conducted audience research with interviews, focus groups, and paper survey questionnaires. Now, information technology can support audience research through additional modalities such as E-mail, internet chat rooms, and Web-based survey software. Advances in information technology have also affected promotion. Communication channels have expanded beyond print media, television, and radio to include E-mail, Web sites, online training software, short message service delivered on mobile communication devices, voice prompt technology, and computer-based decision support. However, it is in the domains of "developing an offering" and enhancing social influence that information technology holds the greatest promise for social marketing. The arrival of a new generation of Web-based communities and hosted services known as "social media" or *Web 2.0* now enable "the people formerly known as the audience" to create and share audience-generated content in the form of blogs (Web logs), syndication feeds, podcasts, wikis (collaborative online documents), folksonomy (collaborative annotation or labeling of Web content), digital images, and videos that can all be found easily with internet search engines (Lefebvre, 2007). Statistics about Web 2.0 usage suggest that large numbers of internet users have been empowered to create and share their own content, and would expect to be active participants in future social innovations that involve them (Lefebvre). Hence, social media offer change leaders an unprecedented opportunity to collaborate with their audiences in the design, implementation, and control of social marketing programs. Indeed, it may now be less efficient for marketers to design, build, and release the "perfect" version of a product or service than to offer the target audience a rapid prototype that they can "hack," improve, and share on their own.

In addition to giving the audience creative and sharing capabilities, Web 2.0 has replaced traditional, one-way communication with interactions. Instead of broadcasting messages to a heterogeneous audience in hopes of reaching some members of their target audience, change leaders can now converse directly with the target audience through blogs and social networking sites. Furthermore, audience members can use social media to bypass experts and talk with each other. This has profound implications for health promotion because health behaviors are not driven by personal risk perception alone: they are also strongly influenced by the conversations that people have with peers who share their condition or have had experiences in seeking help for the condition (Lefebvre, 2007). The new reality of a socially networked world should motivate social marketers to enhance existing social linkages, build and sustain new linkages, empower the peer influence of behavior, and empower communities to develop and manage their own behavior influence programs (Lefebvre).

Blogs provide an example of how the new social media have dramatically altered the communications and marketing landscape. In 2007, the Technorati Website tracked over 71 million blogs in existence on the Web (Lefebvre, 2007). A *blog* or Web log is a frequently updated online diary that can be published by anyone with access to the internet. Each blog entry or posting is instantly available to a global audience, and can be found with internet search engines or sent to E-mail- or Web-based reader accounts using a blog's syndication capability. Blogs also facilitate interaction between authors and readers by allowing readers to post their responses to viewed content. Finally, blogs can disseminate information in viral fashion by linking to other blogs to create a vast network of authors and readers called the "blogosphere" (Scoble & Israel, 2006).

The preceding points reveal that blogging is a digitally enhanced version of the traditional marketer's "word-of-mouth" advertising: "Blogging impacts marketing but also transcends it. Blogging is vital not just to outbound communications but to inbound as well. It is a crisis fighter, a superior research aggregator, a tool for recruiting, a product builder, and customer service and support enhancement. It provides two-way executive access and facilitates employee relations, customer evangelism, and interaction between companies and their constituencies. We have not yet dreamed of some of the ways it will benefit companies in the future" (Scoble et al., 2006).

By now, it should be obvious that the dialogical and creative capacities of Web 2.0 are highly compatible with the desired aims (service provision, co-creation of value, and relationship building) and outcomes (customer satisfaction, trust, and commitment) of relationship marketing. In other words, information technology can now support marketing in a socially networked world. However, information technology is still largely used to support a "command-and-control" management style in healthcare systems. For example, frontline staff members cannot use their institution's information technologies to broadcast messages to the healthcare system without administrative approval and editorial control. But ironically, Web 2.0 empowers those same people to use non-institutional computers to bypass institutional gatekeepers and communicate with a global audience. Thus Web 2.0 radically challenges conventional management norms and poses ethical dilemmas for information technology managers. For example, staff members may make unflattering statements about their institution in a personal blog, violate patient confidentiality by posting video clips recorded in healthcare settings, or create risk management issues by revealing sensitive information on social networking sites. The possibility or reality of such scenarios may prompt administrators to ask information technology managers to block institutional access to social media Websites. As a result, the potential benefits of interactive communication and enhanced creativity would be lost. Alternatively, information technology managers may be asked to introduce user policies and monitoring systems that achieve a balance between the harnessing the benefits and mitigating the risks of using social media within the healthcare industry.

LIMITATIONS AND FUTURE RESEARCH

The most important limitation of the rapidly evolving field of social marketing is an incomplete validation of its effectiveness. Until recently, social marketers needed to cite evaluation studies of communications campaigns as evidence of social marketing's effectiveness even though communications or promotion is but one aspect of the social marketing process. To illustrate, two large systematic reviews of communications campaigns will be mentioned. In the first review that included 28 communications campaigns to promote physical activity, the authors concluded that print media or information technology (telephone help lines or telephone contact) changed short-term behavior, but mass media (television or radio advertising) did not (Marcus, Owen, Forsyth, Cavill, & Fridinger, 1998). In the second review that included 48 health communications campaigns addressing a variety of health promotion issues, the interventions had measurable behavioral effects in the short term (Snyder et al., 2004). Subsequently, a systematic review of full-fledged social marketing interventions based on predefined marketing criteria has been published (Gordon, McDermott, Stead, & Angus, 2006). This review included 31 studies to improve diet, 22 studies to increase physical activity, and 35 studies to decrease substance misuse. Social marketing interventions were found to be effective in changing behavior in a range of target audiences in a variety of settings. In addition, social marketing was effective in influencing the "upstream" determinants of the physical and social environment as well as individual behaviors. However, given the narrow scope of social problems studied, the effectiveness of social marketing for many other issues remains unknown.

There are several explanations for the research deficiency mentioned above. First, social marketers are intuitive thinkers who do not always state the theoretical rationales behind their interventions. Indeed, some social marketers believe that marketing effectiveness results from experience rather than rigid adherence to theories. Second, social marketers prefer to implement flexible programs over time rather than stable ones: while flexibility allows a program to adapt to a dynamic context for the sake of effectiveness, it also weakens the program's ability to establish valid causal inferences. Third, deep-seated behavior change takes many years to attain, but campaigns with short-term funding may be too brief to capture meaningful intervention effects (Chapman et al., 1993; Doner, 2003). Consequently, there is a dearth of research that evaluates the effectiveness of social marketing programs against non-intervention control groups, as well as alternative behavior change approaches. In the absence of thorough documentation of the effectiveness of social marketing interventions in a wide range of social issues, the case for social marketing's utility rests largely upon commercial marketing's undisputed track record of success. However, this assumption may not be warranted because social marketing issues are generally more challenging than commercial ones. So despite concerns about the conflicting aims of research within social marketing, well-designed and well-funded evaluation studies are clearly needed if social marketing is to gain wider acceptance among policy makers and program sponsors.

Besides limited documentation of effectiveness, critics have asserted that social marketing is unsuited to public health issues because it conjures up unfavorable connotations of manipulation that are the legacy of commercial marketing. This is a legitimate concern because Western marketers have tended to avoid ethical debates about their activities, and may also substitute marketing rationales for moral rationales resulting in the portrayal of marketing as an amoral or neutral activity (Peattie & Peattie, 2003; Brenkert, 2002). However, ethical questions about power relations and fairness are unavoidable when social marketers set out to change the behaviors of free individuals within democratic societies. Thus, social marketing academics have begun to discuss the ethics of social marketing (Andreasen, 2001). Conversely, social marketers can provide a service to society by scrutinizing and critiquing the unethical practices of the commercial marketing sector which may contribute to public health problems (Hastings & Saren, 2003); examples include the impacts of the fast food industry on the obesity epidemic, and the tobacco industry on smoking behaviors.

The social marketing field has also been criticized for emphasizing "downstream" individual responsibility for behavior change while neglecting the "upstream" individuals and institutions that control the quality of the physical and social environment in which behavior occurs. For example, applying this concept to the improvement of healthcare services delivery, downstream marketing initiatives could target health services consumption by patients while upstream initiatives could target the diagnostic and therapeutic decisions of healthcare providers. A public health example of the preceding dichotomy is provided by the case of tobacco consumption: downstream initiatives seek to reduce tobacco usage among potential smokers while upstream initiatives target tobacco farmers, cigarette manufacturers, retailers, and politicians. Social marketers have recently begun to pay attention to how they can use the marketing toolbox to influence the upstream determinants of behavior and this will become an increasing concern in future marketing programs (Andreasen, 2006).

Finally, some marketing scholars and practitioners contend that commercial marketing concepts such as exchange theory, the marketing mix, and competition may not be applicable to social issues (Peattie & Peattie, 2003; Wood, 2008). It is asserted that the differences between the social and commercial contexts are at times so substantial as to require that social marketing develop its own methods and vocabulary. Consequently, commercial marketing theories should not be transferred to the social context in an indiscriminant fashion, and social marketers are encouraged to search for innovations in other knowledge domains such as economics, psychology, sociology, and communications theory. For example, the concept of economic exchange, which has been the cornerstone of mainstream marketing, is based on the buying and selling of tangible goods, and may be less useful in the social context than social exchange theory with its focus on friendship building and power relations (Jancic & Zabkar, 2002). In addition, commercial marketing itself continues to evolve, and new concepts such as relationship marketing and branding should be carefully considered for their potential relevance to social marketing.

In addition to the evaluation needs mentioned above, future research in social marketing should answer additional questions: When and where should social marketing be applied? How can social marketing complement other approaches to social change? Which components of the social marketing approach are essential for success? How effective are the new social media in furthering the aims of social marketers? How should relationship marketing and branding be applied to social issues? Can audience research be improved by incorporating ethnography and quantitative research methods? How can social marketers be more creative in their audience segmentation strategies and will this enhance effectiveness? What are the keys to sustaining or maintaining social change?

In conclusion, social marketing is a systematic and dynamic approach to behavior change that draws upon a rich body of multidisciplinary knowledge. Social marketing has strong potential to effect societal good because it offers value, relationships, and empowerment to individuals and communities. However, it needs to establish a more persuasive track record of success if it is to gain wider acceptance among change leaders and sponsors. Without a doubt, social marketing is a work-in-progress and its future praxis will be intimately connected to the rapid advances occurring in information technology.

KEY TERMS AND DEFINITIONS

Audience Orientation: The philosophy that marketing programs should be responsive to the needs of the target audience.

Audience Segmentation: The activity of dividing a heterogeneous group of people into smaller, homogeneous groups with respect to characteristics that affect adherence to a behavior.

Competition: Behavioral alternatives to a desired behavior, or organizations and individuals who oppose a desired behavior.

Exchange Theory: The hypothesis that economic activity is driven by self-interest and the pursuit of value.

Marketing Mix: A strategy for creating an exchange that takes into account the benefits, costs, convenience, and attractiveness of the marketer's offering to the target audience.

Social Marketing: A program approach to behavior change that draws upon knowledge from commercial marketing and social science.

Relationship Marketing: A view of marketing that emphasizes relationships and service as a means to gaining value.

Target Audience: The homogeneous group of people whose behavior social marketers seek to influence.

Transaction Marketing: A view of marketing that emphasizes exchange theory and the transfer of physical goods.

Web 2.0: Web-based communities and hosted services that enable creativity, sharing, and communication.

Chapter 4.17

Social Software for Customer Knowledge Management

Zuopeng (Justin) Zhang
State University of New York at Plattsburgh, USA

ABSTRACT

Social software is assuming a significant role in electronic business, increasingly referred to as e-business, and has been utilized recently on a growing scale by companies in customer relationship management. However, it is largely unclear at what levels firms should implement social software. This chapter addresses the gap by identifying the optimal level of social software deployment for a firm that plans to maximize its transactional benefits through the management of a customer knowledge base. The conclusion reached is that the optimal level of social software depends on a range of factors: for example, the initial volume of knowledge base, transaction benefits, and the estimates of the positive and negative effects of social software use. The chapter offers insights and guidance for business managers and practitioners.

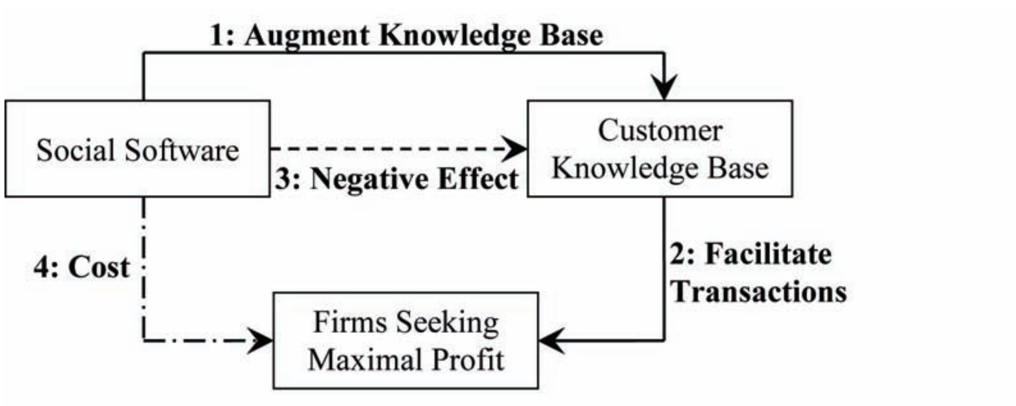
INTRODUCTION

Social software is defined as computer software that "supports, extends, or derives added value from human social behavior" and includes "message-boards, musical taste-sharing, photo-sharing, instant messaging, mailing lists, social networking" (Coates, 2005). In business contexts, social software is commonly referred to as *social and networking software* used by companies to organize internal and external communication. For instance, IBM launched Lotus Connections to compete with Microsoft's SharePoint for the enterprise-wide social software market (Lynch, 2008).

The recent development of Web 2.0 technologies has created remarkable opportunities for Knowledge Management (KM). In particular, companies have recently started to apply social software for managing customer knowledge, maintaining good customer relationships, and enhancing customer satisfaction (Johnston, 2008). Applying social software on their electronic storefronts, firms can create virtual communities for customers to interact with each other and share information and knowledge about products and services. For instance, CircuitCity (2006) launched its online forum to provide better customer experiences and is partnering with IBM to explore the application of virtual worlds in business. Currently available Web 2.0 technologies enable firms to implement different types of social software, from the very basic ones, such as electronic bulletin boards, to

DOI: 10.4018/978-1-60566-368-5.ch044

Figure 1. Four types of effects of social software implementation



those with advanced features, including tagging, blogging, and wikis.

Although social software is gradually assuming a more essential role in e-business, it is still unclear at what level firms should implement social software. Since there exits a wide range of social software applications (including online forums, social tags, blogs, wikis, as well as Lotus Connections and Microsoft SharePoint), firms have to decide which one to implement on their electronic storefronts. This chapter seeks to address this gap by modeling and analyzing the relationship between social software and customer knowledge management. We maintain that social software dynamically influences customer knowledge bases and subsequently describe four types of direct and indirect effects of social software implementation on businesses, as shown in Figure 1. The first and second effects relate to the transactional benefits that firms can obtain by implementing social software to achieve effective customer knowledge management. For instance, social software can provide a platform for customers to interact with each other and acquire valuable information before completing their transactions and supplementing the deficiency of a "static" customer knowledge base. Therefore, social software can complement customer knowledge base by facilitating potential customers' transactions. The third effect describes the negative influence that social software may have on the customer knowledge base. Specifically, customers who are dissatisfied with their shopping experiences may impact the current knowledge base affecting the transactions of future potential customers. Finally, the fourth effect encompasses the costs that firms should incur from maintaining and managing social software.

The purpose of this analysis is to identify the best strategies to implement different types of social software as well as understand the tradeoffs for firms seeking maximal profits.

Specifically, in this chapter we would like to address the following three research questions:

RQ1: *When should firms employ social software to "dynamically" manage customer knowledge*? Most companies have built knowledge bases for "static" customer knowledge management. However, few of them have experiences in utilizing social software as effective tools of "dynamic" customer knowledge management. We are interested in the sufficient conditions for firms to migrate to "dynamic" customer knowledge management with social software.

RQ2: *What is the optimal level for firms to implement social software*? Based on different direct and indirect effects of social software on firms through customer knowledge management, we intend to explore the best level of social software for firms to dynamically manage customer knowledge assets.

RQ3: *How does the optimal level of social software change with different influential factors*? From our framework illustrated in Figure 1, we identify several critical factors of implementing social software and investigate how the optimal level of social software changes with these factors.

The rest of the chapter is organized as follows. The next section presents the background of this research by reviewing related literature on social software and customer knowledge management. The "Analytical Model: Analysis and Discussion" section explicates the main focus of the chapter, detailing our model formulation, derivation of analytical results, and discussion of managerial insights. The "Future Trends" section outlines the directions for future research, and the last section provides a concluding discussion of the results.

BACKGROUND

In this section, we review prior literature, focusing on two recent streams of research in Knowledge Management (KM): that is, the role of social software in knowledge management and customer knowledge management.

Social software provides the following three major types of support for people to interact and communicate with each other: (a) support for conversational interaction between people or groups, (b) support for social feedback, and (c) support for social networks (Boyd, 2006). Therefore, the key areas of social software considered are blogs, wikis, as well as various social network services, such as online forums and social bookmarking.

Recent studies have shown a growing interest in the relationship between social software and KM, especially the role of social software in disseminating and creating knowledge. For instance, Avram (2006) analyzes how to use social software to regulate the core knowledge management activities. Efimova (2005) examines how to use blogs for personal knowledge management, particularly "personal knowledge repositories, learning journals or networking instruments" (p. 1). In a special report, Greenfield (2007) assesses four enterprise social bookmarking solutions that are currently available to e-buisnesses and argues that social bookmarking applications can provide an effective KM platform. From a technical perspective, Kim and others (2007) establish a conceptual framework that combines the social network activities and knowledge processes through social software agents. They build a prototype, called *WANT*, in a wiki-based environment for knowledge workers to collaborate and communicate via a software agent. Based on the survey of a number of different social software websites, Chai, Potdar, and Chang (2007) analyze and categorize the revenue models of social software, including advertising, premium memberships, affiliate programs, donations and merchandise sale.

Customer Knowledge Management (CKM) is the other emerging research stream for knowledge management. *CKM* refers to the management of organizational knowledge residing on the customer side. Gibbert, Leibold, and Probst (2002) illustrate the concept of CKM and propose five styles of CKM: prosumerism, team-based co-learning, mutual innovation, communities of creation, and joint intellectual property. Bueren, et al. (2004) describe how to utilize information technologies to support Customer Relationship Management (CRM) with an integrated CKM process in order to achieve knowledge transparency, knowledge dissemination, knowledge development, and knowledge efficiency. García-Murillo and Annabi (2002) argue that approaches in marketing and CRM cannot successfully capture knowledge from customers, so appropriate methods of CKM have to be employed to retrieve and manage customer knowledge. Rowley (2002) contends that customer knowledge is the indispensable element for firms engaging in e-business. Rowley discusses various topics of customer knowledge: such as, the role of customer communities in CKM, the boundary and structure of knowledge communities, the ownership of knowledge assets, the integration of customer knowledge across different channels, the comparison of customer knowledge management with customer relationship management, and the necessity for organizations to develop strategies to dynamically integrate systems and people. Rollins and Halinen (2005) regard CKM as an integrated management approach with an ongoing process of generating, disseminating, and using customer knowledge; they propose a theoretical framework of CKM that integrates with CRM processes.

Despite the growing interest in social software and customer knowledge management, the economic values of social software for firms are not well understood. Prior research in the field provides a solid foundation for understanding the role of social software in KM and the unique features of CKM; yet, there is a paucity of research investigating social software as it relates to CKM. In particular, the possible economic benefits that social software can bring through managing customer knowledge assets have not been examined.

ANALYTICAL MODEL: ANALYSIS AND DISCUSSION

This section details our model formulation, analysis, and discussion. Beginning with the presentation of our analytical model of social software for customer knowledge management, we then proceed to derive meaningful results from the model and provide managerial insights. Finally, we show the optimal level of social software and discuss how it changes with various influential factors.

We consider a firm which implements social software to manage its external knowledge assets, primarily those related to the customers who regularly visit the firm's electronic storefront. The cost $C(T)$ for implementing the social software is a convexly increasing function of its level T, which means that if the firm wants to implement the more sophisticated social software, it will incur a higher cost.

Customers visit the firm's website to solve certain problems and eventually make transactions. Before completing their transactions, customers would like to utilize both the social software and the customer knowledge base integrated with the firm's website to make sure that their problems are solved and the transactions are beneficial for them. Given the technology level T of the social software and the current volume K of knowledge stored in the customer knowledge base, a customer's problem will be solved, and he or she will eventually consummate the transaction with the probability $p(T, K)$, which benefits the firm with a profit B. Here, the probability function $p(T, K)$ parameterized with T and K is a concavely increasing function of the technology level T of the social software and an increasing function of the volume of the customer knowledge base K; this implies that: (1) when the technology level of the social software is higher, it is more likely that customers will complete their transactions; (2) when the volume of the customer knowledge base is larger, consumers are more likely to complete their transactions; and (3) the rates of both increments of the probability decrease with the level of the social software or the volume of the knowledge base.

We assume that once the transaction is made, the customer will always be satisfied with the service or goods he or she received from the transaction with the support of the social software and the current customer knowledge base. It is also assumed that customers will always tend to participate in the social activities related to the customer knowledge base, such as writing a review of his or her experiences and transactions. Therefore, if the customer makes a transaction, he or she will try to contribute to the current customer knowledge base in a positive manner. The positive contribution σ that a consumer can make to the

Table 1. Summary of notations

B	benefit of individual transactions to the firm
$C(T)$	cost of implementing social software at the level T
δ	negative effect on customer knowledge base
K_0	initial volume of customer knowledge base
K_i	volume of customer knowledge base in i^{th} period
λ	discount rate
n	total number of periods
$p(T, K_i)$	probability of a customer's problem being solved
σ	positive effect on customer knowledge base
T	level of social software

knowledge base is assumed to be equal for all the customers. As a parallel, a customer's problem may not be solved with the probability $1 - p(T, K)$ due to insufficient knowledge in the base or poor capabilities of social software; therefore, the customer may have an unpleasant experience and shall give negative reviews, negatively impacting the knowledge base by the amount of δ. Hence, the influences of current customers' experiences and transactions on the current knowledge base will affect the experiences and transactions of future potential customers.

Consequently, the firm's problem is to maximize its total expected profit π over n periods by determining an optimal level T of social software. We grant that customers are visiting the firm's electronic storefront uniformly. Then, the firm's decision problem [P] can be formulated as

$$\max_{T} \quad \pi = \sum_{i=0}^{n} \lambda^{i} \cdot B \cdot p(T, K_{i}) - C(T), \tag{1}$$

where

$$K_{i+1} = K_{i} + \sigma \cdot p(T, K_{i}) - \delta \cdot (1 - p(T, K_{i})) \tag{2}$$

And λ is the discount rate. All the notations are summarized in Table 1.

To derive meaningful results without compromising the generality of our model, we assume that T and K_i are multiplicatively separable in the function $p(T, K_i)$; and, thus let $p(T, K_i) = \rho(T) \cdot K_i$, where $0 \le K_i \le 1$ and $\rho(T)$ serve as a concavely increasing function of T with $\rho(T) \in [0,1]$. The concave and increasing function of $\rho(T)$ with respect to T ensures that the probability function $p(T, K_i)$ concavely increases in the level T of social software. Based on the simplification of the probability function, we next show the solution to the optimal level of social software in the following proposition.

Proposition 1. *For a infinite time horizon (when $n \to \infty$), the optimal level T of social software can be solved from the following equation*

$$B(K_{0} - \delta\lambda) \cdot \frac{1 - \lambda}{\{1 - \lambda[1 + \rho(T)(\sigma + \delta)]\}^{2}} = \frac{C'(T)}{\rho'(T)} \tag{3}$$

with the sufficient condition as follows,

$$\rho(T) - \frac{2[\rho'(T)]^{2}}{\rho''(T)} \le \frac{1 - \lambda}{\lambda(\sigma + \delta)}. \tag{4}$$

Proof. See Appendix A. ■

In Proposition 1, the condition captured by Inequality (4) ensures that the firm's expected profit is a concave function of the level T of social software so that the global optimal level T^* of the social software can be derived from Equation (3). It can be observed from Equation (3) that the optimal level T^* of social software increases with the transactional benefit B for the firm. This suggests that the firm should consider implementing the most advanced social software applications if transactional profit is significant. In addition to the positive effect of the transactional benefit, several other critical factors modeled in our framework also influence the optimal level T^* of social software. These are summarized and discussed in the next three propositions.

Proposition 2. *When the initial volume K_0 of the customer knowledge base is sufficiently large, such that $K_0 > \delta\lambda$, the feasible solution to the optimal level T^* of social software will exist. In addition, the larger the initial volume K_0 of the customer knowledge base, the higher the optimal level T^* of social software.*

Proof. Equation (3) clearly shows that when $K_0 - \delta\lambda > 0$, the left hand side of the equation is positive and the solution of T may exist. In addition, when K_0 increases, the left hand side of the equation increases as well, resulting in a larger optimal level T^* of social software. ■

Proposition 2 specifies the necessary condition for social software implementation by firms that seek to complement their extant customer knowledge bases. The condition implies that the initial volume of knowledge stored in the customer knowledge base should be large enough for the firm to be able to utilize social software effectively and efficiently. In particular, the initial amount of knowledge data in the knowledge base should be sufficiently large to compensate the discounted negative effect $\delta\lambda$ on the customer knowledge base from customers in one period. Additionally, the proposition demonstrates that the firm should employ advanced social software technologies on its website if it starts with a large consumer knowledge base. This proposition also suggests that the application of social software for "dynamic" CKM is suitable for firms with experience in "static" CKM as well as firms that have established mature knowledge bases for their customers. Only when the above condition is met, firms will be able to withstand the possible negative impact of implementing social software and manage the knowledge assets when dealing with the potential customers. Having illustrated the necessary condition for the adoption of social software products, we next turn to investigating the effects of social software utilization on customer knowledge base. The next proposition indicates how the optimal level of social software changes when the effect of social software is positive.

Proposition 3. *The optimal level T^* of social software increases with σ*, the positive effect of social software on the customer knowledge base.

Proof. See Appendix B. ■

Proposition 3 implies that the larger the incremental positive effect of social software on the customer knowledge base, the more elaborate social software should the firm implement. If social software can bring profit through augmenting the current customer knowledge base, the firm should adopt social software packages with advanced features and take advantage of their positive impact. However, parallel to the positive effect, the negative effect of social software implementation on the customer knowledge base can also influence the level of adoption, which is formally summarized in the next proposition.

Proposition 4. *There exists a threshold level of social software as follows,*

$$T_c = \rho^{-1}[\frac{1-\lambda}{2K_0 + \lambda(\sigma - \delta)}] \quad . \tag{5}$$

When the optimal level T^* of social software is greater than the threshold level T_c of social software, or $T^* > T_c$, the optimal level T^* of social software increases with the negative effect δ of social software on the customer knowledge base; in contrast, when the optimal level of social software is lower than the threshold level of social software, or $T^* < T_c$, the optimal level T^* of social software decreases with the negative effect δ of social software on the customer knowledge base.

Proof. See Appendix B. ■

Proposition 4 demonstrates that there exists a threshold for the level of adoption of social software: only when the optimal level of social software is lower than this threshold, should the firm implement less advanced social software applications. When social software technology applied is not advanced, the firm may continue adopting a less advanced version of social software since potential customers may jeopardize the existing knowledge base by misusing the implemented software. In contrast, the other part of the proposition indicates that when the firm's optimal level of social software is advanced and the negative effect of social software on the consumer knowledge base increases, the firm should apply more elaborate social software products to mitigate the negative effects.

The threshold level of the social software displayed in Equation (5) in Proposition 4 also has some important implications. First of all, when the firm has a fairly large amount of knowledge data in consumer knowledge base, the threshold level of social software will become low; therefore, the optimal level of social software will mostly increase with the negative effect of the social software on the customer knowledge base. Second, when the positive effect of social software on customer knowledge base in each period is significant, the threshold level of social software will be low; so the optimal level of software will mostly increase with the negative effect of social software on the customer knowledge base as well. Finally, when the negative effect of social software on the customer knowledge base in each time period is significant, the threshold level of social software will be high; hence, the optimal level of social software will most likely decrease when the effect of social software on the customer knowledge base is negative.

Based on the above analysis and discussion, firms should implement varying levels of social software under different conditions. Table 2 summarizes the diverse strategies that a firm should consider when it encounters various scenarios regarding the changing parameters: the initial volume of customer knowledge base, the transactional benefit, and the positive, and negative effects of social software on customer knowledge base. For instance, a firm can implement highly sophisticated social software technologies when the potential transactional benefits are foreseeable, when the firm initially has a large volume

Table 2. Changes of optimal level T with various parameters*

Parameters	Optimal Level T^*
transactional benefit $B\uparrow$	increase
initial volume of customer knowledge base $K_0\uparrow$	increase
positive effect of social software $\sigma\uparrow$	increase
negative effect of social software $\delta\uparrow$ when $T^* < T_c$	decrease
negative effect of social software $\delta\uparrow$ when $T^* > T_c$	increase

of knowledge data in customer knowledge base, or when the positive effect of social software has a significant impact on the customer knowledge base. These strategies provide valuable guidance for managers to integrate appropriate levels of social software on their electronic storefronts.

FUTURE TRENDS

Our proposed model and strategies for implementing social software are by no means the best strategies available to manage external customer knowledge assets with the help of social software technologies. However, the suggested social software strategies provide some insights for understanding the relationship between social software and customer knowledge management, which also lays a foundation for related future research.

For the purpose of tractability, the results derived from the above analytical model are based on an unlimited timeframe. For firms who want to seek the best knowledge management strategies within finite periods of time, the model may yield different results. It might be useful in future research to focus on specific scenarios within a certain timeframe, which will offer additional guidance for practicing managers.

The current model considers the expected total profit from a firm's perspective. Future research should investigate customers' rational behaviors by incorporating customers' strategies into the framework and analyze how a firm should design incentives to align customers' interests with the firm's goals utilizing social software applications.

The knowledge management discussed in this chapter is limited to potential customers. The general view of knowledge management can be integrated by utilizing customer knowledge as the interface. In this regard, social software technologies implemented for managing customer knowledge will be able to influence the entire organization. Therefore, future research should examine how social software strategies can be adjusted for managing customer knowledge at different levels, both within and outside of organizations.

Furthermore, the proposed model of social software should be empirically tested to reveal the impact of critical factors of social software adoption and implementation on effective customer knowledge management. Empirical tests may corroborate the usefulness of the implementation strategies outlined in our chapter and help us understand the intricacies of the adoption process.

CONCLUSION

Knowledge management has been commonly regarded as an important business practice for organizations to gain a competitive edge. With the rapid development of Web 2.0 technologies, many organizations begin to use these new tools to manage knowledge assets related to their customers. Based on the analysis of the appropriate strategies for using social software to manage customer knowledge assets, we conclude the following:

The first research question asked about the optimal timeframe for firms to employ social software. The chapter presents an analytical model of implementing social software technologies for effective customer knowledge management over multiple time periods. The model captures the major effects of social software on firms that aspire to maximize the total expected profit through managing customer knowledge base, which lays the foundation for a further discussion of the relationships between social software and customer knowledge management.

The second research question considered the optimal level of social software implementation. The proposed model is solved over an infinite time horizon under certain conditions. The analysis indicates that given a sufficiently large volume of knowledge in a customer knowledge base, a firm can successfully integrate appropriate levels of social software on electronic storefronts to take advantage of the "dynamic" effects of social software on the consumer knowledge base. The initial volume of customer knowledge base ensures the firm to be strong enough to withstand the potential negative effect of the adoption of social software on the customer knowledge base.

The third research question examined the essential properties of the optimal level of social software with respect to several critical factors. Specifically, we investigate how the derived optimal level of social software changes with the initial volume of the customer knowledge base, the transactional benefits, and the positive and negative effects of social software on the consumer knowledge base. The analysis shows that the larger the initial volume of customer knowledge base, the higher the optimal level of the adopted social software. When the transactional benefits are high, the optimal level of the adopted social software is also high and the positive effects of social software on the customer knowledge base increase. Finally, the results demonstrate that there exists a threshold level of social software implementation that may influence the optimal level of change and negatively affect the customer knowledge base.

KEY TERMS AND DEFINITIONS

Customer Knowledge Management (CKM): *Customer knowledge management* is a subfield of knowledge management that deals with the creation, storage, transfer, and application of consumer knowledge assets, typically with the help of information technologies.

Customer Relationship Management (CRM): *Customer relationship management* describes all aspects of a company's strategic relationship with its customers; it is often referred to as *software-based techniques* in order to attract, retain, and manage customers to increase customer satisfaction.

e-Business: *e-Business* stands for electronic business and any kind of sales, purchasing, services or other business activities on the Internet. It also refers to the processes and tools that enable organizations to utilize Internet-based technologies and infrastructure, both internally and externally, in conducting daily business operations.

Knowledge Base: A *knowledge base* is a specialized database with a collection of data, information, and knowledge within an organization that can be used for problem solving, decision making, project management, or other business-related activities.

Knowledge Management (KM): *Knowledge management* involves the design and implementation of both social and technological processes to improve the application of knowledge to achieve organizational objectives. Knowledge management defines the processes organizations utilize to systematically gather, create, store, transfer, and apply knowledge.

Social Software: *Social software* refers to a range of web-based software programs that allow users to interact and share data, information, and knowledge with each other.

Web 2.0: *Web 2.0* refers to the second generation of Internet-based applications and services that encourage people to produce content, share information and engage in social interactions

APPENDICES

A. Proof of Proposition 1

Proof. With our assumption that $p(T, K_i) = \rho(T) \cdot K_i$, where $0 \le K_i \le 1$, Equation (2) can be simplified as

$$K_{i+1} = K_i + \sigma \cdot \rho(T) \cdot K_i - \delta \cdot (1 - \rho(T) \cdot K_i)$$
$$= [1 + \rho(T)(\sigma + \delta)]K_i - \delta,$$

which suggests that the volume of customer knowledge base can be expressed as the function of the initial volume of the customer knowledge base as follows,

$$K_i = [1 + \rho(T)(\sigma + \delta)]^i K_0 - [1 + \rho(T)(\sigma + \delta)]^{i-1}\delta, \forall i = 1, 2, \ldots n.$$

Therefore, the firm's total expected profit can be reformulated as follows,

$$\pi = \rho(T)\sum_{i=0}^{n} \lambda^i \cdot B \cdot K_i - C(T)$$
$$= \rho(T)B\{K_0 + \frac{K_0\lambda[1 + \rho(T)(\sigma + \delta)][1 - \lambda^n(1 + \rho(T)(\sigma + \delta))^n]}{1 - \lambda[1 + \rho(T)(\sigma + \delta)]}$$
$$- \frac{\delta\lambda[1 - \lambda^n(1 + \rho(T)(\sigma + \delta))^n]}{1 - \lambda[1 + \rho(T)(a + \delta)]}\} - C(T).$$

When the total number of periods goes to infinity, i.e., $n \to \infty$, the firm's total expected profit will become

$$\pi = \rho(T)B\left\{K_0 + \frac{K_0\lambda[1 + \rho(T)(\sigma + \delta)] - \delta\lambda}{1 - \lambda[1 + \rho(T)(\sigma + \delta)]}\right\} - C(T)$$
$$= \frac{\rho(T)B(K_0 - \delta\lambda)}{1 - \lambda[1 + \rho(T)(\sigma + \delta)]} - C(T),$$

where first order condition with respect to T can generate the following condition,

$$B(K_0 - \delta\lambda) \cdot \frac{1 - \lambda}{\{1 - \lambda[1 + \rho(T)(\sigma + \delta)]\}^2} = \frac{C'(T)}{\rho'(T)}.$$

In addition, the second order condition indicates that the sufficient condition for T from the above equation to be the optimal solution is

$$\rho''(T)\{1 - \lambda[1 + \rho(T)(\sigma + \delta)]\} + 2\lambda(\sigma + \delta)[\rho'(T)]^2 \le 0,$$

which further implies that

$$\lambda(\sigma + \delta) \leq \frac{1 - \lambda}{\rho(T) - 2[\rho'(T)]^2 / \rho''(T)}$$

or

$$\rho(T) - \frac{2[\rho'(T)]^2}{\rho''(T)} \leq \frac{1 - \lambda}{\lambda(\sigma + \delta)}.$$

Therefore, for an infinite time horizon (when $n \to \infty$), the optimal level T of social software can be solved from the following equation

$$B(K_0 - \delta\lambda) \cdot \frac{1 - \lambda}{\{1 - \lambda[1 + \rho(T)(\sigma + \delta)]\}^2} = \frac{C'(T)}{\rho'(T)}$$

with the sufficient condition as

$$\rho(T) - \frac{2[\rho'(T)]^2}{\rho''(T)} \leq \frac{1 - \lambda}{\lambda(\sigma + \delta)}. \quad \blacksquare$$

B. Proof of Propositions 3 and 4

Proof. When the positive effect σ on the knowledge base increases, the left hand side of Equation (4) will also increase. Therefore, the optimal level T^* will increase as well.

The first order derivative of the left hand side of Equation (3) with respect to the negative effect δon the knowledge base suggests that when the following condition holds, or

$$-(1 - \lambda) + \lambda \cdot \rho(T) \cdot (\sigma + \delta) + 2\rho(T) \cdot (K_0 - \delta\lambda) < 0,$$

the optimal level T^* of social software decreases with the negative effect δon the knowledge base.

The above inequality can be rearranged as

$$\rho(T) < \frac{1 - \lambda}{2K_0 + \lambda(\sigma - \delta)}.$$

Similarly, it can be shown that when the following condition holds, or

$$\rho(T) > \frac{1 - \lambda}{2K_0 + \lambda(\sigma - \delta)},$$

the first order derivative of the left hand side of Equation (3) with respect to the negative effect δon the knowledge base is positive, so the optimal level $T^*$of social software increases with the negative effect δon the knowledge base.

If we define the threshold level for the social software as follows,

$$T_c = \rho^{-1}[\frac{1-\lambda}{2K_0 + \lambda(\sigma - \delta)}],$$

then the optimal level T^* of the social software increases with the negative effect δ on the knowledge base when the optimal level of social software is greater than this threshold, or $T^* > T_c$ and decreases with δ when the optimal level of social software is lower than this threshold or, $T^* > T_c$. ■

Chapter 4.18
Social Networking Behind Student Lines in Japan

Steve McCarty
Osaka Jogakuin College, Japan

ABSTRACT

In a cross-cultural educational context of TEFL in Japan, the author sought to enhance the integrative motivation of students toward the target language community through a supplementary online dimension. The social networking site (SNS), Mixi, was selected because it is familiar to most college students in Japan. The Mixi Japanese language interface is illustrated in this chapter, describing functions possibly applicable to education. A YouTube video that introduces Mixi in English, made in authentic collaboration with students, is also referenced as a representative CALL 2.0 classroom activity. More importantly, joining Mixi presented an opportunity to go behind the lines into student territory. Teachers and students, whether foreign or Japanese, customarily maintain their social distance in terms of separate affiliations. Social networking with Japanese students further involves issues of online technological proficiency, biliteracy, and the necessity of an invitation. The author negotiated with three 2007-08 classes on networking through Mixi, with varying outcomes extending beyond the classroom and the school year. Metaphors of lines and perspectives including "technoscapes" (Appadurai, 1990) are proposed to interpret the results, but Japanese socioculture may be most salient to account for the particulars. Student attitudes are probed as to a possible ambivalence in valuing their free expression in Mixi versus the integrative motivation of social involvement with a teacher. One prediction was that results would differ as to whether or not a teacher was welcome in a student community depending on how students were approached for an invitation. Social networking is proposed as a Web 2.0 educational approach that is authentic, collaborative, and immersive in cutting through power hierarchies and positively blurring the distinction between the classroom and the real life of students and teachers, which nowadays includes a virtual dimension.

INTRODUCTION

This chapter introduces Mixi, a social networking site (SNS) in the purview of most college students in Japan. More importantly, the chapter aims to describe and analyze what happened when a teacher went behind the lines into student territory in order to enhance their integrative motivation toward learning EFL. Metaphors of lines, which do not map predictably across cultures, are employed as a framework for understanding cross-cultural pedagogical issues particular to social networking with students. Among the metaphors employed are reading between the lines, reading and going behind the lines, crossing lines and, as delineated aggregations, territory, maps, and landscapes. Extending the latter perspectivity to technology in Web 2.0, Appadurai's "technoscapes" are considered for possible theoretical support in analyzing students' views of social networking. The methodological approach is to apply an understanding of the languages, cultures and technologies involved, not to generalize about populations but to discern particulars and variations that might be linked to pedagogical interventions. Drawing from sociocultural theory, social constructivism, and the concept of integrative motivation, even one student in a clarified context can provide significant data for understanding complex technology-enhanced L2 learning across non-cognate cultures.

EFL UPTAKE AND TECHNOLOGY USE AMONG STUDENTS IN JAPAN

Briefly with regard to the subjects of this study, the EFL situation in Japan is problematical in a number of dimensions. While nearly everyone studies English for at least six years in secondary school, and children's English is increasingly popular among parents, the Japanese language predominates outside of classes, which do not meet often enough or provide enough listening input and speaking practice. English serves as a test subject for gatekeepers to rank students academically, affecting their future willy-nilly, whether they ever need English or not, so in compulsory EFL classes some students naturally regard the work as an imposition. A disincentive tied to a mutually exclusive sense of cultural identity is that a student who speaks a foreign language fluently may be singled out from her peer group as different or crossing over in affiliation, which threatens the vulnerable young person living in a social world with exclusion. Educational officialdom is more concerned with maintaining Japaneseness than encouraging goals of bilingualism and biculturalism, so there is a pervasive ambivalence about English. Thus motivation tends to be extrinsic or instrumental rather than intrinsic or integrative. Yet teachers are expected to motivate students, so they either read their lines perfunctorily or go to great lengths including innovations in CALL (Computer-Assisted Language Learning).

The technological background of students is that of an advanced nation, but ubiquitous use of Internet-capable mobile phones with cameras and ever more functions has somewhat stunted the computer skills of students beyond what is necessary or convenient for school work. Despite a shortage of IT workers, computer-related courses are relatively less popular in Japan than in many other countries, which heightens the challenge of teachers to innovate while starting from where the students are in computer proficiency. As this chapter will show, however, social networking is very popular among young people and works to converge computers and mobile phones as they access the same platform.

The subjects of this study are female students, who tend to be shy with computers compared to males, as a sort of believed self-stereotype. Osaka Jogakuin College (OJC) has a women's 2-year and 4-year program where everyone majors in English. Unlike the general situation described above, the students have chosen EFL, so intrinsic motives can be activated. The college encourages women's empowerment, so a teacher can promote technological empowerment. The integrated content-based curriculum, recognized as "Good Practice" by the Education Ministry, has the effect of integrating the faculty as well, Japanese and non-Japanese, full-time and part-time. Like most other private colleges in an ageing society, OJC is not difficult to enter, but students have to work hard and therefore tend to achieve remarkable growth in English proficiency. More classes are taught in English by native speakers than at most colleges in Japan. In this institutional culture, teaching is emphasized more than research and each student is valued as an individual.

HYPOTHESES AND PURPOSES OF THIS CHAPTER

The author sought to join the social networking site Mixi in order to go behind the lines into student territory for educational and research purposes. It was hypothesized that voluntarily entering students' virtual communities and friendship networks could help overturn some inhibiting barriers that Japanese students assume in relation to a teacher. Transformative learning experiences might be facilitated in students provided an expanded and more approachable teacher-student relationship is initiated on the simulated level playing field afforded by a social networking site. Particularly in the case of a teacher representing the target culture, social networking is hypothesized to have considerable potential to create a supplementary learning environment enhancing students' integrative motivation to communicate with the L2 target community.

However, in three 2007-2008 classes where most students already belonged to Mixi, results varied in negotiating involvement in this extra social or personal dimension. Thus one purpose of this chapter is to interpret reasons for those particular outcomes, ostensibly within the same culture, hypothesizing that whether a teacher was welcome in a student community or not could depend on precisely how students were approached for the necessary invitation, and in terms of their sociocultural norms. Another reason to join Mixi friendship networks and topical communities was to confirm the hypothesis that more interaction, feedback and collaboration with students beyond the classroom could be realized. An essential purpose of this chapter is therefore to report on what became possible that had hitherto been difficult or piecemeal at best, and to describe what educational potential was realized after receiving an invitation to join Mixi.

THEORETICAL FRAMEWORKS AND METHODOLOGICAL CONSIDERATIONS

Various aspects of Web 2.0 for language learning are defined in complementary ways in this volume. To this author Web 2.0 is imprecise shorthand for a second generation of Web-based technologies that tend to be free, easy to use and to share content, influenced by and therefore reflecting users' collective needs, desires and intelligence. The technologies ascribed to Web 2.0 can be as diverse as mobile phones and 3D virtual worlds, raising the question whether they are related or merely contemporaneous. However, mobile phone Internet content is largely Web-based. As an example, mobile phone home pages can be made and simulated on the Web with Winksite, a free site characteristic of Web 2.0. 3D worlds still have a Web interface, with Second Life SLURLs utilizing Web browsers to open the 3D program at a certain in-world location. Earlier Web-based technologies called Web 1.0 after the fact, such as Web directories or pages or links, tended to be less up-to-date and interactive. For the purposes of this chapter, many Web 2.0 technologies can be applied to education, alluded to in terms such as CALL 2.0, because students in a computer lab can readily sign up for a Web service, including mobile m-learning or 3D sites, and engage in activities that are authentic, collaborative, and immersive. Social networking is characteristic of Web 2.0 and combines many Web 2.0 technologies into a platform that serves as a virtual gathering place. Individual Web 2.0 sites are also useful in activities such as making videos, podcasting student performances, or various means of distance communication (Lee & McLoughlin, 2007; McLoughlin & Lee, 2007). When browsing becomes three-dimensional and activities are native to 3D virtual worlds, then Web 3.0 can be said to have arrived.

Much has been written about social networking sites (SNS) for educational purposes generally (Boyd & Ellison, 2007), and social software as characteristic of Web 2.0 technology (McLoughlin & Lee, 2007). While hybrid or blended media, offline and online, are not entirely new pedagogically, SNS can be regarded as integrated platforms containing communication tools such as blogs, and Web 2.0 functions that students can use much more easily and authentically than they could with Web 1.0 learning management systems (LMS).

For the scope and purposes of this chapter, a general knowledge of SNS is assumed, and comparisons are drawn when discussing the limitations of Mixi functionality. Compared to Facebook, the U.S.-based counterpart to Mixi, little has been published in English about a site with an exclusively Japanese language interface yet experienced by about ten million users. Mixi functions such as blogs are simple to use, and most functions are accessible by mobile phone as well as computer, bringing the technology within the purview of nearly all young people in Japan. Of possible relevance to cross-cultural TEFL situations with high technology but questionable intrinsic motivation, this chapter aims to lift the veils of language and culture while suggesting an approach to foster integrative motivation in students toward the international community using English.

Alm (2006) shows how Web 2.0 activities can be motivating for L2 learning in the case of German in Australia. She mentions that the "phenomenon of social networking shows the strength of the need for relatedness" (p. 32), a component of motivating learning environments along with a sense of competency and autonomy. However, it remains to be investigated whether "self"-centered models such as self-determination theory are as overarching in non-Western cultures such as East Asia. This issue can be revisited after describing the group dynamics of Japanese students deciding about Mixi relationships. Japanese culture includes a strain of rigid conservatism, but the situational relativism of time, place and occasion also informs a repertoire of roles or social gears, and a fluid identity may more readily allow for transformation.

Transformative Learning and Motivational Transformation

The limitations of the seminal theory of "transformative learning" (Mezirow, 1991, pp. 90-91, 167) have been discussed by McCarty (2006). For the purposes of this chapter, learning is understood as transformative when not the content so much as the whole frame of reference of the transaction is expanded to the benefit of the learner's worldview. It is in that sense that transformative learning is hypothesized to become possible through supplementary online technologies, in this case because of the expanded teacher-student relationship afforded by social networking sites (SNS).

Theoretical support for motivation as discussed in this chapter is found in social constructivism and in the psychology of language learning, where individual and social factors are balanced:

[E]ach individual is motivated differently. People make their own sense of the various external influences that surround them in ways that are personal to them ... However, an individual's motivation is also subject to social and contextual influences. These will include the whole culture and context and the social situation, as well as significant other people and the individual's interactions with these people. (Williams & Burden, 1997, p. 120)

Whether or not the teacher is a significant other to the student may correlate with possibilities for transformative learning. Motivation has often been studied in terms of personal attitudes, and despite Gardner's clarifications about dynamism, personality tests in this genre may tend to reify attributes into personality traits that mitigate against change. Lamb (2007) makes similar arguments in the context of EFL in Indonesian schools. Motivation declines on average over the years, and a student may be typecast with the attribute of "unmotivated," yet the main cause of the decline, teaching methods, can also be the source of positive change. If the pedagogy is changed, student motivation is also subject to transformation.

Integrative motivation is also employed in this chapter as subject to change, referring to integrative motives for learning, a learner's sense of integrativeness, and as an orientation, which Dörnyei defines as "a positive disposition toward the L2 group and the desire to interact with and even become similar to valued members of that community" (2001, p. 16). An orientation exists at a certain moment in the changing flow of a person's life. Integrative motivation is thus regarded not as a fixed attribute but as possibly enhanced, with a view to the potential for transformative learning experiences to bring about motivational transformation.

Treating Students as Subjects, not Objects

From a fundamental perspective, treating students as unique individual subjects, not as objects, in research as well as teaching, has methodological support in sociocultural theory (Swain, 2000; Kramsch, 2000; Pavlenko & Lantolf, 2000; van Lier, 2000). Students' contextual and developmental particulars can be of more value for teaching and research than abstract generalizations about populations. To deal even in terms of cultural identities can be constraining, as it may reinforce loyalties that are akin to branding. Social roles may be observed instead, while recognizing individual agency, creativity and self-reformation processes (Roebuck, 2000) as inherent in learners. Thus the interpretation of descriptive and contextual data on even one student can be of interest for research.

Treating students as subjects, not as objects, is evidently practiced in the Osaka Jogakuin College (OJC) curriculum. Classes with one student enrolled have not been canceled outright, and a Computer Communication class with one student enrolled in 2007-2008 will nevertheless be offered again the following year. The educational philosophy of OJC, a women's college where all students major in English, treats each student as "a unique individual of immeasurable worth" (Swenson & Cornwell, 2007, p. 109). Whether due primarily to institutional culture, selection by the student, or treatment by the teacher, an individual student will be seen to make a difference in this research.

Metaphors of Lines, Social Spaces and Perspectives

This chapter attempts to illustrate complex social phenomena with scaffolding metaphors of lines, territories, and perspectives thereupon. In cross-cultural education there are social lines that can be crossed, others that cannot, and further lines that are negotiable with a proper introduction, suitable preparation or pedagogical intervention. In another sense, a teacher may read between the lines of words, behavior or unexpected inaction by students. An observer with second culture literacy might also read *behind* the lines of normative texts, individual behavior, or group dynamics in that culture. But in cross-cultural education the affiliations and socially bounded spaces of the teacher and students differ both culturally and hierarchically within the institution. Yet *going* behind student lines strategically for TEFL in a communicative space such as Mixi is hypothesized to foster integrative motivation, insofar as relationships formed are authentic and collaborative. The territory for teacher-student interaction can be expanded into the virtual with this technology, provided both sides access the SNS for voluntary communication.

Default Lines of Human Relationships

Lines in this metaphorical sense first represent boundaries between affiliations that constrain behavior according to the unwritten social contract of a given culture or subculture. Generally it is safer not to cross these lines but to move within the acceptable paths formed by these boundaries, staying on the side of one's affiliation. These lines are generally heeded as warning signs not to go out of bounds and risk punishment by daring to be different from the prescribed social norm. These default lines are supported by taken-for-granted assumptions about the roles different types of people should play, in this case particularly the social distance or power relationship between teacher and student. Social-constructivist approaches may not transplant smoothly into non-Western classrooms where teachers are expected to be authorities, although Japanese education includes both instructivism and constructivism, depending on whether the objective is academic achievement or social adjustment (McCarty, 2007).

In any case the practitioner needs to know where the invisible lines are drawn in order to estimate the dangers and benefits of a creative intervention. In intercultural communication the invisible signposts or routes to accomplish goals do not readily map onto one other. In a contrasting culture, for instance a native English speaker teaching in Asia, social action can be like navigating a minefield with invisible tripwires. To change default patterns of relationships across cultures thus requires intercultural sensitivity and thoroughgoing negotiations.

Reading Between the Lines in Teaching Across Cultures

Reading between the lines can mean reading the meaning of others' actions or omissions, interpreting the nuances of spoken or written language in a certain cultural context, and discerning implications or motives thereof. The teacher should notice changes in the atmosphere of classes or transformations in the attitude of individual students, accepting it all as feedback on the task or sought objective. Knowledge of the students' native language and cultural literacy about the community beyond the classroom can help in contextualizing observed phenomena, in communicating with the various stakeholders involved in education, and in regarding students as subjects rather than as undifferentiated surfaces that could become psychological screens for unprofessional projection. Knowledge of where students are coming from can help in assessing where they can possibly go, including what social lines they might be inhibited from crossing.

Between and Behind the Lines of Language Policies

Where the lines refer to language policies, "reading between and behind the lines" can turn the focus to the local context and the agency of practitioners, opening up "spaces for transformative pedagogical interventions" (Ramanathan & Morgan, 2007, p. 448). Taking policies not as fixed entities but as engagements subject to interpretation, it is in these "spaces between the lines" of policies "that practitioner agency emerges" (p. 451).

There are also lines of group affiliation between national policy makers and local practitioners, particularly teachers who are on the front lines with students. So the notion of reading behind the lines can point to a deep and empowering understanding of the rationale behind policies, in order for instance to mitigate the effects of political ideologies. In this context, not just to read but to go behind the lines would imply trying to work through channels in the given hierarchy by taking administrative responsibilities or trying to convince governmental authorities to reform policies in response to local needs.

GOING BEHIND STUDENT LINES WITH MIXI

The teacher would be going into student territory by social networking through Mixi, which is popular among students and other denizens of youth culture, since basic exchanges like blog entries and personal messages are available to the mobile phones ubiquitous in Japan as well as to networked computers. As Mixi tends to be a peer medium, with relatively new technologies, a teacher must cross some technological and social lines in order to join. Japanese teachers generally represent different affiliations in terms of age, status, lifestyle, power, and social distance from students, with little in common volitionally, while not many teachers keep up with computer technologies beyond their utilitarian needs. With most foreign teachers there is the further barrier of having to navigate the Japanese language interface of Mixi.

The need for an invitation from an existing member to join Mixi subtly reinforces a social psychology of in-groups and out-groups, pronounced *uchi* and *soto* in Japanese. The latter Chinese character is used in the word for foreigner, literally meaning outside person. Yet even within the culture, anyone outside of a student's peer group would have to negotiate for an invitation, if only because such action would not occur to a student without some prompting. If a teacher expressed a willingness to stay in touch after classes ended, it would probably be a pleasant surprise to students. After a person of interest is known in student circles as a Mixi user, then requests to become a friend or to join a thematic community tend to ensue. This agglutinative process of friend-of-a-friend expansion of individuals' social networks through commonalities not only matches traditional social patterns in Japanese culture but is furthermore enhanced by the affordances of SNS like Mixi.

Yet in a social context where actual teacher-student friendships are not the norm, to do more than is necessary as a faculty member involves crossing some default social lines. Thus a new teacher-student relationship, not incompatible with the institutional culture, must be negotiated in order to bear positive results. A new relationship can be supported by pedagogical consistency in where the lines are redrawn, and reinforced by classroom activities that:

- Promote agency and investment, such as by asking students if they would like to do an activity or offering choices for them to decide.
- Are immersive, not just in a technical sense such as entering a virtual learning environment or 3D virtual world, but any tasks, projects or activities that are interesting and absorbing enough so that students lose a sense of time and other classroom parameters. With content-based real-world activities, voluntary immersion in the target language might also be a part of students' experience of flow.
- Are authentic and involve teacher-student collaboration, such as the YouTube video made about Mixi for an international conference in Japan in 2008 (Thomas, in preparation). Discussing actual global issues with students, assisting in their portfolio products or performances, while de-emphasizing grading and the like, can help cut through power hierarchies and positively blur the distinction between the classroom and the real life of students.
- Could result in polished student performances that merit being published later as student-generated content, for example made available online for other EFL learners or for those interested in Japan (Sener, 2007; Lee & McLoughlin, 2007). When students' work is posted online in some form such as a podcast, they gain a motivating sense of addressivity in their English performance, addressing a global audience as content-creating members of the target

language community. When their efforts receive responses or recognition abroad, it palpably reinforces their integrative motivation to become bilingual and to join that larger world.

TECHNOSCAPES BEHIND STUDENT LINES

With regard to reading the technological landscapes behind student lines from their standpoint, Appadurai's concept of "technoscapes" (1990) may contribute to a theoretical framework calling attention to the technological schemata of students or how they are viewing experiences mediated by information and communication technologies (ICT):

The new global cultural economy has to be understood as a complex, overlapping, disjunctive order ... [A]n elementary framework for exploring such disjunctures is to look at the relationship between five dimensions of global cultural flow which can be termed: (a) ethnoscapes; (b) mediascapes; (c) technoscapes; (d) finanscapes; and (e) ideoscapes. I use terms with the common suffix scape to indicate first of all that these are not objectively given relations which look the same from every angle of vision, but rather that they are deeply perspectival constructs, inflected very much by the historical, linguistic and political situatedness of different sorts of actors ... Indeed, the individual actor is the last locus of this perspectival set of landscapes, for these landscapes are eventually navigated by agents who both experience and constitute larger formations, in part by their own sense of what these landscapes offer. These landscapes thus are the building blocks of what, extending Benedict Anderson, I would like to call "imagined worlds," that is, the multiple worlds which are constituted by the historically situated imaginations of persons and groups spread around the globe. (Appadurai, 1990, para. 4)

The disciplinary context of the author's formulation is the anthropology of globalization, and he comes from India, which, unlike contemporary Japan, has a large diaspora that takes on a collective transnational role such as he describes. A global level of generality can only be painted in broad strokes:

By "technoscape" I mean the global configuration, also ever so fluid, of technology, and of the fact that technology, both high and low, both mechanical and informational, now moves at high speeds across various kinds of previously impervious boundaries. Many countries now are the roots of multinational enterprise ... The odd distribution of technologies, and thus the peculiarities of these technoscapes, are increasingly driven not by obvious economies of scale, of political control, or of market rationality, but of increasingly complex relationships between money flows, political possibilities and the availability of both low and highly-skilled labor. (Appadurai, 1990, para. 7)

The metaphor of landscapes captures in part the perspectivity of the individual Japanese student in a CALL laboratory functioning in English as an International Language (EIL), clearly in the midst of global cultural flows. Yet the definition of technoscapes in the original source could not have anticipated the particulars of current ICT applications to education represented by Web 2.0 activities, m-learning, and rapidly approaching Web 3.0, where activities will be native to 3D virtual worlds such as Second Life. Nevertheless, Appadurai perceived the trend to accelerating technological changes now reaching the intercultural networked classroom, which can be seen as disjunctive or disruptive, hybrid or ambivalent, or in a more positive light as follows:

it is wrong to assume that the electronic media are the opium of the masses ... [T]he consumption of the mass media throughout the world often *provokes resistance, irony, selectivity, and, in general,* **agency**. *(Appadurai, 1996, p. 7)*

However true, for this chapter's analysis a global generalization cannot be assumed to hold for Japan without examining the particulars of the local situation. But nuances in the global perspective that resonate in the case of TEFL in Japan may support Appadurai's theory while shedding light on this study:

[A]s group pasts are becoming increasingly parts of museums, exhibits, and collections, both in national and transnational spectacles, culture becomes less what Pierre Bourdieu would have called a habitus (a tacit realm of reproducible practices and dispositions) and more an arena for conscious choice, justification, and representation, the latter often to multiple and spatially dislocated audiences. (Appadurai, 1996, p. 44)

While critical thinking is essential toward all media, global forces such as advertising on television and other mainstream media are far more insidious and liable to overwhelm the unwary with a false sense of agency than the Web as utilized in higher education. The point in the above quotation about the uses of culture is relevant to the content selected for student homepages and e-portfolio products. Students can imagine correctly that there are Websurfers in other countries interested in Japanese culture, so introducing highlights of their home region provides an educational service that justifies publishing in the global medium of the open Web. When a self-introduction is contextualized by demonstrating the student's cultural background, expectations or communicative conditions are met, and Websurfers are more likely to respond to the product. Teachers in different countries can mutually announce student-generated content, delivering an audience and making the imagined involvement real. As an example, a Computer Communication class activity characteristic of Web 2.0 was to make a narrated slide show with Voicethread, and a student introduced the UNESCO-designated World Heritage Site in her home region. Even though technical obstacles arose and overtime work was needed for its completion, a voice comment posted to the show by an EFL educator in Europe was palpably motivating to the student.

MIXED RESULTS CROSSING STUDENT LINES

To join Mixi in the first place requires an invitation, and it may be pointless at best to try social networking with students in Mixi if the teacher is unable to acquire an invitation from one of their cohort. However, in one class it turned out to be a complex issue to find a student to be the one to implement the invitation among others in the class and, after joining Mixi, to form a topical Mixi community in another class, suggesting that there were invisible lines to cross.

Three 2007-08 classes were negotiated openly, with varying results. To examine why, basic characteristics of each class are next described, starting with the first class approached. Analyzing reasons for the different outcomes, one factor considered is to what extent the class subjects were actually related to social networking. Reading behind the lines, results are interpreted in terms of Japanese cultural values and group dynamics as well as spatial metaphors including technoscapes.

Mixi presents a different situation from mobile phones, which could extend the learning infrastructure informally because of their ubiquitous use among students, or iPods, which all OJC students receive and are thereby an extension of the campus network. While the majority of the OJC students in the classes discussed below already belonged to Mixi, not all did, so there could have been lines dividing the students or cleavages among their technoscapes. They were certainly not monolithic classes but held their own disjunctures, discernible in their various actions and inhibitions. This complexity compounded the challenge of forming new relationships with students above and beyond the class subject matter, but recognizing individual differences along with group dynamics may help explain the diverse outcomes.

A Bridge Too Far in a Bilingual Education Class

A Bilingual Education class at the 4-year college met four hours a week for one semester, with a total of 13 students in their third or fourth year. The class was thematically unrelated to social networking, but with e-mail available, blog links to class-related documents recommended, and lectures of the previous year's course available online, which is termed coursecasting.

The author brought up the subject of Mixi to the class as a whole and asked for an invitation. Attention seemed to turn to one student who had been especially responsive to the teacher in class discussions, otherwise seemingly popular and well-adjusted like many others in her cohort. She agreed, perhaps too quickly in Japanese terms to fully negotiate the issue with her group. Some time later the author asked her again and she agreed, yet she never sent the invitation. One can surmise that she may have had second thoughts about being perceived by her peers as being too much of a teacher's pet. There is a line of affiliation dividing teacher and students that the latter may find safer not to appear to their peer group as having crossed. In general education at many other schools in Japan, students may not speak English in class as fluently as they can for fear of being seen as different from their peers or crossing over in a mutually exclusive sense of cultural allegiance. So this particular student had already crossed some cultural lines, encouraged by OJC course content to embrace bilingualism and biculturalism, yet still finding the invitation to her teacher to join Mixi a bridge too far.

Hierarchical Lines Hard to Cross on Both Sides of the Teacher

To place this issue in a broader perspective, during the same academic year, the author considered trying to start social networking with a Japanese administrator who students had said was active in Mixi. Both the author and administrator were bilingual and on cordial terms in committee work and so forth. Yet this idea evoked inhibitions in the author, evoking a teacher-administrator social boundary difficult to cross, whether Japanese society's reputedly rigid hierarchy truly constituted an obstacle or not. In any case, as a result the author could empathize with any corresponding student embarrassment or hesitancy to cross default student-teacher lines.

Inconclusive Negotiations on a Discussion Class Mixi Community

During the semester after the Bilingual Education class, a year-long Discussion class was in its second semester, meeting three hours a week, with 26 first-year junior college students. The subject of topic discussion was thematically unrelated to SNS, but with e-mail available and Web references recommended. Through OJC faculty-created content-based materials (Swenson & Cornwell, 2007), students had become able to discuss global issues in English to some extent. Some welcomed or sought extra speaking opportunities, again with little connection to SNS. Two students who had won a campus English dialogue contest were excited to record it later as a podcast which, along with their original script, was uploaded for other EFL learners to read while listening, so there was a seed thought in the class about reaching a global audience through the Internet.

In class discussions particularly with a group of four, different from the above-mentioned two, it was agreed that the students would form a Mixi community for this class to stay in touch. It would include the author, who offered technical help if needed, though the Mixi interface is in Japanese. Such a community would be an affordance well-suited to the peer culture and to the situation where their closely-knit class and teacher would be scattered the following year. Yet negotiations proceeded inconclusively. At one point, one of the four, who had palpably worked hard in the second semester to become relatively fluent in English speaking like the other three, mentioned that she did not belong to Mixi yet. Thus it was probably the consideration of the students already in Mixi, not wishing to make any of their peers feel left out, that inhibited them from forming a Mixi community for their class. They may either form a community later or regret not having done so, but they maintained the Japanese cultural value of sacrificing their own wishes rather than risking the appearance of excluding any peers, which they would not wish to happen to themselves. Rather than possibly splitting along fault lines in their technoscapes, they maintained the unity of their peer group.

A Computer Communication Class Fits the Task

In the same second semester, there was a one-semester Computer Communication class that met two hours a week in a computer lab, open to junior college students. The previous years of this class had been enjoyable, but it offered only one credit as a hands-on practicum. This time only one second-year student enrolled, although during three of the 13 two-hour sessions, three other students participated, motivated by intrinsic interest.

For a diminutive Japanese student, being the only student in a class tends to be stressful. She might miss the usual peer solidarity or consider how the teacher views the situation. Online communicative activities simulating distance education with other students in the class were precluded. Mixi was not a formal part of the syllabus or inserted into planned class activities, but Computer Communication was thematically related to social networking. The class subject thus fitted the task. Having one student also made the request for an invitation easier for her to accept, because she was not placed in the position of representing her classmates by extending the invitation.

After several weeks, with rapport established, the Computer Communication student readily invited the author into Mixi. She was a regular user, and the complex group dynamics in other classes alluded to above did not hold in this situation. But the Mixi friend connection with her teacher was by no means kept secret, as friends of hers soon sent friendship requests from within Mixi, some later introducing themselves to the author through this established commonality. As the circle widened, the inference could be drawn that, if there was a student-teacher boundary or social line that was to be crossed, a number of students gladly crossed it after being convinced that it was permissible, or that they were welcome on the other side, responding to the encouragement of integrative motivation as hypothesized in this chapter.

SOCIAL NETWORKING BEHIND STUDENT LINES

Outcomes in the three classes show the importance of the local or immediate context from the vantage point of Asian students. Approaching a group of students for an invitation is evidently more complex, despite or because of the fact that only an individual can issue the invitation. The group may contain greater aggregate desire for relatedness with the teacher, yet the individual extending an invitation becomes a representative or leader, so she needs assurance of representing an unequivocal group consensus lest she become singled out. Establishing new relationships is the hardest part, but it seems quite possible for a teacher to approach a class successfully to network, as evidenced by the invitations the author has been receiving since breaking the ice by becoming a Mixi member.

The small class was conducive to authentic, collaborative activities such as making the YouTube video about Mixi for the Wireless Ready 2008 conference presentation (Thomas, in preparation). The student operated a digital video camera for the first time after learning some techniques. She zoomed in on scenery outside the college window toward Osaka Castle, then focused on the author's introduction of the video. In the main segment, the enrolled student focused the camera on the computer screen while the author browsed his Mixi site, explaining basic functions in the Japanese language interface.

Another student and Mixi user was also present during the filming, and while there was no objection to the idea of inviting Japanese or foreign teachers into their social networks, a sense of ambivalence did emerge. While they themselves had nothing in particular to hide from teachers in their blogs, photos, and other Mixi contents, they could imagine more free-wheeling thoughts and images that some students would prefer only their peers to view. The thought of restraining their free expression because of a wider audience soon occurred to the students, so the opportunity to cross such a social line, or to let others behind one's own lines, is liable to be regarded with ambivalence. All this discussion in English came out before, during and after the filming of the Mixi video in one two-hour class session, so the collaborative authenticity of the activity may have encouraged students to speak out frankly.

SOCIAL NETWORKING WITH MIXI FUNCTIONS

Figures 1-3 introduce the main functions of Mixi that may be of interest for educational purposes. Some limitations of Mixi functions will then be discussed, and comparisons with other social software drawn, particularly with Ning, a more versatile SNS with an English interface that can be used for group collaboration, virtual organizations, academic events, or in lieu of a learning management system. One can enter contents in any language, so with some orientation it may be possible to use Mixi without reading Japanese by clicking intuitively.

Figure 1. Introducing the top of a Mixi member's profile page

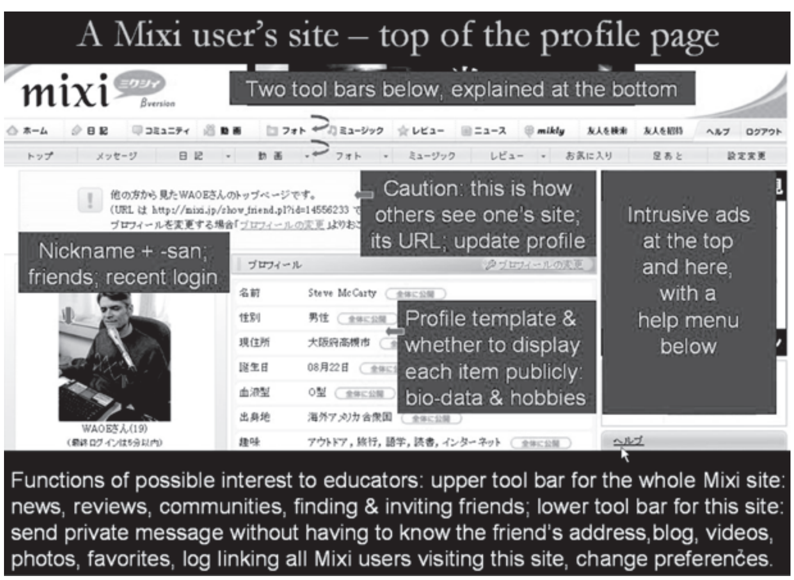

Figure 2. Introducing the middle of a Mixi member's profile page

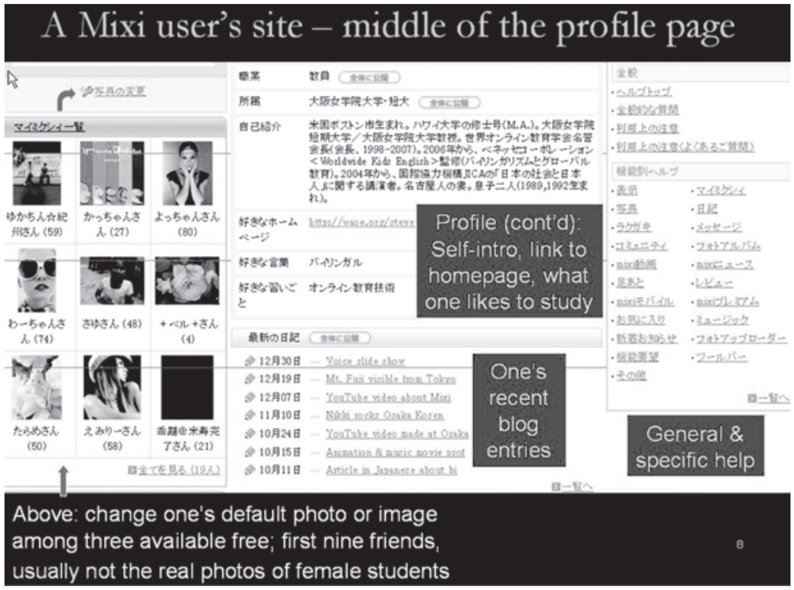
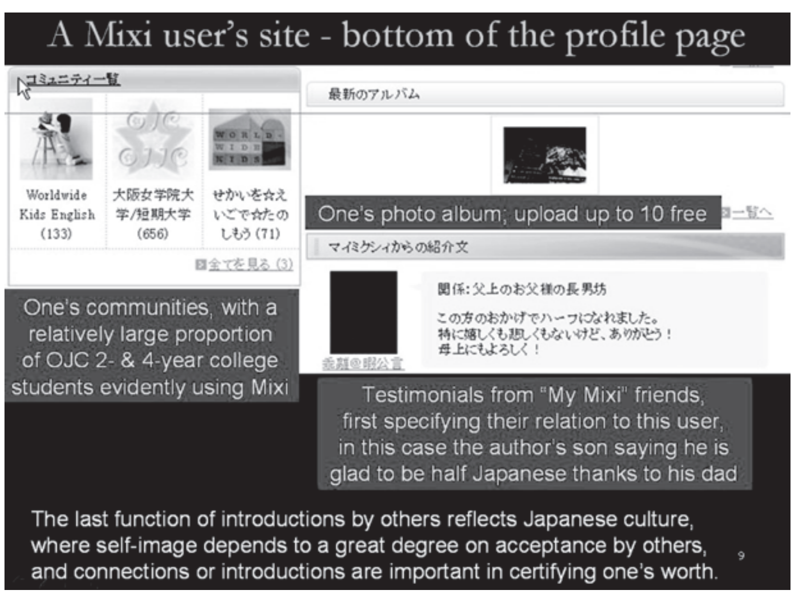


In addition to the above information, if one clicks on links to specific areas such as one's photo album or blog entries, it will be seen that friends can leave messages, often showing appreciation of the content or turning the thread into a dialogue with other users. While the profile page illustrated above is useful for getting started and for indicating how one's site will look to visitors, the user actually adds more content from the top page, which is reached by clicking the link at the extreme left of the lower tool bar for navigating the user's own site. While the top page is largely similar to the profile page, the big difference is that, rather than centering on one's own content

Figure 3. Introducing the bottom of a Mixi member's profile page



such as the personal profile, it features RSS-style syndicated content from blogs, photo albums, and videos of one's friends and topical communities. It also prominently features a search function for various groupings of Mixi content and people. Thus one's Mixi homepage is more outward-looking or socially oriented, while visitors see the profile that the user ordinarily does not need to see.

The top page also includes some widgets such as a weather report for one's region identifiable from the profile bio-data. One's most recent blog entries and photo album are displayed as links with their date of posting shown. There are further links to write a new blog message or a review of a book, event or product, to work on one's photo album, or to upload videos. Clicking on the video link, one is prompted to search for a file on local disk drives or from a mobile phone.

Albeit with a much smaller interface, most of the Mixi functions of browsing, sending and receiving data can be managed from Japanese mobile phones. Widespread use of the mobile mode is simply a result of what users have at hand. Insofar as a networked computer is available, along with a digital or video camera, more powerful content can be created and uploaded more efficiently. However, for simple text functions such as blogging and personal messages, users can do without a networked computer. Moreover, using the Internet on top of the frequent short messaging that Japanese young people enjoy can quickly become prohibitively expensive.

One of the more intriguing and time-consuming affordances of Mixi is the tracking of visitors to one's site. Users can follow links to sites of people who have visited their site, thereby gaining access to the friends of those visitors, and so forth. Their circle can be widened agglutinatively in this manner, but they soon leave the safe ground of certified friends of friends for a world of strangers.

A more integrated approach to uploading media by computer to Mixi is to append files to blog posts along with a text message. After writing the title of a blog post, above the text area are icons to click on to add videos or photos already uploaded to one's Mixi site, or one can make links to embed videos hosted at YouTube, but not other video repositories, by simply specifying the YouTube URL of the video. Another icon is for emoticons, and many Japanese-style pictographs, some animated, are available to enliven blog posts and other messages. These are used extensively by Japanese young people, along with other emoticons created by typing combinations of English letters, symbols, and Japanese characters. Some of the latter are quite elaborate and may not be understandable without background cultural knowledge of gestures such as bowing deeply. Two more icons are a simple paint function for graffiti and Google maps, a vital function for people needing to meet in a land where few streets have names.

It will be found that functions such as writing in HTML code or sharing various media by embedding code are lacking in Mixi, as of this writing, compared to blogging software like Movable Type or a versatile SNS such as Ning. In the latter but not in Mixi, one can select a design template for one's site. More importantly, Mixi limits the amount of media a site can hold, whereas most kinds of media and widgets can be freely uploaded or embedded in a Movable Type blog or Ning SNS.

AFFORDANCES OF SOCIAL NETWORKING WITH STUDENTS

In the context of TEFL in Japan, a key question is what the teacher was able to do with or for students that had not been possible systematically before joining Mixi. These considerations may be applicable to online technologies in Web 2.0 and beyond that can serve as platforms for sustained teacher-student communication outside of limited classroom hours.

Starting with the long view, joining Mixi friendship networks and communities is not only for the sake of students. After a semester or eventually, students move on, and teachers may wish to know milestones in the life of former students, such as their future use of English for intercultural communication. It was hypothesized in this chapter that voluntary supplementary online involvement with students could create a learning environment transformative in terms of their integrative motivation toward L2 learning and a bilingual identity. With SNS involvement now outlasting the face-to-face semesters, longitudinal observation has become possible to gather evidence toward testing such hypotheses. At the very least, after sharing time and mutual effort toward class goals, both teacher and student may wish to keep in touch rather than having arbitrary schedules turn a human relationship into a temporary juxtaposition. Teachers can now find out more about the long-term results of their teaching in their students' actual lives. Conversely, students can continue to draw motivation from messages to them or milestones in the teacher's life and research posted to Mixi.

So far the greater part of one semester has transpired and its aftermath continues with the teacher networking with some students and Mixi communities of the college and beyond. The teacher has posted content to his site in English and Japanese, so as not to set up a bar to participation but rather to nurture a bilingual environment. The photo album and blog posts including videos and other media have included both family milestones and demonstrations of Web 2.0 educational technology. Most of those entries have drawn comments from students and others, often in English. The entries have thus opened up new spaces for authentic English communication in a largely foreign language environment. While a comment or message may be simple, possibly to avoid errors, the very act of using English for an authentic purpose may be significant to the student as a communicator in a social world of broadening scope.

On the level of one-to-one communication through e-mail and Mixi messaging, the author has responded to friendship requests and private messages, with the Mixi affordance that a student can be reached the next time she logs on without having to know her contact information. It may be preferable not to know such personal information in terms of administrative imperatives, for protection of the teacher as well as the students, and for trust and assurance of the teacher's motives. As compared to a blog comment visible to peers, a private message from a Japanese student is not likely to be decided upon lightly, which means that there is probably a strong personal investment in the message. Replying to such messages is therefore important, reinforcing the human bond with that person, and possibly representing a teachable moment or opportunity to enhance a student's integrative motivation to communicate with the L2 target community.

On a broader social level, as soon as the teacher was invited into Mixi, word traveled among students, and it became a lively topic in campus conversations. Establishing a commonality in the usually partitioned teacher-student relationship was a shift that resonated with Japanese socio-culture, while the crossing of lines shook up the default social system in a sense, allowing for new movement. Some former students rekindled an active relationship with the teacher through Mixi. Some friends of the student who had provided the invitation approached the teacher in hallways or at his office, introducing themselves as the teacher's friend in Mixi with a certain nickname. The teacher could also invite former students to stay in touch as Mixi friends when seeing them in the hallways or at their graduation party.

Proactively, the author published his Mixi nickname in campus publications to welcome students to visit his site, as the nickname suffices for a search in Mixi. This kind of identifier signals online technology use while encouraging friendly communication on equal terms. SNS nicknames could be seen as another contact point to include in a 21st Century calling card (*meishi* in Japanese) along with e-mail and messaging addresses, homepage URLs, and graphic images such as QR codes that mobile phone cameras can read like bar codes to access one's mobile phone Website. When the teacher utilizes technologies that students use, the generational barrier is crossed. Furthermore, if the teacher utilizes cutting-edge technologies that students would like to learn, the motivational excitement of curiosity or a sense of challenge can be kindled. If the teacher can do it, perhaps she can, and the teacher becomes a model of technological empowerment as well as of bilingualism.

FURTHER DISCUSSION OF FINDINGS AND HYPOTHESES

The potential affordances of social networking with students, through Mixi in this case for EFL educational purposes, have been shown to run deep in terms of personal engagement, which in turn is linked to motivational factors enhancing possibilities for transformative learning.

Having considered the technical limitations of Mixi compared to other SNS such as Ning, the main reason one would choose Mixi is because it is currently a gathering place for millions of Japanese people. Social networking sites are not sought for solitary self-expression, or even for the latest technology, but rather to connect for social communication where the largest number of potential online acquaintances can be contacted.

Compared to other Web 2.0 technologies, Mixi has been readily indigenized to enhance pre-existing Japanese social communication patterns. Its popularization thus reflects its usability for individuals in pursuing their own desires or social aims.

Unlike nascent technologies such as 3D virtual worlds, which will be attractive to students as powerful graphics computing becomes available to them, Mixi is already a part of Japanese student technoscapes. Not to the ubiquitous extent of mobile phones, but some familiarity with Mixi among college students can be assumed when bringing up the topic of supplementary online teacher-student communication.

As to whether a foreign teacher could smoothly go behind student lines through Mixi, the need for an invitation from an individual activated complex Japanese group dynamics in approaching a class openly as a whole. After the teacher was invited into Mixi in a one-to-one situation the group approach could not be further tested, but it should be quite possible for a teacher to successfully negotiate with a group of students for an invitation, provided the existing sociocultural contours of Japanese group dynamics are respected. At the time of the Discussion class with first year students the teacher was a Mixi member and welcome in the proposed class Mixi community, but the problem was that not all the *students* were members.

As to the desirability of social networking with students in terms of educational principles, Dörnyei (2001, pp. 31-39) finds it quite appropriate in creating basic conditions for motivation to develop personal relationships with students. After the teacher became a Mixi member the unprecedented approaches from students showed that there was an intrinsic demand for such relationships through social networking. It was as if pent-up demand for more personal communication with a foreign teacher was released, perhaps as a proxy or safe halfway house, as it were, for students' intrinsic motivation toward communication with the target language community.

If one were to investigate whether a foreign teacher is welcome or not in student social networks, the complexity has been evidenced by the differences displayed by students when alone with the teacher versus the particular social and technological compatibilities of a certain peer group. The author would predict that surveying students as to whether they would like to invite a foreign teacher into their SNS or not would produce different results depending on precisely how the students were approached. If such a question were circulated by a Japanese student, for example, in Japanese regarding teachers in general, a different set of considerations might be activated than if their foreign teacher surveyed students directly in writing or in person in English. All sorts of variations could result, with variables including individual student motives and their calculus of trust, risk and other attitudes toward a certain teacher. Rather than arriving at a generalization about a presumptively monocultural population, the answer would be more like a question of just what factors in what weighting could cause such variations. Ultimately the question may be rather how the cross-cultural educator can employ technology to create conditions that work in this cultural context to foster bilingual development.

This chapter has alluded to breaking down the artificial distinction between real life and virtual life. What resulted from joining Mixi was not just the supplementation of classroom communication with an online dimension but also a washing back of virtual relationships into so-called real life.

This chapter has also alluded to the metaphor of agglutination, a characteristic of rice that has been ascribed to the Japanese language in JSL and JFL studies (Minami, 2007, p. x). The pattern described in this chapter, where friends of a friend took Mixi linkage as sufficient commonality to boldly introduce themselves, could similarly represent an agglutinative social pattern in Japanese culture.

Educators may have reasons not to cross certain lines or to maintain their authoritative distance from students, in order to meet local expectations or for class management. The supplemental online dimension explored in this chapter is entirely voluntary and soon goes beyond the framework of a certain class into the wider world of human relationships. In the context of that larger frontier, social networking has been shown to provide a way that is congruent with Japanese culture for a cross-cultural educator to go behind student lines and expand the scope for EFL motivation and positive learning experiences beyond the classroom.

CONCLUSION

A number of hypotheses were proposed in connection with going behind student lines with Mixi in the context of TEFL in Japan. Then the findings from actual negotiations and interactions with students were described and interpreted on sociocultural and technological levels. The main functions of the Mixi social software were illustrated, with the Japanese interface explained in English. How the affordances of Mixi were actually utilized by the teacher and students was also detailed. Moreover, Mixi functionality was found to fit and thereby enhance social communication patterns already established in Japanese culture.

The hypotheses and findings raised a number of questions that call for deeper examination. It was shown how results varied in different classes, acknowledging individual differences in intrinsic motivation and so forth. But if social gear-shifting, time-place-occasion sensitivity, and group dynamics are considered as cultural characteristics, Japanese values provided sufficient explanations for student decisions, belying a cultural consistency in the ostensibly varying outcomes.

Another question was whether or not metaphors of lines, social spaces and perspectives served as suitable scaffolding for understanding the cross-cultural educational issues involved. Such metaphors as invisible lines, crossing boundary lines, hierarchical lines, and social territories proved useful at the very least by forefronting sociocultural norms and expectations that most often go unstated, while what is taken for granted differs between interlocutors in cross-cultural encounters. Extending the metaphors consistently, particularly reading or going behind the lines, seemed to bolster the explanatory framework. But “technoscapes” did not seem so salient to map individual and group perspectives on technology in this case. "Global flows" lack precision to account for the particular context in Japan. While the notion of landscapes could serve to place the focus on perspectives, student perspectivity was already acknowledged in treating them as unique subjects.

Another question is whether or not social networking with students, as hypothesized, actually enhances their L2 motivation. It could not be confirmed longitudinally, and yet communication is continuing autonomously through Mixi where it would have otherwise ended with the semester class or graduation. Science tends to be tone-deaf in gauging the significance of what is normally observed as palpable excitement, and which in education is believed to be a sign of positive if not optimal motivation.

It can be reasoned in many ways from the results that motivation was enhanced. If a supplementary educational opportunity is offered in a purely voluntary online environment, for students to go out of their way and engage with it represents a movement that must have a motive or motivation corresponding to the opportunity. If a student was already intrinsically motivated, for it to be reinforced as opposed to being neglected outside of class also represents a relative enhancement of their L2 motivation. As another example, students previously unrelated to the teacher agglutinated to the social networking involving English once the wall was breached by one student. A commonality can provide an opening for new relationships in Japanese socioculture when a formal introduction or group connection is not available. When students introduced themselves to the foreign teacher of their own volition in writing or in person, such a movement out of familiar circles reflected their motivation. If they felt welcome in such a new relationship involving English, then it stands to reason, since people cannot remain the same, that their integrative motivation was enhanced.

Nevertheless, myriad issues in social networking and other technologies applied to education call for further research. But one-size-fits-all theories and multiple-choice grids cannot be prescribed as global standards to all local contexts. This chapter attempted to acknowledge the variegated particulars in one sociocultural context, and meanings emerged bottom-up from the details and patterns observed in the Japanese social repertoire. In the motivation literature, self-determination theory figures prominently, but it remains to be shown just how well the map fits the actual terrain in non-Western educational situations including instructivist institutional cultures. Alm (2006) cites self-determination theory in finding Web 2.0 activities motivating in an Australian context. But even aside from student views of the technology itself, it remains to be shown whether individualistic theories could most accurately account for both success stories in EFL education and trends toward declining motivation in East and Southeast Asia (Lamb, 2008). In any case, further study is warranted to avoid overgeneralizations.

This chapter, while recognizing individual agency, often traced student decisions to group dynamics in Japanese socioculture. In this balance, "self"-centered theories may be less salient than socially grounded explanations, particularly with respect to SNS. Sociocultural and social-constructivist theories and methodologies, perhaps combined with local or indigenous knowledge of the educational context, may shed new light on motivational transformation. A fluid concept of self as continually created, often in social situations including education, may be more suitable to a Japanese style repertoire of shifting gears or roles, while also allowing for identity transformation free of typecasting. For as identity changes, particularly as EFL learning experiences open up new avenues for bilingual and bicultural development, motives and motivations constitutive of the individual also transform.

KEY TERMS AND DEFINITIONS

Integrative Motivation: A type of motivation that is particularly relevant to learning foreign languages, it refers to a learner's intrinsic orientation or desire to communicate with, be more like, or to join the L2 (second or foreign language) user community. Developed chiefly by R. C. Gardner, the concept has been refined by Z. Dörnyei and others, moving away from fixed attitudes toward the possibility of transformation as hypothesized in this chapter.

Mixi: The most popular SNS in Japan with users estimated at over ten million, possibly over a tenth of the whole population, predominantly students and young adults. Most of its functions are accessible from the mobile phones ubiquitous in Japan. In this chapter Mixi provides a supplementary online dimension for a teacher to motivate EFL students and continue the human relationship after classes end.

Second Life: Sometimes referred to as simply SL, Second Life is a 3D virtual reality developed by the Linden Lab in California, USA, that was launched in 2003. It became more prominent in late 2006 as a number of global corporations and educational institutions opened buildings there. Based on a free downloadable client, Second Life estimates that up to 18 million accounts have been registered there as of early 2008.

SNS: Social networking site or sites, sometimes social networking service or services. To users it is an online gathering place for enhancing relationships and making new acquaintances by sharing words and media about oneself and one's world. Successful SNS companies provide mostly free services and gain revenues through advertisements rotating on users' Web pages. Functionality differs according to technology and culture, but common functions are profiles, blogging, photos and short videos, with messaging and RSS-style notifications of new entries by a user's friends and topical communities.

Socioculture: The combination of social factors, some of which may be incidental to contemporary institutions, with cultural factors that are deeply ingrained and passed across generations, strongly coloring people's identity and communication style. The resultant combination affects people's tendencies to affiliations that can be related to languages, and this chapter utilizes metaphors of lines to symbolize existing sociocultural borders that may constrain cross-cultural communication along with other patterns of behavior.

Technoscapes: A type of global cultural flow in A. Appadurai's anthropology of globalization. It foregrounds the various perspectives people have on technologies, and this "perspectivity" can be useful in considering the varying background knowledge of students in CALL (computer-assisted language learning) classes. Globalization generally affects such students in Japan, but this chapter finds that knowing the specific cultural background of students is essential to interpreting their use of social networking technology.

TEFL: Teaching English as a Foreign Language (EFL). Teaching English where another language is predominant in the environment. Therefore, English input or practice in a country like Japan often depends on classes that do not meet often or long enough to match the results of an ESL environment where, by contrast with EFL, English pervades the environment outside of class as well.

Chapter 4.19
WEB 2.0, Social Marketing Strategies and Distribution Channels for City Destinations:
Enhancing the Participatory Role of Travelers and Exploiting their Collective Intelligence

Marianna Sigala
University of the Aegean, Greece

ABSTRACT

During the last decades, the use of Web 2.0 applications for the generation, dissemination, and sharing of user-generated content (UGC) and the creation of new value added services are enormous. Web 2.0 tools have tremendously changed the way people search, find, read, gather, share, develop, and consume information, as well as on the way people communicate with each other and collaboratively create new knowledge. UGC and Web 2.0 are also having a tremendous impact not only on the behaviour and decision-making of Internet users, but also on the e-business model that organizations need to develop and/or adapt in order to conduct business on the Internet. Organizations responsible to market and promote cities on the Internet are not an exception from these developments. This chapter aims to inform city tourism organizations responsible for the development of city portals about (a) the use of the major Web 2.0 tools in tourism and their impact on the tourism demand and supply; and (b) the ways and practices for integrating the use of Web 2.0 into their e-business model and e-marketing practices.

DOI: 10.4018/978-1-60566-134-6.ch011

INTRODUCTION

During the last years, the number and use of numerous Web 2.0 tools, whereby Internet users produce, read and share multimedia content (User Generated Content, UGC), is mushrooming (eMarketer, 2007a). It is estimated (eMarketer, 2007b) that 75.2 million USA Internet users currently use UGC, and this is expected to increase to 101 million by 2011.

eMarketer (2007c) also found that over 25 million USA adults regularly share advice on products or services online.

The Web 2.0 technologies and applications (e.g. tags, RSS, blogs, wikis, podcasts, etc.) are considered as the *tools of mass collaboration*, since they empower Internet users to collaboratively produce, consume and distribute information and knowledge. In other words, Web 2.0 tools do nothing more than realizing and exploiting the full potential of the genuine concept and role of the Internet (i.e. the network of the networks that is created and exists for its users). This has tremendously changed the way people search, find, read, gather, share, develop and consume information, as well as on the way people communicate with each other and collaboratively create new knowledge (Sigala, 2008). UGC and Web 2.0 technologies are also having a tremendous impact not only on the behavior and decision-making of Internet users, but also on the e-business model that organizations need to develop and/or adapt in order to conduct business on the Internet (Bughin, 2007).

The tourism industry is not an exception from such developments. On the contrary, as information is the lifeblood of tourism, the use and diffusion of Web 2.0 technologies have a substantial impact of both tourism demand and supply. Indeed, more than ¼ of Internet users have used a weblog to review information about a destination or travel supplier in the last 12 months (Harteveldt, Johnson, Epps & Tesch, 2006), many new Web 2.0 enabled tourism cyber-intermediaries have risen challenging the e-business model of existing online tourism suppliers and intermediaries who in turn need to transform their e-business model and e-marketing practices in order to survive (Adam, Cobos & Liu, 2007). As the Internet plays an important role for the e-marketing of city destinations (Sigala, 2003; Yuan, Gretzel, & Fesenmaier, 2006), Web 2.0 tools and applications also create both threats and opportunities for organizations developing and maintaining destination management systems and portals. In this vein, this chapter aims to inform city tourism organizations responsible for the development of city portals about: a) the use of the major Web 2.0 tools in tourism and their impact on tourism demand and supply; and b) the ways and practices for integrating the use of Web 2.0 into their e-business model and e-marketing practices.

WEB 2.0 TOOLS IN TOURISM: USE, IMPACT AND APPLICATIONS IN CITY MARKETING

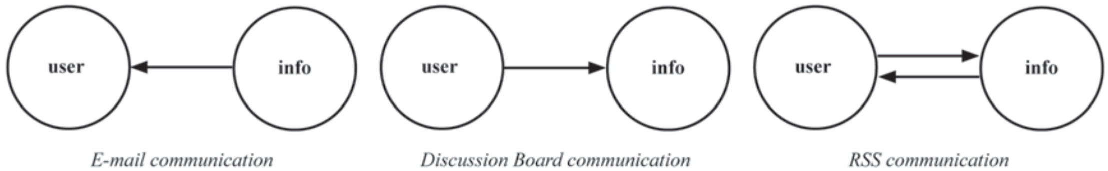
RSS (Really Simple Syndication)

Definition, Features and Use

RSS allow users to subscribe to a webpage for receiving new content, e.g. subscribe to receive online distributions of news, blogs, podcasts etc, and so, RSS allows the creation of links and interactive communication amongst other Web 2.0 applications and users. This is done either through a news aggregator (similar to an email inbox) or a news reader (a web-based environment) (Winer, 2005). By doing so, one does not have to visit each individual website that he/she is interesting to read any new information, but rather the RSS feeds all new updated information to the users' RSS reader. RSS readers enable Internet users to gather and read all new information that is customized to the user's profile within one consolidated message. Many free RSS exist on the Internet, e.g. FeedDemon, NewsGator, Rojo, software on the website of Google™, MyYahoo®, etc.

RSS allows new communication and interaction modes with information (Figure 1) (Farmer, 2004). In e-mail, the control of the communication channel is held entirely by the instigator of the communication. Consequently, e-mail communication is characterized at times by flame wars, antisocial behavior and feelings of intrusion by the participants, while the information artifact is transitory, unfixed and not archived except in indi-

Figure 1. Communication types



vidual instances. In discussion boards, information artifacts are fixed, frequently archived and can be interacted with through threading and comments, but for accessing information, the user must deliberately visit a dedicated online area. In contrast, in RSS, both the communicator and the reader of information have control of the communication process, i.e. the former sends information only to those that users have selected to aggregate the RSS feed, while the later select from where and how (e.g. summaries, titles, or full entries) to receive communication. Further, as most RSS aggregators are either integrated with or stand-alone desktop/web applications, readers need only to check the aggregator for new items.

Impact on Tourism Demand

RSS feeders have a tremendous impact on the way consumers search and read information nowadays. RSS has the following benefits for users:

- saves a lot of time spent on information searching;
- provides users with consolidated personalized information;
- is less obstructive and more personalized to users' interests than other Internet based communication, and so, RSS entice subscribers to visit the related websites, thus helping in building website traffic and visitation;
- RSS boosts viral marketing and online word-of-mouth as users tend to forward items in RSS feeds to their friends, family and co-workers, much like the 'forward this message' feature in eNewsletters.

Business Applications for City Marketing

As RSS is an information distribution technology that is characterized as a demand pull rather than a supply push model, many tourism destination organizations have adopted and incorporated RSS feeds in their websites in order to communicate with their potential and current travelers in a less disrupted and personal way. Some examples of RSS include:

- Keep a communication with their travelers such as sending them Newsletters and/or updates of the programme of cultural events organized in the city.
- RSS helps organizations to enhance their Search Engine Optimization by creating inbound links to a company's website and by informing search engines whenever new content is uploaded on a website, so that they can index it.
- RSS is used for syndicating content to other Websites expanding the original website's readership and reach.

For example, the destination marketing organization of Las Vegas has included an RSS on its website (visitlasvegas.com), whereby users can subscribe to feeds that automatically notify them of current travel specials. Almost all of the information (e.g. events' news, weather updates, special offers, etc.) on the official city website of Dublin created by the city tourism board (visitdublin.com) is available to any traveler and/or other website through RSS. RSS are offered for free for anyone for reading and/or enriching his/her own web site, provided that the latter follows the proper format, terms and conditions and attribution, e.g. attribution such as *"Content provided by Dublin Tourism"*. In such a way, visitdublin.com aims to enhance readership of its content, continuous personal communication with its customers, viral marketing, and search engine optimization through content syndication and incoming links.

Blogs (or Weblogs)

Definition, Features and Use

Weblogs began as personal writing spaces that store and update regularly multimedia content (in reverse chronological order) and links of interest to the author. Thus, blogs are used for recording its author's journey and sharing it with others by using links, RSS, trackbacks, comments, taglines, archives, permanent links, blogrolls, etc. (Blood, 2000). Weblogs are defined as a ''… site consists of dated entries'' (Blood, 2000), whereby entries are episodic or conversational in a diary or ''story telling'' format. Motivated by different reasons (Forrester Research, 2006), such as documenting one's life, providing commentary and opinions, expressing deeply felt emotions, articulating ideas through writing, and forming and maintaining community forum, weblogs (or blogs) are a *''new form of mainstream personal communication''* (Rosenbloom, 2004, p. 31) for millions of people to publish and exchange knowledge/information, and to establish networks or build relationships in the world of all blogs. Indeed, blogging tools enabling between-blog interactivity are building up the ''blogosphere'' whereby social networks among bloggers are created. Du and Wagner (2006) identified the following characteristics of blogs:

- **Personalized:** blogs are designed for individual use and their style is personal and informal. Blogger.com offers a ''team blog'' collaborative feature enabling also multi-person weblog.
- **Web-based:** blogs are easy to access and frequently maintain by simply using a web browser.
- **Community-supported:** Weblogs can link to other weblogs and websites (e.g. photos, videos, web-texts), enabling the synthesis and linkage of ideas from different users, and so, stimulating meta-knowledge, i.e. the generation of new knowledge through sharing.
- **Automated:** Blogging tools are easy to create and maintain without the need of HTML programming skills and knowledge; so, bloggers can solely concentrate on the content.

Du & Wagner (2006) also identified 3 types of blogging tools and features: type I features of blogging (such as text, diary, hyperlinks, user friendly editor) provide easy-to-use and learn tools for editing, presentation, publishing and interlinking of content. Such blogs are heavily used by those that solely seek a channel of self-expression. Type II blogging tools (such as Indexed archive, search, "permalink": a permanent URL for each weblog entry enabling referencing of specific past entries like other web-source. ''Trackback'': a reverse hyperlink tracking the referrer weblogs ''making these formally invisible connections visible'', categorisation & syndication) are used by bloggers who wish to easily share rich media (e.g. videos, pictures etc), to have a sophisticated content management system and to enable between-blog commenting or hyper linking, e.g. through ''permalink'' or trackback (Blood, 2000).

Nowadays, the emerging Type III of blogging tools provide improved content distribution and between-blog connectivity (e.g. “pingback”, alert of other bloggers’ comments or new posts), as well as integrated applications for further enhancing social networking and community building such as the following examples:

- Workflow or project management (e.g. Lycos Circles workflow for a party, from invitation to management of responses and to travel directions),
- Polls, Intrasite messaging (e.g. ModBlog allows users to track friends’ newest entries, or to know who are the most “recent visitors”),
- Web invitation, picture/music sharing (e.g. MSN Space picture/music sharing, and remote posting of updates via email or mobile devices).

Impact on Tourism Demand

Numerous examples of general and-or (content or user) specific blogs have been created in the tourism industry, such as tripadvisor.com, hotelchatter.com, bugbitten.com, placeblogger.com, realtravel.com, travelpod.com, igougo.com, gazetters.com (a B2B blog for travel agents). Many travelers and tourists also develop and maintain their own blogs for sharing their travel experiences with others and distributing their feedback (reviews) of travel suppliers for achieving fun, social recognition, prestige and-or self-expression. Due to the unbiased information shared in blogs based on first-hand authentic travel experiences, many travelers tend to use and trust blogs’ information for searching for travel information, tips and selecting travel suppliers and destinations. Blogs have the power of the impartial information and the electronic word-of-mouth that is diffusing online like a virus. Hence, blogs are becoming a very important information source for international travelers for getting travel advice and suggestions. Moreover, when reading others’ travel experiences through weblogs, this also creates to the reader the willingness to travel and visit the same destination or suppliers. Indeed, research has shown that UGC at blogs has a similar AIDA effect to users as paid advertisements have. The latter is because blog’s content can (Lin & Huang, 2006): 1) **A**ttract the attention, eyeballs of other Internet users and increase traffic on a website, 2) create **I**nterest to users who can now seek more and additional information, 3) develop someone’s **D**esire to also visit a destination and/or buy the product and 4) foster an **A**ction (e.g. book a hotel or organize a trip to a destination). Of course, it should be noted that the power of blogs can also be negative, i.e. spread a bad experience of a tourist to million of online Internet users. Therefore, it is very important that tourism companies authorize a public relations staff as the responsible representative of the company to first scan and read blogs’ content and then respond to formally any positive and negative users’ comments. Guidelines and corporate policies for responding to UGC should also be established. Nowadays, many blogs take the form and are presented in a video format (Vlog, video blog). The first travel website to implement vlogs exclusively is endlesseurope.com. Due to the multimedia features of video content and the intangible nature of the tourism product, it is argued that vlogs are going to have a much greater impact and influence on travelers’ decision making and evaluation of alternative tourism products and suppliers.

Business Applications for City Marketing

Blogs generate and distribute a plethora of UGC related to travelers’ experiences, suppliers’ and destination reviews, travel tips and advices. City destination management organizations can exploit and use such content for:

- monitoring and influencing electronic word-of-mouth;

- conducting an easy, free, timely and reliable market research about travelers' preferences, feedback and profile;
- communicating with current and prospective travelers in a very personal and informal way;
- gathering travelers' feedback and responding to customers' complaints;
- enhancing search engine optimization: blogs are becoming very important tools affecting information search since their links, content and popularity can dictate the position of a company on a search engine search.

There are many search engines that one can use for identifying and locating weblogs. The most popular one is technorati.com, which also provides statistics about the online activity of weblogs, e.g. about the popularity of a blog and its potential influence on search engines results.

Apart from exploiting others' blogs, many tourism suppliers and destination management organizations have also adopted a pro-active strategy by creating and incorporating blogs on their own websites. For example, Marriott has created its own blog on its website (www.blogs.marriott.com), while Starwood has created a blog to communicate with its Preferred Guests and enhance their loyalty through the website www.thelobby.com. Company initiated and moderated blogs can offer the following benefits: solicit and gather feedback from customers; conduct free online market research; become recognized as an expert on a specific topic; communicate and update your customers with latest news; and use others' customers' suggestions for helping customers select and evaluate products such as what amazon.com is doing by allowing users to upload books' reviews on its website. For example, Eurostar has initiated a blog (www.voiceofacity.com) whereby it has commissioned local Parisians to post blogs for creating a travelers' guidebook with a truly ground-roots feel. The destination organization of the city of Los Angeles has created a blog supporting the sharing of bloggers' experiences and insights on their adventures of the diversity of Los Angeles' arts and culture (http://blog.experiencela.com/). The fully Web 2.0 enabled official portal of Holland features a blog capability (i.e. the triplog) enabling Dutch travelers and locals to share and post the experiences they lived in Holland (http://us.holland.com/blog.php?sf=e.pagerank&so=DESC&sel=popular). In this vein, blogs are becoming a useful tool for enabling local communities to get more involved in destination marketing, communicate and blur with tourists. As a result, blogs and web 2.0 tools can support and foster community participation in city tourism development and marketing practices. Community participation can ensure a better blend between locals and tourists reducing any inter-cultural conflicts, creating social relations and respect and understanding amongst different cultures as well as enabling multi-stakeholder understanding and communication in tourism decision making and activities.

Social Networking–Collaborative Networking

Definition, Features and Use

Social networking websites enable users to create their profile and invite others with similar profile to take part in their online community. The most popular websites such as myspace.com and bebo.com reflect the willingness of Internet users to transform websites as a gathering place of people with similar profiles.

Impact on Tourism Demand

Many social networking websites have been created in the tourism industry allowing travelers and prospective travelers to network with one another based on shared interests or attributes, such as tripmates.com, gusto.com, triporama.com, triphub.com, traveltogether.com and wayn.com. Travelers log into websites and create a personal profile detailing their travel experience and interests, then network with others o share travel advice and stories, and even plan trips together. Hence, social networking websites have a tremendous impact on how tourists nowadays create, organize and consume tourism experiences. Many tourists nowadays prefer to have the reassurance of other users sharing similar profile with them that the trip, the travel company, destination and/or the itinerary that they have scheduled is a good one and it matches their preferences and tastes. Many tourists also wish to use the Internet for collaboratively organizing a group trip with their friends. Websites such as tripup.com, traveltogether.com and travelpost.com enable tourists to create an itinerary, e-mail and share it online with others, who in turn can edit, modify and enhance it, post it back to others for further comments and / or invite and read other travelers' comments and advices on the trip they organized in order to finally achieve a consensus and proceed to a group booking.

Business Applications for City Marketing

Since sharing travel experiences in a social website can significantly inspire travel and boosts one's willingness to visit a destination or supplier, several tourism websites are incorporating social networking tools in their e-business models. For example, existing cyberintermediaries, such as Yahoo!® Trip Planner has adopted a collaborative trip organizing and booking tools. The official website of the city of Philadelphia has also features a collaborative trip planning tool (www.planit.pcvb.org), that potential travelers can use for organizing their itinerary in Philadelphia with friends as well as soliciting feedback and comments from other travelers and locals.

Lufthansa created and operates its own social networking website, named as Jetfriends, for enabling its young flyers to share flight experiences and indoctrinate them into the Lufthansa brand and frequent flyers' club (http://www.jetfriends.com/jetfriends/kids/). Sheraton also re-organized and re-designed its website (which is nowadays titled as the Sheraton Belong Neighborhood), whereby Sheraton's guests can subscribe to the website, upload their experiences, stories, pictures, videos and comments for sharing them with other website visitors and users. The social networking of Sheraton's website enables potential travelers to organize and book their holiday and hotel experience at any Sheraton property that matches their profile and preferences by reading and reflecting on the comments and first-hand experiences written by previous Sheraton customers. The impact of social networking features for persuading potential travelers to select a particular hotel and/or destination is very powerful, because through social networking websites, travelers can search website content based on keywords and stories contributed by other travelers that may be more relevant and make more sense to them than keywords and experiences being created and pushed by the website developers themselves. For example, on Sheraton's website one can search an hotel experience based on the comments and tags contributed by a previous guests referring to *"nice walking in beaches nearby Sheraton hotels*" or *"relaxing family holidays in Sheraton properties"* rather than using the Sheraton's search engine to find hotel based on its location, facilities etc.

Nowadays, many city destination organizations have also incorporated social networking features into their e-business model and strategy in order to further enhance their communication with customers and take benefit of the electronic word-of-mouth that they can create. For example, the official website of Los Angeles invites any cultural and art organization-institution to become a partner with experiencela.com in order to share and distribute related content on their website. Experiencela.com has also created a cooperation e-business strategy with the social networking websites clickr.com and myspace.com. Specifically, the destination management organization of LA created a special webpage for LA on flickr.com (http://www.flickr.com/groups/21164279@N00/pool/) and myspace.com (http://www.myspace.com/experiencela) in order to enable the users of the formers that are also funs and travelers of LA to share personal photographs, comments and stories about LA. The city of LA has realized that such UGC can crucially drive traffic to their website, boost their search engine optimization strategy, instil travelers' desire to visit LA and use customer intelligence for providing reliable and timely advice and suggestions for trips to potential travelers to LA.

Tagging (Social Search and Tag clouds)

Definition, Features and Use

Tagging represents a new way for categorizing information. Users tag a piece of content (e.g. an audio, a picture, a word) with a meaning (a word or phrase) and then this information is categorized in categories based on this meaning. Community tagging is a bottom-up, grass-roots phenomenon, in which users classify resources with searchable keywords. The tags are free-form labels chosen by the user, not selected from a controlled vocabulary. Tagging is also known as consumer-generated taxonomy. Forrester (2006) defines tagging as 'the act of categorizing and retrieving Web content using open-ended labels called tags'. Tagging provides customer value, because it allows them to assign their own word or words to mark products and content online in order to categorize content that they find relevant, i.e. such as what bookmarking allows users to do. Words that users choose for categorizing website and content then become a navigation shortcut that a person can use to browse and search content throughout that site.

Tagging is used not only for saving and sorting a user's content but also for sharing content with others. Websites with tagging capabilities can also allow users to share their personal tags and navigation ways with other users. Moreover, some tag enabled websites enable users not only to share their tag navigations, but also their profile. In this way, users can see who has tagged something, and try to search and find information based on the search behavior of users with similar profiles and mental maps with them (personalized social searching). In this vein, tagging has a great effect on how search engines identify and present information results in keyword searches to users.

Flickr.com represents the first wide-spread of tags, whereby users can add their own tags to any photo they wish to share, aggregate pictures into photosets, create public or private groups, search photos by tags and easily add flickr-stored photos to a blog. Nowadays, there are numerous websites enabling tagging and searching based on tags, e.g. del.icio.us, a bookmarking service, Technorati, a blog cataloging site, and digg, a gathering place for tech fans. These sites create clickable "tag clouds" for resources, groupings of tags arranged alphabetically, with the most used or popular keywords shown in a larger font. In this way, these websites present other websites that users think are important or relevant to them. Many such sites make use of RSS to notify interested users of changes and new developments, e.g. in flickr.com, RSS feeds can be attached to individual tags, or to photos and discussions. In addition to RSS, flickr.com and other social networking sites typically offer functions such as search (for users and tags), comments (and comment trails), and APIs (application program interfaces) for posting to or from the tools, that can be used in combination with blogs. An interesting use of RSS that is combined with tagging is the Flashcard exchange, where, one can view or subscribe to all flashcards posted for learning Spanish (or other languages).

Although the tagging process is by no means simply technical—a way of categorizing resources—it has a strong social dimension as users of the website find common interests and create on-line communities. It represents another example of the fuzziness separating consumers and creators on the Web. A contribution to a tagging site, seen by other users, may cause additional tags or comments to be added, automatically building and updating and thus ultimately defining a resource. Instead of one person making a judgment about a blog entry, photo, or other resource, a consensual classification is created. In effect, a text or object identifies itself over time. This creation of "folksonomies" (as the user defines how to sort information which in turn defines how others search and find information) can be seen as a democratic implementation of the Semantic Web. Thus, for some, tagging helps and boosts the creation of the semantic web (Web 3.0), whereby web content and search is directly related to its meaning for the users.

Impact on Tourism Demand

Several websites offer the capability for users to sort, share and categories travel related content based on tagging, e.g. flickr.com (for pictures sorting and sharing), travbuddy.com (for travel experiences sharing), travelistic.com (for tagging video content). However, although more and more users are using collaborative tools for identifying and sorting travel content, tagging is still an emerging technology: only 5% of USA online leisure travelers—slightly more than 5 million of the 114 million USA adults who travel for leisure and go online regularly—tag Web pages or other content on sites like del.icio.us or Flickr™ (Epps, 2007). Moreover, the social capabilities of tagging for community building and social collaboratively construction of concepts' meaning and of travel experiences could have numerous innovative applications in tourism as well. For examples, travelers may be enabled and offered the opportunity to build structural tags in a text using XML for creating word groups or simply finding appropriate keywords to describe a travel experience. This would offer additional options to Internet users to collaboratively develop travel itineraries and search of travel information with others sharing a similar profile with them.

Business Applications for City Marketing

Because of the power of the folsconomy to provide enhanced user-value and influence the results/page ranking of search engines' search, many tourism firms nowadays include and consider tagging when designing their websites and e-business strategy. For example, Thomson's website provides an affiliate link to deli.ci.ous.com (http://www.thomson.co.uk/), so that its users can tag and sort its website content through this technology.

However, tourism firms may adopt different strategies regarding the way they use and incorporate tagging into their websites (Epps et al., 2007). For example, Triporama.com has launched its tagging system, titled "Triporama Bookmarks", which allows its website users to download a free software in their PC for tagging content in their own words from anywhere on the Web to their Triporama group trip plan, which they can then share with their travel companions. Such a solution provides differentiation customer value for Triporama, because as travelers visit many different Websites while planning a trip, Triporama's bookmarking tool lets travelers collect, label, and share the content they have found on the Web with other members of their group. Users also have the option to make their tags publicly available, while Triporama also aims to edit and curate these public tags into features like "top 10" lists to give other users ideas for planning their own group trips. When redesigning its website, Sheraton introduced its "Vacation Ideas" feature whereby guests are invited to write stories about their hotel stay, users give Sheraton their consent for publishing their stories online and the entire story becomes a tag. A tag cloud is created, titled the "Buzz Barometer", whereby word occurring most frequently in stories appear in bigger fonts, while based on the number of stories shared containing different words a "Vacation Ideas page" is created (http://www.starwoodhotels.com/sheraton/index.html). For example, by clicking on the "Beach" guide brings up the five hotels whose stories mention "beach" most frequently (weighted by the number of stories relative to the size of the property). By making storytelling the method by which the tags are created, Sheraton has made tagging so friendly and easy for its guests that they do not even know that they are tagging content. Sheraton benefits from this tagging strategy because:

- It helps first time website users: Vacation Ideas gives travelers, not knowing where they want to go and/or not familiar with the Sheraton brand, a more creative, user friendly and understandable way to search and book hotels than the customary destination-based and company pushed search.
- It helps Sheraton to build long lasting relations with its guests by maintaining a close relationship with the travelers before, during and after the trip. This is because the website provides guests having stayed at a Sheraton's hotel to return to the Sheraton's website in order to contribute, solicit or read other travelers' stories.
- It improves organizational learning, since Sheraton gets insights into Sheraton's hotel properties and customers' experiences. Instead of conducting expensive and time consuming research, Sheraton uses tagging as a simple and reliable way for gathering customer feedback and intelligence about its products and services. Based on the customer knowledge that is gained, operation managers can improve organizational processes, while marketers get to know what and how customers think and talk about the brand, in order to better position the Sheraton brand in the market and enhance the guest experience at the hotels in ways that reinforce guests' perspective of the Sheraton brand.

Yahoo!® Travel introduced new tagging features into its Yahoo!® TripPlanner that enable users to tag their own or others' Trip Plans with suggested or custom tags, which are later analyzed and used by Yahoo! for identifying and feeding recommendations on the Yahoo! Travel home. Users can set their preferred level of privacy at the level of the Trip Plan (private, shared with invited friends, or visible to any user). Users are provided around 30 tags (e.g. ("budget," "luxury", "weekend", "honeymoon") to choose from for labeling trip plans from the style of the trip, however, Yahoo! monitors the tags used most frequently by its users for augmenting its list of proposed tags. By using taxonomy-directed tagging, Yahoo!® eliminates many of the inherent problems of folksonomies created when users label similar things differently using synonyms or different forms of the same word (e.g. lodging, accommodation, hotel etc.). Tagging has helped Yahoo!® to: a) make its content (750,000 Trips Maps, photos, users' comments etc.) more useful, accessible, searchable and understandable to its users; and b) to gather, analyze and use customers' intelligence (where they live, where they have traveled, and what content they have viewed) and further refines that knowledge through the lens of the tags they use to search in order to create targeted, personalized recommendations for destinations and deals sold through its vertical search website Yahoo!® FareChase. In other words, tagging helps to further refine the collaborative filtering process that Yahoo! uses in order to provide personalized recommendations and suggestions to its users. Personalized suggestions for cross and up sales can significantly drive and enhance booking and sales levels as well as provide additional functional and emotional value to website users that in turn enhances customer loyalty.

In the same vein, the official destination portal of Holland uses tagging technology in order to provide travelers an easy way to search the website content and its multimedia information (video, photos etc.) (http://us.holland.com/). Actually, tags are used as an user constructed and defined search engine rather than providing a search engine designed by the website developer that reflects a top down business defined search process. Tag clouds appear on the left with different font sizes to reflect words used more or less frequently, while "Top 10" suggestions for each tag (e.g. restaurant) are also constructed and updated continuously when new content and UGC is shared on the website. The portal also provides users the possibility to comment each others' contributions and comments as well as to tag the Holland's webpage content by using different social booking technology such as Digg and Furl.

Overall, it becomes evident that city tourism organizations should consider including tagging into their websites, as tagging can help them overcome the following issues (Epps, Harteverldt & McGowan, 2007):

- Very frequently websites do not speak the same language and they do not use the same terminology as their users. City destination organizations should consider using tagging in order to make their website content more accessible, understandable and appealing to its users. For example, the marketer of a city might promote as the major value of the destination its easy accessibility by air transportation, however, travelers may perceive as the most valuable feature of the destination the fact that it is "a safe city to walk around".
- Tagging can help and further enhance keyword search by supporting nuanced, adjective-based searches. Tagging also enables social search whereby users can see who has tagged something, how credible or relevant its suggestions are based on his/her profile and his/her evaluation by other users.
- Tagging helps organize and display user-generated content uploaded on websites. As more and more city tourism organizations invite their users to upload and share their UGC (e.g. reviews, itineraries, photos, videos, and podcasts), they later struggle to make this UGC relevant and accessible to their users and tags can help in addressing the latter.
- City tourism organizations can gather reliable and timely customer intelligence and feedback regarding the image of their destination, the mental maps of their travelers and how they view and perceive their destination etc. Such customer knowledge can be later used for marketing campaigns as well as for improving the products and services of the city as a destination.
- Customer information gathered through social tagging can also be used for improving search engine optimization campaigns. For example, words used frequently as tags by travelers can be used as metatags-metadata for building the portal's website as well as for spending money on keyword sensitive search engines such as Google™ AdWords.

However, when deciding whether and how to use tagging, city tourism organizations responsible for the development of the city portal should also decide the process, the policy and the way for developing their tagging system regarding the following issues: a) does the company edit the tags incorporated by users? This is important specifically if tags are uploaded with spelling mistakes or they include anti-social and embarrassing words. In other words, editing and a clear policy may be required in order to protect the consistency, the ethos and the good image of the website; b) are the tags and taggers' profiles made publicly available for everyone? What consent and agreement are required to take from the users and how the privacy policy of the website should be amended to incorporate the former?; c) is a software going to be purchased to manage the tagging process or is this going to be done manually? Are the required and skilled labor sources available? and d) how tags are going to be created? Are the tags going to be provided by the users or are the tags restricted by the website owner? Forrester (2006) recommends that companies use *taxonomy-directed* tagging, as it makes the tagging process more efficient and easier to use and it promotes consistency among tags. This is because when users create a tag, they can choose from existing suggested tags, or they can add their own.

Wikis

Definition, Features and Use

Wiki is a piece of server software permitting users to freely create and edit (hyperlinked) content via any browser and without the need to have access to and know to use any programming language. A wiki is a collaborative website whose content can be edited by anyone who has access to it. Wiki features include easy editing, versioning capabilities, and article discussions. So, wiki technologies enable users to add, delete, and in general edit the content of a website. Wiki users-creators are notified about new content, and they review only new content. As a result, such websites are developed collaboratively through their users, and a wiki becomes a collaboratively expandable collection of interlinked webpages, a hypertext system for storing and modifying information—a database, where each page is easily edited by any user with a forms-capable Web browser client. Neus and Scherf (2005) defined wiki as web content management systems allowing collaborative creation, connection and edition of contents, while Pereira and Soares (2007) defined wiki as a shared information work space that facilitates access to information content, organizational communications, and group collaboration. In other words, wikis represent another way of content publishing and communication as well as for group collaboration. In this vein, wikis and blogs have some similarities but they differ regarding the notification of new content, editing format, and structure. In other words, *'a wiki can be a blog, but a blog does not have to be a wiki'*.

Impact on Tourism Demand

The most popular wiki is the famous online encyclopedia, titled wikipedia.com, that is created and continually updated by its users. In tourism, wikitravel.org represents a wiki based effort of Internet users to collaboratively create and continuously update an online global travel guide including world-wide destinations. The number of readers, creators and content at wikitravel.org are continuously mushrooming. At wikitravel.org, one can find guides for any destination irrespective of its size and/or geographic location, as well as create a guide for any destination that he/she wishes. Wikitravel.com is further enriched with other web 2.0 tools and technologies such as maps, tags, podcasts etc.

Business Applications for City Marketing

Many tourism organizations take the opportunity to promote and create links to their websites through wikitravel.com in order to create and drive traffic to their own websites (http://wikitravel.org/en/London). Many other destination management organizations exploit and incorporate the wiki technology in their website portals in order to enable its users (travelers and locals) to collaboratively create and share their perceptions and mental images and opinions about their destination. For example, the National Library of Australia has included a wiki on its portal (http://wiki.nla.gov.au) inviting users to share their understanding and knowledge of local Australian dances as well as negotiate their meaning and create metaknowledge by synthesizing different views and perspectives. The National Library of Australia has also developed a wiki and social network website (www.pictureaustralia.org) whereby users can share their pictures about Australia and tell their story. In this way, the Library aims to help democratize history and establish a collective memory of places and events around the country. Ancient Times website (http://ancient.arts.ubc.ca/community.html) includes several collaborative tools, such as a wiki, blog and an arts metaverse enabling any user and history student to collaboratively develop and negotiate the meaning and construction of old cities and destinations, such as Giza and Athens. These cultural guides can significantly enhance the appeal and the interpretation of the cultural artifacts of historical cities and destination by providing several edutainment services and benefits to their users/visitors (Sigala, 2005a). Other wiki applications can also be provided on the city portals in order to boost website loyalty, repeat traffic, and travelers' desire to visit the destination. For example, a destination organization can design and incorporate a wiki on its portal for enabling potential travelers and locals to exchange and collaboratively develop recipes of local dishes and food.

Podcasting and Online Video

Definition, Features and Use

Podcasting refers to the uploading of audio and video files by users on websites. The most popular website for sharing such content with others is youtobe.com. Podcasting represents repositories of audio (podcasts) and video (vodcasts) or "video podcasting" materials that can be "pushed" to subscribers, even without user intervention, through RSS aggregate feeds of audio and video content facilitating users to search the latest services. Podcasting-capable aggregators or "podcatchers" are used to download podcasts. These files can also be downloaded to portable media players that can be taken anywhere, providing the potential for "anytime, anywhere" learning experiences (mobile learning). Podcasting's essence is about creating content (audio or video) for an audience that wants to listen when they want, where they want, and how they want. Podcasting differs from webcasting. A podcast has a persistent site, capable of synchronizing with a portable multimedia device, e.g. an MP3 player or iPod, whereas webcasting is streamed from the internet and requires the user to be connected to the internet while playing or viewing the webcast files. Webcasting is closely related to real-time downloading and synchronous broadcasting. Podcasting adds spatial flexibility to the temporal flexibility that webcasting offers and affords itself for creating personally-customizable media environments. Podcasting offers customer value in terms of the flexibility possibilities to hear personalized content whenever and whatever device one wishes, e.g. one can download the "Economist"'s or "CNN"'s personalized news' and press releases to his/her iPod and listen to its favorite news while he/she driving at work. As podcasting does not rely on the visual senses, it allows users to carry out other tasks while listening.

Impact on Tourism Demand

Tourism experiences are intangible. One cannot experience, feel and try a travel experience before he/she buys and before he/she travels to a destination. As a result, the purchase risk of a travel—tourism experience is high and it is difficult to persuade a user for the qualities of a tourism service. Due to its multimedia features, podcasting helps users to better and easier evaluate travel alternatives by experiencing in someway a travel experience before they decide to buy and consume it and/or travel to a destination. This is because audio and video files of hotels, destinations, and other travel products created and uploaded for sharing by other users are considered as more unbiased information and not staged experiences produced by the supplier aiming to promote his/her own product as the best one. Podcasting has also been used as mobile guides for travelers, e.g. Virgin Atlantic provides through its website free podcasts-guides of cities whereby they fly to.

Impact on Tourism Supply

Many tourism suppliers are using Podcasting as a marketing, information and customer communication tool. For example, Jumeirah hotel uploads podcasts on its website for delivering and updating its potential guests about what is happening in its properties at every single day, and-or delivering to website users and potential buyers the experiences of VIPs that have stayed at their property. Tate Gallery enables their visitors that have experienced their paintings and exhibition to record themselves, upload their audio-video on the Tate Gallery website, and which others can later download and use them as a mobile interpretation guide while visiting the gallery. Orbitz.com provides podcasting of many destinations that travelers can download to their MP3 players and use them as guides while visiting the destination. In a similar way, MGM Grand Hotel Las Vegas has lauded online video on its website under the title "Maximum Vegas" in order to better illustrate to its potential guests the experience and services of its hotel and gaming resort. Similarly, city destination organizations should consider enhancing the content and marketing appeal of their website portals by enabling podcasting opportunities, i.e. either allow users to share content or push their own created podcasting content (e.g. http://www.visitlondon.com/maps/podcasts/, Podcasts at the official portal of London). For developing podcasts, city tourism organizations can outsource this function to companies such as soundwalk.com, podtrip.com and heartbeatguides.com that specialize in the development and dissemination of destination podcasts.

METAVERSES: MASSIVELY MULTIPLAYER ONLINE ROLE PLAYING GAME (MMORPG)

Definition, Features and Use

Metaverses are three dimensional virtual worlds whereby Internet users collaboratively play "online MMORPG games" with others. However, these platforms are wrongly perceived as "simple games" and "virtual" worlds, since they frequently represent an extension to our physical day-to-day world to which users add new socio-economic and political situations. MMORPG are games that are played by numerous players (e.g. millions of users) and they could be considered as an intermediate step from 'computer' to 'ambient' era. Some of these games (e.g. World of Warcraft) develop around a theme defining the goals of the game, while other games, such as SecondLife.com, there.com, cokemusic.com, habbohotel.com and http://play.toontown.com/about.php, encourage a free-style of playing, allowing the users to make what they want out of it. Metaverse environments are internet-based 3-D virtual world whereby their users, called residents, can interact with each other through motional avatars (an internet user's representation of him/herself) providing an advanced level of a social network service. Although it is difficult to measure the size and growth of such games, it is estimated that the market for massively multiplayer online games is now worth more than $1bn in the West world (Book, 2003). For example, one can simply consider the size of and growth of Second Life®® itself. Second Life® has more than 5 million users, while about half a billion US$ are being transacted every year on Second Life's® website (as reported on SecondLife.com on April 2007).

Impact on Tourism Demand

Tourists and travelers participate in such games either for fun and-or for ways of expression of oneself and for achieving satisfaction through task—accomplishment, self-actualization and creation—design of something new. For example, many people dream and try to become and excel on a profession that they could not achieve in their real life, others try to design a new product and service hoping that other players will adapt and pay for it and so they can gain money and/or head hunters would spot their talents and recruit them in their real or virtual companies.

Business Applications for City Marketing

Many tourism and travel related companies have already created their representative offices and headquarters in metaverse environments such as SecondLife.com. Embassies (e.g. that of Sweden), Tourism Authorities (e.g. that of Maldives) of many countries and many tourism companies (e.g. TUI, Burj Al Arab Hotel, Marriott, Costa Cruises) have created their offices and companies on islands of SecondLife.com for boosting their marketing practices such as enhancing customer communication and education about their products/services, building brand reputation and user communities, and achieving word of mouth (WOM) and advertising. Hyatt used residents of Second Life® and exploited their intelligence and knowledge for designing a new hotel concept, named as Aloft; architects and guests were involved in designing the hotel providing their feedback, preferences and specialist knowledge (read the related blog at http://www.virtualaloft.com/). As a result of the popularity of the new hotel, the first Aloft hotel will open and operate in real life in New York in January 2008. Apart from collaborative new product development, a firm can further exploit the social intelligence gathered and generated at SecondLife.com and other metaverse environments in order to conduct market research and to test new product ideas and new advertising campaigns, e.g. Toyota first tested the campaign of its new brand Scion on SecondLife® and then, widely broadcasted the new campaign in real life. Other companies, use SecondLife® for recruiting and identifying new talents e.g. CNN does head hunting of new journalists online.

Many destinations are also moving into the futuristic world of virtual reality and metaverse, as many city and country destination organizations create their virtual destinations. Netherlands Tourism Board recently opened a national tourism board in SecondLife® (http://us.holland.com/secondlife.php), the city of Galveston launched a virtual replica of itself in SecondLife® (http://www.galveston.com/secondlife/), providing their visitors with the chance to become part of an interactive community (Figure 10 and 11). The aim is to provide digital travelers the chance to take guided virtual tours, learn about the history, culture and daily life of the destination, and interact with new virtual friends from around the world. Tourism Ireland has also launched the world's first tourism marketing campaign in SecondLife® (http://dublinsl.com/index.php) including the sponsorship of a range of events and activities, including concerts, fashion shows, and photographic exhibitions, in Second Life's® replica city of Dublin. Dublin's representation in SecondLife.com is the first place-location in Ireland that the Tourism Board created its representation in Second Life®. Similiar to the Dublin creation, Amsterdam in Second Life® comes complete with Dutch signs, canals, trams and a lot of attention to detail. Overall, when investigating the impact of SecondLife.com on its residents' behavior, it becomes evident that historical landmarks and buildings such as Tour Eiffel, London Bridge, Ajax Football stadium etc., have a great effect in building virtual communities of people spending a lot of time on dwelling them. Since it is apparent that real world modern-day cities and their landmark attraction are probably the most effective at driving and retaining visitor traffic, city tourism organizations should exploit this inherent advantage and exploit their cultural and heritage assets in metaverse environments for boosting their city brand name, recognition and promotion.

Mash-Ups

Definition, Features and Use

Mash-ups describe the seamlessly combination of two or more different sources of content and-or software for creating a new value added service to users. Many mash-ups enrich their services with some geographical content such as Google™ Maps; e.g. *The New York Times Travel Section's "36 Hours In…"* mash-up, which allows users to search the *"36 Hours in …"* story archive from a Google™ Map. For example, when visiting the website traintimes.org.uk, one can see on real time where trains are located and when they will arrive at destinations, since the website combines information from Google™ maps, and information from the British rail website about train time tables, delays etc.

There are several mash-up applications in tourism such as new cyberintermediaries including mapping services (e.g. earthbooker.com, tripmojo.com, reservemy.com) and meta-search engines such as farecompare.com. Other examples include: www.43places.com that combines Flickr photos, RSS feeds and Google™ Maps with tagging and user-generated content, allowing users to share their favorite destinations; www.randomdayout.co.uk combines a number of data sources to create a mapped itinerary, using Virtual Earth (Microsoft's equivalent of Google™ Maps). An innovate example related to destination marketing management is the case of the city of Pennsylvania (http://www.visitpa.com): based on a project amongst Google™ Earth, Carnegie Mellon University, NASA, the Pennsylvania Tourism Office and the National Civil War Museum, virtual tourists would have the chance to view Pennsylvania's Civil War trails online. More sophisticated examples of mash-ups are the "Marco Polo" function on triptie.com and the "Trip Planner" function on Yahoo!® Travel, which allow users to integrate content from other websites into the user's own itinerary planning toolkit on the host website.

Impact on Tourism Demand

Travel decisions are complex and involve the searching, comparison and combination of several information located in many different websites. For example, a decision to travel to a destination requires various and a plethora of information about weather conditions, exchange rates, travel and accommodation alternatives and prices, attractions etc. As a result, tourists increasingly demand and expect to combine and cross-check information from different sources, so that they can better and easier make a holistic decision. For example, tourists may not be able to clearly understand where a hotel may be located when the description of the hotel websites states that the hotel is located on the beach, near the beach etc. Tourists easily get confused from different descriptions found in different websites. On the contrary, mash-up websites empowered with maps (e.g. earthbooker.com) enable users to see where exactly a hotel or other attraction is located (sometimes even locate the exact orientation and view of a hotel room and then decide whether to book this room at this hotel).

Business Implications for City Marketing

Mash-up applications have empowered the rise of new cyber- and info- intermediaries offering new sophisticated information services (e.g. flightcompare.com search and compare all flight information from different websites in order to provide comparable flight information within one webpage to its users). Moreover, many tourism suppliers and organizations also enrich their website content with maps in order to make it more user friendly and useful to their visitors, e.g. the official website of London and Dublin use Google™ Maps with geotags for enabling tourists to identify points of interest, hotels etc. Moreover, many companies leave their software as an Open Application Programme Interface (API), so that users can create limitless combinations of their services. For example, backstage.bbc.co.uk represents BCC's services and opportunities offered to its users, who are enabled to take content from the BBC, re-structure it and present it the way they prefer. Enabling user innovation is another way that companies aim to exploit on users' creativity and intelligence instead of investigating solely on company's R&D efforts.

FUTURE TRENDS

It has become evident from the above mentioned analysis that the two major impacts of web 2.0 and its UGC on consumer behavior and marketing practices are: 1) the electronic word-of-mouth that is created; and b) the opportunities to build and maintain customer communities for enhancing the practices of Customer relationship Management and social marketing. Exploiting web 2.0 for city marketing can have a tremendous effect on the marketing effectiveness, since, as the following analysis and discussion illustrates, both previous issues significantly affect consumer loyalty and purchasing behavior.

Web 2.0 and Electronic Word-of-Mouth (WOM)

Word-of-mouth (WOM) is very important in tourism and in services in general, since objective information about a service experience cannot be easily provided before one buys and consumes the services themselves. Services are intangible and so they are difficult to be tested, tried and evaluated before buying them. Consumers also tend to rely more on consumer reviews when purchasing high involvement products (Park, Lee & Han, 2007), such as several travel products e.g. a honeymoon trip, an adventure travel etc. In this vein, tourism decisions are very complex and risky. Indeed, the literature about information search in the tourism field has recognized the important role of WOM in travel planning and decision making (Hwang, Gretzell, Xiang & Fesenmaier, 2006; Murphy, Moscardo & Benckendorff, 2007). WOM has been found to be one of the most influential information sources for travel (Morrison, 2002). Research has also shown that those with past experience with a specific travel destination and that engage in digital word-of-mouth communication are most likely to be the most preferred and the most influential source of information in the pre-trip stage of travel decision making (Crotts, 1999).

To make travel decisions easier, travelers need to reduce the inherent information complexity of travel decisions as well as the risk related to the service firm (i.e. is that a good and reliable company), the service risk (i.e. is that a service that fits my preferences and needs?) and the purchasing risk (i.e. is that a trustworthy booking and buying channel to use for buying a travel service?). To achieve that, consumers use recommendation-based heuristics and other users' feedback to reduce uncertainty, eliminate the related risks as well as filter and process the plethora of information that must be processed when making decisions (Olshavsky & Granbois, 1979). WOM-based information is heavily used and trusted by consumers for taking travel decisions, because it is seen as more vivid, easier to use, and more trustworthy as it is based on actual experience and typically provided without direct benefits (Smith, Menon & Sivakumar, 2005).

As demonstrated in the above mentioned analysis of UGC in Web 2.0 websites, electronic WOM can take different names and forms such as virtual opinion platforms, consumer portals, social networking, blogs' comments, tag words, podcasting, virtual communities and online feedback mechanisms (Armstrong & Hagel, 1997; Bellman, 2006; Sigala, 2008). Users of Web 2.0 websites and tools may post their own experiences, videos, share their opinion, give advice, or look for answers to their questions. Consumers also perceive electronic WOM to be a reliable source of information (Gruen, Osmonbekov & Czaplewski, 2006). Dellarocas (2003) identified three different characteristics of online WOM relative to traditional WOM: 1) electronic WOM is larger in scale (both in terms of quantity and people impact) due to the Internet's low-cost and networking features; 2) electronic WOM is a powerful and reliable market research tool giving organizations the ability to monitor on real time their operations; and 3) it is difficult to convey contextual cues (e.g. facial expression) through the Internet and peer review websites for example, and so not knowing or seeing who the information provider is makes, it is harder to interpret the subjective information in online interaction. To address this problem, websites often display demographic or other data about reviewers (for example, the length of membership, their location, etc.) in order to help build credibility and trust. Websites may even provide the possibility to users to upload and share their own feedback and evaluation (by incorporating each review into a rating of the reviewer) about the quality of the reviews written by other members. Moreover, because Web 2.0 enables users to identify and use personalized and contextual information (e.g. look at what others' with similar profiles are saying), electronic WOM is considered as both more relevant and unbiased than traditional WOM, whereby one cannot easily track and relate the content with the profile of its original messenger.

Smith, Menon and Sivakumar (2005) claim that consumers prefer such peer recommendations over other forms of input, while Amis (2007) advocated that social network sites have as much influence on consumers as television and more than newspapers. Statistics actually provide evidence of consumers' reliance on electronic word-of-mouth. More than 80% of web shoppers said they use other consumers' reviews when making purchasing decisions (Forrester, 2006). eMarketer (2007d) reports that nearly 6/10 consumers prefer websites with peer-written reviews, and that websites with reviews experience greater conversion rates.

Overall, Dellarocas (2003) summarized organizations' benefits of electronic WOM in the following: brand building; customer relationship management; customer acquisition; addressing customer complaints; market research; product development; quality control and supply chain quality assurance activities.

Web 2.0, Customer Relationship Management (CRM) and Social Marketing

The major aim of CRM is to personalize business services and products as well as develop a 1:1 communications and long lasting relation with profitable customers (Sigala, 2005b). eCRM also requires the development of customers' communities for providing loyal customers with functional, emotional and social benefits and value (Sigala, 2006). The previous section provided practical examples illustrating the way in which web 2.0 applications and tools enable the formation and development of customer virtual communities. By identifying and reviewing the limited related studies that have been conducted so far, the following analysis further supports the capability of web 2.0 to build virtual communities of users and enhance the community benefits (functional and emotional/social) to its users.

Ying and Davis (2007) and, Lento, Welser, Gu and Smith (2006) illustrated how blogs create and maintain strong online communities through their social ties tools such as blogrolls, permalinks, comments and trackbacks. Indeed, many authors (e.g. Lin, Su & Chien, 2006; Ying & Davis, 2007) have started to apply social network analysis for measuring and illustrating the social bonds, networking and communication structures created within the blogsphere. Li and Stronberg (2007) summarized blogs' benefits for firms as follows: search engine optimization; e-word-of-mouth (eWOW); improved brand perception and visibility; instantaneous client feedback; market research and insight; increased sales efficiency; and reduced impact from negative user-generated content. Damianos et al. (2007) advocated that social bookmarking generates social influence and bonds as well as creates value by: enabling resource management, information sharing and discovery, expert finding, and social networking; providing teams with a place to share resources; forming and supporting social networks around interest areas; and feeding expertise finding and user profiling. Awad and Zhang (2007) discussed the marketing benefits of eWOW generated in online review communities and debated firms' efforts and strategies addressing it. By examining the communication tools and social cues of myspace.com, Dwyer (2007) demonstrated the impact of social networking sites on developing customer interrelations and communities. In their study of videos' tags on Del.ici.ous, Paolillo and Penumarthy (2007) found that social tagging can generate community benefits such as: easy retrieval (as users use words they can remember and have useful meaning to them); contribution and sharing; attract attention; opinion expression; play; and self-presentation. Thus, since tagging can be used for providing functional services, creating social ties, market research on users' opinions and interests, and WOW, social tagging's ability in creating user communities is evident. Forrester (2006) demonstrated web 2.0's ability to generate customer and business value in different processes: customer service (e.g. community self-service savings); sales (e.g. community loyalty and sales reduces commissions and price competitions); marketing (e.g. credibility of eWOW); production (e.g. co-design reduces waste); and R&D (e.g. community input raises success rate).

A significant amount of literature also highlights the business benefits from developing virtual communities particularly in the area of CRM and social marketing. Analytically, Wang and Fesenmaier (2004) illustrated that virtual tourist communities are useful for managing customer relations by: attracting customers through in-depth, focused and member-generated content; engaging customers through social interactions; and retaining customers through relation building with other members. Online communities also build customer value (Wang & Fesenmaier, 2004) by generating users with all types of relational benefits namely functional, social, hedonic and psychological (Gwinner, Gremmler & Bitner, 1998). Kim, Lee and Hiemstra (2004) provided evidence of the impact of virtual communities on travelers' loyalty and product purchase decision making. Andersen (2005) explored the use of on-line brand communities for developing interactive communication channels and establishing social and structural bonds with devoted users. Jang, Ko and Koh (2007) showed that online brand communities posses and develop features - such as, quality and credibility of information, service quality, member interaction and leadership, brand reputation and (intrinsic and extrinsic) rewards for members' activities- that in turn, contribute to increased users' brand loyalty, commitment and sales. Erat, Desouza, Schafer-Juger and Kurzawa (2006) discussed how different types of communities of practice (e.g. B2C, C2C) can be used for acquiring and sharing customer knowledge in order to improve business processes and performance. Beyond collecting customer knowledge, online communities can also be used for co-operating with customers for New Product Development (NPD) and innovation (Rowley, Teahan & Leeming, 2007). A plethora of cases and research studies (e.g. in Lagrosen, 2005; Pitta & Fowler, 2006) reflects the possibility to use virtual communities for NPD as well.

Proposed Models for Exploiting Web 2.0 in Enhancing Marketing Communication and CRM

The previous analysis and industry examples illustrate that web 2.0 tools and applications have a twofold impact on the way CRM is implemented: 1) web 2.0's networking and connectivity capabilities provide enormous opportunities to communicate and co-operate with customers and industry

Table 1. Web 2.0 extended CRM implementation

	Low market integration	High market integration
High customer integration	**Many-to-one** Target: clients' networks Active customers' involvement *e.g. Lonelyplanet.com, Sheraton.com*	**Many-to-many** Co-exploitation of customers' profiles with other network partners *e.g. mash-ups, earthbooker.com, flightcompare.com*
Low customer integration	**One-to-one** Target: individual customers	**One-to-many** Ecosystems of partners offering a seamless experience to individual clients (cross-selling, products' bundling) *e.g. travelocity.com*

partners in many different directions (e.g. many-to-one, many-to-many) (Table 1) the social intelligence and knowledge created collaboratively in web 2.0 platforms (i.e. the user-generated content) can be exploited in different ways for identifying, developing, enhancing and maintaining relations with profitable customers (Table 2).

In other words, CRM cannot anymore be considered as synonymous to one-to-one communication and personalized service at an individual basis. Web 2.0 augment CRM practices and implementation to include various forms of communications with clients and business partners. Following Gibbert, Leibold and Probst (2002), Table 3 reflects

Table 2. Exploiting social intelligence for managing and enhancing customer relationships through their lifecycle

Phase	**Type of customer information/intelligence**	**CRM implementation activities**
Acquisition	Of the customer information: transaction and personal data	Create brand awareness and recognition amongst customers and virtual communities by building and supporting electronic word-of-mouth
		Develop brand reinforcement and trust by educating and informing customers about the brand, its services, functionalities etc
		Use customer intelligence in order to identify and target new customers, e.g. clone the profile of existing product-service users, use the connections and recommendations of existing customers etc.
		Use customer intelligence to understand how customers use the service, what functionalities they prefer or not
		Use customer intelligence for profiling customers
Retention	For the customer information: relationship and product data	Use customer intelligence for enhancing customer service and transactions
		Use customer intelligence for personalizing services and products
		Build and develop community of customers-users
		Use customer intelligence for innovation & NPD
Expansion	For the customer information: relationship and product data	Use customer intelligence for cross selling, e.g. suggest compatible products based on other users' purchases
		Use customer intelligence for up-selling
		Use customer intelligence for developing affiliation and loyalty programmes
Win back	By the customer information: feedback and monitoring data	Use customer intelligence (feedback, reviews etc) for identifying pitfalls and faults
		Use customer intelligence and communities for handling customers' complaints
		Use customer intelligence and communities for monitoring and managing the firm's reputation, status and prestige

a two dimensional matrix, whereby the vertical axis represents how firms integrate customers into their value chains and the horizontal axis represents the integration of business partners into the firm's value chain. Companies can use web 2.0 technologies to communicate and enable dialogues and interactions not only between them and their customers, but also between customers themselves (C2C), between business partners, among all of them etc. When engaged in two directional communication both customers and partners, firms can involve the former in their value chain in order to create customer value and benefits. For example, as explained earlier, when customers communicate with other customers in virtual communities, customers provide social and emotional support to others as well as functional benefits (e.g. free consultancy in trip planning). Also, when co-operating and sharing content and applications with other businesses (e.g. in mash-up websites), firms can collaborate with and integrate other partners in their value chain in order to provide additional services to their clients, e.g. a holistic tourism product-services such as a dynamic packaging.

Moreover, in developing successful relationships with profitable clients, firms need to understand and manage all phases through which relations are evolved, as each phase is characterized by differences in behaviors and orientations and so, it requires different CRM approaches. Theory and practical evidence has shown that customer relations evolve over three major distinct phases related to the customer lifecycle (see Sigala, 2008): initiation, maintenance and retention or termination. Hence, all CRM implementation models reflect practices that collect and use three forms of customer information / intelligence in order to manage each relational phase. "Of-the-customer" information includes customers' personal and transaction data for understanding and measuring their profile, e.g. sales, profitability, purchasing patterns, preferences. "For-the-customer" information refers to product, service and firm information perceived as useful by clients for making more informed decisions. "By-the-customer" information reflects customer feedback (e.g. customer complaints, suggestions, reviews) used for new product development or business improvement. As illustrated previously, Web 2.0's user-generated content mushrooms these three types of customer information and provides firms with several opportunities not only to collect, but also to get access to such types of customer intelligence. In other words, Web 2.0 platforms can be exploited as a free and real time market research and intelligence tool. Table 2 summarizes how firms can exploit web 2.0 tools and platforms for collecting and analyzing this customer intelligence for augmenting and supporting their CRM practices.

Overall, it becomes evident that web 2.0 enabled CRM reflects a cultural shift from product *'designing for customers'* to *'designing with'* and *'design by'* customers. For firms to achieve such a cultural shift, crucial organizational changes should also take place. Importantly, the role of marketers should be changed from being sales people to becoming community builders and perceiving customers not as targets to identify and sell, but as partners to collaborate with. Firms should also realize that they should use customer intelligence not only for learning about their customers and identifying new target markets (opportunistic behavior), that they should also use customer intelligence for learning and improving processes and products with their customers as well as with different business partners (partnership relation). In other words, firms derive and realize maximum benefits when they exploit web 2.0 tools for establishing and maintaining co-creation and co-learning adaptable and flexible ecosystems with their customers and business partners (Table 3).

CONCLUSION

Internet users and travelers are nowadays empowered to create and synthesize in their own way the travel content that they also wish to distribute and share it with others through users' controlled distribution channels. In this vein, Web 2.0 technologies enable Internet users to become the co-producers, the co-designers, the co-marketers and the co-distributors of tourism experiences and services as well as the co-entrepreneurs of new tourism products and new e-business models. As the diffusion of Web 2.0 applications becomes wide and consumers incorporate them within their daily and professional life, travelers expect tourism firms and organizations to provide similar Web 2.0 enabled services. The previous analysis aimed at identifying and illustrating the business implications created for tourism and hospitality enterprises as well as strategies and tactics that they can adopt for eliminating threats while exploiting the arising opportunities. Therefore, as Web 2.0 is here to stay, it is evident that unless a city tourism organization adopts and incorporates Web 2.0 tools into its e-business model and strategies for marketing and managing its destination, the competitiveness of the latter is threaten. Nevertheless, in order to be successful, the adoption and use of any web 2.0 tools should be accompanied with appropriate organizational and cultural changes within the firm regarding the roles, job descriptions and tasks of its staff, users and business partners. Further research is required in order to understand and examine how firms are achieving and trying to implement such organizational changes when incorporating web 2.0 into their e-business model.

Chapter 4.20

Marketing for Children Using Social Interaction Technologies

Ruth E. Brown
The University of Nebraska - Lincoln, USA

ABSTRACT

Children are spending more time online and, in most cases, this means they are using social interaction technologies. Beyond the concern for safety, another issue is gathering strength: namely, interactive marketing to children. This chapter looks at the immersive nature of interactive marketing, which can be found in blogs, chat rooms, virtual worlds, advergaming, and other forms of advertainment. The chapter also examines: the ages of targetable audiences (some of whom cannot yet read the "advertisement" label), websites for children that use interactive marketing, where and how ads are displayed, the effects of interactive marketing, the potential for data collection through interactive marketing, the lack of regulation in interactive marketing, and the future trends of interactive marketing to children.

INTRODUCTION

Early use of social interaction technologies by young people seemed to elicit one primary concern from adults. That concern was safety, because children and teens often reveal too much private information online in blogs, chat rooms, and such social networking sites as MySpace. However, a related issue is gaining momentum. It is the power of interactive marketing on social networking sites and similarly interactive websites for children. The concerns are that (1) young children are unable to discern marketing messages, and (2) even for older children, much of the advertising on social networking sites is so closely tied to the environment that it may be seen more for its participatory nature rather than for its marketing purpose. This chapter will look briefly at the safety issue and then move to explanation and discussion of the growing concern over marketing branded products to children through immersive interactive environments of the Internet.

DOI: 10.4018/978-1-60566-368-5.ch041

BACKGROUND

The proportion of children with access to computers and the Internet at home is steadily increasing. A 2005 Kaiser Family Foundation report stated that 86 percent of eight-year-olds to eighteen-year-olds had computers in their homes compared to 73 percent in 1999, and 74 percent had Internet access compared to 47 percent in 1999. Time spent by eight-year-olds to eighteen-year-olds on the computer for recreational purposes alone averaged a little over an hour each day in 2005. Eight-year-olds to ten-year-olds clocked in at thirty-seven minutes, eleven-year-olds to fourteen-year-olds at an hour and two minutes, and fifteen-year-olds to eighteen-year-olds at one hour and twenty-two minutes (Roberts, Foehr, & Rideout, 2005). Those numbers are expected to be higher today with the popularity of social networking sites, such as MySpace and Facebook, plus the many online communities for children.

About 55 percent of American youths ages twelve to seventeen use an online social networking site, according to a national survey of teenagers conducted by Pew Internet & American Life Project (Lenhart & Madden, 2007). The number of children and youth who use social networking sites and create online profiles is growing daily. Although some participants choose to make their profiles available only to those in their network, much information is still available to all. A study by Huffaker & Calvert (2005) of teenagers' blogs found that the teens volunteered far too much private information. Two-thirds provided their ages and at least their first names, while 60 percent gave their locations and contact information. One in five told their full names.

MySpace.com has a policy that does not allow children under age sixteen to become members. Spokesman Bennet Ratcliff said the firm immediately removes members' sites that are in violation of the terms of service, including those with too much personal information. However, participants can get around the rule by lying about their age, according to Sullivan (2005), who browsed the site and quickly turned up several pages on which children stated they were sixteen, but in their personal descriptions provided information that they were actually younger.

Parry Aftab, who runs the WiredSafety.org program, stressed that she does not think any blogs or community sites are safe for children. Her organization receives complaints every day: "There are underage kids on every social networking site on the Net. They are engaging in highly provocative conversations and doing things they would never do offline" (cited in Sullivan, 2005, p. 2). Now add to this issue the fact that marketers have found social networking sites and are trying to establish their brands in the minds of youthful consumers.

INTERACTIVE MARKETING TARGETS CHILDREN

Marketers have already created MySpace profile pages for characters from their advertisements and have invited users to add those characters to their list of friends. On Facebook, marketers have created groups around branded products and are trying to use those groups to increase word-of-mouth advertising about their product. Marketer sites often include video clips and quizzes to increase engagement, as well as free downloadable ring tones and other promotions to increase traffic. Some of these promotions utilize viral marketing, offering incentives for users to send information to friends. Chase financial services had a promotion on Facebook that rewarded site visitors for getting friends to sign up for credit cards (Hansell, 2006). Of course marketers' social networking sites all have links to their brands' websites, which have more games and activities for a variety of ages.

Younger children are not left out of the interactive social networking strategy of marketers. Virtual worlds are three-dimensional environments where preteens and children can go to play and to interact with others from around the world. Unlike television ads that children view for thirty seconds to a minute, marketers' virtual worlds often create a video game-like atmosphere in which children may be immersed for thirty minutes or more. Some of these virtual worlds were created by brands (such as Barbie, Bratz, Disney, Nabisco, and Nickelodeon). These worlds are loaded with "advergaming" and other "advertainment" that use the brand's own products. Children as young as preschoolers are playing games that involve some of these branded products. In addition, the sites sell products, such as toys, clothes, and DVDs.

Other virtual worlds (such as Whyville, Gaia Online, and Stardoll) were not created by and for brands to push their products. Whyville was created as a safe social networking site with an educational platform. However, that does not exclude Whyville or similar sites from marketing influence. Children are driving virtual Toyota Scions at Whyville.net and Gaia Online, and they are wearing the latest digital fashions from DKNY at Stardoll.com. In these virtual worlds, children can craft their own "avatars" (representations of themselves), customize a car, play games and socialize.

Marketing of this nature is designed to function at a subconscious level, according to Kathryn Montgomery, author of *Generation Digital: Politics, Commerce and Childhood in the Age of the Internet* (Olsen, 2007). She noted the purpose of ads and product placements in three-dimensional worlds is often to blur the line between content and advertising. What makes virtual worlds and their interactive games such powerful delivery tools is that a child's emotional engagement is so high: "With their engaging, interactive properties, the new digital media are likely to have a more profound impact on how children grow and learn, what they value, and ultimately who they become than any medium that has come before" (Montgomery, 2001, pp. 635-6).

SOME VIRTUAL WORLDS REQUIRE PURCHASE

Webkinz was the first company that required purchase of a toy for children to enter its virtual world online. The Webkinz plush animals are sold with special codes that permit children to access the website where they can play games, chat, participate in other activities, or "work" to earn KinzCash to purchase virtual things for their virtual rooms or their virtual pets. More recently, Barbie began selling a bundle that includes a fashion doll, a pink portable MP3 player, and a USB key that provides access to BarbieGirls.ca where children can play games, chat, and buy other Barbie things. Similarly, a Bratz doll can be purchased with a necklace that has a special "key" to provide access to Be-Bratz.com where children can play games, decorate their virtual rooms, communicate with each other, and buy more Bratz products.

Time spent with a brand generally translates to brand preference and purchase intent. However, for children who are not old enough to purchase these products on their own, some marketers may value their engagement more for its "nag factor" – that is, children's ability to influence their parents – and for the positive impression it is making as a foundation for children's future interaction with the brand. When a child creates a character in a virtual world or when the child plays a game online, the child is using a first-person perspective, so interaction with a brand will likely form, revise, or challenge the child's association, emotions, and attitudes toward that brand (Nelson, 2005).

Toyota is hoping that the youthful car enthusiasts at Whyville and Gaia will influence their parents' car purchases and that the children will grow up with some Toyota brand loyalty. According to the *New York Times*, Toyota believes the product placement in Whyville is working. After only ten days, the word "Scion" had been used in chats on the Whyville website more than

78,000 times; hundreds of virtual Scions were purchased by children using "clams," the currency of Whyville; and the community meeting place, Club Scion, was visited 33,741 times. These new virtual Scion owners customized their cars online, drove around the website, and picked up their non-car-owning friends for a ride around Whyville (Bosman, 2006).

Toyota may well be experimenting with "cradle-to-grave marketing" which emerged in the mid-1990s and refers to attracting a customer early in life and keeping that customer through adulthood and into old age: "It has been estimated that corporations whose marketing campaigns appeal to a toddler can expect to collect as much as $100,000 from her over the course of her lifetime – starting with the money spent on her as a child and, later, the money she spends on her own children and grandchildren" (Thomas, 2007, p. 125).

Targeting young people before they can buy the product is a tactic being utilized by more and more marketers. "It's early branding," said Matthew Diamond, the chief executive of Alloy Media and Marketing, a consultancy in New York that specializes in youth marketing. "You are branding your product at a relevant time to the young person. You're establishing that brand presence and positive association, since important buying decisions are forthcoming" (Bosman, 2006, p. 2). Capture them before they have any opinions on brands. Talk to young people in their environments in a relevant way: "Too often advertisers wait to convert them later, and then it's too late" (Bosman, 2006, p. 2).

CHILDREN'S VIRTUAL WORLDS MULTIPLYING

Virtual worlds targeting children are a relatively new market, but one that seems to be growing quickly. It is anticipated that more than half of the young people online will belong to a virtual world by 2011 (Olsen, 2007). Ad spending in these environments is expected to increase tenfold, and that "excludes marketers spending on their own virtual worlds, like BarbieGirls.com" (Olsen, 2007). The anticipated increased ad spending is one reason that Montgomery (2001), who helped found the Center for Digital Democracy advocacy group, emphasized that advertisements need to be labeled as such.

Nickelodeon labeled ads in its Nicktropolis three-dimensional environment for kids ages seven to fourteen. Other sites are also labeling ads, but the labels are small and the ads look flashy and exciting. Color, movement and sound are just some of the features that draw in children. Identifiable characters, such as Mickey Mouse or Barbie, are also heavily used. Disney has a special section on its website for preschoolers who can be enrolled by a parent in Club Mickey. These preschoolers probably can neither read nor understand the meaning of the label, "Advertisement." Premiums are yet another method used to draw children's attention to a product and move them to action (Comstock, Scharrer, 2007). In addition, many ads online and off that target young children use symbols (such as flowers, butterflies, cars, or soccer balls) to attract children and help them identify with the message being sent.

Although most children's virtual worlds are now targeted for those ages seven to fourteen or eight to fifteen, some are being created for even younger children. MGA Entertainment, the toy company that makes Bratz dolls, launched MyePets.com in 2007. It targets five-year-olds to seven-year-olds, using plush animal toys that need to be "rescued" (purchased). Similar to Webkinz, the site is closed to all except those who have purchased a pet, which provides a password that allows access to the website (York, 2007).

Kurnit (2000), founder and president of KidShop youth marketing company, said there are now five different age groups that are considered addressable targets for marketing to children. They are as follows:

- toddlers, considered children from birth to age three
- preschoolers ages two to five
- kids ages six to eight
- tweens ages nine to twelve
- teens ages thirteen to fifteen.

This presents a dilemma since television research shows that most children who are ages eight years and under do not understand the persuasive intent of marketing, and most children ages four and under cannot consistently determine the difference between advertising and programming on television, much less on the Internet (McGinnis, Gootman, & Kraak, 2006).

To learn more about computer use by children, Kurnit (2000) surveyed sixty-two mothers with children ages two to five. Nearly all acknowledged their children used a computer, most started at the age of two, and they spend between one and three hours a week on computer activities. Special software, dubbed "lapware," is available for parents to purchase so that infants and toddlers, sitting on a grownup's lap, can learn to use the keyboard for the reward of seeing stars or shapes fly across the monitor (Thomas, 2007). "Moms unanimously agree that what they like best about their child's computer interaction is the educational benefit their kids derive from it" (Kurnit, 2000, p.5). The computer "enjoys a special halo effect because it is seen as an educational tool that replaces television" (p. 5). A study by the Kaiser Family Foundation confirmed that finding. The 1,000 parents of children ages six months through six years who were studied were more enthusiastic about computers than any other electronic media, with 72 percent saying that it "mostly helps" children's learning (Rideout, Vandewater, & Wartella, 2003).

'KIDS GETTING OLDER YOUNGER'

Although computers have this halo effect, Kurnit (2000) argued that they contribute to a phenomenon referred to as "kids growing older younger." Computers and the Internet give children access to learning and experiences that previously would have occurred much later in life, probably with more parental supervision. Two-thirds of Kurnit's sample of mothers confirmed that their children are brand aware. Most thought that brand awareness began around age two or three, but about a quarter of the sample said their children began to recognize brands as early as twelve to eighteen months (Kurnit, 2000). Thomas (2007) noted other marketing studies found that children can distinguish brands as early as eighteen months and are asking for branded products, such as Cheerios, Pop-Tarts, Coke, and McDonald's, by age two. She added that since the 1980s, marketers have been refining ways of mining the tween market, which has always been brand conscious, but now this brand consciousness is dribbling down to even younger ages.

In the past, marketers that wanted to reach children did so with campaigns targeting both mothers and children, but today's marketers are able to send their messages directly to the children, primarily because of heavy media use by the children and knowledge of children's preferences. According to Schor (2004), marketers create direct connections with children in isolation from parents and are sometimes allied with children against parents. Furthermore, marketers reach children in parent-free environments, such as school and the Internet, and while children are watching television alone. There the marketers can speak directly to the children. Sometimes this leads to conflict with parents as children make their wants known and parents attempt to defend their ground, often unsuccessfully.

The estimated $2 billion of advertising funds directed specifically at children – a larger proportion of which are going to the Internet each day – are believed to be creating a consumer culture among many children (Sheehan, 2007). Seventy-five percent of tweens in the United States want to be rich when they grow up, and more children in the U.S. than anywhere else in the world believe that the brands they wear define who they are and identify their social status (Schor, 2004). Two-thirds of parents say that their children describe their self-worth in terms of possessions, and half of the parents say their children would rather be at the mall than at other activities or with family (Gibbs, et. al., 2001). Critics are concerned that children are developing a consumer-based value system in which problems can be solved and happiness attained by buying things. "Contemporary American 'tweens and teens have emerged as the most brand-oriented, consumer-involved, and materialistic generations in history. And they top the list globally" (Schor, 2004, p. 13). Experts increasingly describe them as "bonded to brands."

Schor (2004) claimed her research shows that, in addition to obesity, involvement in consumer culture appears to be at least partly responsible for dysfunction in the form of depression, anxiety, low self-esteem, and psychosomatic complaints. Additionally, reports of addiction to web surfing and online games are beginning to surface.

DATA MINING AND LAWS

As if the explosion of marketing material disguised as content on websites for children were not enough, there is yet another concern – data mining. Children play games, take quizzes and fill out surveys to earn the currency of the social networking site in order to purchase items from the website store for their virtual environments. While they are doing this, their actions are being monitored, and data is being collected. Data mining technology can create detailed profiles of children online which can then be used to document trends in youth markets. Sometimes the information is used only by that website, but sometimes it is sold in the aggregate to other marketers (Chung & Grimes, 2005). One site that was found selling its information was Neopets.com, an online community launched in 1999, where children can care for virtual pets, play games, participate in contests, and purchase items for their pets using online currency. Neopets collected and processed its users' data, then sold it in the aggregate as Youth Pulse reports (Grimes & Shade, 2005). This demographic and behavioral data is valuable to marketers who want to construct highly targeted marketing campaigns.

As yet, there are no laws that deal with privacy regarding aggregate data. The only law that has been enacted in the United States to protect children on the Internet is the Children's Online Privacy Protection Act (COPPA), which became effective April 21, 2000. Regulated by the Federal Trade Commission, the law prohibits online sites from collecting personal information from children under the age of 13. This includes full name, address, email address, telephone number, information on hobbies and interests, as well as information gleaned through cookies or other types of tracking mechanisms "when they are tied to individually identifiable information" (COPPA, 2000, p. 1). The COPPA law has helped control websites' harvesting information from children but has left teenagers open to websites' innovative methods of gathering names, addresses, and product preferences through memberships, surveys, polls, games, newsletters, premiums, and the like. Further, no law addresses the commercialization of children of any age through immersive interaction made possible by the Internet and social interaction technology.

The Children's Television Act (CTA), passed by Congress in 1990, limited advertising in programming aimed primarily at children twelve years old and younger to ten and a half minutes an hour on weekends and twelve minutes an hour on weekdays. In addition, the CTA banned host selling which was defined as any product endorsement by a character in the program being viewed that confused a child viewer so that the child had difficulty distinguishing between the program and the advertisement (Federal

Communications Commission, 1990). However, neither of these limitations affects the Internet where marketing messages are likely to be more immersive, of longer duration, and processed with less skepticism.

Moore and Rideout (2007) studied online marketing directed at children and identified six issues that they thought were significant in terms of public policy relevance. They are as follows:

- Questionable nutritional profiles of promoted brands; an overwhelming majority of the products promoted to children online were of poor nutritional quality.
- Tacit persuasion that occurs through games; the simple enjoyment of an advergame can influence children.
- Absence of limits on total time exposed to ads; children can participate in advertainment for as long as they want and can return as often as they want.
- Use of viral marketing; children are asked to e-mail their friends with brand-related information, which is often influential because it comes from a peer.
- Lack of breaks between ads; children need to be reminded that they are watching or participating in an advertisement and so should be vigilant.
- Direct inducements to purchase through special rewards offered; for example, purchase product X for access to game tips, or for access to a secret site, or to save your game score in the Hall of Fame.

FUTURE TRENDS

The future may bring even more personal interaction. Technology is now able to put talking heads on websites so that visitors can interact with them. The idea is that visitors will spend more time on a site that has interactive characters, explore it further, remember it more easily, and return to it more often. How long will it be before these talking heads are brand-related icons that interact with children, using data mined from the child's previous visits, to build a trusting relationship and instill loyalty? As technology advances to offer more bells and whistles on the web, more ways of collecting data, and more opportunities for marketers to connect with children, it behooves the players involved to step back and assess the pros and cons of this technology, of the opportunities that it enables, and to look with the concern of a parent at the long-term consequences that could result.

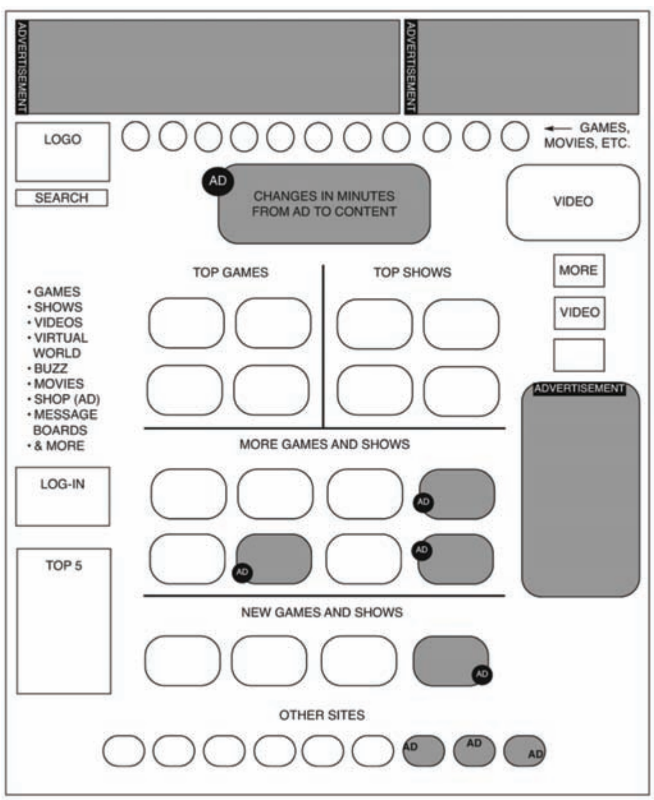
Schor (2004) quoted a critic who pointed out that parents are put in the position of "playing David to the corporate Goliaths" (p. 184). Schor stressed that parents blame the advertising industry, and the industry blames parents, when both bear responsibility. Advertising agencies, clients, and media should recognize that children are vulnerable subjects and place the "need to do well by kids" over and above the pressure to make money. This could mean eliminating the "nag factor," providing shorter and less immersive games, or including less product placement and branding in them. It also might mean that online sites determine uniform style and placement of ads. Parents should not shrug off the consumptive society as inevitable but should take proactive measures to assure the well being of their children. This might mean limiting their children's time on the computer, spending time with their children on the computer, or teaching them about the nature and intent of advertising.

The concept of advertising is a complex one for children to understand. Very young children see television ads simply as sound and visuals presented in a brief, entertaining format. By age four, most preschoolers recognize commercials as being distinct from television programming. Also, these children can match characters shown in a commercial with the products that they promote. However, it is between the ages of seven-and-a-half and eight-and-a-half that the selling nature of a commercial is understood by a majority of the children (Comstock & Sharrer). No research has yet been done on children's comprehension of Internet advertising which, it seems, would be much more difficult to differentiate and for which it would be more difficult to recognize the selling intent. Websites are available to help educate children, teens, and even parents and law enforcement officers regarding Internet use. One such site is NetSmartz.org; yet even it includes Opinion Polls clearly, although inconspicuously, labeled "Marketing Research."

The advertising industry has addressed concerns regarding online marketing to children through self-regulatory guidelines established by the Children's Advertising Review Unit (2006), which is a branch of the National Advertising Review Council. The guidelines apply to children under age twelve and address blurring of advertising and editorial content online, use of program personalities, premiums, kids' clubs, sweepstakes and contests both online and off. For example, the guidelines state that when an advertiser integrates an ad into a game or activity, the advertiser should make clear, "in a manner that is easily understood by the intended audience," that it is an ad (p. 7). This is easier said than done. Simply labeling it may not be enough.

Take a look at a map of the Nickelodeon website (Figure 1), and you will see the word "Advertisement" reversed with white type on black. It is run horizontally in some places, rotated so that it is vertical in other places, and shortened to "Ad" in still other places. Sometimes the word "Ad" is not

Figure 1. The Nickelodeon website has ads that are scattered throughout. It demonstrates that merely labeling an ad is not enough. The ads should be placed together in an area clearly designated and easily understood by the intended audience.



reversed (white on black) and is, therefore, even more difficult to find. On the left side of the page are buttons to click for more games and movies plus podcasts, a virtual world, blogs, message boards, and shopping. When a child selects something from this list, ads appear on the new page, sometimes as a window that has to be closed. Because the ads are sprinkled throughout, the site is a virtual minefield of commercial messages for children attempting to navigate it. Simply placing all of the ads in a clearly designated area would help children differentiate ads from page content, but that will not solve all of the related issues.

CONCLUSION

Children fall into three general categories as consumers of marketing communication. They are viewed as the primary target for some goods, such as cereals and toys. Other marketers see them as an influence market, one that is sought after for its ability to affect purchases made by parents and other caregivers. Still other marketers see children as a future market that must be courted so that brand preference is instilled long before the need for the branded product arises (Comstock & Sharrer, 2004). All of these marketers are sending their messages to younger and younger audiences, and the messages are coming in more interactive and immersive media with little regulation. Children, some of whom do not yet understand what advertising is, are encountering it on a regular basis.

Although the self-regulatory guidelines adopted by the Children's Advertising Review Unit are an excellent start, they must be enforced through attentive monitoring. The websites themselves need to find better ways to arrange and display ads so children can more easily and knowledgeably choose whether or not to participate in their many enticements. Close parental supervision is, of course, a deterrent, but parents first must understand that Disney, Barbie, and even Whyville are commercial enterprises with marketing messages, both apparent and discreet, and often undeserving of a halo effect. Parental vigilance is needed, and explanations are necessary to prepare children for the marketing messages aimed at them. Advertising agencies and clients should place themselves in the parental role and find ways to connect with their vulnerable subjects in ways that are ethically acceptable so that government is not called to step in.

Thus, as online interactive marketing becomes progressively more common for increasingly younger online audiences, it requires increasingly more attention from those who need to be aware of its dynamic and immersive nature, moderate its effects, and from those in positions to control its use – be they industry watchdogs, advertising agencies, clients, media, parents, or government officials.

KEY TERMS AND DEFINITIONS

Advergaming: Advertising a product through a game. Originally coined in reference to video games, the term is now also used for online games.

Advertainment: Entertainment that incorporates brand advertising.

Children's Online Privacy Protection Act (COPPA): Children's Online Privacy Protection Act, which became effective April 21, 2000. It prohibits websites from collecting personal information from children under the age of thirteen.

Children's Television Act (CTA): Children's Television Act of 1990 that limited commercial advertising in children's TV programming for twelve-year old children and younger to ten and a half minutes an hour on weekends and twelve minutes an hour on weekdays.

Host Selling: Product endorsement by a TV character.

Interactive Marketing: Conversation-based form of marketing enhanced by technology.

Viral Marketing: Self-replicating marketing messages ranging from text to video that are spread by the word of mouth through social networks.

Virtual World: Computer-simulated environment in which individuals interact with others through avatars.

This work was previously published in Handbook of Research on Social Interaction Technologies and Collaboration Software; Concepts and Trends, edited by T. Dumova; R. Fiordo, pp. 462-472, copyright 2010 by Information Science Reference (an imprint of IGI Global).

Section V
Organizational and Social Implications

This section includes a wide range of research pertaining to the individual and organizational impact of social computing tools and technologies. Chapters included in this section analyze the usability of social software, the creation of social relationships in virtual communities, and social networking in educational settings. The inquiries and methods presented in this section offer insight into the implications of ubiquitous and pervasive computing at both an individual and organizational level, while also emphasizing potential areas of study within the discipline.

Chapter 5.1
Managing Organizational Knowledge in the Age of Social Computing

V. P. Kochikar
Infosys Technologies Ltd., India

INTRODUCTION

Technology, since the days of the Industrial Revolution, has been used by large corporations, such as factories and the railways, to great advantage. Starting around the end of the 19th century, technology began to be used directly by the consumer, but remained essentially a means of satisfying a *personal* need, such as lighting or listening to music. In the past decade, as technologies such as e-mail, Web, Weblogs (blogs), Wikis, and instant messaging have become pervasive, the way technology is used by individuals has changed—it has increasingly been put to use to meet *social* needs, such as interaction, sharing, and networking. This new paradigm of technology use, and the technologies that have enabled it, may be termed social computing.

By its very nature, social computing facilitates the sharing and leveraging of knowledge residing within a community of people. In this article, we discuss how social computing can act as the primary mechanism that enables the management of knowledge within an organization.

BACKGROUND: THE DISCIPLINE OF KNOWLEDGE MANAGEMENT

There are several ingredients that go into organizational success, and leveraging assets well is one of these. As intangible assets represent a rising proportion of total assets, they have come to represent an important area of management focus. The discipline of *knowledge management* (KM) thus encompasses the organizational activities directed toward the assimilation, dissemination, harvest, and reuse of knowledge. In simpler terms, KM is the answer to the question, "How can the organization update and use its knowledge more effectively?" (Kochikar, 2000).

Some of the world's most successful organizations, be they corporate, academic, or government, invest considerably in KM, and substantial benefits have been reported across industries (Berkman, 2001; Frappaolo, 2006; Kochikar & Suresh, 2005).

Knowledge Management Review magazine's survey of 400 global corporations revealed that the following are key objectives of KM programs (KM Review, 2002):

a. Increasing organizational communication
b. Gaining competitive advantage
c. Increasing collaboration among employees
d. Improving customer relationships
e. Raising efficiency
f. Innovating
g. Learning from mistakes and successes
h. Capturing and retaining tacit knowledge

Using the framework of Nahapiet and Ghoshal (1998), these objectives can be classified as improving *financial capital* (b, e); improving *social capital* (a, c, d); and improving *intellectual capital* (f, g, h).

Each organization must fashion a KM strategy that takes cognizance of its unique competencies, aspirations, and business context. Mechanisms for organizational KM typically take the form of setting up strongly engineered governance mechanisms, focusing on four key aspects: people, processes, technology, and content (see, e.g., Kochikar, Mahesh, and Mahind, 2002).

As an exemplar, Infosys Technologies (*NASDAQ: INFY*) has had a KM program since 1999, which aims to *empower every employee with the knowledge of every other employee.* Key elements of the KM architecture include the *Knowledge Currency Unit* scheme, a comprehensive mechanism for reward, recognition, and measurement of KM benefits; *KShop*, the corporate knowledge portal built in-house; and the *knowledge hierarchy*, a four-level taxonomy of over 2000 subject areas that constitute knowledge in the Infosys context (Kochikar et al., 2002).

For more on KM and its organizational uses, see work by Davenport and Prusak (1998), Drucker, Garvin, andLeonard (1998), Nonaka and Ichijo (2006), and Nonaka and Takeuchi (1995).

BACKGROUND: SOCIAL COMPUTING COMES OF AGE

Social computing is the name given to a slew of technologies that collectively allow people to pool their knowledge, keep in touch with, and interact better with others who belong to their community.

The stellar rise in the popularity of e-mail in the 1990s (the number of users skyrocketed from a few thousand at the beginning of that decade, to several hundred million at the end of it) clearly provides a pointer to the potential that social computing has—people are eager to take up technologies that will help them meet their social needs better. For example, there are as of May 2006 a total of 39 million blogs worldwide, with 75,000 being added each day (Klein, 2006). In an academic/research sense, social computing is a relatively new field—a fact reflected in the relative paucity of books and research papers in the reference section of this article.

What has spurred this gain in the importance of social computing? While there are several reasons, two in particular stand out:

- The steady march of advances in computing that have put more computing power in the hands of the users, allowing them to use it to achieve ends that they truly consider useful;
- Network effects as encapsulated in Metcalfe's Law: As the number of users of a particular technology that supports interaction or networking increases, the benefits perceived by all users accelerate significantly, causing even more users to adopt the technology.

Technologies that commonly go by the name of social computing include e-mail,instant messaging (IM), blogs, wikis, podcasting, and really simple syndication (RSS). They also include Web sites or portals supporting a variety of social interactions (examples include Yahoo!, Myspace, Flickr, del.icio.us).

A key sign of the coming of age of a new technology bubbling up from the masses is large corporations taking note of that technology. In the common view, technology diffuses by a "trickle-down effect," that is, a new technology first finds use within large corporations and then, as it becomes more affordable, trickles down to smaller businesses and finally becomes inexpensive enough to be used by the individual consumer. While such a top-down view is valid, it hardly represents the sole mechanism of technological diffusion. Equally, technology diffuses bottom-up too (Kochikar, 2006). The Internet was for decades used almost exclusively by researchers, then by academics, and subsequently (in the early 1990s) by individuals for publishing information using personal Web sites and so forth. Even when business uses were discovered for the Internet, it was small startups such as Amazon that leveraged it best—large corporations were in many ways the last to embrace the Internet. The same pattern can be seen with e-mail, instant messaging, gaming (which began with children and teenagers and is now finding uses in business such as for strategy formulation), and several other technologies. Other examples can be found in Kochikar (2006), which enumerates a few simple pointers for foreseeing emerging technologies that are "below-the-radar." Thus, large corporations must routinely monitor technologies that have not yet become visible on the corporate radar—that is, in use with small businesses, researchers, or individuals—or else they may miss an important source from where new technologies emerge. Social computing represents precisely such a "below-the-radar" technology.

Social computing is now beginning to find uses within large corporations and has elicited considerable enthusiasm from early adopters (BusinessWeek, 2006; McAfee, 2006).

SOCIAL COMPUTING: A NEW BACKBONE FOR ORGANIZATIONAL KM

Two key principles of social computing (or social software) are that

- It is highly participatory, or allows rich interaction between diverse and possibly dispersed members of a community, and
- It is evolutionary, or supports means for constant updating by the members of the community.

Together, these two characteristics indicate a mechanism for the collaborative creation and updating of content that constantly moves in such a direction as to better reflect the knowledge, beliefs, opinions, and/or aspirations of the community. This is precisely the goal of organizational KM—leveraging the combined knowledge of the organizational community.

To wit, a great deal of what has been learned and practiced by KM thinkers and practitioners over the past few years is finding expression now in the traction that social computing is getting. There has been recognition that social computing technologies can facilitate a new approach to KM. Say Caldwell and Linden (2004, p. 1):

Personal knowledge networking and social networks give individual knowledge workers direct control over the enterprise's intellectual capital and enable a new 'grass-roots' approach to knowledge management. KM can happen without a lot of explicit governance.

While conventional KM systems often act as an additional "layer" on top of existing business processes and require people to devote time specifically for creating shareable content, or making existing content shareable, social computing technologies are more organic and integrate naturally into people's work habits or social needs. Harvard Professor Andrew McAfee writes (McAfee, 2006, p. 21):

There is a new wave of business communication tools including blogs, wikis and group messaging software—which may be dubbed, collectively, Enterprise 2.0 — that allow for more spontaneous, knowledge-based collaboration. These new tools may well supplant other communication and knowledge management systems with their superior ability to capture tacit knowledge, best practices and relevant experiences from throughout a company and make them readily available to more users.

Social computing technologies can help in a variety of organizational knowledge-sharing needs, such as

- Sharing useful materials, viz., documents, presentations, plans, and best practices
- Expressing opinions, reaching out, and getting feedback
- Finding experts in a specific domain
- Learning—sharing lessons learned, tips, and tricks
- Forming communities of like-minded individuals interested in a common activity, or sharing a common area of expertise; for example, a community dedicated to innovative product design may be formed
- Pooling knowledge about a product's market potential
- Finding products and services by means such as collaborative filtering

We illustrate with two or three sample technologies.

Wikis, which are one major component of social computing technologies, can find the following uses in the corporate activity of managing knowledge:

1. **Collaborative Publishing:** Creating documents that need input from multiple authors and reviewers, for example, user documentation for a product.
2. **Capturing Evolutionary Learning:** Creating and maintaining documents or reference material that change often and need to reflect knowledge being acquired on an ongoing basis. Examples include
   - Capturing tips and tricks on how to use a particular technology product or platform
   - Recording experiences of working in, or selling to, a new country
3. **Communication on Shared Concerns, Issues:** Providing a single location where a group of people can pool their views, opinions, and ideas on a concern that is common across the group, for example, how a new initiative can be designed to deliver results efficiently.

Blogging, another archetypal social computing technology, is essentially a "one-to-many" means of communication, while wikis are "many-to-many." Thus, while blogging can fulfill to a degree the three classes of use outlined previously, the quintessential nature of wikis, viz., the ability to capture multiple voices and multiple experiences easily and effectively, is absent. On the other hand, the ability to achieve more personal and individualistic ends, such as projecting one's expertise in a particular area, or enhancing one's credibility as an authoritative commentator on a specific topic or subject, is strongly supported by blogging.

A technology not commonly included in the list of social computing technologies is that of prediction markets. Since these are a mechanism for collecting and aggregating the opinions of a large number of people and making the output useful to the entire community, they can be seen as a form of social computing technology. And since diverse people form their opinions of the outcome based on the knowledge/expertise available to them, these markets, at a fundamental level, form a mechanism to bring together knowledge from across the organization—a goal fully consonant with that of KM. Sure enough, these are used at, for example, Microsoft (Kaihla, 2006) and Google (Google, 2005) to predict product launch dates by aggregating opinions of a large community of developers. Employees from across the company contribute knowledge and opinions, which are aggregated into a forecast by the market (Google, 2005). Eli Lilly Co. uses prediction markets to forecast the success of candidate drugs in the research pipeline (Giles, 2005). Interestingly, prediction markets have been found to be enormously accurate—often more so than conventional forecasting methods (Wolpers & Zitzevitz, 2006).

Can a social computing-based KM approach support KM programs at high maturity? Perhaps what social computing technologies do best within the organizational context is to allow content and human interaction to come together judiciously in carrying out organizational tasks. Referring to the five-level knowledge management maturity model (KMM) (Kochikar, 2000), one finds that two key result areas (KRAs or building blocks) at the highest levels of KM maturity—level 4 (Convinced) and level 5 (Sharing)—are *Content Enlivenment*, where content can be said to be truly "enlivened" with human expertise, and *Expertise Integration*, the notion that appropriate expertise is available to help understand content and tailor it to specific need. Kochikar (2000) states that,

Expertise integration represents the highest level of maturity of the sharing process, as true sharing requires a judicious mix of synchronous and asynchronous mechanisms, to achieve significant gains with optimal utilization of experts' time.

Social computing technologies, by acting as a mechanism to stitch together content and human interaction, facilitate both content enlivenment and expertise integration admirably, and are thus fully capable of supporting KM programs at high maturity.

CAVEATS

Most social computing technologies, by their very nature, involve the members of a community directly accessing and modifying content. Thus, they assume a certain degree of access to, and comfort with, computers, and so organizations/groups where the members do not meet this requirement may not find this technology very productive.

Accountability for content is an issue to be addressed. Accountability is direct in the case of some technologies such as blogging, as a blog typically is written by one person. However, with the appropriate security and auditing mechanisms, accountability can be very high with technologies that allow collaborative content creation, such as wikis, too.

Social computing also takes away a significant degree of responsibility, and hence control, from centralized corporate groups and puts it in the hands of a broader community. It thus engenders a mindset change in organizational governance, without which it may be difficult to absorb effectively.

Also, since a key tenet of social computing is trust, a culture of transparency is important.

FUTURE TRENDS

Considerable work is going into getting social computing technologies to better support various aspects of organizational knowledge sharing. One key area of focus is studying how groups and organizations "remember," and attempting to build systems to support various types of structured online activity such as design. The socially translucent system approach to KM, predicated on the notion that knowledge is discovered, shared, and used in a social context, is perhaps representative of the direction in which organizational KM systems will evolve (IBM, 2006).

Projects such as Cyc (http://www.cyc.com/) and MIT's Open Mind Project (MIT, 2006) also typify approaches for better organizing human knowledge and making machines more "aware," albeit in a societal rather than organizational context. However, the principles are valid in the organizational context, and likely to gain acceptance for managing organizational knowledge.

The Economist Intelligence Unit (Economist, 2006) identifies knowledge management as one of the five trends that will shape business and economy in the coming 15 years. However, in the era of social computing, corporate knowledge management systems will grow "lighter," ceding some of the hitherto centralized responsibility to the community.

CONCLUSION

In the final analysis, social computing is emblematic of the steady power shift that technology itself embodies—from governments, large institutions, and organizations to communities and the individual. Nobody decides on behalf of the user—the user decides what works. This stunningly simple principle is what has made social computing a phenomenon so powerful that it can be termed a profound social mega trend.

As this article illustrates, social computing is increasingly finding use in corporate environments, and is in the process of gaining traction as a mechanism for KM. This can only be a positive development, as ultimately the most effective way of ensuring that content represents what users want is to put the users in charge of managing it.

KEY TERMS

Collaborative Filtering: A technique for producing recommendations that are likely to meet an individual's taste, by looking at the preferences of "like-minded" other people.

Intangible Assets: Organizational assets that do not have any physical manifestation, or whose physical measures have no bearing on their value. The following is a typical list of intangible assets:

- fragmented knowledge residing with individuals, or encapsulated in artifacts such as documentation and software code;
- codified and classified knowledge residing in repositories;
- unique systems, processes, methodologies, and frameworks that the organization follows;
- "formalized" intellectual property such as patents, trademarks, and brands; and
- relationships and alliances that the organization may have shaped (Kochikar, 2002).

Intellectual Capital (IC): The "stock" of knowledge that exists in an organization, that can be used for generating value for stakeholders (Bontis, Crossan, & Hulland 2002).

Knowledge Currency Units (KCU): A mechanism defined at Infosys Technologies to convert all knowledge-sharing activities to a common denominator, in order to enable their measurement in quantitative terms.

Knowledge Management (KM): The gamut of organizational processes, responsibilities, and systems directed toward the assimilation, dissemination, harvest, and reuse of knowledge (Kochikar, 2000).

Metcalfe's Law: The utility of a network rises in proportion to the square of the number of its users. This means that as more users get connected into a network, the marginal utility perceived by new users increases dramatically (Metcalfe, 1996).

Prediction Markets: Speculative markets that can aggregate the opinions of a large number of users regarding the outcome of a particular event (Wikipedia, 2006).

Social Capital: The resources available through and derived from the network of relationships possessed by an individual or social unit within an organization (Nahapiet & Ghoshal, 1998).

Chapter 5.2
Social Software for Bottom-Up Knowledge Networking and Community Building

Mohamed Amine Chatti
RWTH Aachen University, Germany

Matthias Jarke
RWTH Aachen University, Germany

ABSTRACT

Recognizing that knowledge is a key asset for better performance and that knowledge is a human and social activity, building ecologies that foster knowledge networking and community building becomes crucial. Over the past few years, social software has become an important medium to connect people, bridge communities, and leverage collaborative knowledge creation and sharing. In this chapter we explore how social software can support the building and maintaining of knowledge ecologies and discuss the social landscape within different social software mediated communities and networks.

INTRODUCTION

Peter Drucker, among others, argues that in the emerging economy, knowledge is the primary resource for individuals and for the economy overall; land, labour, and capital. He further argues that improving front-line worker productivity is the greatest challenge of the 21st century (Drucker, 1999). Knowledge management has become an important topic for the CSCW community within the last couple of years (Davenport and Prusak 1998). A specific contribution of CSCW to the knowledge management field has been to draw attention to the social aspect of knowledge. Within the CSCW community, some important research emphasises the social properties of knowledge and how it is shared among and between communities and networks (Wenger, 1998a; Engeström et al., 1999; Zager, 2002; Nardi et al., 2002; Stahl, 2005). Over the past few years, social software has become a crucial means to connect people not only to digital knowledge repositories but also to other people, in order to share knowledge and create new forms of social networks and communities. In this chapter, we explore how the emerging social software technologies can support collaborative knowledge creation and

sharing and discuss the social landscape within different social software mediated communities and networks.

KNOWLEDGE, COMMUNITIES, AND NETWORKS

The Social Aspect of Knowledge

Many researchers have provided different definitions for the term knowledge. Nonaka and Takeuchi (1995) define knowledge as justified true belief. Davenport and Prusak (1998) view knowledge as a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms. Drucker (1989) states that Knowledge is information that changes something or somebody, either by becoming grounds for actions, or by making an individual (or an institution) capable of different or more effective action. Drucker further distinguishes between data, information and knowledge and stresses that information is data endowed with relevance and purpose. Converting data into information thus requires knowledge. And knowledge, by definition, is specialized. Naeve (2005) defines knowledge as "efficient fantasies", with a context, a purpose and a target group, with respect to all of which their efficiency should be evaluated. Recently, Siemens (2006) points out that due to the nature of knowledge, it is very difficult to find a common definition and states that knowledge can be described in many ways; an entity and a process, a sequence of continuums: type, level, and application, implicit, explicit, tacit, procedural, declarative, inductive, deductive, qualitative, and quantitative.

Different views of knowledge exist and many researchers have developed classifications of knowledge, most of them in form of opposites (Hildreth and Kimble, 2002). A distinction that is often cited in the literature is made between explicit and tacit knowledge. Explicit knowledge is systematic knowledge that is easily codified in formal language and objective. In contrast, tacit knowledge is not easily codified, difficult to express and subjective. Examples of tacit knowledge are know how, expertise, understandings, experiences and skills resulting from previous activities (Nonaka and Takeuchi, 1995; Nonaka and Konno, 1998). Similarly, Davenport and Prusak (1998) differentiate between structured and less structured knowledge. Seely Brown and Duguid (1998) adopt the terms know what and know how, while Hildreth and Kimble (2002) distinguish between hard and soft knowledge.

Although there is no common definition of the term knowledge, there is a wide agreement that knowledge is social in nature. Many researchers emphasise the social, collective and distributed aspect of knowledge. Polanyi (1967) places a strong emphasis on dialogue and conversation within an open community to leverage tacit knowledge and one of his three main theses is that knowledge is socially constructed. Nonaka and Takeuchi (1995) state that the dynamic model of knowledge creation is anchored to a critical assumption that human knowledge is created and expanded through social interaction between tacit knowledge and explicit knowledge. They further note that this conversion is a socialprocess between individuals and not confined within an individual. Wenger (1998a) points out that knowledge does not exist either in a world of its own or in individual minds but is an aspect of participation in cultural practices. He uses the term participation to describe the social experience of living in the world in terms of membership in social communities and active involvement in social enterprises. Participation in this sense is both personal and social. It is a complex process that combines doing, talking, thinking, feeling, and belonging. It involves our whole person, including our bodies, minds, emotions, and social relations. Wenger stresses that participation is not tantamount to collaboration. It can involve all kinds of relations, conflictual as well as harmonious, intimate as well as political, competitive as well as cooperative. Paavola et al. (2002) propose the metaphor of collective knowledge creation. They discuss three models of innovative knowledge communities; Nonaka and Takeuchi's model of knowledge-creating organization, Engeström's expansive learning model, and Bereiter's theory of knowledge building and point out that all of these models agree that knowledge creation is a fundamentally social process in nature. More recently, Stahl (2005) points out that beliefs become knowledge through social interaction, communication, discussion, clarification and negotiation and that knowledge is a socially mediated product. Siemens (2006) stresses that the challenge today is not what you know but who you know and states that knowledge rests in an individual and resides in the collective. Recognizing that knowledge is a key asset for better performance and that knowledge is a human and social activity, building and maintaining communities and networks that support collaborative knowledge creation and sharing become crucial.

Communities and Networks

Siemens (2006) defines a community as the clustering of similar areas of interest that allows for interaction, sharing, dialoguing, and thinking together.Lave and Wenger (1991) point out that community does not imply necessarily co- presence, a well-defined, identifiable group or socially visible boundaries. It does imply participation in an activity system about which participants share understanding concerning what they are doing and what that means in their lives and for their communities. Quoting Packwood (2004), White (2005) states that a community is present when individual and collective identity begins to be expressed; when we care about who said what, not just the what; when relationship is part of the dynamic and links are no longer the only currency of exchange. The concept of community is very close to the concept of social network. Siemens (2006) defines a network as connections between entities to create an integrated whole. The power of networks rests in their ability to expand, grow, react, and adapt. A network grows in diversity and value through the process of connecting to other nodes or networks. A node in a network can consist of a person, a content resource, or other networks. Nardi et al. (2002) stress that a network is not a collective subject. A network is an important source of labour for the formation of a collective subject. The authors further define a social network as a complex, dynamic system in which, at any given time, various versions of the network exist in different instantiations. Part of the network may be actively embodied through intense communications as a major project is underway. Other parts of the network are instantiated differently, through less intense communications as well as acts of remembering.

Social networks and communities have been viewed from different perspectives and diverse social forms have been introduced in the CSCW literature. These include "communities of practice" (Wenger, 1998a), "knots" (Engeström et al., 1999), "coalitions" (Zager, 2000), and "intensional networks" (Nardi et al., 2002). As a special type of community, Wenger (1998a) introduces the concept of **communities of practice** (CoP). Wenger defines CoP as groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly. According to Wenger, a CoP is characterised by: (a) The domain; a CoP has an identity defined by a shared domain of interest. Membership therefore implies a commitment to the domain, and therefore a shared competence that distinguishes members from other people. (b) The community; in pursuing their interest in their domain, members engage in joint activities and discussions, help each other, and share information. They build relationships that enable them to learn from each other. A website in itself is not a community of practice. (c) The practice; members of a community of practice are practitioners. They develop a shared repertoire of resources: experiences, stories, tools, ways of addressing recurring problems, in short a shared practice. This takes time and sustained interaction. To differentiate between CoP and network, Wenger (1998b) states that a CoP is different from a network in the sense that it is about something; it is not just a set of relationships. It has an identity as a community, and thus shapes the identities of its members. A CoP exists because it produces a shared practice as members engage in a collective process of learning.

Within an activity theory framework, Engeström et al. (1999) note that a great deal of work in today's workplace is not taking place in teams with predetermined rules or central authority but in work communities in which combinations of people, tasks and tools are unique, of relatively short duration. The authors introduce the concept of **knotworking** to describe temporal situation-driven combinations of people, tasks, and tools, emerging within or between activity systems. According to the authors, the notion of **knot** refers to rapidly pulsating, distributed, and partially improvised orchestration of collaborative performance between otherwise loosely connected actors and organizational units. Knotworking is characterized by a movement of tying, untying, and retying together seemingly separate threads of activity. In knotworking the centre does not hold, meaning that the tying and dissolution of a knot of collaborative work is not reducible to any specific individual or fixed organizational entity as the centre of control or authority. The authors contrast knots to communities of practice, noting the differences between the two in terms of knots' loose connections, short duration of relationships, and lack of shared lore. They also contrast knots to networks, stating that a network is commonly understood as a relatively stable web of links or connections between organizational units, often materially anchored in shared information systems. Knotworking, on the other hand, is a much more elusive and improvised phenomenon.

Zager (2002) explores a collaboration configuration called a **coalition** and notes that coalitions are temporary collaborative groups where shared concerns and interests connect constituent individuals and teams. Constituents are part-time members of the coalition, making the coalition loosely bound. At any moment, the coalition's membership is fluid and diffuse, and communications among constituents may be non-existent, hindering coordination of the coalition. The organization of the coalition is bottom-up, comprising independent participants acting on their own, with little or no reference to the other participants. Nardi et al. (2002) point out that coalitions share many of the characteristics of knots in being temporary, loosely bound, and fluid. The authors further note that while knots and coalitions are similar, it is worth making a distinction between smaller, more discrete knots where certain kind of interactions are possible, and more distributed coalitions. Coalitions differ from knots in that they occur in large distributed organizations where people involved in the knot are in separate parts of the organization and often out of communication with one another.

Nardi et al. (2002) note that the most fundamental unit of analysis for computer supported cooperative work is not at the group level for many tasks and settings, but at the individual level as personal social networks come to be more and more important. The authors develop the concept of **intensional networks** to describe the personal social networks workers draw from and collaborate with to get their work done. The authors further use the term **NetWORK** to refer to the ongoing process of keeping a personal network in good repair. Key netWORK tasks include (1) building a network, i.e. adding new contacts to the network so that there are available resources when it is time to conduct joint work; (2) maintaining the network, where a central task is keeping in touch with extant contacts; (3) activating selected contacts at the time the work is to be done. Nardi et al. compare intensional networks to communities of practice, knots, and coalitions. The authors note that intensional networks differ considerably from communities of practice stating that Intensional networks are personal, more heterogeneous, and more distributed than communities of practices. According to the authors, intensional networks also differ from knots in several ways. First, intensional networks often involve long- term relationships. Second, the joint work may last for long or short periods of time. Third, the knotworking that occurs within established institutions is more structured in terms of the roles it draws upon. In contrast, work that is mediated by intensional networks results in more flexible and less predictable configurations of workers. Fourth, in intensional networks, workers are not thrown together in situation dependent ways or assembled through outside forces. Instead, work activities are accomplished through the deliberate activation of workers' personal networks. Nardi et al. further point out that intensional networks differ from coalitions on the dimension of intentionality. An intensional network is a deliberately configured and persistent personal network created for joint work, whereas a coalition is highly emergent, fluid, and responsive to state changes in a large system.

SOCIAL SOFTWARE: TECHNOLOGY FOR COMMUNITIES

Web 2.0 and Social Software

Over the past few years, the Web was shifting from being a medium into being a platform that has a social dimension. We are entering a new phase of Web evolution: The read-write Web (also called **Web 2.0**) where everyone can be a consumer as well as a producer of knowledge in new settings that place a significant value on collaboration. Web 2.0 is a new generation of user-centric, open, dynamic Web, with peer production, sharing, collaboration, distributed content and decentralized authority in the foreground. **Harnessing collective intelligence** has become the driving force behind Web 2.0. Jenkins et al. (2006) define collective intelligence as the ability to pool knowledge and compare notes with others towards a common goal. Levy (1999) sees collective intelligence as an important source of power in knowledge communities to confront problems of greater scale and complexity than any single person might be able to handle.He argues that everyone knows something, nobody knows everything, and what any one person knows can be tapped by the group as a whole.Collective intelligence is similar to the concept of the **wisdom of crowds** introduced by James Surowiecki in his book with the same name. Surowiecki (2004) explores the idea that large groups of people are smarter than an elite few, no matter how brilliant. He argues that the many are better at solving problems, fostering innovation, coming to wise decisions, and predicting the future than the few.

Social software, also called **social media**, has emerged as the leading edge of Web 2.0 and has become a crucial medium to connect people not only to digital knowledge repositories but also to other people, in order to share and collaboratively create new forms of dynamic knowledge. Rapidly evolving examples of social software include wikis, blogs, Web feeds, media sharing, social tagging, and pod/vodcasting. Social software is however not restricted to these technologies. Below we provide a brief outline of characteristics of each social software technology.

Recently, wikis have seen a growing mainstream interest. A wiki is a collaborative Web site which can be constantly edited online through the web browser by anyone who cares to contribute. Once created, a wiki can be revised collaboratively, items can be added or deleted easily, and changes can be made quickly, thereby building a shared knowledge repository.

Another form of Web publishing, which has seen an increase in popularityover the past few years, is blogging. Blog creation is rapidly growing. In contradiction to wikis, where anyone can add and edit items, a blog can only be edited by one individual (personal blog) or a small number of persons (group blog or organizational/business blog). A blog is a frequently updated Web site made up of dated entries presented in reverse chronological order, addressed as posts. The posts normally consist of texts, often accompanied by pictures or other media, generally containing links to other blog entries recommended or commented by the author. Each post can be assigned one or multiple tags/keywords as well as a permanent pointer (permalink) through which it can be addressed later. Older posts are moved to a searchable tag-based archive. Additionally, displayed on the sidebar of a blog, there often is available a list of other blogs that the author reads on a regular basis, called blogrolls. Readers can attach comments to a particular blog post. Trackbacks enable to track citations and references to a blog post from other posts in other blogs and automatically link back to these references. New variants of blogs are gaining more popularity each day. Examples include photoblogs (phlogs) which have photographs as primary content, video blogs (vlogs) which focus on videos and mobile blogs (moblogs) which offer a way for users to post content (e.g. pictures, video and text) from a mobile or portable device directly to their blogs. An enhancement of blogs are Web feeds e.g. RSS and Atom feeds. Web feeds are a new mode of communication that allows e.g. blog-authors to syndicate their posts and gives blog-readers the opportunity to subscribe to selected blogs with topics they are interested in and receive new published content.

Another popular example of social software is media sharing and social tagging. Today, Web users are sharing almost everything: ideas, goals, wish lists, hobbies, files, photos, videos, bookmarks. Additionally they are using tags to organize their own digital collections. Tagging can be defined as user- driven, freeform labelling of content. Users create tags in order to be able to classify, categorize and refind their own digital collections at a later time. Tagging is implemented on the most popular social sites such as on Flickr to organize photos, on YouTube to classify videos, on del.icio.us or Yahoo's My Web to categorize bookmarks, and on 43 things to describe lifetime goals.

Podcasting is also becoming mainstream. The term is a combination of the two words iPod and broadcasting and refers to digital audio files that are recorded by individuals and then made available for subscription and download via Webfeeds. These files can then be accessed on a variety of digital audio devices. A variant of podcasting, called vodcasting (the "vod" stands for "video-on-demand), works in an almost identical way but offers videos for streaming and download.

Social software offers new opportunities for social closeness and foster changes in the ways how people network and interact with each other. In the next section, we discuss the social landscape within different social software mediated communities.

Social Software Mediated Communities

Social software has been opening new doors for social knowledge networking and dynamic community building. Social software mediated communities are organized from the bottom up. Bottom-up communities are co-constructed and maintained by individual actors. They emerge naturally and are derived from the overlapping of different personal social networks. In contrast, top-down communities are hierarchical social structures under the control mechanisms of outside forces. The social structures evolving around social software are close to Engeström's knots. In fact, social software enables the formation of networks between loosely connected individual actors using distributed tools. These networks have no centre or stable configuration and are characterized by distributed control and coordinated action between individual actors. Furthermore, social software supports the netWORKing perspective in Nardi et al. (2002); that is building and maintaining personal social networks. Social software driven networks are similar to what Nardi et al. describe as intensional networks in that they arise from individual actors that self-organize in flexible and less predictable configurations of actors. The social software networking model is based on personal environments, loosely joined. Rather than belonging to hierarchical and controlledgroups, each person has her own personal network. Based on their needs and preferences, different actors come together for a particular task. They work together until the task is achieved and thereby do not have a permanent relationship with a formal organization or institution. Owen et al. (2006) point out that an important benefit from social software is the ability to cross boundaries. People might be able to join communities that they would not otherwise join. They have the opportunity to move beyond their geographic or social community and enter other communities and at the same time others can move into theirs. Moreover, there is no barrier to be member of communities that contain other ages, cultures and expertise.

Blogs, Web feeds, wikis, podcasts, and social tagging services have developed new means to connect people and link distributed knowledge communities. Blogging began as a personal publishing phenomenon and evolved into a powerful social networking tool. Besides their usage as simple personal publishing tool, blogs can be used as (a) personal knowledge management system to help us capturing, annotating, organizing, reflecting, and exchanging our personal knowledge; (b) distributed knowledge repository that we can use to access and search for appropriate knowledge resources; (c) communication medium that enables us to comment, rate, review, criticize, recommend and discuss a wide range of knowledge assets with peers worldwide; and (d) community forming service to sustain existing social ties and develop new social ties with others sharing similar practices or interests. Moreover, blogging is a good example of a technology that starts with individuals and supports bottom-up dynamic building of personal social networks. Commenting on blog posts makes the interaction between blog-authors and -readers possible and can lead to interesting discussions. New blog-readers can then join the discussion by commenting or writing a post on their own blog with a reference to the blog post that they want to comment on. Trackbacks detect these remote references and enable to establish a distributed discussion across multiple blogs. Web feeds offer a powerful communication medium that enables people to keep track of various blogs and receive notification of up-to-date content. Through comments, citations, trackbacks and Web feeds, a social network from people with similar practices or interests can be created and even enlarged by blogrolls. White (2006) identifies three types of blog based communities: (a) the Single Blog/Blogger Centric Community emerging around a single blogger where readers return to the bloggers' site, comment and get to know not only the blogger, but the community of commentors; (b) the Central Connecting Topic Community that arises between blogs linked by a common passion or topic. What links them is hyperlinks, in the form of blogrolls, links to other blogs within blog posts, tagging, aggregated feeds, trackbacks and comments; and (c) the Boundaried Community where blogs are hosted on a central site or platform. Typically members register and join the community and are offered the chance to create a blog. The communities that emerge from blogging establish their own rules and roles. Citing Cross and Parker (2004), White (2006) points to different roles in blog based communities; i.e. Central Connectors, Unsung Heroes, Bottlenecks, Boundary Spanners and Peripheral People.

Wikis have evolved in recent years to become a simple and lightweight tool for knowledge capturing, asynchronous collaborative content creation, information organization, peer editing, and working on a team project. A wiki is also an important community service that has the potential to build communities coming in from the bottom up. A wiki can connect multiple authors across organizations and institutions. Everyone is able to post, edit, delete, and comment content. Over time, a collaborative social space and a shared knowledge repository will emerge. The most successful model for a wiki is surely the open and freely editable encyclopaedia Wikipedia. Additionally, several wiki-like, more professional services, such as Google Docs, have emerged as collaborative writing tools which let users come and work together on a shared project and rapidly create a new collaborative space. The fact that knowledge created by many is much more likely to be of better value makes wikis a key technology in collective intelligence communities that ensures that the captured knowledge is up-to-date and more accurate.

Media sharing sites, e.g. Flickr, YouTube, del.icio.us, Digg, Slideshare, CiteULike provide innovative collaborative ways of organizing media. These sites have powerful community features. Users can upload, rate, tag different media, post comments, interact with other members by forming groups, and track their activities by adding contacts. Social tagging is being used by most of the media sharing sites to classify, categorize, and manage media in a collaborative, emergent, and dynamic way. This classification scheme has been referred to as "folksonomy", a combination of "folks" and "taxonomy", which implies a bottom-up approach of organizing content as opposed to a hierarchical and top-down taxonomy. The folksonomy is a good example of the collective intelligence at work. Media sharing, social tagging and folksonomies provide a powerful way to foster bottom-up community building as users share, organize, filter interesting information for each other, browse related topics, discover unexpected resources that otherwise they would never know existing, look for what others have tagged, subscribe to an interesting tag and receive new content labelled with that tag via Web feeds, and find unknown people with similar interests.

SOCIAL SOFTWARE AND SOCIAL NETWORK ANALYSIS

As social software becomes important for building and bridging communities, tools that enable people to manage, analyze, and visualize their social software mediated networks gain popularity. Thereby, different social network analysis methods have been applied. Social network analysis (SNA) is the quantitative study of the relationships between individuals or organizations. Social network analysts represent relationships in graphs where individuals or organizations are portrayed as nodes (also referred to as actors or vertices) and their connections to one another as edges (also referred to as ties or links). By quantifying social structures, social network analysts can determine the most important nodes in the network (Wasserman and Faust, 1994). One of the key characteristics of networks is centrality. Centrality relates to the structural position of a node within a network and details the prominence of a node and the nature of its relation to the rest of the network. The centrality of a node is influenced by the following factors: (a) degree, which determines the root by identifying the object with the most direct connections to other objects within the network. This finds the object with the most influence over the network, (b) closeness, which determines the root as the object with the lowest number of links to all other objects within the network. This finds the object with the quickest access to the highest number of other objects within the network, and (c) betweenness, which determines the root as the object between the most other linked objects. This measure finds objects that control the information flow of the network (Siemens, 2005).

Our literature survey on the analysis of social software mediated networks has revealed that there is limited empirical work on the analysis of social networks issued through wikis or social tagging. There is however a growing interest in blog social network analysis. Recognizing that blogging is a highly social activity, recent blog research has focused on citations, comments, trackbacks, and blogrolls as indicators of cross-blog conversational activities and has employed social network analysis techniques to detect the linking patterns of blogs, the development of blog based communities, and the popularity of blog-authors. In fact, comments, trackbacks, and blogrolls are a measure of reputation and influence of a blog-author, as an interesting blog post will be frequently commented or cited in other blogs and a popular blog will be often listed in the blog-rolls. Blog social network analysis research has adopted different metrics for blog analysis, i.e. the link mass metric, the converstaion mass metric, and the content and conversation mass metric. Different studies have used the link structure of the blogosphere for authority detection and community identification (link mass). For example Marlow (2004) assumes thatlinks to a given blog are a proxy to the authority of that blog and uses the social network analysis metrics in-degree (links in) and out-degree (links out)to identify authoritative blog authors. Similarly, Adar et al. (2004) propose the use of link structure in blog networks to infer the dynamics of information epidemics in the blogspace and show that the PageRank algorithm identifies authoritative blogs. Kumar et al. (2005) examine the structure of the blogosphere in terms of the bursty nature of linking activity. By comparing two large blog datasets, Shi et al. (2007) demonstrate that samples may differ significantly in their coverage but still show consistency in their aggregate network properties. The authors show that properties such as degree distributions and clustering coefficients depend on the time frame over which the network is aggregated. McGlohon et al. (2007) observe that the usual method of blog ranking is in-links and stress that simply counting the number of in-links does not capture the amount of buzz a particular post or blog creates. The authors argue that the conversation mass metric is a better proxy for measuring influence. This metric captures the mass of the total conversation generated by a blogger, while number of in-links captures only direct responses to the blogger's posts. Similarly, Ali-Hasan and Adamic (2007) notice that most of the blog research to date has only focused on blogrolls and citation links. The authors stress that much of the interesting interaction occurs in comments and point out that reciprocal blogroll links indicate possibly only a mutual awareness, whereasreciprocal comments and citations imply a greater level of interaction. Bulters and de Rijke (2007) point out that traditional methods for community finding focus almost exclusively on topology analysis. The authors present a method for discovering blog communities that incorporates both topology- and content analysis (content and conversation mass). The proposed method builds on three core ingredients: content analysis, co-citation, and reciprocity.

CONCLUSION

In this chapter, we mainly discussed how social software can support the building and maintaining of ecologies that foster knowledge networking and community building. We explored the social structures emerging around social software and found out that social software mediated communities are organized from the bottom up. Finally, we would like to stress two important issues. Firstly, a sole social software technology cannot build a community. Often, relationships start with a social software technology and then extend to other communication media such as email, instant messaging, and face-to-face meetings. Secondly, successful community building and effective knowledge sharing are not primarily dependent on social software technologies. Key prerequisites for knowledge sharing are (a) trust and (b) a participatory culture that allows knowledge to flow and rewards rather than punishes collaboration initiatives. Collaboration has to become the norm and a meaningful part of the performance evaluation of knowledge workers.

Chapter 5.3
The Essence of Organizational Knowledge:
A Social Epistemology Perspective

Fei Gao
East China University of Science and Technology Business School, China

ABSTRACT

The relationships between organizational static substance knowledge with 'belief', 'the true', 'true belief', or 'justified true belief' have been outlined briefly in 2003. In this article, through combining new research outcomes, I further explore why different kinds of organizational static substance knowledge can be counted as belief, the true, true belief, or justified true belief. The discussion on the subtle differences between belief, the true, true belief and justified true belief will shed light on our comprehensive and intensive understanding of different kinds of organizational knowledge and will enable managers or chief knowledge officers (CKO) to effectively and efficiently manage knowledge related activities in our knowledge era. [Article copies are available for purchase from InfoSci-on-Demand.com]

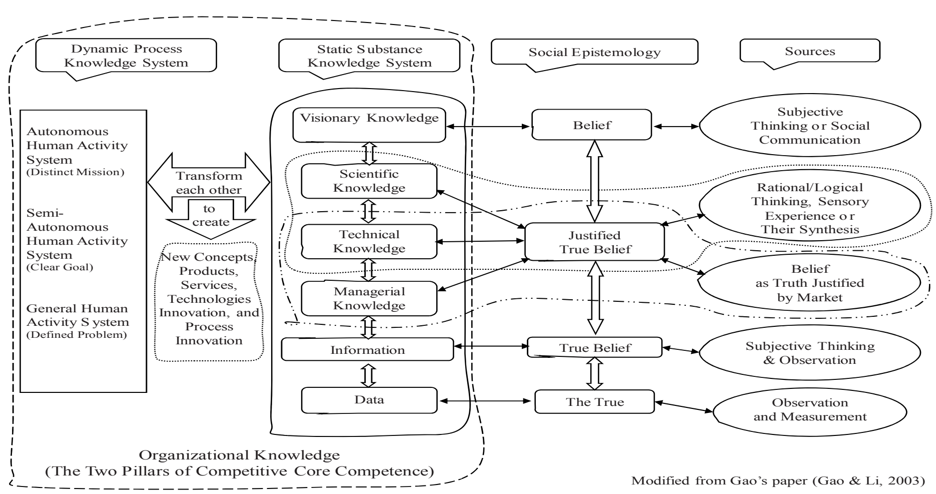
INTRODUCTION

The attributive term 'organizational' in the phrase of 'organizational knowledge' makes the phrase very different from the meaning of the single term 'knowledge'. On the one hand, organizational knowledge, as it was discussed in Gao et al (2003), must be judged by objective criteria (such as through strict scientific thinking based on scientific method, approaches, and tools like logical and rational thinking (i.e. logical deduction, rational induction, and/or rational interpretation); sensory experience (i.e. experiment or field study); and the synthesis of rational thinking and sensory experience; and Nonaka's evaluating criteria of the market[1]). On the other hand, organizational knowledge has also to be judged by subjective criteria, and further, these subjective criteria are established by the organization based on its own social and cultural background, history, and actual environmental position. This subjective aspect of organizational knowledge is different from

Polanyi's postmodern philosophical meaning i.e. the tacit dimension of knowledge (Polanyi, 1958, 1962; Li & Gao, 2003). It also means that some justified true belief, such as a scientific theory or an advanced technology, can be excluded from organizational knowledge if this scientific knowledge and technological knowledge has no relationship to the organizational operation or business. What is more, a false statement might be understood as organizational knowledge and considered highly useful, as long as the people in that organization have reached some sort of consensus as to its value, such as a false interpretation of a piece of information, or a false description of an event. Although such phenomena generally would not last a long time, its negative influence on organization may. In nature, organizational knowledge is a product of the organizational social/human activity through social communication. Therefore, misunderstandings can happen. To reduce these types of mistake, organizational knowledge needs to be carefully reviewed from a social epistemology perspective as in our following paragraph.

In Gao et al's paper (2003), organizational knowledge was defined as *organizational static substance knowledge* and *organizational dynamic process knowledge*. Organizational static substance knowledge is classified further into visionary knowledge (i.e. corporate vision, mission, and norm, plus corporate culture and value); scientific knowledge; technological knowledge; managerial knowledge; information; and data. Organizational dynamic process knowledge is then defined as knowledge related human activities, which are classified into the autonomous human activity of distinct mission; semi-autonomous human activity with a clear goal; and the general human activity surrounding a defined problem, because organizational knowledge in modern high-tech corporations consist of natural sciences, applied sciences/technologies, and social/human sciences (Gao, 2007; Gao, et al, 2003, 2008). Human activities here are the activities of creating, codifying, acquiring, categorizing, distributing, transferring, and utilizing various kinds of static substance knowledge and the knowledge workers' own personal knowledge to create new products; better services; advanced technologies (both hard and soft technology); and technical/process innovations for realizing the economic value of this knowledge for the good of the organization, society, and individuals (see the left-hand side of Figure 1).

Figure 1. Organizational knowledge, sources, and social epistemology perspective



On exploring how we know what we know and in what way we know them, a concept model is built to illustrate the differences between science, technology/applied science, and social/human science (see Figure 2, Gao, 2007, 2008). Figure 2 is a concise map that points out the underlying theories and philosophies of various systems methodologies (i.e. hard systems methodology, soft systems methodology, emancipatory systems methodology, and post-modern systems methodology), and in what way and how, the different kinds of systems methodologies were generated for dealing with their corresponding ideal problem contexts i.e. unitary, pluralist, simple coercive, and complex coercive (Jackson, 2000, 2003; Jackson and Gao, 2004). The different ways of approaching different knowledge in different fields results in different standards of justification and different criteria of evaluation for both research outcomes and research approaches.

Here we introduce the concepts of 'belief', the true, true belief, or justified true belief and their relationships with organizational static substance knowledge are explored from a perspective of social epistemology. Through exploring why organizational static substance knowledge should be counted as belief, the true, true belief, or justified true belief, the different characteristics of different static substance knowledge can be better understood and thus proper criteria can be used for their accurate evaluation and correct justification. Organizations may pay dearly when they confuse the different kinds of organizational knowledge (i.e. mistaking one kind of organizational knowledge for another kind of organizational knowledge), because it can lead to incorrect decisions being made. Therefore, distinguishing between different kinds of organizational static substance knowledge is one of the most important factors to be considered in relation to undertaking quality control of knowledge related activities.

Figure 2. Reality, perceived reality, problem contexts, underlying philosophies, and management methodologies

BELIEF; THE TRUE, TRUE BELIEF; JUSTIFIED TRUE BELIEF; AND ORGANIZATIONAL STATIC SUBSTANCE KNOWLEDGE

In discussions of social epistemology, the terms 'belief', 'the true, true belief', or 'justified true belief' are often mentioned as useful for the assessment and validation of knowledge. Here we relate belief; the true, true belief; and justified true belief to organizational static substance knowledge (see the right-hand side of Figure 1). This connection between them sheds new light on our understanding of organizational static substance knowledge and its management.

Belief

'Belief' is something believed or accepted as true, especially a particular tenet or a body of tenets accepted by a group of people. It is a mental acceptance of, and conviction in, the truth, actuality, or validity of something by some person. Belief has weak relationship with whether what was believed in is true or false, rational or irrational, agreed to or not agreed to by other members of the believers' community. It comes from subjective thinking or social communication. What an individual believes in greatly depends on his/her education background, social environment, cultural tradition, and personal experiences.

An individual's belief decides not only what the believer does but also by what means and how the believer can carry out it. Ramsey and Armstrong said that 'Beliefs are maps by which we steer' (Armstrong, 1973 p193; Ramsey, 1931, p238). And further Armstrong (1973) said that the belief-map will include a map of the believer's own mind, and even, as a sub-part of this sub-map, a map of the believer's belief-map (that is, his beliefs that he holds certain beliefs). Beliefs are thought of as maps, which carry their interpretation of reality within themselves. It is due to this characteristic that no objective rational judgment is involved. To an individual, his/her belief is his/her personal knowledge such as value, morals, and ethics.

In knowledge management, a knowledge worker's belief is their professional value and professional moral and ethics. It is the 'map for steering' in their career and daily life. Equivalently, an organization's belief is its visionary knowledge in the form of organizational vision and mission embedded in corporate culture, value, norm, and evaluation system. Organizational visionary knowledge is the outcome of subjective thinking or social communication and has close relationship with its tradition and social environment. Organizational visionary knowledge reflects its founders' personality. It can be radically changed by some powerful strong person/s or through special influential events. In general, it is often modified in an evolutionary way with the development of organizations. The modified statements of organizational vision or mission with a corresponding change in evaluation will guide the evolution of corporate culture and business pattern. Organizational visionary knowledge should be of humanity, justice, fairness, and honesty.

An organization's good visionary knowledge not only reveals the vision and mission of an organization but also sets clear criteria to evaluate different kinds of knowledge work. The evaluation of knowledge workers' work should be different from the evaluation of other organizational operation work. The reasons for the separation are that first, knowledge work and knowledge related activities are very different from conventional operational work and activities in organization (Gao et al, 2000); and second, that highly autonomous knowledge related human activity needs sound support from top management group rather than only from the middle level managers in organization. A Chief Knowledge Officer (CKO) needs to be empowered to distribute a budget, reward outstanding elites, and make decisions on personnel. Due to the different characteristics between different kinds of knowledge work they cannot all be evaluated using the same approach. The evaluation system of knowledge work should ensure that the organization's desired personal beliefs come true and the undesired ones are eliminated. Or in other words, it is to align the individual's vision and mission with the organizational vision and mission.

Most management evaluation systems pay great attention to the operational process. It is believed that if the process is correct, the desired results will be obtained, but this is not true for knowledge related activities. In Gao's articles (Gao et al, 2002, 2003), it was pointed out that no one knows the knowledge work better than the knowledge workers, so it is useless to judge knowledge work by laymen observing the working process. To them the knowledge work process is a black box. The most important thing is not the process being observed but the content and outcomes of knowledge work. If one lacks the ability to identify the quality of knowledge related work, the work has to be evaluated by its outcomes through the markets[2]. Knowledge management, to some extent, is to build various enabling 'Bas' of knowledge sharing and creating based on the organizational visionary knowledge for a given organization (Li & Gao, 2003; Nonaka & Konno, 1998; Nonaka & Takeuchi, 1995). This then is the function of organizational visionary knowledge.

True Belief

Putting the term 'true' in front of belief to form the phrase 'true belief' implies that the meaning of this phrase may be not true, but is intended to lead others to believe that the statement of this true belief is in fact true. In other words, whether the believer/s (the sender/s) believe that the 'true belief' itself is true or not, the believer/s (the sender/s) expect/s others (the receivers) to accept it as true. So something labeled as true belief may be not true at all. Here we relate organizational information to true belief, because organizational information often has such a character.

In general, information is something told (i.e. message) or facts or details about somebody/something; from a professional perspective, information is the meaning given to data by the way it is interpreted or data in context (Earl, 1994; Davenport, 1997). Information should be sufficient, reliable, relevant, simple, objective, and timely; but it is actually a subjective outcome and could be created from nothing for a special purpose (such as Hwuang Woo-Suk's academic fraud disclosed in 2005 in South Korea[3]). In knowledge management, managers or CKOs should be carefully to distinguish true belief (i.e. information especially those deliberately created) from the true (data), belief (visionary knowledge), or justified true belief (scientific knowledge, technological knowledge, or managerial knowledge).

The True

'The true' as a concept means right or correct (not false), or being what exists rather than what was thought, intended, or claimed. The use of *true* here requires the statement of the *tru*e to be consistent with reality in the eyes of everyone. In other words, if something is described to be the truth, it requires that statement to be objective, accurate, and reliable.

Data, and the representations of events or signs or symbols of facts collected through observation and measurement without value judgment, are characteristics of the meaning described by the phrase *the true*. People objectively and accurately collect data to obtain a true representation of facts based on the individuals' ability and experiences or social communication. Data are the representations of facts or events; therefore, data are counted as *the true* in organizational knowledge system. To collect and judge data, sometimes professional knowledge is a necessity.

Although data, or the true, should be objective, accurate, and reliable, the same data could be interpreted into very different information by different individuals for different purposes, or because of their different abilities or background. Therefore, the true (i.e. data) and true belief (i.e. information) are very different in nature. Managers or CKOs should understand, or at least know, in what way and how data or facts are interpreted/manipulated/presented into information, because it is these items that determine the quality and characteristics of information. Information and data are normally seen as generic knowledge (Gao, el at, 2003).

In general, people often take information as facts i.e. take true belief as *the tru*e. This is very dangerous, because it leaves impostors space to work. Like fortune-tellers and illusionists, impostors, especially academic fraudsters, are good at creating/producing events [for their own special purposes] to make others believe that what they spread was *the true*. It is due to this reason that honesty and professional morality and ethics are viewed as one of the most important characteristics of knowledge workers. When knowledge becomes the synonym of intellectual asset and knowledge work implies not only fame and social status but also high salary and other benefits, knowledge management must take the responsibility of discerning the fake from the true - distinguishing information from facts. Under any condition, purposeful cheats must be forbidden. Facing the current global financial crisis started from America, it is time for all professionals, academics or practitioners to rethink the standards of professional ethics and morals and corporate social responsibility because we need some more criteria beyond market requirements. The success of Wall Street financial derivatives on global capital market, which have been mainly invented to reduce the risk that the value of the underlying asset will change unexpectedly, actually became the very source of the current global financial crisis and now is spreading to our real economy. Therefore, a new task has emerged for knowledge management, which is to prevent purposeful professional fraud in the name of innovation or 'over innovation'. Otherwise, the Enron scandal or Hwuang Woo-Suk's case will happen again and again. Blurring the boundary between information and facts is one of the tricks of the imposter.

Justified True Belief

Organizational scientific knowledge, technological knowledge, and managerial knowledge are judged here as justified true belief, because all of them, besides holding their corresponding characteristics, need to be justified by a third party. The third party, as Nonaka said, is the market. Business practical success is the final criteria for evaluating organizational knowledge. In the following section, the characteristics of scientific knowledge, technological knowledge, and managerial knowledge are briefly introduced.

The arguments of the characteristics of scientific knowledge, technological knowledge, and managerial knowledge can be found in philosophy, sociology, and organization studies (Burrell & Morgan, 1979; Clegg et al, 1996; Kuhn, 1970; Russell, 1961). In philosophy, if something is considered as 'justified true belief', it is called the 'truth'. Justified true belief means that a belief was justified as being true in some way. If the method of justification is through reasoning in terms of rational and logical deduction (such as Plato and Descartes), by empirical induction from sensory experiences (Aristotle and Locke), or by the synthesis of rational deduction and empirical induction (Kant, Hegel, or Marx), the statement of justified true belief is to be counted as either science or technology. If the method of justification is mainly through collective subjectivism and/or individual subjectivism, the statement of justified true belief is to be to counted as social science or humanity (as shown in Figure 2, Gao et al, 2003; Gao, 2007, 2008; Russell, 1961, 1989). Science and technology take objectivity and rationality as a necessity and both natural scientists and technologists/engineers tend to separate their work objects, research discoveries and inventions, from individual subjectivity; while social science is based on subjectivity or personal understanding and interpretation and social scientists cannot separate their personal value judgment from their research objects, approaches, and conclusions. Scientific knowledge in organizational knowledge management, as Drucker (1969) asserted, is part of the 'history of technology', which recounts how man puts tools to work.

Therefore the body of knowledge of social/human sciences is social scientists' personal understanding and interpretation about the social reality of human society. The difference between science, technology/applied science, and social science/the humanities, as well as the difference between scientists, applied scientists/engineers, and intellectuals are incompatible because of their different cultures (Gao, 2007; Snow, 1998). Natural scientists aim to *answer a question*; technologists/engineers aim to *solve a problem* (Ackoff, 1999); and social scientists/practitioners aim to interpret/change social phenomena. Natural scientists, technologists/engineers, and social scientists/practitioners take different objects as their research targets in different fields with different approaches, and by different means, for different purposes. They believe in different philosophies. Figure 2 illustrates the relationships of different elements and their connection roads. Management/organization theories, methodologies, approaches, and skills have been developed for dealing with man-made systems and human society; they belong to social/human science as shown in Figure 2 (Gao, 2008).

SUMMARY

The different kinds of organizational static substance knowledge can be counted as belief, the true, true belief, or justified true belief because of their different ways of generation as showed in Figure 2. Human subjective opinion and social consensus play an important role in the creation and formation of organizational business knowledge. Therefore, to build a high quality organizational knowledge system and make full use of this valuable resource, i.e. to effectively and efficiently manage organizational knowledge for the organizational vision and mission; means that how to organize the processes of human activity, and how to evaluate the results of human activity, become the key points of successful knowledge management. As the subjective factors of a human being cannot be avoided in dealing with organizational knowledge, the various kinds of organizational knowledge should be treated based on their different characteristics, in this way, critical systems thinking is of great help in carrying out fairness, justice, and is objective (unbiased) for individuals, groups, organizations, community, and society (Gao, 2008).

The definition of knowledge in Nonaka's knowledge-creating theory directly points out that we should study organizational knowledge from a social epistemology perspective, because knowledge is defined as a dynamic human/social process of justifying personal belief and skill towards the truth (Nonaka, 2000, 2002). With Takeuchi he not only confirmed the social process of knowledge creation but also established a SECI model (Socialization, Externalization, Combination, and Internalization between tacit knowledge and explicit knowledge) to facilitate the dynamic social process of knowledge conversion (Nonaka and Takeuchi, 1995).

For static substance knowledge, the evaluation should be based on the different criteria as shown in Table 1. With regard to knowledge workers, besides separating knowledge managers from knowledge workers, we further classify the workers into knowledge brokers, knowledge processors, and knowledge creators, to identify who actually create knowledge in organizations; who add new value; what they contribute to the organizations; and what roles these various actors play. It does not mean some roles are superior to others; the aim is to identify what each player does and what role he actually plays. Based on

Table 1. Organizational static substance knowledge and their corresponding evaluation criteria

	Name	**Contents**	**Criteria**
Organizational Static Substance Knowledge	Visionary Knowledge	Vision Mission Ethics Moral	Humanity Justice Fairness Honesty
	Objective and/or Subjective Knowledge	Scientific Knowledge	Justification Falsification
		Technological Knowledge	Advancement New Applicability
		Managerial Knowledge	Performance Applicability
	Generic Knowledge	Information	Reliability Simplicity Timeliness
		Data	Objectivity Accuracy Reliability

this, organizations can make decisions based on their actual situations and value systems. When an organization pays attention to what each player actually does, what results they obtains, and what role/s the actor plays, professional/academic frauds will be reduced. Although past achievements of individuals, either failure or success, cannot decide their future performance, their tacit knowledge, especially professional knowledge and skills, can. As professional, systematic and theoretic knowledge is the basic element or background of a qualified knowledge worker, to evaluate each knowledge worker longitudinally will help to identify the fake from the true expert. To some generalists, it is more important to find out (in each field) whether they are evaluated as an expert by the experts in that field. To professionals, generalists usually mean no profession. As they know some basic terms or principles in a few fields, it is easy for them to disguise themselves as gurus. The question of what they really know must be asked and examined carefully before recruiting knowledge workers.

CONCLUSION

The article discusses the nature of organizational static substance knowledge, what various business related knowledge are, and how and where they come from. Based on this, organizations can establish effective management system to organize, support, and motivate knowledge related activities, and manage them through evaluating the outcomes of the activities. Business related knowledge as both a production factor and a means of production, as well as an intangible asset to organization has very different characteristics from other production factors. Knowledge workers with special personal knowledge determine the success or failure of the knowledge related activity. Because belief, true belief, the true, and justified true belief are different and interconnected, how to manage organizational knowledge and maximize its economic value through transforming its form or position among individuals or between organizations, and embodying it into routines of operation, products, and service, is the essential role of knowledge management.

ENDNOTES

1 Nonaka believes that organizational knowledge must be evaluated by the market (personal discussion with Professor Nonaka). This implies that organizational knowledge has to be business related knowledge and market is a necessity for evaluating organizational knowledge. The different viewpoints about knowledge conceived by the intellectual in general and by the people in business organization are at that intellectuals care about the answer to the statement of the knowledge itself; people in business organization care more about the function of knowledge (Gao, 2003a, 2003b). Figure 1 and 2 are supposed to help managers or CKOs to justify the answer to organizational static substance knowledge, while Table 1 provides criteria to evaluate it.

2 Markets here means the academic community and business world.

3 South Korea scientist Hwang Woo-Suk, with some of his co-workers together, conducted scientific fraud through faking original scientific experiment data. This is a typical example of blurring the line between 'the true' and 'true belief' (i.e. blurring the line between data and information). Unfortunately, Hwang and his group were intending to clone human embryos (which is repeatable) and had failed to do this before the fraud was disclosed.If they had succeeded in cloning human embryos before its disclosure, the scientific fraud might have never been found. In this case, through faking data, they would become known as the first scientists to know how to clone human embryos even if some other scientists had cloned human embryos before Huang's group. However, if Hwang's research was in the field of social science, where what had been done might have been unrepeatable, could such collective frauds have ever been found? To this, I raise some questions here: should we question such inventions or discoveries that are similar to those well developed theories or approaches in social sciences in today's international academic community (seems such inventions or discoveries are developing more and more)? How do we identify such similar theories or approaches were not faked as developments from the original well developed ones? What can knowledge management do to reduce collective academic frauds?

Chapter 5.4
Social Identities, Group Formation, and the Analysis of Online Communities

ABSTRACT

Central to research in social psychology is the means in which communities form, attract new members, and develop over time. Research has found that the relative anonymity of Internet communication encourages self-expression and facilitates the formation of relationships based on shared values and beliefs. Self-expression in online social networks enables identity experimentation and development. As identities are fluid, situationally contingent, and are the perpetual subject and object of negotiation within the individual, the presented and perceived identity of the individual may not match reality. In this chapter, the authors consider the psychological challenges unique to understanding the dynamics of social identity formation and strategic interaction in online social networks. The psychological development of social identities in online social network interaction is discussed, highlighting how collective identity and self-categorization associates social identity to online group formation. The overall aim of this chapter is to explore how social identity affects the formation and development of online communities, how to analyze the development of these communities, and the implications such social networks have within education.

INTRODUCTION

Central to research in social psychology is the means in which communities form, attract new members, and develop over time. The mechanisms in which communities grow depend on an individual's ability to find and collaborate with others with relevant knowledge, skills, and beliefs that meet a particular need. While these mechanisms of social collaboration are not unlike traditional face-to-face interactions (Tyler, 2002), there are some important differences in the way in which group members interact in online environments. Relative anonymity, selective self-disclosure, physical appearance, and the ease in finding 'familiar others' through search, embedded traits, and predefined groups, are some of the important differences between Internet communication and face-to-face interactions (Bargh & McKenna, 2004; McKenna, Green, & Gleason, 2002; Walther, 2007). Research into Internet social interaction has led to an increased understanding of face-to-face communications and brings into focus the implicit assumptions and biases that exist in traditional communication (Lea & Spears, 1995; Tyler, 2002). Assumptions that mediate face-to-face interactions such as physical proximity and non-verbal cues, assumed necessary to communicate and relate, do not exist in most Internet communications. However, given these limitations, online social communities continue to thrive and grow. The evolution of online communities confronts current views of how social and psychological dynamics contribute to human relationships, communication, and community formation.

Research supports the idea that the relative anonymity of Internet communication encourages self-expression and facilitates the formation of relationships outside of what is considered 'normal' socially mediated communication (Wallace, 1999). The complex origins of shared values and beliefs (Bargh & McKenna, 2004), self-expression through identity experimentation (Ruitenberg, 2003), and relative anonymous interaction (i.e. strangers on the train effect; Derlega & Chaikin, 1977; Rubin, 1975) challenge ideas of an 'individual' identity in relationship formation (Lea & Spears, 1995). As individual identities are malleable, adaptable, and the perpetual subject and object of negotiation within each context (Jenkins, 2004), the notion of identity requires an incessant comparison between the individual, the context in which they are interacting, their intentionality in the context of that interaction, and their 'true' (nominal) identity. The irregular nature in which individuals present arbitrary identities in various contexts, with multiple intentions, and within different social groups, results in a novel dynamic to human community formation and evolution.

In this chapter, we consider the psychological challenges unique to understanding the dynamics of social identity formation and strategic interaction in online social networks. We start with a brief overview of aspects within social psychology that are pertinent to a discussion on social identity formation in online social networks. Specifically, we introduce Social Identity Theory as a perspective in which to frame our current understanding of online social network formation. Next, the psychological development of *social (virtual) identities* (Jenkins, 2004) are explored in online social networks using the conceptualization of *self-presentation* (Goffman, 1959/1997). A discussion of collective identity and self-categorization follows and relates how social identity contributes to online group formation and evolution. Further, to illustrate how to evaluate the effectiveness of online social networks, we review several studies on online social networks using ethnographic methodologies, visualization techniques, and social network analysis (SNA). Finally, we present practical teaching and learning strategies educators can use to facilitate the use of social software for online social network formation within educational environments. The overall aim of this chapter is to explore how social identity affects the formation and development of online communities, to present some methodologies for evaluating the effectiveness of group formation, and to explore the implications of online social networks within education.

SOCIAL IDENTITY AND THE INTERNET

All human identities are social identities (Jenkins, 2004). Social identity concerns how we identify our similarities and differences to other known groups of individuals. Social identify is an ongoing interplay between how we identify ourselves and how others identify us. To identify with any given group of people, whether it is an ethnic group or an online organization, we look for similarities between the group members and ourselves. While similarities initially attract an individual to a group, this initial attraction enables an individual to recognize their individual differences. This comparative process is identified in Social Identity Theory as "*internal* and *external moments of dialectic identification*" (emphasis in original; Jenkins, 2000, p. 7). These internal comparisons are how individuals distinguish themselves from others in both the similarities they share and the differences they recognize. Alternatively, external comparisons involve how others identify individuals, in the similarities and differences they see between that individual, themselves, and a particular group. As internal and external comparisons determine the *active* and *socialized* aspects of a person, they enable the differentiation of the *I* and *me* which make up an integrated *Self* (James, 1891/1950). Given that social identification involves the interplay of internal and external dialectic processes, the Internet further enables individuals to develop and express multiple social identities and experiment with new virtual identities. As individuals' social identities evolve from within social groups, they also facilitate the alignment or differentiation of an individual from the group. This alignment or differentiation reaffirms an individuals' social identity.

Social identity is a central construct in understanding intergroup relations and is a key element in linking an individual to his or her social group (Tajfel, 1974, 1981). According to Tajfel (Tajfel, 1974, 1981), the foundation of the Social Identity Theory of group membership and behavior recognizes that grouping (social categorization) influences people's perception of others and one's Self. Social identity is "that part of the individual's self-concept [or self-identity] which derives from his or her knowledge of membership to a social group (or groups) together with the value and emotional significance attached to it" (Tajfel, 1981, p. 255). As individuals belong to a variety of social groups, their overall self-concept is composed of multiple social identities (Ashforth & Mael, 1989; Hogg, Terry, & White, 1995; James, 1891/1950; Jenkins, 2004). These multiple social identities enable an individual to adopt various roles and adapt to a variety of social contexts. The contexts in which a social identity exists, supports the pluralistic nature of the Self. As social groups exist at multiple levels, i.e. societal, cultural, industrial, organizational, functional, and professional (Korte, 2007), individual's social identities are facilitated through communication *within* and *amongst* these levels. For example, a professor can identify him or herself as teacher, parent, friend, advocate, and administrator based on social context. The use of Internet-based communication technologies, such as Internet messaging (IM), chat, and social networks, provide an extension of social contexts in which individuals can interact. The various social context and relationships developed using such social technologies, facilitates the development and recognition of an individual's social identification.

Social Identification

Social identification is an emergent product of internal-external dialectic processes (Jenkins, 2004). Emphasizing a distinction between internal and external dialectical processes (Barth, 1969) allows a "wider distinction to be drawn between *nominal identity* and the *virtual identity*: between the *name* and the *experience* of an identity" (emphasis added; Jenkins, 2004, p. 22). A nominal identity is the label an individual identifies his or her Self with, and a virtual identity is the *experience* of that nominal identity. In other words, your nominal identity is who you believe you are (internal dialectic), and your virtual identity is the experience of being that person (external dialectic). In addition, nominal identification varies from context to context and can be associated with numerous virtual identities (Jenkins, 2004). For example, one may identify him or herself as a student (internal identification, nominal identity), but his or her identity and experience as a student is quite different from high school to university (external identification, virtual identity). Similarly, the same student may consider him or herself a quiet, shy person in face-to-face meetings (nominal identity), however, when online they present themself as having an outgoing, animated personality (virtual identity). The experience of an individual's identity, as perceived through thought and action, is influenced through the interplay of the individual and social others. The evolution and development of internal and external dialectic processes occurs through social identity experimentation.

Social Identity Experimentation

Experimenting with social identities is an important part of lifespan development (Wallace, 1999). As individuals develop, particularly through adolescence, they begin to question their place in society; leading them to question their identity and personal values (Erikson, 1963, 1980). Within today's fast paced environment, where lifestyle and career options are abundant and change quickly, many individuals return repeatedly to question their values, beliefs and life goals (Archer, 1989; Wallace, 1999). In particular, the Internet plays an important role in social identity formation and development as it allows individuals to explore their values and beliefs within environments that they perceive to be safe. The anonymity of online interactions facilitates the perception of safety of an individual's nominal identity, allowing users to experiment with multiple virtual identities. As the Internet expands opportunities for social identity experimentation, through online chat, massively multiplayer online games (MMOG), 3D online virtual worlds, and social networks, individuals readily test and experiment with multiple identities. The ambiguity of the Internet in one's life course, is an enabling factor for individuals to explore identities that they could not explore in their 'regular' everyday lives or in their youth (Archer, 1989).

Through adolescence, the uncertainty of identity dominates an individual's development and definition of who they feel they are. As identity is a process of 'becoming', identity experimentation becomes a means of self-exploration. A recent study by Valkenburg, Schouten, & Peter (2005) investigated identity experiments by adolescents and whether pre- and early adolescents engage more often in Internet-based identity experimentation and self-presentational strategies than middle and late adolescents. Of the 600 adolescents surveyed (ages 9-18, M = 13.37, SD = 1.98), 82% indicated that they used chat or Internet Messaging (IM) on a regular basis. Of those who used these technologies, 50% of them reported that they willingly experimented with their identity. Using such self-presentation strategies as presenting his or herself as older, more 'macho', more 'beautiful', more 'flirtatious', as the opposite gender, as a real-life acquaintance, or as a 'fantasy' person, these adolescents were actively engaged in conscious identity experimentation. The majority of the adolescents surveyed in the study (49.8%) presented themselves as older. Further findings reveal that relative to age differences in the group surveyed, there was a strong influence of age on Internet-based identity experimentation ($b = -.50$, $p < .001$). Meaning, that younger adolescences are significantly more likely than older adolescences to experiment with their social identities, and more frequently use their social identities to facilitate social interaction. Valkenburg et al. also report that introverts engage in identity experiments as social compensation more often than extraverts do. The results indicate that introverts were more likely to experiment with their social identity as a means to explore social communication they lack in the face-to-face world. The study concludes that older teenagers used the Internet most often to communicate with their existing personal network, whereas younger adolescents are more likely to use the Internet more frequently to communicate with strangers. The results of the Valkenburg et al. study validate some existing assumptions about why adolescents use the Internet as a predominate medium of communication, and provides additional evidence of Internet identity experimentation as a means for uninhibited self-exploration

Motives for identity experimentation are varied and diverse. Self-exploration (i.e. to explore how others react), social compensation (i.e. to overcome shyness), and social facilitation (i.e. to facilitate relationship-formation) are a few motives for identity experimentation. Identity experiments such as the one explored in the Valkenburg et al. study, demonstrate the reciprocal nature of Self and social group interaction in the formation of identity. For an individual to develop a social identity, what that individual thinks of him or herself is significant, but no less significant than what others think about him or her. To return to the internal-external dialectic discussed previously, what the Valkenburg study demonstrates is that it is not enough to assert a social identity; others must also validate that social identity through its reception and recognition. Self-presentation then, is an assertion of a social identity.

Self-Presentation

Self-presentation is an individual's projection of Self and identity in the social world (Valkenburg et al., 2005). In a traditional face-to-face setting, the reality that the individual is concerned with is generally unperceivable. The individual observes the situation and acts according to their perceptions; even if their perceptions are inaccurate. "Paradoxically, the more the individual is concerned with the reality that is not available to perception, the more must he concentrate his attention on appearances" (Goffman, 1959/1997, p. 21). People can change their persona to reflect the social audience and can have as many social 'selves' as there are situations (William James as cited in Abrams & Hogg, 2001). According to Goffman (1959), individuals present an impression by *performing* and observers are the *audience* that judges the effectiveness or the believability of the performance. Goffman describes the performer-audience dialectic as one concerning the maintenance of the impression that the performer is 'living up' to the standards by which their actions are judged. Whether or not these actions are true of the individual's identity, remain the subject of the audience's judgment. Studies reveal that in virtual settings, such as online social networks, inaccuracy of interpretation resulting from individual presentation is a major challenge with Internet communication (Donath, 1999; Lynch, 2005; Valkenburg et al., 2005; Walther, 2007). As previously discussed in the study by Valkenburg et al. (2005) and in the literature on identity experimentation (e.g. Wallace, 1999), the Internet presents many opportunities and motives for identity experimentation. As most participants in online social networks are likely to be actively experimenting with different social identities, 'audience' members need to be aware that people may be presenting an identity that may only be a small part of the 'performers' nominal identity (e.g. Walther, 2007). This awareness brings literal meaning to Shakespeare's assertion that "All the world's a stage, and all men and women players" (As You Like It cited in Haney, Banks, & Zimbardo, 1973).

GROUP FORMATION

Group membership is crucial to the internal-external dialectic negotiation that is identity (Amiot, de la Sablionniere, Terry, & Smith, 2007). Self-categorization theory (Turner, 1985, 1987) suggests that identification with any group is based on the extent to which individuals can enhance their social identity through categorizing themselves as group members (Chattopadhyay, George, & Lawrence, 2004). This theory suggests that individuals must associate themselves and others with particular social categories to derive social identities (Turner, 1985).

Self-Categorization

Social identity involves a process of self-categorization. Categorization as a cognitive function enables individuals to perceive the world as structured and predictable. Categorization is one of the most basic and essential of all cognitive processes that helps one focus on contextually relevant and meaningful aspects of the world; highlighting important distinctions and de-emphasizing unimportant ones (Hogg, 2001). For example, a student may categorize himself or herself as a football player, or other students may categorize that student as a football player. Given this 'football player' categorization, students (and even teachers) make certain assumptions about how that student is likely to behave, with whom he or she associates, and even his or her ability for academic achievement. Categorization of Self, relative to group membership, emphasizes perceived similarities among group members and the characteristics that best define the group in that particular context (Hogg, Cooper-Shaw, & Holzworth, 1993). Self-categorization accentuates attitudinal, emotional, and behavioral similarity to a group *prototype* (Hogg & Hains, 1996). A group prototype involves the salient characteristics that define a typical member of that group. As a prototype is shared amongst group members, it also identifies group norms and stereotypes (Hogg et al., 1993). For example, the *prototypical* football player is an individual who has superior physical abilities, is disruptive in class, and does not obtain high grades in academic subjects. Further to our prototypical football player, if this student deviates from what is stereotypical or 'normal' for this group, such as achieving high grades in their academic subjects, they may be subjected to ridicule from their peers. A group may ostracize a fringe member based on what the group deems as deviant behavior or for ideas that are contradictory to the norms of the group (Marques, Abrams, Paez, & Hogg, 2001). Ultimately, self-categorization depersonalizes perception and conduct such that individual members are not 'processed' as complex multidimensional whole persons, but rather as embodiments of the group prototype (Birchmeier, Joinson, & Dietz-Uhler, 2005; Chattopadhyay et al., 2004; Haney et al., 1973). Research has found that social and group identities are generally more powerful than individual identities, and there is a tendency for individuals to go along with the group in which they identify (Hogg & McGarty, 1990; Korte, 2007; Tyler, 2002). The sense of group identity and the degree of personal identifiability to other group members are conditions known to influence this power relationship (Taylor & MacDonald, 2002). There is also a tendency of the individual to downplay personal attributes in favor of the group prototype or collective identity.

Collective Identification

Collective identification is a representation of how people are similar to each other based on the psychological connection between Self and social group (Abrams & Hogg, 2001; Jenkins, 2004). As discussed previously, social identity is a part of the Self that one identifies with a particular category or group. Put another way, social identity is "the *perception* of self in terms of stereotypical ingroup (*sic)* attributes" (emphasis added; Abrams & Hogg, 2001, p. 433). The in-group is simply the group in which one identifies, conversely, the out-group are those individuals who are not exclusive members. Collective identification, thus, results in a strong association between an individual and the group in which they are member. The individual then assumes the collective identity. Barnum and Markovsky (2007) hypothesized that in-group members would be more influential than out-group members on the collective. For example, using two theoretical approaches based on disagreements with in-group members (self-categorization theory) and the performance expectations (status characteristics theory) of the in-group members, Barnum and Markovsky (2005) observed that group membership affected social influence and that in-group members influenced their subjects more than out-group members. The results of this study support the argument that in the development of a social identity, the new group or collective identity tends to depersonalize the individual in favor of becoming a group member.

Depersonalization

Depersonalization causes people to conform to group prototypes and behave according to group norms. Similar to deindividuation of identity (Festinger, Pepitone, & Newcomb, 1952; Zimbardo, 1969), depersonalization gives an individual a sense of anonymity, in which he or she submits themself to the collective identity. Postmes, Spears and Lea (2002) hypothesized that depersonalization would increase the tendency for intergroup differentiation in attitudes and stereotypes specifically with computer mediated communications (CMC). Based upon previous research (Postmes, Spears, & Lea, 1998), Postmes et al. state that communication via CMC would potentially increase differentiation between groups on dimensions of bias, stereotyping, and attitude divergence. In addition, they postulate that CMC shifts intergroup interactions from interpersonal ("me" and "you") to intergroup ("us" vs. "them") ultimately depersonalizing interactions and stimulating a tendency for differentiation between social categories (Postmes et al., 2002). Postmes et al. (2002) could not attribute differences in their findings between the groups studied, rather, that CMC likely accentuated differences that already existed. Postmes et al. claim that the results of their study were heightened because of the online context despite the group differences that already existed. The transition from the personal (nominal) to the social (virtual) identity (as originally postulated by Turner, 1987) in which group membership (collective identification) is facilitated, is important for understanding the dynamics of individuals acting as a collective unit or group. The mixed results of the Postmes et al. study reveal that both individuals and groups are in a constant state of social flux. The dynamic nature and negotiation of these groups online makes their structure and evolution fluid and uncertain. Tools, techniques, and technologies for analyzing social networks, will enable further our understanding in social identity development and group formation, and aid in determining the measurable impact of social network tools in education.

ANALYSING ONLINE SOCIAL NETWORKS

Social network formation is a complex process in which individuals simultaneously attempt to satisfy goals under multiple, often conflicting, constraints (Kossinets & Watts, 2006). Social network analysis (SNA) involves theorizing, model building and empirical research focused on uncovering the patterns of links among network members (Freeman, 2000). Social network analysis conceives social structure as a social network. A set of social actors and a set of relational ties connecting pairs of these actors (Wellman, 2000) forms the social network. Social network structures are analyzed using measures such as density, centrality, prestige, mutuality, and role. Demographic data, such as age, gender, and ethnicity, and information about 'user' attitudes and beliefs are collected to gain an understanding of the ethnographic characteristics of group members. Methods used in SNA include graph theoretic, algebraic, and statistical models (Wellman, 2000). Due to the focus and length constraints of this chapter, the specifics of SNA methodologies and analysis are not explored in-depth. Instead, we focus on the analysis of online social networks using examples from the literature that consider linking individuals with community growth, ethnography, social discourse, and data visualization.

Examining Links

Examining links between group members enables researchers to understand how individuals influence, relate, and interact in social networks. Kossinets & Watts (2006), in an analysis of a dynamic social network of more than 45,000 students, faculty, and staff at a large university, found that networks evolve as a result of effects arising between the network topology and the organizational structure the network embodies. Of particular interest is that network characteristics (measures) appear to approach an equilibrium state, whereas individual properties such as linking and bridging are considerably more complex and are more appropriately analyzed using ethnographic techniques (as discussed in a later section). Linking and bridging of individuals-to-individuals and groups-to-groups facilitate connections outside of an individual's circle of acquaintances and promotes a diffusion of information and growth of existing and new communities (Kossinets & Watts, 2006). The rapid and dynamic nature of linking and bridging in the growth and development of social networks within a relatively stable infrastructure is recognized in the rapid growth of websites such as Facebook (2008), MySpace (2008), Second Life (Linden Research Inc., 2008), and Bebo (2008). Within these web communities, social network connections are far more complex than the technological infrastructure in which they are situated. Understanding how and why bridges occur is central in understanding the circumstances surrounding the formation and growth of online communities.

Research on Community Growth in Online Social Networks

Community growth in online social networks is of great importance to both commercial and social enterprises. As online social networks offer commercial advertising space to a captive audience and is a rapidly evolving environment for social research, understanding how, why, and under what conditions these groups thrive is of paramount importance. For example, a recent study by Backstrom, Huttenlocher, Kleinberg, & Lan (2006) explored three questions in regards to online social network growth and evolution. First, they considered membership and the structural features that influence whether a given individual will join a particular group. Second, they examined how structural features that influence a given group and whether that group will grow significantly over time. Finally, Backstrom et al. explored aspects of group change and how group foci or topics change over time and whether this dynamic affects underlying group membership. Backstrom et al. found that the formation of groups and the determining factors of membership significantly relate to the internal connectedness of an individual's friends. Meaning, individuals whose friends are in a community are significantly more likely to join that community. In a similar way to bridging, as discussed in the last section, information diffusion is similar to membership diffusion in that the more links or bridges one obtains affects the development of the social network and expedites its growth. Backstrom et al. also examined the flow of information within groups; specifically they questioned that "given a set of overlapping communities, do topics tend to follow people, or do people tend to follow topics?" (Backstrom et al., 2006, p. 8). The results to this final query were inconclusive indicating that less technical approaches to understanding community formation and growth, such as the methods used in ethnographic research, would likely provide clearer answers as to the complex dynamics that take place in online social networks.

Ethnography and Social Discourse

Ethnography is a method of research primarily concerned with the description of natural human communities (Munroe, 2000). Ethnography enables the interpretation of the flow of social discourse (Gertz, 1973/2000). In the study of online social networks, ethnography is particularly useful in studying online groups as unique cultural communities. The methodologies and perspectives of ethnography, aids in establishing new questions for research in social networks and complements existing quantitative methodologies. A recent study by boyd & Heer (2006) used ethnographic techniques to study the dynamics of the popular international social networking site Friendster (2008). The ethnographic components consisted of a 9-month participant observation, including interviews, qualitative surveys, and focus groups. Boyd and Heer's particular research questions involved examining how context is created and interpreted in digital environments, how conversations are initiated online, what are the goals of digital conversations, and how are they maintained. Exploring the possibilities and consequences of replicabilitiy, searchability, and persistence, boyd and Heer's ethnographic study revealed several interesting findings. First, in order to derive contextual cues in lieu of the physical cues present during face-to-face interactions, members of the social network interpreted what boyd and Heer describe as "artifacts of digital performance." The 'artifacts' they describe are traces of interaction history (Wexelblat & Maes, 1999), such as previous discussion postings and images. These artifacts served existing and new network members who use these virtual cues to interpret and build a social profile of the individual who left them. Second, as individuals invited existing friends to their social network, the groups grew and quickly became homogenous. Although boyd and Heer infer that homogeneity is due to the limiting nature of the website itself, the emergence of a homogenous social group exemplifies the homophily principle that similarity breeds connections to "people like us" (McPherson, Smith-Lovin, & Cook, 2001). Homophily, as demonstrated by the boyd and Heer study, serves as a limiter in individuals' social world. As social networks consist of people who know each other offline and who are similar in sociodemographic, behavioral, and intrapersonal characteristics, these networks are less dynamic and are more often a digital representation of most face-to-face social groups. As individuals interact with others similar to themselves (Baym & Zhang, 2004; Jones & Madden, 2002) and attempt to avoid conflicting relationships (Bargh & McKenna, 2004; Gross, 2004), homophily is limiting because it proliferates the divides in our personal environments and limits exposure to people and networks different from our own. Finally, boyd and Heer describe a phenomenon they call "negotiating unknown audiences" (boyd & Heer, 2006, p. 4); meaning as users generate online contexts to serve the needs of a particular group, the individuals in those groups come together already associated the group. Informed by their ethnographic investigation, boyd and Heer used data visualization to provide a macroscopic view of many of the most common behaviors they observed, such as browsing photos, exploring profiles, and searching for common interests. As qualitative and quantitative analysis of social networks provides insight into the interactions of individuals within the group, data visualization enables a macroscopic view of the social networks in question.

Data Visualization

Visualization aids in the presentation of abstract data. Data visualization enables a visual means to confirm observations made at a local (in this case individual) level, as in the boyd and Heer study (2006), but also provides an alternative perspective on the patterns the data presents, as in a recent study by Golbeck (2007). In the boyd and Heer (2006) study, the visualization served particularly useful in confirming the ethnographic observations concerning the presence and composition of network clusters which allowed the researchers to develop additional narratives. An example of the visualization presented in the boyd and Heer (2006) and Heer and boyd (2008) and represents a single user profile, and demonstrates the interconnectedness between his or her example profile and their 'friends.'

A recent study by Golbeck (2007) used visualization techniques to analyze social network membership and relationship dynamics. The visualization Golbeck uses in the study of social network growth of a sample of social networks show a steady linear growth rate. As awareness of the networks existence grew, mostly through advertising, the membership among the selected networks grew rapidly from 1000 members to more than 10 million. In analyzing the rate of relationship growth relative to membership growth, the 'spacing' of relationships increased significantly over time. 'Spacing' suggests that social networks become more densely connected as they grow larger, which was also observed in the Backstrom et al. (2006) study discussed earlier. Golbeck used visualization to illustrate this spacing effect.

The analysis of online social networks from the macro level provides specific information on community growth, social discourse, and general group dynamics. The addition of this macro-level information to the research on social identity provides further information on the ongoing interplay between the groups in which we identify ourselves and how others respond to this dynamic. The relative strength of collective associations within the group, as evidenced through density, linking, and bridging, associates individual activity with collective (group) level properties. Through this process, further detail of group prototypes and the salient characteristics that define a typical member of that group can be identified, and additional 'narratives' can be developed that further understanding of social identity and group dynamics at the micro (i.e. individual) and macro (i.e. community) levels.

STRATEGIES FOR USING SOCIAL SOFTWARE IN EDUCATION

Social networks already exist in education. Sports teams, social clubs, cheer squads, and social cliques are a few examples that are recognizable in any educational institution. As the context in which social identity supports the pluralistic nature of the Self, the learning environment is a particularly appropriate place for students to explore their nominal identities and experiment with new social (virtual) identities. For educators to capitalize and facilitate identity experimentation within online social networks, such as Facebook, MySpace, Second Life, and Bebo, they need to facilitate social interaction in all learning contexts. We have identified four important areas of research that support identity experimentation and promote the use of online social networks in education. Research important in the use of online social networks in education involves investigating ways in which educators can preserve relative anonymity, enable identity experimentation, manipulate self-categorization, and measuring the effectiveness of online social networks in education.

Preserve Relative Anonymity

To establish an equality of participation, relative anonymity should be preserved (Taylor & MacDonald, 2002). In order for online social networks to be successful in an educational context, anonymity needs to be maintained until social links are established. If anonymity is not maintained, then the social network is likely to fail given that relatively few will participate, and if they do participate, they will 'self-present' in such a way as to make the environment seem false. For example, in traditional or formal learning settings, a student will often demonstrate behaviours expected by the teacher as opposed to behaving as they actually feel. In an online environment, students should feel that they have the freedom to express and interact in ways that are not reflective of outside social influence. The use of anonymity has implications within formal learning structures where anonymity is not often preserved. Further research in this area is necessary to delineate teaching and learning strategies for use within formal learning contexts.

Enable Identity Experimentation

Encouraging identity experimentation facilitates the development of social networks that continually evolve and change with each different educational context. Identity experimentation, keeping a modicum of anonymity, enables a student to present various social identities to his or her peers and the instructor. In other words, identity experimentation through various modes of self-presentation encourages expressions of self that are accepted or rejected by members of the in-group. Identity experimentation is important to education, as it is something that all individuals 'do' and is uniquely possible within online social networking. Incorporating strategies within the educational context that encourage such experimentation in a safe and equitable way will foster tolerance and understanding of other differing points of view. Identity experimentation promotes social interaction as the individual's identity is in constant negotiation between the individual and social group.

Manipulate Self-Categorization

Building on the first two factors results in a manipulation of self-categorization. Manipulating self-categorization raises individual and collective awareness of the various effects of collective identification. In other words, teaching and learning strategies that enable self-experimentation will also influence how a student develops awareness of their impact on others in their peer group and illustrates how they are accountable for their actions. Through the manipulation of self-categorization, students are able to recognize how their participation within a social group affects the social network and remain accountable for their actions. The use of roles within group interactions enables individuals to understand the difference of their nominal identity and virtual identity in social contexts. This realization can only help students become more cognizant of the influence of social roles in identity formation.

Measuring Social Network Effectiveness

A measurable means for observing changes in the various properties of a social network, such as bridging, linking, and spacing within the network, is important in helping educators determine the level of interactivity in the network overall. For example, a network with low interactivity would have few bridges, few links, and very large spaces between individuals in the network. Alternatively, an active network is one with high interactivity, has bridges, several links, and has less space between individuals in the network. From an educational perspective, an active classroom network, whether face-to-face or online, that has many bridges and many links is a more productive learning environment. It is the ability of the instructor to facilitate these links that will provide an effective social learning environment.

CONCLUSION

Experimenting with social identities is an important part of lifespan development (Wallace, 1999). As individuals develop and change, they question their place in society leading them to question their identity and personal values (Erikson, 1963, 1980). People often change their persona (James, 1891/1950) and have as many social 'selves' as situations (Abrams & Hogg, 2001) and social groups. Categorization of the Self relative to a group accentuates the perceived similarity between individual group members and one's representation of the features that best define the group in a particular context (Hogg et al., 1993). A representation of how people are similar to each other, is based on the psychological connection between the self and social group (Abrams & Hogg, 2001; Jenkins, 2004). Collective identity aids in the development of social identity, but tends to depersonalize the individual in favor of becoming a group member. Although depersonalization facilitates a transition from a personal (nominal) to social (virtual) identity, where group membership (collective identification) becomes increasingly important, social network formation is a complex process in which many individuals simultaneously attempt to satisfy their goals under multiple, conflicting constraints (Kossinets & Watts, 2006).

The use of Internet-based communication technologies facilitates the development of social groups and social identification. Social identity is central in understanding intergroup relations and is a key element linking individuals to their social group (Tajfel, 1974, 1981). As social groups exist at multiple levels, social identity development is facilitated through communication within and amongst these levels. Social identification, as an emergent product of internal-external dialectic processes (Jenkins, 2004), enables an individual to experiment with different virtual identities and explore what it is like to experience those identities in the social world.

Motives for identity experimentation, such as self-exploration (i.e. to explore how others react), social compensation (i.e. to overcome shyness), and social facilitation (i.e. to facilitate relationship-formation) are all important factors in social development. As schools are inherently social institutions, the factors that contribute to healthy social development are of paramount importance for educators to consider for students growth. The strategies for social identity experimentation in classrooms, allows students to become active interpreters of social interaction. Educators that facilitate participation, experimentation, and research of social identity, will ultimately contribute to student's insight into the dynamics of learning and development as a social process.

KEY TERMS AND DEFINITIONS

Artifacts of Digital Performance: Artifacts of digital performance refer to traces of interaction history (Wexelblat & Maes, 1999), such as previous discussion postings and posted images, that new network members use as virtual cues to interpret and build social context.

Collective Identity: Collective identification is a representation of how people are similar to each other based on the psychological connection between the self and social group (Abrams & Hogg, 2001; Jenkins, 2004).

Depersonalization: Depersonalization causes people to conform to the group prototype and behave according to group norms.

Ethnography: Ethnography is a method of research primarily concerned with the description of natural human communities (Munroe, 2000) and enables the interpretation of the flow of social discourse (Gertz, 1973/2000).

Nominal and Virtual Identity: A nominal identity is the label with which an individual is identified and a virtual identity is an individual's *experience* of the nominal identity. In other words, your nominal identity is what you believe you *are* (internal dialectic), and your virtual identity is the experience of being (external dialectic).

Self-Categorization: Self-categorization theory (Turner, 1985, 1987) suggests that identification with any group is based on the extent to which individuals can enhance their social identity through categorizing themselves as group members (Chattopadhyay et al., 2004).

Social Identity: Social identity is central in understanding intergroup relations and is the key element linking an individual to his or her social group (Tajfel, 1974, 1981).

Social Network Analysis: Social network analysis involves the theorizing, model building and empirical research focused on uncovering the patterning of links among network members (Freeman, 2000). Social network analysis conceives of social structure as a social network: a set of social actors and a set of relations ties connecting pairs of these actors (Wellman, 2000).

Chapter 5.5
Enhanced Interaction in Mixed Social Environments

James Oliverio
Digital Worlds Institute, University of Florida, USA

Dennis Beck
Digital Worlds Institute, University of Florida, USA

ABSTRACT

We introduce the term 'mixed social environments' as a strategic learning construct to augment student interaction when utilizing virtual world environments such as Second Life in the classroom. While an increasing number of institutions are investigating the use of virtual world environments for enhanced learning, at present there are at least three major areas that are underdeveloped: interdisciplinary research, documentation of best practices, and exploration of the use of mixed social environments. In the spring of 2007, a new interdisciplinary research seminar addressing these aspects was offered at a large American university. We present an overview of the resultant learning artifacts, outcomes, and research questions in hopes of helping to inform best practices, expand interdisciplinary research, and assist in the design of future mixed social environments for enhanced learning.

DOI: 10.4018/978-1-59904-808-6.ch009

INTRODUCTION AND CONTEXT

For the purposes of this chapter, games and other interactive graphical scenarios that consist of multiple environments (compared with a single-focus virtual reality simulation such as flight training in a virtual cockpit or emergency room training inside a simulated hospital) are referred to as virtual world environments (VWEs) due to the large "world-like" scale of the virtual reality they create. Games are broadly defined in the literature and may cover a wide range of educational purposes. User-driven VWEs (pronounced "vyoo-eez") can often be considered games and have great potential for teaching and learning (Foreman, 2003). As a VWE, Second Life (SL) affords a sense of social interaction, visual indication of level of participation, and 3D models for instruction or simulation—all factors that can be utilized for enhanced learning environments. This potential flows across various academic disciplines. In spring 2007, a new course utilizing SL entitled Interdisciplinary Research Seminar was offered as a collaborative effort between a professor of biomedical engineering and a professor of digital media at the University of Florida's Digital Worlds Institute.

This chapter frames a context for the course from the gaming, virtual reality, and simulation literature; provides an overview of the learning artifacts produced and research developed in the course; and suggests potential future directions for researchers and practitioners who are interested in exploring mixed social environments (MSEs) as a means of merging traditional and virtual classroom spaces. We define a MSE (pronounced "mis-ee") as a physical space wherein multiple scales of screen display and simultaneous points of view of a shared VWE can be seen, heard, experienced, and collaborated upon by persons physically present in the space, in addition to remote participants. Both personal and group displays are integrated into the space in such a way as to allow simultaneous social interaction among those in the physical space of the room and multi-perspective displays of the participants' virtual interaction in the VWE.

GAMES IN EDUCATION

A succession of theorists and philosophers have found 'games' and 'play' difficult concepts to define (Huizinga, 1980; Salen & Zimmerman, 2004; Wittgenstein, 1972). Equally challenging is the understanding of the processes that assist game-play. Games in general can be defined in surprisingly numerous ways, often changing the way games are used and perceived (Wittgenstein, 1958). Some popular definitions define games as a series of choices or as rule-based play.

To refer to different types of games, current terminology utilizes terms such as: computer games, video games, serious games, game-based learning, massively multiplayer online role-play games (MMORPGs), massively multiplayer online games (MMOGs), persistent games, massively multiplayer online first-person shooter (MMOFPS), educational games, game-based learning, instructional games, sim games, gamesims, electronic simulations, virtual reality systems, training simulations, or simulators. Gaming environments now utilize diverse resources, including streaming video and audio, multiple-user interactivity, simulations of real-world circumstances, and immersive non-linear exploratory environments (Aldrich, 2004, 2006).

Since we are primarily interested in the uses of electronic games in education, we will use a definition that focuses on learning: "applications that can use the characteristics of video and computer games to create engaging and immersive learning experiences for delivering specified learning goals, outcomes and experiences" (de Freitas, 2006, p. 15). These uses tend to cluster around the activities highlighted in Table 1.

Table 1. Uses of games for learning (de Freitas, 2006)

Selected Uses of Games	References
To motivate and engage learners, e.g., underserved learner groups (e.g., with low literacy/language levels)	Amory et al., 1999; de Freitas et al., 2006; Garris et al., 2002; Gee, 2003; Mitchell & Savill-Smith, 2005
For skill or part-task rehearsal and practice, e.g., literacy and numeracy skills	de Freitas et al., 2006; Delanghe, 2001
To provide therapy for pain relief and cognitive difficulties	Pelletier, 2005c
To role-play particular jobs and professions in advance of real-life practice	Aldrich, 2004, 2006; Maharg, 2006
To empower learners as authors and producers of multimedia, mixed media, and game-based content	Pelletier, 2005b; Druin, 2002; Dickey, 2005

There are many aspects of gaming that can be educationally sound. Games are supportive and safe, a quality that supports higher-level learning (Diamantes & Williams, 1999). They also include a strong aspect of play, which is important in the development of "flow," which is "the mental state of operation in which the person is fully immersed in what he or she is doing" (Csikszentmihalyi, 1990, p. 21). Promotion of flow and play in childhood is important because their absence can have a negative impact upon social development and socialization (de Freitas et al., 2006). Games also encourage multiple opportunities for practice, which is important because the reinforcement of practiced tasks and activities has been found to accelerate learning (Delanghe, 2001). They can also be highly motivational, which is a key aspect of effective learning (Garris et al., 2002). Multiplayer games enhance computer literacy (Benedict, 1990), visual attention (Bavelier & Green, 1993), and reaction time (Orosy-Fildes & Allan, 1989), and give multiple opportunities for making mistakes, which is an important aspect of learning (Jones, 1997). They also teach players to become problem solvers through role-playing (Gee, 2003; Johnson, 2005). Games based on historical events or stories that explore real-world social issues allow learners to step out of the immediacy of the present and imagine what it might be like to be someone else who may have lived at a different time, place, or under different social or historical circumstances (Francis, 2006).

VIRTUAL WORLD ENVIRONMENTS AND GAME-LIKE CHARACTERISTICS

Under the definition and scope defined above, VWEs can often be considered games. Such games are deeply immersive and highly scalable three-dimensional systems. In the VWE called Second Life, people enter the virtual world through the use of an avatar, a character that embodies their presence and intent. Many popular VWEs allow for multiple users to be in the same virtual space and interrelate with each other at the same time (New Media Consortium, 2007a). Even in their nascent state, virtual worlds allow for the development of real-life cultures through the use of individuated dialects, political configurations, multifaceted social customs, social networks, social capital, and common history (Steinkuehler, 2004; Jakobsson & Taylor, 2003). VWEs combine social networking, seamless sharing of rich media, and a feeling of presence in a generalized, persistent non-contextual environment that is applicable to almost all disciplines (Castronova, 2001).

Virtual worlds also offer an opportunity for people to interact in a way that conveys a sense of presence lacking in other media (Castronova, 2001; New Media Consortium, 2007a). This aspect lends itself to role-playing and situation construction, freeing up learners to assume the responsibilities of a physicist, artist, physician, or architect without the real-world training (or the real-world consequences). The effect is two-fold, providing an environment free of the limiting "thought boxes" that often accompany deep single-disciplinary training, while allowing for risk-free experimentation (Delwiche, 2006) and thinking outside the proverbial "box." This can lead to expanded understanding of cultural and societal experiences, as well as broad experimentation with new forms of human expression and endeavor.

VWEs have significant and largely untapped educational potential. Foreman (2003) predicts that shared graphical worlds are "the learning environments of the future" (p. 14). Steinkuehler (2004, 2006) and Gee (2003) argue that the educational promise of VWEs can only be fulfilled through a social constructivist approach to learning. VWEs hold considerable potential for the development of complex social practices such as leadership, collaboration, and relationships. These worlds are complex rational groups distinguished by their social practices (Steinkuehler, 2004). When novices enter a virtual world, they can be progressively initiated into intricate social scaffolding by means of the support of other group members. Virtual worlds are compelling because social relations, collaboration, and information sharing are essential ingredients, and they encourage collaboration both within and beyond game parameters (Delwiche, 2006). According to Yee, Bailenson, Urbanek, Chang, and Merget (2003), more than half of those involved in virtual worlds have gained proficiency in mediation and leadership, such as solving conflict in groups.

Although also present in many types of electronic games, the concept of flow can positively enhance the educational experience in virtual worlds. Hoffman and Novak (1996) and Csikszentmihalyi (1990) explain that the flow state is characterized by factors including user confidence, exploratory behaviors, enjoyment, distorted time perception, and greater learning. Peng (2004) notes that people learn in a flow condition when they are not passive receivers of information, but are actively participating in and owning the learning activity and reaching a personally derived goal. In a recent study of 30,000 VWE users, Yee et al. (2006) found that 70% had spent at least 10 continuous hours in a virtual world at one sitting. If the amount of continuous time spent is any indication of interest and immersion in the activity, this is evidence of a compelling and flow-oriented environment that can enhance learning.

Virtual environments can also facilitate enhanced exploration of and experimentation with various social roles. Although many electronic games provide such role exploration and experimentation, student use of VWEs provides a period during which the emerging adult is free to delay taking on adult commitments. The student can explore new social roles in an authentic situation while interacting with other individuals, a situation that has been shown to have significant psychological and learning advantages (Turkle, 1995). Virtual worlds have been shown to promote role-playing behaviors (Delwiche, 2006), which have been shown to help students escape the grip of contemporary norms and beliefs (Luff, 2000), affect attitudes and behavior (Bell, 2001), and can have significant therapeutic benefits (Douse & McManus, 1993; Hughes, 1998). Yellowlees (2006) documents the use of Second Life to help students experience the role of the patient. Students learn about the subjective experience of psychosis as they navigate through a virtual psychiatric ward. "In this environment, users can literally see and hear hallucinations as a patient might, as they walk through the halls of the virtual hospital" (Yellowlees, 2006, p. 441). This application of SL enables students to explore and experiment with the role of the patient, thus gaining important insights into particular psychoses and developing a deeper empathy than through more traditional means.

SECOND LIFE AS A VIRTUAL WORLD ENVIRONMENT

As a well-known and widely distributed VWE, Second Life possesses significant potential for innovations in learning. For example, Dave Taylor, knowledge transfer leader at the National Physical Laboratory, says that the use of SL opens up "new opportunities for collaboration across disciplines and geographies that would not otherwise occur" (Edwards, 2006, p. 32). The development of complex social practices such as collaboration is enhanced by two major benefits: social context and visual context (Harris & Lowendahl, 2007). In a learning experience, students are more likely to develop as leaders, collaborators, and relators; experience flow; and deeply experience alternative roles when there is a social and visual context. The emergent benefits of VWEs include:

1. An enhanced sense of social interaction
2. Visual indication of level of participation
3. Ability to see conceptually and spatially through the use of 3D models for instruction or simulation.

Table 2. Comparison of virtual world environments

Characteristics	Second Life	World of Warcraft	SimCity
Base	Based in reality	Based in fantasy	Based in reality
Intellectual Property	Belongs to the user	Belongs to the company	Belongs to the company
Purpose or Goal	User-defined	Pre-ordained—quest oriented	Pre-ordained—procreation/population
Open or Closed System	Open—trajectory determined by the will of the user	Closed—trajectory determined by computer algorithm	Closed—trajectory determined by computer algorithm
Educational Capabilities	Supports a wide variety of tasks, social interactions, contextual situations, and technical affordances	Outcomes limited by preprogrammed algorithm	Outcomes limited by preprogrammed algorithm
Access to Software Code	Open source	Closed—proprietary	Closed—proprietary

The VWE Second Life (created by Linden Labs) currently boasts more than 6.6 million residents worldwide, and more than US$7 million are spent in a given month. The top 80% of residents hail from more developed nations, but a significant portion also log on from places like Africa, Southeast Asia, and Latin America. The typical resident is male, between 25 and 34 years old, and among the top 5% of the world's wealthiest individuals.

Second Life is reality based in its economic and legal system in order to maximize the quality and quantity of user-created content. This approach is quite different than conventional massively multi-player online games. Most companies that own and operate online games: (a) own all of the content in their world, (b) own any content generated by the player, and (c) specifically deny residents the right to earn real-world incomes while using the online game (see Table 2). For example, Sony (Koster, 2002) and Turbine (Castronova, 2004a) have banned the sale of digital items and currency on eBay. Additionally, while basic membership in SL is a free service, most other MMOGs are subscription services, requiring ongoing monthly fees from players in order to stay in the games. As mentioned above, SL has a somewhat unique approach to intellectual property (Herman, Coombe, & Kaye, 2006). Linden Labs acknowledged the value of the creative contributions that game players made to the virtual worlds that they otherwise controlled by granting their players intellectual property rights in their creations both within the game and in reality. This allowance has resulted in an entrepreneurial spirit that has made SL one of the fastest growing online games (SimTeach, 2007).

Another unique quality of SL concerns the game's purpose, or in this case, lack of purpose (Edwards, 2006). Unlike the popular online game World of Warcraft (Blizzard Entertainment, 2007), in which users interact in a closed, quest-oriented system, everything in the SL universe is user created and user driven. There are no overarching quests or game-created goals handed down by the game developers. Much like real life, there are only individual and group goals such as business, education, or personal quests. Users are not required to advance through levels in the way they must in a controlled game. All activity in the VWE is actually created by the users themselves. This user-created purpose leads to another unique characteristic of SL—freewill. Unlike the popular game SimCity (Electronic Arts, 2007), which uses a computer algorithm to simulate how a city will evolve, activities in SL are governed by real people with the ability to act individually. Giving users the ability to freely determine their fate has opened up a wide variety of tasks, social and linguistic interactions,

and technical affordances that may not otherwise have been available (Peterson, 2006).

A significant number of universities, colleges, schools, organizations, and businesses are exploring the educational potential of Second Life. According to the *Chronicle of Higher Education* (Foster, 2007), as of September 21, 2007, more than 150 colleges in the United States and in 13 other countries have a presence in SL. Additionally, according to the Second Life Wiki (SimTeach, 2007), 17 educational organizations, four libraries, and four museums are currently active in SL. Second Life education-related Web sites number more than 200. The purposes of these groups' involvement in SL are as varied as their creators (see Table 3).

Second Life and other virtual worlds also possess great potential for research. According to Yee et al. (2007) and Blascovich et al. (2002), social norms of gender, interpersonal distance, and eye gaze transfer into virtual environments even though the modality of movement is entirely different (i.e., via keyboard and mouse as opposed to eyes and legs). As a result, these online environments are also being explored as unique research platforms for the social sciences and clinical therapy.

These environments can be customized through the use of in-world 3D construction tools. Settings can be created to pertain to any subject or area of study, locations and artifacts can be as realistic and detailed or as generic and undefined as desired. Even objects of large or micro scale can be easily portrayed. The combined effect of recorded interactions and customizable environments provides the ideal conditions for future interdisciplinary research.

For all of its potential and current uses, there are still three major educational aspects that are underdeveloped in VWEs such as SL: interdisciplinary research, development of best practices (Delwiche, 2006; Keesey, 2007), and exploration of the use of a mixed social environment. The New Media Consortium (2007b) is attempting to work toward interdisciplinary research in the social sciences, but the inclusion of other academic disciplines could provide great benefit. Much could be learned by including biology, chemistry, physics, and other disciplines not typically included in social science research. Whereas the 2007 Second Life Best Practices in Education Conference (http://slbest-practices2007.wikispaces.com) was a major step forward in developing best practices in education, it served to highlight the need to move beyond simple re-creation of the classroom experience to more of an emphasis on creative practices when using VWEs (Keesey, 2007). Given the current state of interest in usage of VWEs in education, there are other emergent parameters that can and ought to be cultivated within the template of a mixed social environment. These parameters are discussed in the context of the course presented below.

WELCOME TO OUR ISLAND: BACKGROUND AND PROCESS

The University of Florida's Digital Worlds Institute is a transdisciplinary research and academic entity that provides strategic integration of arts, technology, and culture across traditional academic boundaries. Digital Worlds (DW) planned to offer a new Interdisciplinary Research Seminar (IRS) in Spring 2007 as a collaborative effort between a professor of biomedical engineering and a professor of digital media. Second Life was to be used as the VWE within which the onscreen interaction would take place.

Prior to the beginning of the spring semester 2007, an island was acquired and two staff members at DW created three initial buildings on the barren landscape in preparation for the first cohort of students. First, the university's iconic Century Tower was re-created. This tower was built in the physical world in 1953 to commemorate the 100th anniversary of the university and was dedicated to University of Florida students who perished in World Wars I and II. Included in the virtual tower's features were replicas of the unusual cast-bells carillon that mark the time of day and often play musical interludes during class breaks. Second, a multi-level virtual representation of the Digital Worlds Research, Education and Visualization Environment (REVE) was built. The structure itself was modeled on the metaphor of ascending levels of achievement, a common construct in quest-based video games. In this case the ascending levels of the free-floating building structures themselves formed virtual platforms that marked levels of interaction and achievement in interdisciplinary research (i.e., brainstorming, laboratory, invention, and prototype). Finally, a biomedical engineering building was added, based on architectural plans of a structure that has not yet been built in real life. On the first day of class, students had these three structures, which provided landmarks and functional space in which to meet and interact, but the rest of the island remained undeveloped.

Students from a wide variety of disciplines enrolled in the class, which was offered as a means of investigating the use of VWEs in collaborative team-based research. The physical class sessions were held in the Digital Worlds' REVE [pronounced "rev" as in Rêve, the French word for "dream"]. The REVE was designed as a multi-purpose social and learning space, and featured a 52-foot wide immersive display screen, allowing local participants the opportunity to engage the VWE at near-life-size scales. This MSE afforded students and faculty a multiplicity of perspectives that proved integral to a groundswell of creativity and interdisciplinary achievement within the class.

The goal of the research seminar was to investigate if the VWE (dubbed "Gator Nation Island") could provide a compelling non-traditional framework for rapid prototyping, interdisciplinary collaboration, and invention.

RAPID PROTOTYPING IN A MIXED SOCIAL ENVIRONMENT

Wilson, Jonassen, and Cole (1993) define rapid prototyping as follows: "In a design process, early development of a small-scale prototype used to test out certain key features of the design. Most useful for large-scale or projects" (p. 21.1). The REVE provided an effective rapid prototyping environment because it readily offered a facility in which the students could meet physically, virtually, or in a hybrid MSE. This immersive environment encouraged the initial development of system sketches and virtual mock-ups, followed by user evaluation, concept refinement, and implementation of refined requirements in a spiral cycle. The rapid prototyping environment was enhanced by the multiplicity of perspectives simultaneously provided to students and instructors on the REVE's large-scale projection surfaces. While each person had their individuated laptop perspective, everyone in the room could also simultaneously share the common space from the perspective of other individuals' diverse points of view during each phase of the design process. This MSE provided an enormous amount of visual information to inform design choices, allowing students and instructors alike to see the results of their ideas early on, detect errors in judgment and accuracy, and apply creative solutions through real-time feedback. The MSE also encouraged active student participation and enhanced collaboration throughout the design process.

The "enhanced" aspect of this process emerged from several affordances not typically offered in traditional classroom settings. These include the ability of each of the students to interact either proximally in the REVE classroom, virtually within the VWE displayed on the REVE immersive displays and on their own laptops, or in any mixture of the two social environments deemed appropriate to the activities at hand. Additionally, the persistence of the virtual environment and the artifacts being created over the course of the semester, coupled with their accessibility both during and outside of class time, provided another mechanism not available when students collaboratively create "real" objects and prototypes in the physical world.

Using SL as the platform for the VWE, the IRS professors established interdisciplinary student teams and assigned an ambitious number of projects. Over the course of the semester, each of the students participated in several team-based projects. Each of their tasks involved creating a process or artifact in SL that did not currently exist in the physical world. At the end of the semester, a significant number of diverse student projects had come to fruition as a result of the rapid-prototyping process. These included:

1. A suite of MIDI-based musical instruments
2. A dance/music entertainment complex and a Visual Arts Gallery
3. The Protein Pavilion
4. A large Welcome Center for the island
5. Numerous media clips and playback interfaces for island visitors.

Within these original designs, structures, and conceptual developments, a number of interdisciplinary concepts and potentials were embedded:

1. The Protein Pavilion provided a 3D environment for learners to visualize protein folding, the physical process by which a polypeptide folds into its characteristic three-dimensional structure. While students from humanities and arts backgrounds had never encountered the concept of protein folding in their standard courses of study, being able to visualize this ongoing physical process provided a compelling introduction to biomechanics. The outdoor structure resembles a large veranda in which three large screens can be user activated to reveal animated 3D visualizations of various processes at the sub-molecular level.

2. The Visual Arts Gallery featured the work of an internationally renowned photojournalist from the university's College of Journalism and Communications. Students who typically would not have visited an art gallery in real life explored this virtual space as part of their IRS experience, viewing two exhibitions of the photographer's work in the process.
3. The NoteMaker's Lounge is a large, complex structure featuring a dance floor, multi-level social spaces, and recording studios containing novel musical instruments designed in the class. Guests could either walk in on the ground floor or fly into upper-level public rooms. One of the computer engineers in the class designed a secure entry system that permitted only paying customers or predetermined VIPs to pass through a force-field structure to gain admittance to exclusive upper levels. When guests entered the music studio portions of the NoteMaker's Lounge, a variety of non-traditional instruments acted as a catalyst for the development of original music compositions created when visitors interacted with the virtual devices.
4. The multi-level Welcome Center was designed and constructed by students with no previous experience in computer coding or architecture. The students took it upon themselves to learn how to create automated glass doors and numerous teleport jumps directly to many of the island's facilities, each accompanied by a detailed pictorial and narrative description of the intended site to be visited.
5. An ultra-modern Experimental Media Space combined 3D computer graphics with live and pre-recorded video capabilities. Numerous interactive media artifacts were designed and built by students with little or no previous experience with computer graphics or programming.
6. The class also experimented with creating its own currency and banking system, and created a series of interactive video billboards and kiosks where visitors could obtain useful information about their surroundings.

SOCIAL INTERACTION AND ENTROPY: A NOVEL FORM OF RAPID PROTOTYPING

A number of events were planned to be included in the Open House, ranging from guided tours to musical performances. The first 45 minutes of the Open House proceeded according to plan. But after that, a number of surprising developments occurred. While the majority of the online interactions during the semester were modeled after the usual and customary modes of generally accepted social practice, three-quarters of an hour after the Open House began, entropy—defined as "inevitable and steady deterioration of a system or society" (American Heritage, 2000)—broke out.

Previously courteous student interaction rapidly gave way to blasts from laser guns, unicorn riding through the shared space, driving vehicles up walls, and so forth. While end-of-semester enthusiasm and excitement about the culmination of students' projects is understandable, there is also another potential explanation: a rapidly emergent social entropy.

Whether a social construct or artifact seems to be contributing to the development or deterioration of a society or system is a socially constructed assessment, rather than an intrinsic property of the artifact (Bijker, 1995). As a result, we should consider the observation of one of the social scientists in the IRS class, who noted that this seemingly entropic development could be a manner of rapid prototyping of social constructs and artifacts in the VWE (Black, Beck, Dawson, Jinks, & DiPietro, 2007). These results should not automatically be discounted as a negative or simple anarchy, but instead should be explored. The use

Figure 1. Visitors perform on the new MIDI musical instruments (center screen) in the REVE's Mixed Social Environment

of the VWE to explore this novel type of social construct rapid prototyping should be investigated in future work. One potential application for this type of transdisciplinary research might be in the collaborative design and population testing of new urban environments or large-scale public facilities (stadiums, shopping complexes). Said structures could be placed within VWEs to assess traffic and user patterns created by live virtual users (as opposed to pre-programmed simulation algorithms) before finalizing the municipal approval of the building plans. (Figure 1, 2, 3)

Figure 2. The Protein Pavilion (center screen) shows visualizations of complex sub-molecular protein structure and folding

IMPLICATIONS AND FUTURE WORK

From the developments during one short semester using SL as the VWE in a research and education setting, a number of observations come to light that lead us to the following recommendations:

1. **Observation:** Students worked effectively across disciplines as diverse as biomedical engineering, economics, fine arts, journalism, law, and computer science both in class and online in the VWE. *Recommendation:* Encourage partnerships with other departments and programs within your institution in to facilitate collaborative learning. An interdisciplinary partnership between departments or programs sponsoring the course will result in a greater breadth of cultural, academic, and social diversity among students and faculty.
2. **Observation***:* Students and instructors appeared to be in a state of flow (Csikszentmihalyi, 1990) during most of the course. The flow state provided greater confidence, exploratory behaviors, enjoyment, distorted time perception, and greater learning than had occurred in past experiences with rapid prototyping by both instructors and students. Specifically, the added immersion provided by the REVE's MSE appeared to enhance enthusiasm for the tasks at hand and fruitful collaboration by the interdisciplinary student teams. Access to the VWE and projects-in-process from outside of the classroom provided another collaborative potential. In addition to the proximal interaction in the REVE, students frequently met online in the VWE on their own time during evenings and weekends from their own personal spaces. *Recommendation:* Encourage gaming and involvement in other MMOGs by students and faculty. Instructors should consider hosting a hands-on seminar on using VWEs such as SL for education for other faculty and graduate students to attend. This exposure will help students to be more comfortable with various gaming interfaces and make it easier for them to enter the flow state in and out of class.

3. **Observation:** Students exhibited significant enthusiasm for creating their own architectural models and invention prototypes. This is resonant with the current trend towards user-generated content in the broader online world (Bruns, 2007). *Recommendation:* Instructors should allow as much latitude as possible for students to create their own content- and concept-driven prototypes. Instructors should also build on the enthusiasm generated with customized content that will aid each student in his or her development. Also, in light of what occurred at the open house, students should be given opportunities to socially construct their own models and prototypes in groups and not just individually.
4. **Observation:** With the assistance of two designated teaching assistants (a graphic artist and a digital media specialist), students were able to overcome their lack of background in design and technical areas (i.e., computer programming, 3D graphics, architecture, etc.) and create significant results despite lack of formal training in these areas. *Recommendation:* Instructors should consider avoiding disciplinary limitations on students in such a course and allow open enrollment from across disciplines and academic levels. This will also result in greater diversity and a multiplicity of academic perspectives as students enter the course from a wider variety of educational backgrounds. Instructors should also consider scaffolding their students by providing additional resources for those interested in pursuing independent studies in the areas of computer programming, 3D graphics, architecture, and so forth.
5. **Observation:** Rapid prototyping of social constructs and artifacts within VWEs is an intriguing area that needs further exploration. *Recommendation:* Faculty and students need to overcome personal value judgments and biases against particular social constructs and artifacts. Researchers need to explore the potential for social construct rapid prototyping within VWEs for the insights it may provide into the relationship between artifact creation and population behavior in the "real" world, and how potential crossover effects between real and virtual worlds may lead to new understanding of system dynamics.

A number of challenges for interdisciplinary research within SL and other VWEs also emerged from this seminar:

1. **Challenge:** Current technological constraints (i.e., limitations on the importing and exporting of objects and processes created within the VME, lack of interoperability standards with other business applications such as learning management systems (LMSs) and HR management systems (HRMSs), system access and security, etc.). *Recommendation:* Integration with other software applications may not seem necessary, but it could greatly affect the adoption of the VWE innovation into your learning community (Black et al., 2007). Unfortunately, the technical inefficiencies of some business applications, such as LMSs, utilized by most higher education institutions have hindered integration, as vendors provide little in the way of easy, plug-and-play systems that can be implemented with little effort (Egan, 2002). While current generation VWEs such as SL hold enormous potential for learners, getting them to work efficiently with easy interaction with LMSs can be time consuming, frustrating, and expensive. By spending the extra resources necessary to achieve integration with your LMS and other software systems, an institution will be paving the way for an easier adoption process.
2. **Challenge:** Access to appropriately designed class and lab space for group interaction.

Recommendation: Provide both individuated and group display to create an effective mixed social environment. The larger and more immersive the common display, the more conducive it will be to shared group interaction. Hertz (2002) observes that "the interaction that happens through and around games as players critique, rebuild, and add on to them, teaching each other in the process. Players learn through active engagement not only with the software but with each other" (p. 173). These kinds of environments do not have to be prohibitively expensive (Oliverio et al., 2004).

3. **Challenge:** Clear guidelines on ownership of intellectual property created in classroom VWE. *Recommendation:* In keeping with your institution's intellectual property guidelines, encourage faculty and administration to give ownership of intellectual property (IP) created within the VWE to the person or team that created it. The increased production of authentic learning objects and innovative research concepts is a desirable outcome (SimTeach, 2007). Continued use of original IP in subsequent classes can then easily be arranged by simple permission from the creator/owner of the desired IP.
4. **Challenge:** Overhead in setting up and maintaining the VWE. *Recommendation:* Seek out partnerships with other programs and departments within and outside your university in order to spread the overhead cost. Your course will not only benefit from lessened financial constraints, but will also benefit from an increased diversity in students and faculty.
5. **Challenge:** Acceptance within established academic traditions and cultures. *Recommendation:* The chalkboard, filmstrip, and overhead projector are all examples of technologies that enabled increased interaction and shared experience in the classroom. VWEs are an inevitable and evolutionary step in the same direction, but they also must face some of the same hindrances as their predecessors. Development of quality best practices for using VWEs in education will equip teachers to overcome these hindrances and utilize them more fully.

It is apparent that network-based interaction in VWEs has much to offer in terms of contemporary learning and research applications. In our work we are particularly interested in facilitating effective MSEs by designing scalable physical classroom spaces whose affordances can maximize the effectiveness of interdisciplinary activities in research and education (Oliverio & Pagano, 2004).

Future studies should focus on in-class social interaction in mixed reality settings and the cultural and technical potential for rapid prototyping of objects, inventions, social constructs, and dynamic interaction systems.

KEY TERMS AND DEFINITIONS

Best Practices: Processes and activities that have been shown in practice to be the most effective (Delwiche, 2006; Keesey, 2007).

Flow: Concept developed by Csikszentmihalyi (1990). "The mental state of operation in which the person is fully immersed in what he or she is doing." Flow is the feeling of complete and energized focus in an activity, with a high level of enjoyment and fulfillment. (Wikipedia, 2007a)

Interdisciplinary Research: Research efforts that bring together the humanities, physical sciences, and social sciences to develop and enhance a broad understanding of particular populations, cultures, or other related areas of research. (NCCS, 2007)

Massively Multiplayer Online Game (MMOG): A type of computer game that enables hundreds or thousands of players to simultaneously interact in a game world they are connected to via the Internet. Typically this kind of game is played in an online, multiplayer-only persistent world. Some MMOGs are played on a mobile device (usually a phone) and are thus mobile MMOGs or MMMOGs or 3MOGs. (Wikipedia, 2007b)

Mixed Social Environments: Meeting places, such as the Polymodal Immersive Theatre (PIT) in the Digital Worlds Institute's REVE, that allow both proximal social interaction typical of traditional classroom or auditorium settings and simultaneous shared display of virtual world environments in which the physically present persons can also interact virtually.

Research, Education and Visualization Environment (REVE): A multi-purpose social and learning space that features a 52-foot-wide immersive display screen, allowing local participants the opportunity to engage a VWE at near-life-size scales. The REVE allows students and faculty a multiplicity of perspectives that promote creativity and interdisciplinary achievement within the classroom.

Second Life: An open-ended virtual world created by San Francisco-based Linden Lab. Its foci are socialization, economic activity, and non-profit interactions. The creation of former RealNetworks CTO Philip Rosedale, Second Life gives its users (referred to as residents) tools to shape its world. (Wikipedia, 2007c)

SimCity: A real-time strategy/simulation computer game created by game developer Maxis. There are four versions: the original SimCity (1989, later renamed SimCity Classic), SimCity 2000 (1993), SimCity 3000 (1999), and SimCity 4 (2003). All of the games were re-released with various add-ons including extra scenarios. In addition, SimCity Classic is available for a palm-connected organizer and on the *SimCity.com* Web site as Classic Live. (Wikipedia, 2007d)

Virtual World Environments: A virtual world is a computer-simulated environment intended for its users to inhabit and interact with via avatars. This habitation usually is represented in the form of two- or three-dimensional graphical representations of humanoids (or other graphical or text-based avatars). Some, but not all, virtual worlds allow for multiple users. (Wikipedia, 2007e)

World of Warcraft: A class-based massively multiplayer online role-playing game developed by Blizzard Entertainment. It is the fifth Blizzard game and is set in the Warcraft Universe, a fantasy setting introduced by Warcraft: Orcs & Humans in 1994. World of Warcraft is set four years after the events at the conclusion of Blizzard's previous release. (Wikipedia, 2007f)

Chapter 5.6
The Usability of Social Software

Lorna Uden
Staffordshire University, UK

Alan Eardley
Staffordshire University, UK

ABSTRACT

Emergent Web 2.0 technologies and applications (such as blogs, wikis, podcasts, mashups, and folksonomies) present a range of opportunities and benefits and are increasingly used by people to interact with each other. Despite the growing popularity of social software, there is a lack of research on the usability of these tools. This chapter focuses on how users interact with Web 2.0 technology, discusses a conceptual framework for a usability evaluation of social software, describes the different types of social software applications, and offers guidelines for their usability evaluation. The argument advanced is that social software usability should be viewed as a set of principles and practices aimed to deliver more service-orientated Web 2.0-based applications.

DOI: 10.4018/978-1-60566-368-5.ch050

INTRODUCTION AND BACKGROUND

Social software has emerged as a driving force of Web 2.0. The term *Web 2.0* was coined by Tim O'Reilly (2005) to describe a sea change in web services and technologies. It should be noted that Web 2.0 is not a single development but rather a heterogeneous mix of new and emergent technologies. Overall, there is an increasing presence of social software applications that allow users to communicate, collaborate, and share their personal interests. This chapter introduces a usability perspective on social software and offers guidance for evaluating the usability of social software applications.

Bryant (2007) defines *social software* as a combination of various social tools within a growing ecosystem of online data and services, all joined together (aggregated) using common protocols, micro-formats and Application Programming Interface (API) methods. It is also underpinned by some general principles about engaging people as active participants in online social networks and communities to achieve new and exciting effects through distributed collaboration, co-production and sharing. Central to the notion of Web 2.0 is the ideas of scale, the belief that the tools become more useful as more people apply them, and changing the world through the Social Web.

According to Leadbeater (2007), the tools associated with social software transform our capacity for civic activism. Firstly, these tools allow people to participate by creating, publishing and distributing content, such as video, pictures, music and texts through the Internet. Secondly, social software allows people with similar interests to find one another and connect through social networking sites, such as MySpace, Facebook, and Bebo. People can also use search tools and systems for collaborative tagging of information and ideas. Thirdly, people can coordinate their activities and collaborate through raising petitions and funds, and planning and conducting mobile campaigns and communities programs. Fourthly, through large-scale collaborations, people can create reliable, robust, and complex products such as open source software applications such as Linux. As to Leadbeater (2007), the rubric of social software is: contribute, connect, collaborate, and create.

There are three characteristics commonly attributed to social software, namely:

- Support for conversational interaction between individuals or groups, ranging from real-time instant messaging to asynchronous collaborative teamwork spaces. This category also includes collaborative commenting on and within blog spaces.
- Support for social feedback that allows a group to rate the contributions of others, perhaps implicitly, leading to the creation of digital reputation.
- Support for social networks to explicitly create and manage a digital expression of people's personal relationships, and to help them build new relationships (Boyd, 2003).

Owen and others (2006) suggest that social software can be also characterized by community gains, that is, many users benefit from other users acting in sociable and community-oriented ways:

- Social software delivers communication between groups
- Enables communication between many people
- Provides gathering and sharing resources
- Delivers collaborative collecting and indexing of information
- Allows syndication and assists personalization of priorities
- Has new tools for knowledge aggregation and creation of new knowledge
- Delivers to different platforms as is appropriate to the creator, recipient, and context.

In addition, social software offers great promise for education as it supports group interaction. Phipps (2007) lists the following educational benefits of social software:

- Using instant messaging to conduct tutorials at a distance with a distributed group
- Providing easier opportunities for students to collaborate and make word of mouth recommendations about sites including, or related to, course content
- Allowing students to create their own interest groups allied to their studies
- Allowing students to interact with students from different universities and countries
- Providing researchers with ways to share results faster and with opportunities for instant feedback
- Allowing the formation of *ad hoc* research groups
- Providing a way of having material peer reviewed by a broad audience before publication

USABILITY PERSPECTIVE

Usability is central to the use of any software application. Jacob Nielsen defines *usability* as the quality attribute that assesses how easy a user interface is to use (Nielsen, 2003; Nielsen & Loranger, 2006). Despite the rapid growth of social software, there is little research of its usability. According to Silva and Dix (2007), when a social software application such as YouTube was subjected to usability evaluation, it failed the test. The main aim of usability examination is to ensure that interactive products such as social software are easy to learn, effective to use, and enjoyable from the user's perspective (Preece, Rogers, & Sharp, 2002). Usability goals include:

- Effective to use (effectiveness)
- Efficient to use (efficiency)
- Safe to use (safety)
- Have good utility (utility)
- Easy to learn (learnability)
- Easy to remember how to use (memorability)

Usability goals are typically turned into specific criteria to enable the usability of a product to be assessed in terms of how it can improve a user's performance. Usability tests are often used to orient web product designers towards thinking about different aspects of their applications. Social software design principles are derived from a mix of theory-based knowledge, experience, and common sense. Some well-known design principles include well-established testing criteria, such as visibility, feedback, constraints, mapping consistency, and affordances (Norman, 1998). When design principles are used in practice, they are referred to as *heuristics*.

Whereas design principles are used mainly for informing a product development, usability principles are used mostly as the basis for evaluating prototypes and existing systems. They provide the framework for heuristics evaluation (Preece et al., 2002). Nielsen and his colleagues (2001) have developed ten main usability principles that can be equally applied to social software usability examination:

1. **Visibility of system status:** Always keep users informed about what is going on, through appropriate feedback within a reasonable time.
2. **Match between system and the real world:** Speak the user's language using words, phrases and concepts familiar to the user, rather than system-oriented terms.
3. **User control and freedom:** Provide ways of allowing users to easily escape from places they unexpectedly find themselves by using clearly marked "emergency exits."
4. **Consistency and standards:** Avoid making users wonder whether different works, situations, or actions mean the same thing.
5. **Help users recognise, diagnose, and recover from errors:** Use plain language to describe the nature of the problem and suggest a way of solving it.
6. **Error prevention:** Where possible, prevent errors occurring in the first place.
7. **Recognition rather than recall:** Make objects, actors, and options visible.
8. **Flexibility and efficiency of use:** Provide accelerators that are invisible to novice users but allow more experienced users to carry out tasks more quickly.
9. **Aesthetic and minimal:** Avoid using information that is irrelevant or rarely needed.
10. **Help and documentation**: Provide information that can be easily searched and provides help in a set of concrete steps that can be easily followed.

Evaluation can be broadly divided into two types: evaluation by the designer (or a usability expert without direct involvement by users) and evaluation that studies actual use of the system. The former is useful for assessing early designs and prototypes. On the other hand, the latter typically involves a working prototype or implementation. The goals of evaluation are: (a) to assess the extent and accessibility of the system's functionality, (b) to assess user's experience of the interaction and (c) to identify any specific problems with the system.

Evaluation of the usability of social software should be tackled throughout the design life cycle, with the results of the evaluation feeding back into the modification of the design. Although it is not possible to carry out extensive experimental testing continuously throughout the design, analytic and informal techniques can and should be used (Silva & Dix, 2007).

The functionality of the system is also important. It must be in accord with the users' requirements as well as matching the use of the system to the users' expectations of the task. In addition, it is important to assess the users' experience of the interaction and its impact upon him/her. Usability testing is the approach typically used to carry out users' evaluation. Although users should be involved in the evaluation of the software throughout the design process, this may not be possible because it is rather expensive. Another approach is to use experts to carry out the evaluation. This approach is relatively inexpensive because it does not require user involvement. However, this approach does not assess actual use of the system, only whether or not a system upholds accepted usability principles.

According to Tognazzini (1995), user testing is an integral part of the design process. Usability evaluation is important to determine that software meets user needs and one can use the product and adopt it. Without evaluation we cannot be sure that the social software is usable and what the users want. Preece and colleagues (2002) identified four different evaluation paradigms:

1. **Quick and dirty evaluations:** This is a practice in which designers informally get feedback from users or consultants to confirm that their ideas are in line with users' needs. This method is called *dirty* because this can be don*e in* a short space of time. It is particularly useful for applications that need to be completed in a short timescale.
2. **Usability testing:** Usability testing involves measuring typical users' performance on carefully prepared tasks that are typical of those for which the system was designed (Preece et al., 2002). In this evaluation, it is strongly controlled by the evaluator. Tests typically take place in laboratory-like conditions that are controlled. Everything that the participant does is recorded. Quantifying users' performance is a dominant theme in usability testing.
3. **Field studies:** Field studies are done in the natural settings where the aim is to increase understanding about what users do naturally and how technology impacts them. There are two approaches to field studies. The first involves observing explicitly and revealing what is happening, as an outsider looking on. Qualitative techniques are used to collect the data that can then be analysed qualitatively or quantitatively. The other approach is where the evaluator may be an insider or even a participant. A typical type of inside evaluation is ethnography. The aim of ethnography is to explore the details of what happens in a particular social setting,
4. **Predictable evaluation:** In this method, experts apply their knowledge of typical users, often guided by heuristics, to predict usability problems. Users need not be present in predictable evaluation. This makes the process quick, relatively inexpensive, and attractive to companies.

Typical expert methods include heuristic evaluation and cognitive walkthrough. Heuristic evaluation is an informal usability inspection technique developed by Nielsen (1994), in which experts, guided by a set of usability principles (known as *heuristics*) evaluate whether user interface elements, such as dialog boxes, menus, navigation structures, online help, etc. conform to the principles. Expert evaluators work with the product, role-playing typical users and noting the problems encountered (Preece et al., 2002). The main advantage of this approach is, because users are not involved in the evaluation, it is quick and cheap. Heuristic evaluation is thus known as "discount evaluation."

Walkthroughs are another method for heuristic evaluation for predicting users' problems without doing user testing. These involve performing a task and noting problems associated with system usability. There are cognitive walkthroughs and pluralistic walkthroughs. Cognitive walkthroughs involve simulating a user's problem-solving processes at each step in the human-computer dialog, checking that the user's goals and memory for actions can be assumed to lead to the next correct action (Preece et al., 2002). The steps involved are:

1. Characteristics of typical users are identified and documented, and sample tasks are developed that focus on the aspects of the design to be evaluated.
2. A designer and expert evaluators come together to do the analysis.
3. The evaluators walk through the action sequence for each task replacing it within the context of a typical scenario. As they do this, they try to answer the following questions:
    ◦ Will the correct action be sufficiently evident to the user?
    ◦ Will the user notice that the correct action is available?
    ◦ Will the user associate and interpret the response from the action correctly?
4. A record of critical information is compiled as the walkthrough is being performed.
5. The design is revised to fix the problems presented.

Pluralistic walkthroughs are a method in which users, developers, and usability experts work together to step through a task scenario, discussing usability issues associated with dialog elements involved in the scenario steps. Each group of experts is asked to assume the role of typical users. Interestingly enough, Silva and Dix (2007) found that conventional usability evaluation does not work well for social software, such as YouTube. Despite this, You Tube has been a great success. Even though we know what *usability* means for such sites; how do the site developers take into account the usability of a radically configurable site? What about consistency? How do we effectively communicate with 10 million end-user designers? These and other issues should be addressed by further research of social software usability.

SOCIAL SOFTWARE USABILITY

Blogs

A *blog* is a system that allows a single author (or group of authors) to write and publicly display time-ordered articles (called *posts*). Readers can add comments to posts. Increasingly, blogs incorporate multimedia, and you can also upload and read them via mobile devices. The main benefits of blogs are that users with disabilities can access an online blog using assistive technology (for example text-to-speech tools or voice recognition software) in a way that would be impossible to replicate in paper-based update reports. The inbuilt templates, content management, tracking and searching facilities of a blog system can make the organization and retrieval of information much simpler than using a process that depended on their own organizational skills. The main disadvantage of a blog is that users with learning difficulties may struggle to acquire the range of skills necessary to effectively keep records via an online system. Different blog systems will have different levels of usability and accessibility, in the navigation and retrieval of content and their usability with different assistive technologies.

Wikis

A *wiki* is a system that allows one or more people to build up a corpus of knowledge in a set of interlinked web pages, using a process of creating and editing pages. Wikipedia is the most famous wiki. There are many possible uses for a wiki, including research collaboration, multi-authored papers, project work, and maintenance of documents which require regular updating.

There are several advantages of using wikis. These include giving an opportunity for users with different types of knowledge, confidence, and communication to contribute equally to a joint publication, reducing e-mail traffic. Collaborators who lack confidence to argue a case in a "live" face-to-face debate can feel more comfortable making the same points in a wiki environment where the pace of discussion is slower and the quality of the thinking is more significant than force of personality. The main drawback of a wiki is its iterative nature (sections appearing and disappearing as a document evolves), which can be very difficult to track, especially for those with slow reading speeds.

Podcasts

A *podcast* is a collection of digital media files which are distributed over the Internet, often using syndication feeds, for playback on portable media players and personal computers. Many podcasts also allow users to directly download, by giving a link to the audio file in an RSS feed or web page. The ability to listen to content rather than read it offers many benefits to users. Users with poor reading skills or visual impairment particularly benefit; however, there are also significant benefits for all users who want to absorb content while doing something else, such as driving. Users need not only be recipients – it can be very easy to create personal audio content and in some circumstances it may be a more successful way of recording knowledge and understanding than a blog or a traditional textual write-up. The main problem with podcasts is that audio-only resources pose significant problems for people with hearing disability.

Social Networking Tools

Social network services allow people to come together online around shared interests, hobbies, or causes. For example, some websites provide dating services where users post personal profiles, locations, ages, gender, etc, and are able to search for a partner. Other services enable business networking (Ryze, XING, and LinkedIn) and social event meetups (Meetup). More recent developments include virtual reality worlds, such as Second Life.

Nowadays, social networking sites such as MySpace, Facebook, and Bebo attract millions of users, and the services grow exponentially, with each new user encouraged to introduce others. The main benefits of social networking tools enable the creation of online communities, whether geographical communities, people linked by a particular interest, or simply random networks of online users. It also offers such benefits as expanded networks, informal positive filtering (e.g., "friend of a friend" recommendations) and opportunities to both advertise and search for specific skills and experiences. There is no disadvantage if the tool is built with accessibility in mind.

Mashups

A *mashup* is a web application that combines data from more than one source into a single integrated tool. An example is the use of cartographic data from Google Maps to add location information to real-estate data from Craigslist, thereby creating a new and distinct web service that was not originally provided by either source. The benefit is in being able to combine datasets in new ways. The limitation is that with a high reliance on spatial data, mashups are very difficult for visually impaired users. People with poor spatial skills (for example, those who prefer a list of directions rather than a map image) may also find mashups difficult to use.

Sharing Tools

This provides users with the ability to record (bookmark) web pages and tags these records with significant words (tags) that describe the pages being recorded. Most websites enable the uploading of your own resources, and viewing of those uploaded by others, through configuration options that usually enable you to make your resources available only to a private group if required. Del.icio.us and Furl are two of the most popular bookmark-sharing services, while CiteULike and Connoteaare more academically oriented, for sharing bibliographical references. Image-sharing sites include Flickr and Phlog, while Odeo focuses on audio material. The benefits include: the ability to visualize information in different ways (for example, cloud tagging in Del.icio.us); the ability to collaborate effectively without needing physical access or physical proximity to other collaborators. The main problem is the interface. If the interface is designed for accessibility, there should be few difficulties.

Folksonomies

Folksonomy is also known as *collaborative tagging*, *social classification*, *social indexing*, and *social tagging*. It is the practice and method of collaboratively creating and managing tags to annotate and categorize content. A folksonomy is a user generated taxonomy. Folksonomic tagging is intended to make a body of information increasingly easy to search, discover, and navigate over time. Among the most widely cited examples of websites using folksonomic tagging are Flickr and Del.icio.us. The main benefit of folksonomy is that by using them, we can discover new and more current digital content due to its ability to be updated immediately. Folksonomies can also be organized so that one can explore the "long tail interests" – the less frequently used keywords that people choose that can help users focus their searches and applications. However it is criticized for a lack of terminological control causing it to produce unreliable and inconsistent results. Another problem is the lack of precision inherent in tags (Guy & Tonkin, 2006).

Usability Evaluation Guidelines

Nielsen (1994) derived his heuristics evaluation from an analysis of 249 usability problems. Preece and others (2002) expanded on that and produced the following guidelines:

- Visibility of system states
- Match between system and real world
- User control and freedom
- Consistency and standards
- Help users recognise, diagnose, and recover from errors
- Error prevention
- Recognition rather than recall
- Flexibility and efficiency of use
- Aesthetic and minimalist design
- Help and documentation.

Nielsen (1999) argues that the above guidelines are too general for evaluating new products: such as, online communities, WAP devices, and others. Instead, Nielsen suggested an easy to remember constellation of usability principles (acronym HOMERUN):

1. **H**igh-quality content
2. **O**ften updated
3. **M**inimal download time
4. **E**ase of use
5. **R**elevant to user's needs
6. **U**nique to the online medium
7. **N**et-centric corporate culture

The authors concur with Preece and colleagues (2002) that it is important to develop heuristics that are best tailored to the specific product. The heuristic evaluation method consists of three stages (Preece et al., 2002):

1. The briefing session in which the experts are told what to do
2. The evaluation period in which each expert typically spends 1-2 hours independently inspecting the product using the heuristics for guidance
3. The debriefing session in which the experts come together to discuss their findings and to prioritise the problems they found and to suggest solutions.

Whereas usability is concerned with how users interact with technology, sociability is concerned with how members of a community interact with each other through the enabling technology (Preece 2001). The success of professional learning social software is determined not only by its high usability, but also good sociability, with both of these principles comprising a set of criteria and measures (Law & Hvannberg, 2006).

We concur with Klamma and others (2006) that four key quality attributes and their sub-attributes for social software are needed: functionality, usability, interactivity, and naturalness.

1. Functionality
   - How do I join the group?
   - Do I feel part of a thriving community?
   - What are the rules?
   - Can I express myself as I wish?
   - Is the community safe?
   - Can I trust the application?
   - Do people behave themselves appropriately?
   - Would it support me to carry out the activities I want to do?
   - Can I find out who is there?
2. Usability
   - Can I use the application easily?
   - Do I feel that I am able to follow and understand what I am doing?
   - Do I enjoy using the application?
   - Do I know how to join the group?
   - Can I get, read, and send messages?
   - Can I send a private message?
   - Can I find the information and people easily?
   - Can I navigate the site easily?
   - Do I feel comfortable using the application?
3. Interactivity
   - Does the application allow me to communicate easily?
   - Does the application offer simple, consistent pages and clear navigation?
   - Does the application know where I am at all times?
   - Does it let me know clearly where I can go from here?
   - Does it let me know where I have been?
   - Does it make it obvious what to do to get somewhere?
   - Does it indicate what clicking a link will do?
   - Does the application give appropriate feedback?
   - Does the application give concise, timely and polite help?
4. Naturalness
   - Is the layout simply and easy to use?
   - Is the text clear and easy to read?
   - Is the page consistent?

- Is the colour natural and pleasing?
- Are the navigation items large and bold:
    a. Using clear text to make the purpose of each link apart from unambiguous?
    b. Positioning permanent navigation links apart from content?
    c. Differentiating navigation using colour, tone, and shape?
- Does it have too many columns?
- Does the application provide appropriate help when I get stuck?

Currently no standard ways exist to measure the above attributes, making benchmarking studies especially difficult. Evaluation of social software is difficult, given the high variability in users, tasks, and contexts. Despite this, we believe that the principles of functionality, usability, interactivity, and naturalness can be successfully used for evaluating social software.

FUTURE TRENDS

Emerging social interaction technologies present opportunities and benefits to institutionally based and personal learning. As familiarity with social software grows in the larger community, these tools are now being increasingly explored for their pedagogic value. According to Aspin and Chapman (2000), "life-long learning" refers to a society in which learning possibilities exist for those who want to learn (Fischer, 2001). There is an increasing demand for new approaches towards fostering life-long learning perspectives. Emergent Web 2.0 concepts and technologies are opening new doors for more effective learning and have the potential to support life-long competence development.

Social software techniques enable richer capturing of context in which content has been produced. This allows for automating the generation of metadata ("descriptions"): e.g., by reusing metadata from artefacts produced by "close neighbours" in the social network) (Klamma et al., 2007). This sort of mining of social information can enhance the Automated Metadata Generation framework (Cardinaels et al., 2005). According to Klamma and colleagues (2007), social software based context capturing offers great potential to create advanced tools and services for dealing with the need for content. A simple example is to augment user queries with metadata that constrain results to those that are relevant to the context at hand (e.g., in a language that the user has demonstrated mastery). A more advanced example is to alert users to relevant content, even before they are aware that it may help them in the task at hand (e.g., because the actions of their peers and colleagues have indicated that this content is relevant in this situation).

CONCLUSION

Users will not adopt an application if they find it difficult to use. Designers cannot expect that user-friendliness can be achieved automatically by following the product design guidelines. Usability evaluation is necessary to make sure that users approve the application. Creators of a usable Web 2.0 site should: 1) adhere to standards; 2) think about what users will actually do; and, 3) think about user tasks. The difference between traditional applications and social software is that users become both designers and end-users. As we argue above, many of the already established principles for software usability can be successfully applied to evaluating the usability of the Social Web. In addition, some new features have to be considered to take into account the specific nature of social software. Overall, social software usability should be viewed as a set of principles and practices aimed to deliver more service-orientated Web 2.0-based applications.

KEY TERMS AND DEFINITIONS

Heuristic Evaluation: A usability inspection technique based on a set of established usability principles.

Social Software Usability: A set of principles and practices aimed to deliver more service-orientated Web 2.0-based applications.

Usability: A qualitative attribute that refers to the ease of use of computer software and web-based applications.

Usability Evaluation: Refers to an assessment of the degree of efficiency to which a software product can be operated by the users.

Usability Testing: Involves procedures and techniques to measure the users' performance of most typical tasks.

Walkthrough: A usability evaluation technique used for identifying potential problems.

Chapter 5.7
Social Impact of Collaborative Services to Maintain Electronic Business Relationships

Stefan Klink
Universität Karlsruhe (TH) – Research University, Germany

Peter Weiß
FZI Research Center for Information Technology, Germany

ABSTRACT

This chapter looks at the impact and opportunities of semantic technologies and Web services to business relationships and how social Semantic Web techniques foster e-business and collaborative networks in many dimensions. For this the authors follow the vision to support collaborative services for business relationship management within semantic services. Based on a newly approach for business partner management with ontologies in large business communities, the chapter elaborates the conceptual framework for the design and implementation of collaborative services. The often postulated adaptiveness and intelligence of novel collaborative structures, foremost collaborative networks, require new approaches to deal with the increasing difficulty to cope with the resulting complexity of relational ties in communities and business networks. This research strives to leverage the capabilities to deal with large number of business relationships. The chapter formulates a vision based on three stages developing digital business ecosystems. Semantic Web technologies, mainly modelling business partner profiles (BPP) with ontology, combined with sound techniques of information retrieval and selected concepts and methods of social network analysis build the conceptual framework. On this basis, a newly approach is elaborated which offers support for communication processes and complex interactions of business entities in collaborative spaces.

INTRODUCTION

During the last decade, along with growing interest and increasing use of electronic networks, society, science and business have been affected by remarkable changes. Electronically networks have had a tremendous impact on the every day and working life changing the way people interact, live and work. In our economy today, networking plays a crucial role in various application domains. Services are designed to support collaboration and networking among agents, whether humans or machines, in electronic networks.

Services are designed to overcome identified boundaries for Collaborative Networks (Martin-Flatin et al., 2006). The focus of this research is social ties between network entities. In electronic networks the linkages of entities (e.g., business partners, employees, experts, etc.) have to be supported by electronic services. Semantics, self-organization, security, trust and privacy, awareness and incentives are variables influencing the relational ties between units. However, linkages between agents require the right climate and conditions of a collaboration environment. This environment should provide opportunities for or constraints on individual action in a specific given context. These horizontal dimensions facilitate and catalyze the emergence of relational processes and structures to evolve.

This chapter claims that organisational structures with the asked abilities to self-manage, self-configure and self-optimise require besides the necessary culture, and "[…] semantic-informed self-organizing structures […]" (Camarinha-Matos et al., 2003, p. 8). Culture and structure are constituted in the collaboration and innovation environment and provides the "breeding environment" for establishing relational ties between agents (e.g., units, actors, etc.).

In this environment relational ties are to emerge between agents (e.g., units, actors, etc.). From a network perspective, linkages and related relational processes and structures are subject of analysis. The status of relational ties is either latent (passive) or evident (active). If made evident in a specific context given, they offer the channels for transfer or "flow" of resources (either material or nonmaterial). Our research aims at provisioning of a framework allowing to analyse and to conceptualise structures in form of models as lasting patterns of emerging relationships among agents. Again the conditions and environment catalysing the emergence of relational processes and structures in the context of collaboration and innovation processes are looked into. The goal is to analyse related interactions at the level of individuals, teams (or groups), organisations, networks and communities (After Figure 1, see Figure 2).

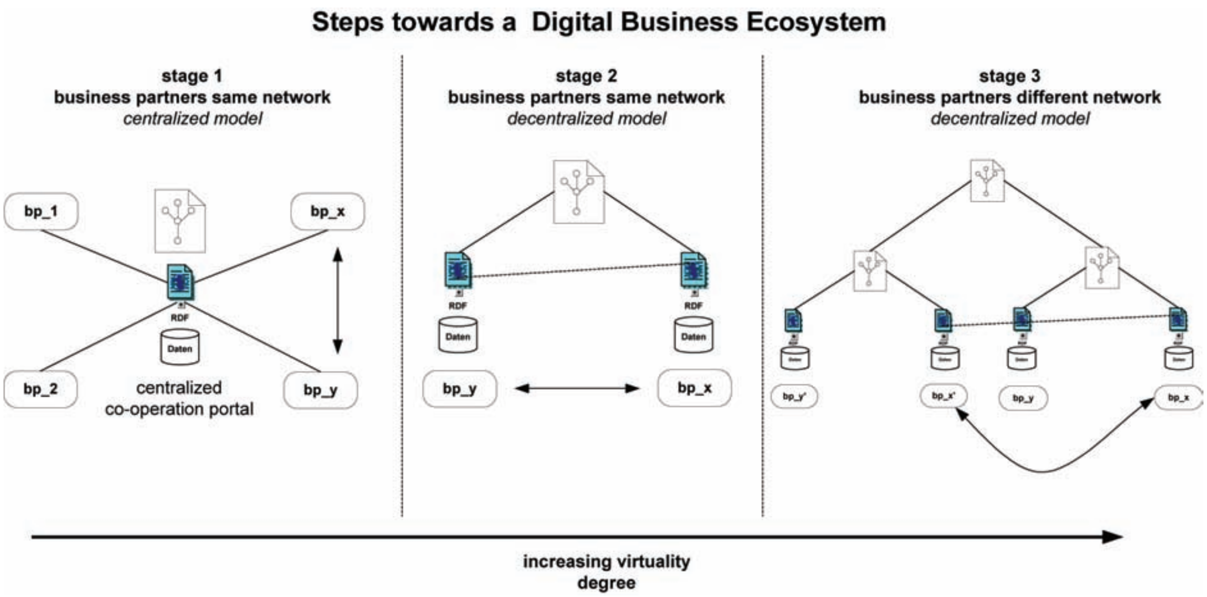
The concept of semantically enriched business partner profiles and sound, proven techniques of information retrieval, data mining, and machine learning, respectively, are combined together to develop a collaborative service environment. Discovery, matching and trust services provide the field for further enhanced services and functionality in collaborative networks.

One of the challenging tasks analysing business networks is to propose the clearest possible view of network characteristics. The concept of network suggests the existence of nodes, which interplay in different patterns according to the network structure. In the future networks will be characterised by the ability to self-organise their shape and to adapt rapidly to changes in their direct environment as e.g. the change of market conditions or new developments in technology. In this chapter we look at the fundamental basis for the design, development and implementation of collaborative services for the efficient partner relationship management in dynamic business ecosystems.

The approach aims to extent existing b2b integration technology architectures. For this, Weiß (2005, 2007) developed a methodology ODAMY[1] transforming the metrics of an empirical model into an ontology based model. The conceptual framework is based on the KAON tool set and infrastructure (KAON 2003). KAON tool set allows iteratively checking at this early stage of development how the conceptual framework shall be used and implemented.

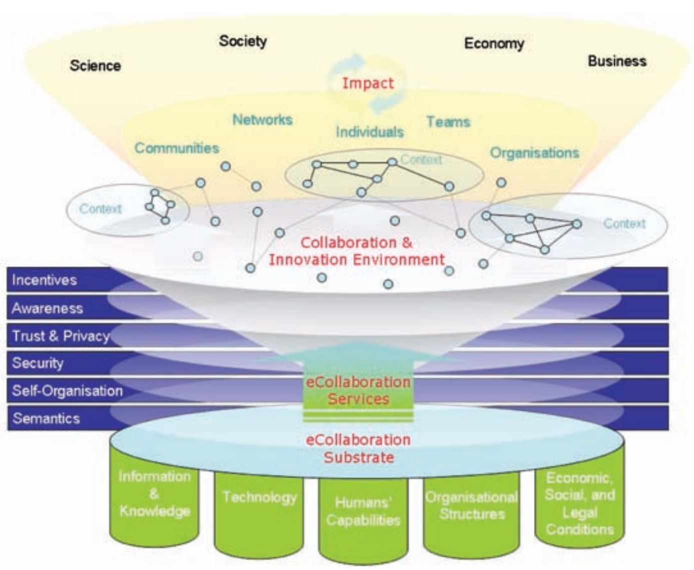
Our research concentrates on the extension of the centralised approach presented by Weiß

Figure 1. Steps towards a Digital Business Ecosystem (Weiß 2005)



(2005, 2007) by using a decentralized model for the fingerprints. It focuses on dynamic integration of business partners in the light of emerging digital business ecosystems. The work followed the approach to assess decision criteria in order to support the self-formation and self-organisation of adaptive business networks. Business partner profiles are build based on a shared explicit data model. An ontology-based model describes underlying data structures and concepts which have been taken from an empirical model. The empirical model encompasses important dimensions for the

Figure 2. Framework of collaborative networks' infrastructure (Klink and Weiß 2007)



configuration and analysis of business relationships. Weiß (2005, 2007) discussed and overlooked the future and emerging trends.

In Figure 1 the three stages towards a digital business ecosystem are illustrated. Research described in (Weiß 2005) addressed foremost the scenario at stage 1 (left side in Figure 1). At this stage a centralised model for the business partner profiles is applied. Business partners that can be accessed through the ICT infrastructure are limited to information stored and accessible through the registry in form of an Enterprise Portal of the domain network. Related work can be found in the area of business registries for Web services, e.g., UDDI[2] and ebXML[3].

Our research gravitates around the realisation of the scenario shown at stage 2 (middle in Figure 1). At this stage, a decentralised model is developed which is analogous to peer2peer networks. Business Partner Profiles are no longer stored in a central information portal. Instead, they are stored decentralised but are created on basis of a shared conceptual model in form of a domain ontology. Business partners maintain latent business relationships solely within the boundaries of the business network they have registered. Boundaries of this network are defined by the number of registered users.

At stage 3 (left side of Figure 1) the approach strives for an advanced decentralised model that allows contacting and querying business partners not limited to any boundaries of the defined network. The information desired for discovery and selection of business partners is retrieved beforehand through machines in form of agents or Web crawlers.

The semantics of data in profiles has to be made explicit and has to be stored in a machine-processable form. The described approach fulfils the needs of the described scenario but has to be further elaborated and developed. Especially, retrieval of collaborative information and data stored in business partner profiles poses interesting questions for future research endeavours. Future developments in adaptive business networks will be driven and dominated by current paradigms of service oriented architecture (SOA) and technologies related to Web services (Weiß, 2007), (Klink and Weiß, 2007).

STATE-OF-THE-ART/BACKGROUND

In the past, network perspective has proved fruitful in a wide range of social and behavioural science disciplines. Today, network perspective noticeably impacts other research disciplines, namely informatics, economics, engineering, law, etc. Network concepts are conceived increasingly as fundamental components for research activities in the field of virtual organisation (Sydow 1992), (Krystek et al. 1997), (Ritter 1998), (Picot et al. 2003), (Weiß 2005).

In today's b2b (business-to-business) integration concepts, strategic aspects are mostly not addressed adequately. In this context Bussler (2003) discusses the problem of integrating business partners into an existing information and communication technology (ICT) infrastructure depicting options by looking into types of b2b integration concepts and scenarios. Current b2b integration concepts are focused merely on technical needs and aspects as definition of interfaces for information exchange, remote invocation of applications or formalisation of business transactions and processes as well as business semantics (Weiß and Stucky 2004). Most influential initiatives to be mentioned here are EDI[4]-based and/or XML[5]-based (Weiß 2005).

New business patterns are characterised by diminishing geographical and time boundaries, globalisation of the labour market, increased connectivity, extended or virtual enterprises, new forms of customer management, and individualised marketing (Lengrand and Chatrie 2000). Beyond doubt, the relevance of networked co-operations in business can be expected to increase strongly in future. Delic and Dayal (2003) discuss and describe future enterprises that will transform themselves into better forms by becoming "more intelligent".

"Intelligent" in this context is perceived as the capability of a business entity to exploit emerging business opportunities and to adapt its operations to changing market conditions. It is also perceived as the capability of a business entity to sense its environment, to understand the situation, and to adapt its business objectives and behaviour accordingly. Enterprises form strategic partnerships with other enterprises "[…] to create dynamic business ecosystems" (Delic and Dayal 2002), that will be self-managed, self-configured and self-optimized. Adaptation can be identified as a key behaviour derived from the behaviour of natural systems. Both systems, natural and business systems, share the same ultimate objective: to survive in an evolving environment and changing circumstances (Delic and Dayal 2002).

Survival in an evolving environment is also a question of how far away is the actual business reality today from the future dynamic business ecosystem. Currently, new efficiencies can be mainly achieved through automation of core business processes, and exploitation of knowledge. In this connexion popular concepts are customer relationship management (CRM), enterprise resource planning (ERP), enterprise application integration (EAI), and enterprise knowledge management (EKM). In essence they encompass enterprise activities aimed at improving efficiency or injecting intelligence into operations (Delic and Dayal 2002). The mission is offering interfaces for integrating proprietary information systems from both internal perspective and external perspective encompassing integration of respective business partners, suppliers, and customers into the enterprise's own operations. In consequence, enterprise's borders are blurring, turning into fuzzy and dynamic borders.

Today, many research endeavours noticeably gravitate around the realisation and problems related to the implementation of concepts mentioned above. Common denominator and underlying problem of many business endeavours can be summarised in the appropriate combination of two extremes: self-organisation versus extrinsic organisation; or more general evolution versus organisation.

This vision sets clear targets for our research endeavour. After having motivated the background of our research, actual needs and aims of this research are further elicited in the following.

Collaborative Networks

Further flexibility and interoperability of the underlying ICT infrastructure is expected to have a tremendous impact on the ways business is conducted. Semantics and related technologies are expected to be of growing importance and are an important enabler for the scenario described above. Enterprise modelling has to respond to these developments through the development and take up of appropriate technologies, methods and tools. Subsequently, we look at important characteristics and show possible ways forward for the development of intelligence of and emergence of structures in business networks.

Collaborative Networks as research discipline are facing noticeably a renewal of interest due to newly emerging trends such as Web2.0 and other emerging paradigms of future applications and software architectures. Strong communities emerged which address in particular research topics and questions related to collaborative networks. (Camarinha-Matos et al., 2002 - 2006). From a network perspective, linkages and related relational processes and structures are subject of analysis. The need of a comprehensive scientific framework of collaborative networks (see Figure 2) is argued facilitating to structure interdisciplinary research activities towards common goals and visions. Subject of analysis are related interactions at the level of individuals, teams (or groups), organisations, networks and communities. It supports evolution of dynamic networks and self-organisation of network entities. The required emergence of relational structures re-quires specific services within collaborative networks.

Conceptual Model of Digital Business Ecosystems

Three stages towards a digital business ecosystem as already highlighted can be realized in literature (see Figure 1). Research described so far addressed foremost the scenario at stage 1. At this stage a centralised model for the business partner profiles (BPPs) is applied. These profiles represent information required to discover, select, and integrate business partners preferably dynamic, on demand into emerging or existing value chains. Business partners that can be accessed through the ICT infrastructure are limited to information stored and accessible through the registry in form of an Enterprise Portal of the domain network.

Current research gravitates around the realisation of the scenario shown at stage 2. At this stage, a decentralised model is developed. BPPs are no longer stored centrally in an information portal. These profiles are stored decentralised but are created on basis of a shared conceptual model in form of a domain ontology. Business partners maintain latent business relationships solely within the boundaries of business network they have registered to. Boundaries of this network are defined by the number of registered users.

At stage 3, the approach strives for an advanced decentralised model that allows to contact and query business partners not limited to the boundaries of the defined network. Information desired for discovery and selection of business partners is retrieved beforehand through machines in form of agents or Web crawlers. The semantics of data in profiles has to be made explicit and has to be stored in a machine-processable form.

Conceptual Framework

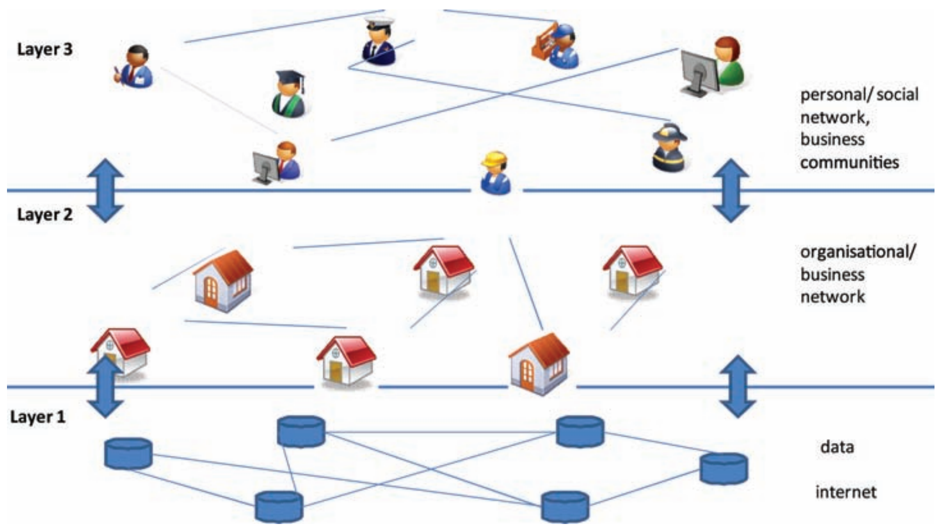
Our work follows the approach to assess decision criteria in order to support the self-formation and self-organisation of adaptive business networks. Based on a centralized approach with a shared explicit data model for the BPPs as "fingerprints", it is looked at further development of this approach to fulfil the envisioned scenario and requirement at stage two and three of our model. Thus, profiles are again regarded as a major concept which we will uptake. Profiles as a concept to store collaborative data will be the major approach we follow. Profiles are based on an ontology-based model (based on an ontology structure) which has been developed on basis of an empirical model encompassing important dimensions for configuration and analysis of business relationships (Weiß 2007).

BPPs are stored either in a central or a distributed database for retrieval and for further analysis. Klink (2006) investigated how information retrieval query techniques can be used to extract concepts from various information resources. Thus, the results of this research flow into our conceptual framework. As shown in Figure 1, we have to deal with some difficult questions and challenges for realising the scenario described at stage 2 and stage 3. Information retrieval as a core discipline seems to have some answers to these questions. Mainly, these questions relate how to deal with different semantics of semi-structured (Web) resources.

There are "[…] multiple theoretical mechanisms that contribute to the emergence of organizational networks" (Huang et al., 2008). Huang et al. (2008) discuss:

[…] multi-theoretical, multilevel (MTML) hypotheses about the structural tendencies of networks. The study suggests that the social drivers for organizing networks in communities have diverse goals such as exploring new ideas and resource, exploiting existing resources and capabilities, social bonding, mobilizing for action, and rapid

Figure 3. Electronic business relationships



response (or "swarming"). These drivers have different levels of impact within and across communities and hence change the mechanisms of recommender systems. For example, looking for a quick solution and producing innovative ideas will result in completely different recommendation systems" (Huang et al., 2008).

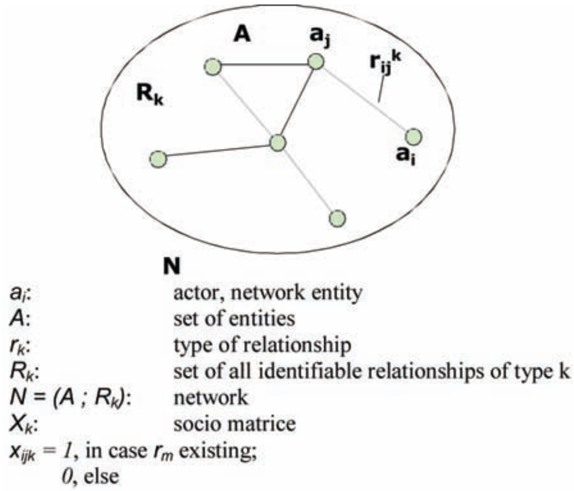
Figure 3 shows three perspectives or levels to analyse business communities. It can be assumed that the rapid emergence and growing popularity of online communities to initiate, manage and maintain business relationships will have tremendous impact on the way business is conducted in the future. The astonishing success of online community portals as Xing[6], LinkedIn[7], Plaxo[8], etc. underline these developments and further motivate the vision of collaborative networks which are self-managed, self-configured and self-organised – a behaviour that can be summarised as a sort of "intelligence".

This relates to the ability to create structures in a self-organised way. This behaviour is often characterised as "emergence"[9]. Looking at concepts and ideas that stand behind emergence would be interesting but shall and can not be covered in the given scope of this chapter. We stress that the basic understanding of self-organising processes is required to come up with any solutions and thus need to be analysed in detail to be clearly understood. Network abilities as "self-reference" and "emergence" are key concepts to be primarily looked into.

Organisation research has identified this as an interesting topic since decades (see for example (Sydow, 1992), (Krystek, 1997)). With the emergence of new ICT technologies and new trends and developments, e.g., concepts discussed as SOA and Web 2.0, bring this fundamental research work back again into the foreground and many technical and conceptual elements can be derived. This applies as well to the fields of information retrieval and social network analysis. (See Figure 4)

Social Network Analysis has emerged as a key paradigm in modern sociology, technology, and information sciences. The paradigm stems from the view that the attributes of an individual in a network are less important than their ties (relationships) with other individuals in the network. Exploring the nature and strength of these ties can help understand the structure and dynamics

Figure 4.



of social networks and explain real-world phenomena, ranging from organizational efficiency to the spread of information and disease. (Dasgupta et al., 2008)

Let us come back to central question which we already posed previously in this chapter: *how far are future dynamic business ecosystems from real business reality?*

For answering this difficult question, let us have a look at current developments, in particular in the field of online communities and social network analysis. The latter has gained tremendous popularity and revival due to growing importance of collaborative networks.

The selection of business partners is to be seen as key to success for the realisation of dynamic business ecosystems in near future. Therefore, business relationships need to be conceived increasingly as intangible asset of an enterprise that needs special care. Namely, they have to be maintained continuously through an adequate management. Thus, the areas under investigation are relational ties and enabling organisational structures and cultures in the light of aspired intelligence and ability of systems to self-organise (Weiß, 2007).

There is an obvious need to construct complex data structures to express the complexity of business related information. Besides, there is a need to be able to access these complex data structures and extract relevant information from them within a specification of requirements (Field and Hoffner, 2003).

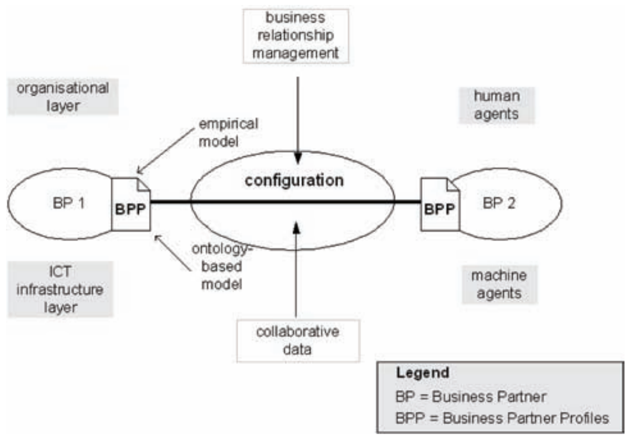
Figure 5 depicts the core of the research approach. The configuration of business relationships takes place primarily on the organisational layer. To involve the ICT infrastructure collaborative data has to be represented in machine-processable form. This can be realised using ontology for structuring and modelling of the BPP. Profiles are a prominent concept also used by Web services to store service descriptions.

Therefore, this is seen as an appropriate way to approach the problem at hand. BPP are anticipated to bridge the existing barrier between the organisational and ICT infrastructure layer. Through the application of ontology, collaborative services as, e.g., for discovery and/or matching of BPP can be used to support the self-reference and emergence of collaborative structure and cultures. Especially zones of trust can be established with filtering collaborative information and an intensified interaction and information exchange of business entities in advance of concrete business endeavours (Weiß 2007).

For analysing a social network of business partners and their relationships we use the following basic definitions based on typical concepts used in social network analysis:

More concrete, in contrast to classical network analysis our approach is to introduce different types of relationships r_k. In this way we describe business relationships using a multi-dimensional model. In case a relationship type is existing x_{ijk} has the value 1 in the socio matrice, else 0 indicates that this type of relationship does not exist (Weiß 2005, 2007). Various other types of matrices are used to display interactions and connectivity of network nodes (see e.g., Musolesi et al. 2007; Wassermann and Faust 1994; Scott 2000). (See Figure 6)

Figure 5. Design of approach for business partner relationship management with ontology (Weiß, 2007)



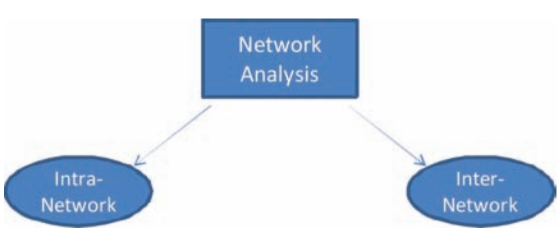
Measurement

The measurement is realised on basis of an empirical model which lays the foundations for later configuration of business relationship. In the following we look at the empirical model which aims analysing the network structure. The network structure encompasses network entities and relational ties between them.

The analysis framework distincts two views: intra- and inter-network view. The intra-network analysis looks at entities inside the network. One particular challenge in analysing business networks is to define boundaries of a network. For this purpose social network analysis offers various techniques how this information can be extracted from business cases.

Network analysis looks at the network itself without describing the quality of the relationships between entities. Presented model delivers additional dimensions which allow analysing business relationships in more detail.

Figure 6. Empirical model for network analysis



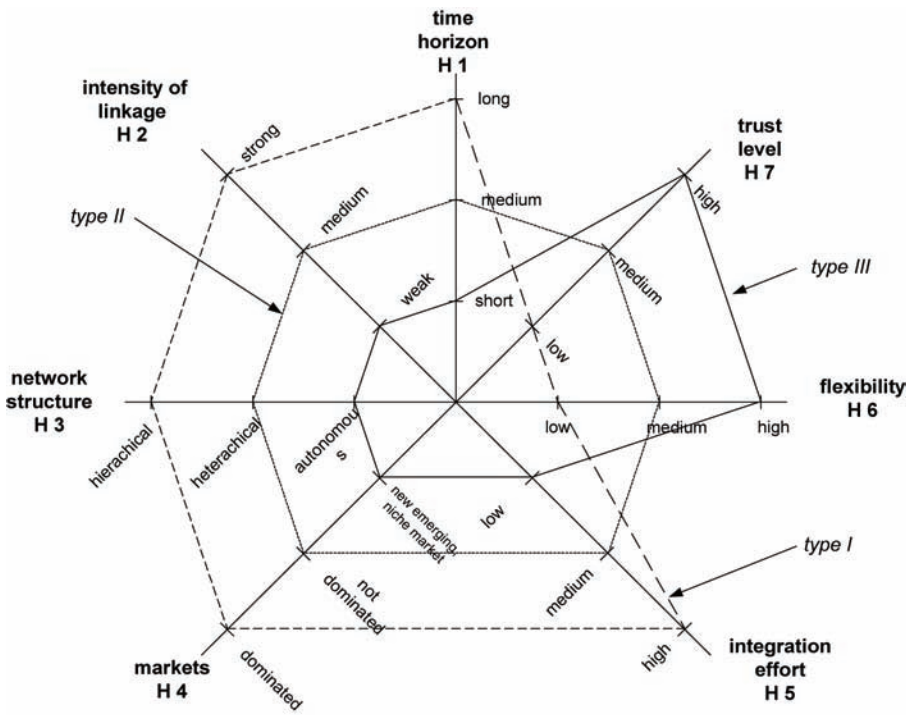
Inter-Network Analysis

The inter-network analysis looks at characteristics of relationships between companies. The perspective is not restricted to boundaries of a network. The measurement assess collaborative about preferences and behaviour of companies (in retrospect). The analysis framework delivers information concerning the configuration of business relationships. Based on this profile the entity is able to find business partners in the network corresponding to their collaboration requirements.

Figure 7 displays in a diagram the seven areas or dimensions that are analysed: flexibility, time horizon (th), network structure (ns), intensity of linkage (il), market (m), trust level (tl), integration effort (ie). Each dimension is supported by a hypothesis which expresses the assumptions made.

The aim of this analysis is to classify network entities according to the given seven dimensions. Quantitative values are aggregated to qualitative values in the range of low, medium and high. How this information is processed will be looked

Figure 7. Dimensions of inter-network analysis (Weiß 2007, 2005)



at later on in more detail. Table 1 describes three types of "idealised" network types which span a "continuum of virtuality" according to which cases can be classified and positioned. For more details about development and information about the empirical model readers are recommended to consult (Weiß 2005).

Intra-Network Analysis

Inter-network analysis mainly can be seen as "external" perspective having the network company or entity in focus and its cooperation behaviour and preferences. Whereas, intra-network analysis complements our measurement with an additional "internal" view. From this perspective, we are interested to analyse existing network ties within boundaries of an identified business network within its boundaries. But, defining boundaries of a network is a difficult task (Scott 2000), (Wasserman and Faust 1994). While the inter-network perspective determines the co-operation behaviour in retrospect, the intra-network perspective aims analysing the degree of strategic fitness between network partners. Dimensions for the analysis are: roles in network, information exchange performance, co-operation, goal definition, profit share, success, goal binding. Again, quantitative values of variables are aggregated to qualitative values in the range of low, medium, and high. Later on, we will primarily look at the seven dimensions of the inter-network analysis. Nevertheless, implementing the intra-network analysis follows the same principles.

Ontology-Based Model

"*Ontologies are a formal conceptualization of a particular domain that is shared by a group of people*" (Maedche, 2002). Social network analysis combined with ontologies offer new ways to analyse and to deal with collaborative information of networks. Available methods, techniques and tools have considerably improved during the last years, namely KAON[10] and Protégé[11].

Table 1. Types of network partnerships, based on (Weiß, 2005)

Type	Description
Type I	long term oriented partnerships focal partners dominate (contracts) optimisation of the supply or value chain high intensity of linkage (contracts) high level of integration centralised network structure main objective: efficiency
Type II	dynamic project oriented partnerships heterarchical network structure latent business relationships loosely coupled partnerships main objective: efficiency and flexibility Web-based portals and collaborative solutions democratic structures (code of conducts, constitutions)
Type III	spontaneous, temporary partnerships main objective: flexibility business opportunities at short term Service-oriented architectures win-win-driven

In the following, the empirical model presented above is transformed step by step into an ontology structure.

An ontology structure O is defined is a tuple $O = \{C, R, H^C, rel, A^O\}$, where (Maedche 2002):

1. C is a set whose elements are called concepts.
2. $R \subseteq C \times C$ is a set whose elements are called relations. For $r = (c_1, c_2) \in R$ one may write $r(c_1) = c_2$. C and R are two disjoint sets.
3. $H^C \subseteq C \times C$ is a concept hierarchy in form of directed relationship $H^C \subseteq C \times C$, also called taxonomy. $H^C (C_1 \times C_2)$ means C_1 is subconcept of C_2.
4. *rel*: function $rel: R \rightarrow C \times C$ which sets to concepts in non-taxonomic relationship
5. A^O is a set of axioms on O expressed in an appropriate logical language, e.g., FOL.

To cope with the lexical level, the notion of a lexicon is introduced. For an ontology structure $O = \{C, R, A^O\}$ a lexicon L is defined as $L = \{L^C, L^R, F, G\}$, where:

1. L^C is a set whose elements are called lexical entries for concepts.
2. L^R is a set whose elements are called lexical entries for relations.
3. $F \subseteq L^C \times C$ is a reference for concepts such that: $F(l_C) \{c \in C{::}\ (l_C,c) \in F\}$ for all $l_C \in L$; $F^{-1}(c) = \{l_C \in L^C{:}\ (l_C,c) \in F\}$ for all $c \in C$.
4. $G \subseteq L^R \times R$ is a reference for relations such that: $G(l_R) = \{r \in R{:}\ (l_R, r) \in G\}$ for all $l_R \in L^R$; $G^{-1}(r) = \{l_R \in L^R{:}\ (l_R, r) \in G\}$ for all $r \in R$.

In summary, ontology can be formally defined to be a structure O. Whereas, L is a corresponding lexicon. Ontology structure O represents an explicit specification of a conceptualisation of some domain. Agreed vocabulary is delivered through lexicon L and allows communicating about this formal conceptualization.

Collaborative data stored in BPP builds the knowledge base of the network about characteristics of network entities, available capabilities. It is important to understand the relations between ontology and knowledge-base. Ontology aims to capture the *conceptual structures* of a domain consisting of intentional logical definitions (characteristics that distinguish concepts). Whereas, a *knowledge-base* aims to specify a concrete state of the domain comprising of extensional parts (entity instances).

At this stage of development, the resulting model does not intend to fulfil the criteria of the formalism presented above. We derive a full-fledged ontology-based model with maximum of expressivity. Aim is to realise a complete transformation of the empirical model into an ontology-based structure. We do not claim at this stage to fulfil all requirements of above defined ontology structure. Thus, the model processed maximum semantics and expressivity during modelling process without considering requirements of information processing through machines. At this stage of development human agents are in the foreground.

Ontology-based model includes concepts of ontology structure. The model does not fulfil formal requirements of ontology. Requirements for reasoning and inference have to be considered. This requires a further step of transformations so that these models fulfil requirements imposed such as OWL-DL, OWL-Lite and OWL-Full.

OWL is a family of richer ontology languages that enhance RDF schema. The simplest language is OWL-Lite, a limited version of OWL-Full that enables simple and efficient implementation. Finally, OWL-DL is a more simple subset for which reasoning is known to be decidable so that complete reasoners can be constructed on this basis, even if less efficient than OWL-Lite reasoners. OWL-Full is the full ontology language which is in theory undecidable, but in practice useful reasoners can be constructed (Motik et al., 2003), (Weiß, 2005). In order to achieve a better understanding of the measurement we describe the seven dimensions of the inter-network analysis (see Table 2).

The example following shows the dimensions of the inter-network analysis in OWL-notation. In the domain of network-company and typology we see the corresponding concepts subsumed under the object property typology is of the empirical dimensions or areas of measurement.

Example:

```

```

Excerpt of BPP: Network Typology in OWL

Next, we continue looking at the structure of business partner profiles.

Business Partner Profile

Business partner profiles (BPP) may differ concerning their structure based on probably varying requirements resulting from type of network, type of involved organisations in a network and as well the objectives and last but not least the branch regarded.

The typical structure of a BPP looks as follows (see Table 3).

Table 2. Measurement – description of dimensions (Weiß, 2005)

no.	concept *network-company*	description/ measured as
1	time horizon	time frame or duration of co-operation (depends on co-operation objectives)
2	trust level	degree of information filtering (exchange of data/ information) degree of trust compensating/ substituting measures (such as control structures, contracts, formal agreements, etc.)
3	flexibility	ability to adapt to/ to react on external developments openness of the network (barriers for entering and leaving the network)
4	integration effort	system interfaces (data formats, standards, soft- and hardware, structure and business processes) case/ work item: complexity, variability, structuredness
5	markets	market structure and constellation in branches (culture: code of conducts, established structures, etc.) strongly influence the emerging structures of collaborative networks Characteristics of markets are maturity (stage of development), intensity of technology, discontinuities, intensity of competition, etc. emerging markets (such as bio-technology, nano-technology, etc.) dominated markets (dominated by multi-national companies, e.g. chemical and automotive industry, etc.) heterarchical markets (no dominating actor)
6	network structure	management of network way decisions are taken in the network hierarchical (focal partner) heterachical (democratic) autonomous (self-organisation)
7	intensity of linkage	measures/ means to control the network (such as contracts, financial and structural dependencies and influence, etc.)

In this chapter we concentrate on descriptions about requirements concerning strategy, structure (organisational) and culture.

Network entities are characterised within the object property “characteristic-is” with the following attributes:

```
<owl:ObjectProperty rdf:ID=
”characteristic-is”>
<rdfs:label xml:lang=
”en”>characteristic is</rdfs:label>
<rdfs:domain rdf:resource=
”#characteristic”/>
<rdfs:domain rdf:resource=
”#network-company”/>
<rdfs:range rdf:resource=
”#contact-person”/>
<rdfs:range rdf:resource=”#branch”/>
<rdfs:range rdf:resource=”#employee”/>
<rdfs:range rdf:resource=”#address”/>
<rdfs:range rdf:resource=
”#performance”/>
</owl:ObjectProperty>
```

(Excerpt BPP of property “characteristics-is” in the domain of concept “network company” in OWL).

Figure 8 shows in a diagram the realisation of the transformation of measurement metrics (empirical model). Despite the fact, that the perspective of intra- and inter-network perspective is illustrated, we focus on inter-network analysis (see right part of the figure).

As described in the previous section, the Semantic Web technology stack was applied for modelling. Figure 9 shows an excerpt of a business partner profile represented in RDF(S). Again, concepts “network company” and “strategic fit” are marked and information of business partners is stored in RDF. Now, that the BPPs containing

Table 3. Business partner profiles (BPP)

topic/ area	description
drivers business relationship	strategy: strategic factors to configure business relationship
	process:b2b-integration concepts and -standards
	information system: description of interfaces, data formats, standards, etc.
output	standardised output of business relationships
partner-specific requirements	needs and preferences concerning strategically, structural, cultural configuration of the business relationship
specific set of co-operation requirements	information concerning implementation of collaborative business processes and collaborative information systems

meta data has been explained, we are looking next at some concrete examples. In this way, underlying principles of the approach chosen are pointed out (Weiß 2007).

At the beginning of the chapter we have described the scenario of digital business ecosystems providing context and background of this research. Figure 1 displays three development stages on the way to electronic networks in the sense of digital business ecosystems. Today, the challenge for electronic networks exists in dealing with resulting complexity of a multitude of social ties, explicit or implicit, latent or activated linking the network nodes.

Weiß (2005, 2007) presents a solution for the scenario illustrated at stage 1. In this scenario a centralised repository or data base is used to store the collaborative data. Despite the fact, that BPP are build as "fingerprint" of network entities, semantics of data relies on a shared data structure or model. On stage 2 collaborative data is no longer stored in a central repository but decentral in BPPs which are possibly part of company's Web site, or any other location on the Web such as portals of online communities, etc. In this scenario which is already far more challenging with regard to processing of collaborative data we still use a common conceptualisation or data model for describing data stored in BPPs. At stage 3 which constitutes from our point of view the most challenging scenario, we have to deal in contrast with different semantics and data structures. Thus, collaborative data stored in BPPs can be retrieved but not interpreted without semantic annotations or meta data describing the retrieved data entries. (See Figure 10)

Whereas, scenario one can be solved with classic data base techniques, the latter scenario requires explicit semantics at stage of processing of retrieved collaborative data. We envision that this meta data is stored in ontologies which describe the data structure and data stored in BPPs. Techniques of information retrieval are therefore analysed as this discipline has already methods and techniques which fulfil our requirements.

The values of variables before stored are aggregated to factors as e.g. trust level according to predefined rules that are as well stored in the ontology-based model. Questionnaire is as well modelled as ontology structure with the subconcepts questions, answers and code. The latter concept contains the appropriate rules how the answers of respondents that are stored as values of variables are to be aggregated to qualitative values (low, medium, high). To determine the degree of similarity of two different profiles relative distances of values are computed. In order to achieve best possible results the stored original values of respondents are applied.

Figure 11 depicts the reference ontology. Company profiles are assessed using a Web-based questionnaire. Profiles are stored as instances of the reference ontology.

Figure 8. Business partner profiles

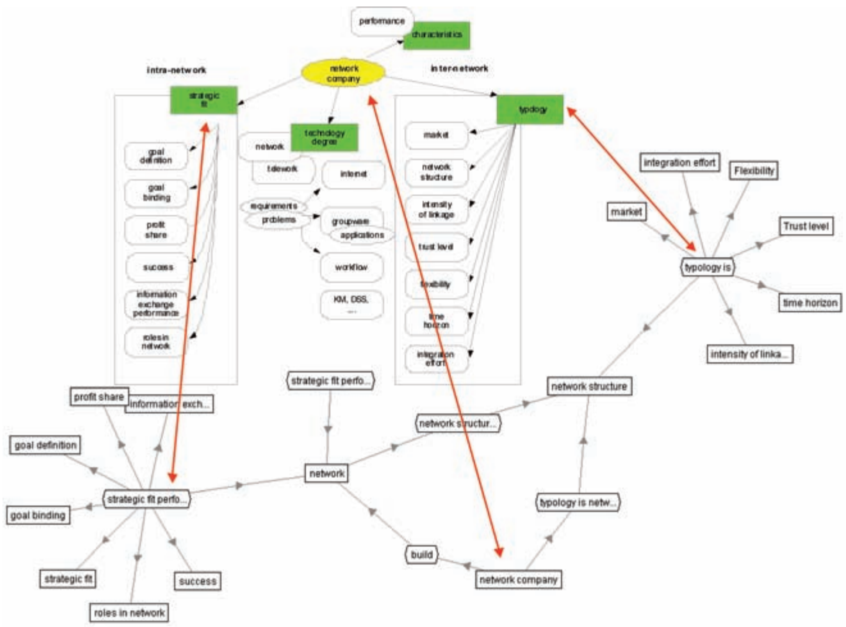

Figure 11 shows a contact person "Hubert" with contact details. "Hubert" is working for a network company "EBV-Elektronik" has a function "others". The strategic fit of the company is medium with regard to the defined criteria. The ICT infrastructure is heterogeneous. The goal binding (gb) with the virtual organisations is medium. The company intends to cooperate in long term with business partners.

Figure 9. Business partner profiles

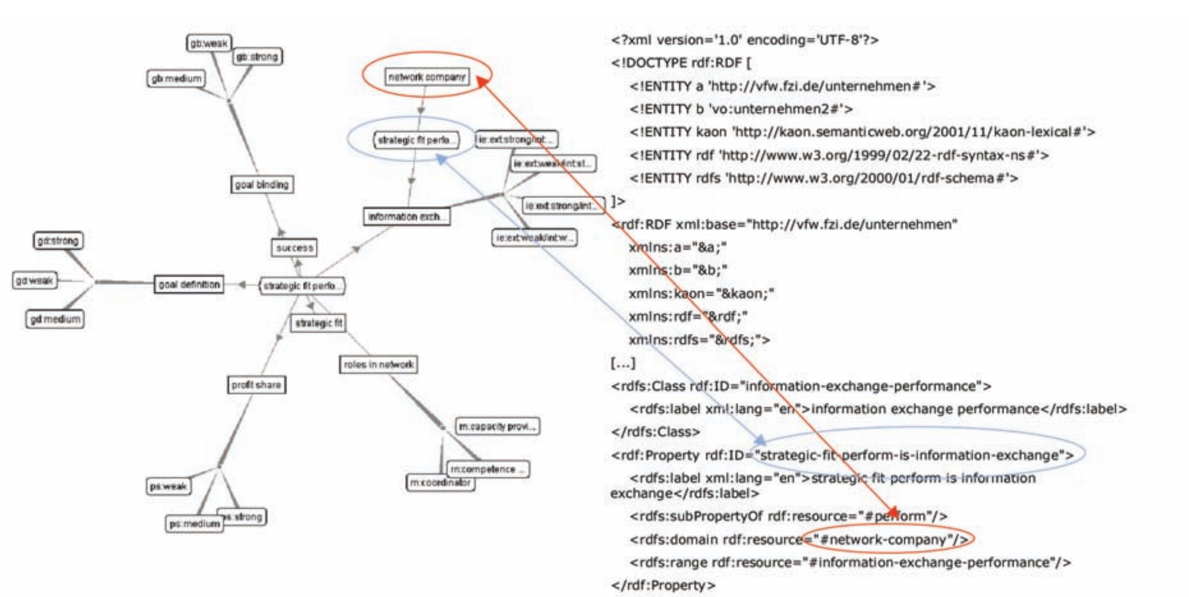

Figure 10. Concept „network company“ and concept „market“

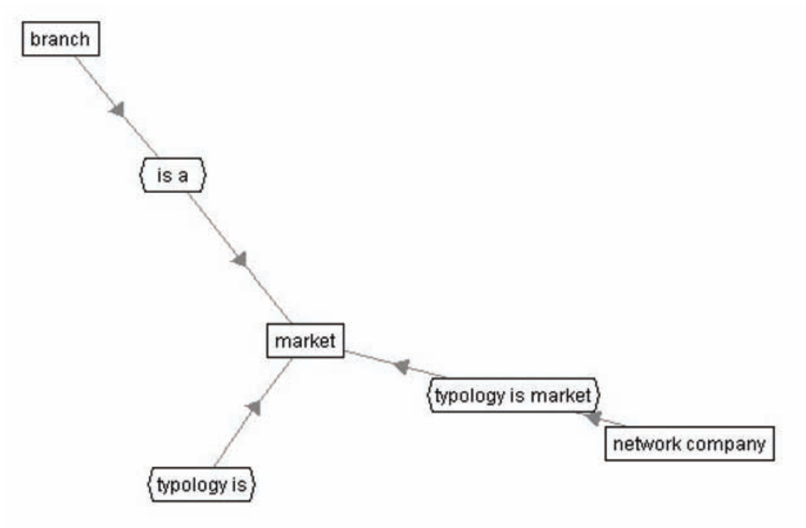


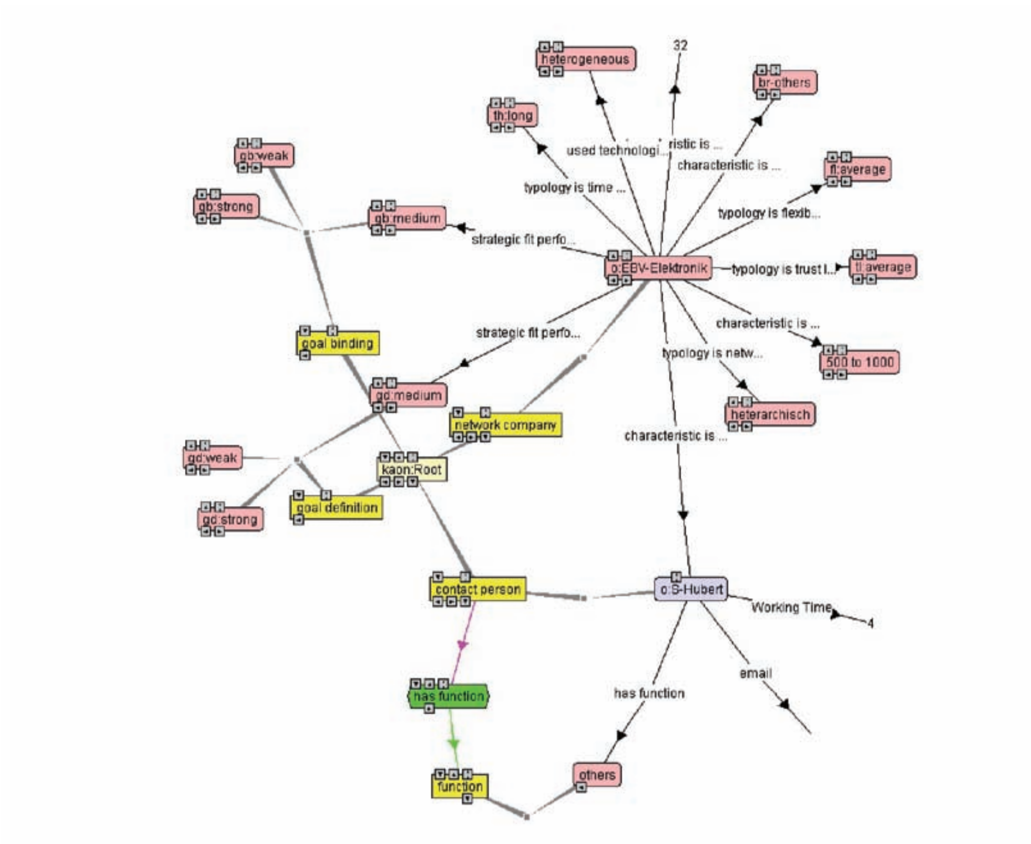
Use Case

Nowadays, cluster management gains momentum and turns out to become an important capability for economic development and management of regions. Following case shall underline the relevance of this research on basis of a concrete use case. Therefore, we describe subsequently cluster management as one possible application scenario to which presented conceptual can be applied to.

Today, cluster management is discussed in the light of regional development and building clusters of excellence and innovation. One important element of cluster management is to set up a central portal which collects and provides information about capabilities, competences, technologies, contacts, etc. in a particular region. Aim is establishing an infrastructure (according to what we have shown in the figure at the beginning: network layers, services, etc.) which supports the interaction of organisations and fosters development of a digital business ecosystem.

In Figure 3 we have already shown the three different layers (personal/ social network (1), organisational network (2) and data sources/ Internet (3)). Following use case describes a real life application scenario in the technology region Karlsruhe. In our region, social networking amongst companies is supported with various organisations. Industry and education, but as well governmental bodies build relational ties. However, what we find are rather small sub-communities which emerge on basis of personal networks and regular physical meetings. It was decided to support the "networking" and interaction of companies electronically with collaborative services. A research group has been established which is currently looking at the design of such collaborative services. Aim is to set up an infrastructure which allows relational ties to emerge. In total, four collaborative services have been considered to be crucial: (1) search for new business partners with required competences, (2) interact with business partners to plan future activities on basis of collaboration scenario, (3) skill/ competences database (in the form of an inventory what is available in the region, (4) classification of network entities by means of standard classification frameworks so that companies can be found in and beyond boundaries of the region or network. Figure 2 presented a possible framework for collaborative network's infrastructure.

Figure 11. Descriptors of concept "network company" in OI-Modeller



The following questions occurred in the process of project planning: *How and who collects collaborative data required? How will it be stored? Shall information be stored in a central repository (data base)? How can this information be explored? Who keeps this data up to date? How can networking be catalysed relational ties to emerge?* Most of these questions are related to designing collaborative services which access and process the collaborate data. In the following, we look in particular at discovery and matchmaking of business partners which shall be seen as basic concepts for design and implementation. We describe how a possible solution and process shall look like. First, we will present the conceptual base on which base we can achieve required services. Then, we sketch how the solution can be implemented and provide an outlook about next steps and future work.

Looking at the scenario shown in Figure 1, we envision a solution fulfilling the requirements at stage 3. This means that collaborative data is stored decentral in profiles. The profiling process is realised using a self-auditing tool, which supports companies to assess necessary data and to build a BPP. Companies which have no BPP can not be searched and consequently, not processed by collaborative services, because no data is provided to feed discovery and matchmaking services. Profile of a company contains ideally information as shown in Table 3.(See Table 4)

BPPs are stored on the Web site of a network company. Thus, collaborative data is kept up to date by the companies itself. Furthermore, this reduces

Table 4. Example BPPs for cluster management

no.	**company details** *(set of attributes: name, location, address, contact, Web site, etc.)*	**branch** *(branch code based on international classification systems, such as NACE)*	**business** *free key words or reference to classification system*	**products/ skills** *classification system such as eCl@ss, UNSPSC, ETIM, etc.*
1	company a	J62.0.1	software, data base, data warehouse management software	19-21-02-11[1] 19-21-02-90 19-23-20-02

3	company c	C33.1.3	industrial maintenance, facility management, equipment f. NF metal production (maintenance, service, unclassified)	25-04-90-90 18-03-98-90

the amount of data to be stored in a central data base. Boundaries of digital business ecosystem are then determined by the reach of their collaborative services and their ability to interpret collected data. Semantic Web technologies, namely ontology, are able to overcome existing barriers by combining with retrieval techniques all over the world. The Internet provides the required infrastructure and new possibilities. Figure 12 shows the ontology as OI-Model with its sub-concepts and related properties.

Primary information to be retrieved is data about location and capabilities of a company. This comprises as well offers of companies which can be imagined to be accessed automatically through respective Web services.

“Company_details” encompass attributes describing the company such as name of company, contact details, etc. Branch of company is described through an international branch encoding system. Business area can be either described by free key words or a key word system such as a classification system. Products and skills are characterised through descriptors taken from product and service classification systems such as eCl@ss[12], ETIM[13], NACE[14] and UNSPSC[15] or skills/ competences frameworks (such as European e-Competences Framework[16]). Alternatively, e-catalogue systems can be considered to offer more detailed product descriptions and pricing.

(Excerpt of BPP of concept "network company": Instances of concepts).

The example illustrates in which way data and information is accessible for collaborative services. Each concept, property and instance can be located with a unique identifier (URI).

RESULTS/RESEARCH

In this section we will discuss the elements of our conceptual framework. First, trust in electronic networks is looked at, before two collaborative services are regarded in more detail, namely discovery and matchmaking. Those kinds of services support business partners to search for business partners in a pool of potential business partners. Matchmaking services support the decision making process through comparing the profiles of the querying company with profiles of other companies. The collaborative data is processed and the degree of similarity expressed as "strategic fit" is determined.

Trust in Electronic Business Networks

Giving a comprehensive explanation and a discussion of trust in electronic business networks is far beyond the scope of this chapter. But nevertheless, it is required to highlight how essential trust is for the success of "networking". Many authors believe that trust can replace contractual agreements and obligations between the network partners. However, business realities show us that most business partners still co-operate on legal basis and a normative document in form of a contract which regulates objectives, purpose, scope and rights and obligations in a co-operation of business partners.

The results yielded from empirical analysis have sustained that information, communication and trust are strongly correlated and inter-dependent (for example see (Jung 1999), (Bienert 2002)). Trust per se requires interaction of business partner over a longer period of time. Thus, some authors argue that relationships in a network are either latent or evident (activated). Latent relationships help to build required trust in business networks.

Commitment is another concept typically referred to in context of business relationships. Commitment expresses the degree of personal bonding, in the sense of the willingness of a network partner to invest in a business relationship in long term. This implies that drawbacks in the co-operation are eventually overlooked for the sake of a prosperous long term business relationship. Thus, commitment of a business partner expresses even stronger ties between network partners that those based on trust. Nevertheless, both terms are strongly interdependent and it is difficult to distinct them. Commitment requires trust that a business partner behaves in the expected way and in the interest of common objectives.

Against this background it becomes clearer that communication and interaction of business entities is vital for the process of trust building. They have to be supported already at early stage of co-operation. Networks rely per se on the personal ties between its members. They are essential for emergence of relational ties within a collaborative and innovation environment. Obviously, increasing dynamics in the interaction of business partners combined with shortening life-cycle of co-operations contradict the nature and actual needs of business relationships regarding trust and commitment. Both concepts occur over a longer period of time and necessitate stable relationships. Once trust is established it reduces opportunistic behaviour. This is substantiated by existing organisation theories as, e.g., transaction cost, principal-agent and property-rights (Picot et al. 2003, pp. 45; Sydow 1992, pp. 130).

Goal is to ease fast and easy docking and quick formation of network entities or new business partners. Whereby, evaluation criteria applied in discovery and selection process have been identified as main study area. Prior criterion to be applied in connexion with selection of business partners is offered business value and ability to complement knowledge, skills and competencies of the network. Aim is to enhance quality and to add value to existing or new products and/or services. As already been pointed out besides these "harder" facts, however, in particular "softer" aspects need to flow into the decision making process.

The proposed ontology-based framework for partner integration aims at developing and supporting trust building mechanisms. Trust building is, beyond any question, a complex issue that offers and necessitates different research perspectives and therefore has been subject to many investigations through different scientific disciplines (Weiß 2005, pp. 81). However, trust building evidently depends on the quality and intensity of communication and information exchange in a collaborative environment. This could be shown by empirical studies (e.g., Jung 1999, p.180; Bienert 2002, p.102). An ontology-based methodology is outlined that facilitates harmonisation and parallelizing of different cultures. In this way, a breeding environment comes into existence from which relational ties and organisational structures are likely to emerge. Moreover, the required characteristic and ability to self-organise are facilitated with self-reference and an initiated learning curve. In this way, a kind of "fingerprint" represents network entities by describing their co-operation ability and requirements. In a process of self-reflection and self-reference relational structures and cultures are then supposed to emerge (Weiß 2007).

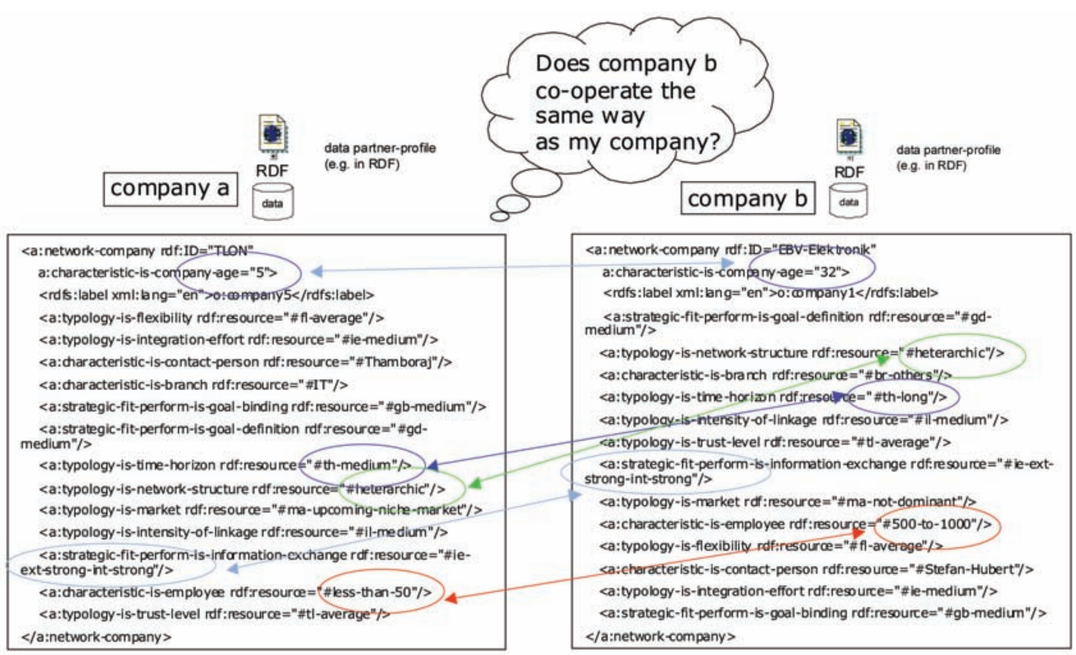
Discovery and Matchmaking

Network companies search for potential business partners using the query user interface of the demonstrator. As an advantage of using an explicit information model in form of an ontology based model, ODAMY is able to use semantic discovery to identify the best fitting partners based on the selected search criteria and applied weightings. Use of ontology brings service provider and service requestor to a common conceptual space and helps in semantic matching of requirements and specifications.

The fingerprint of a network company is produced using a formal explicit ontology-based model structuring criteria for measuring strategic partner fit. In this way, the underlying ICT infrastructure is capable for example to infer that a network company "has" a typology based on 'time horizon', 'integration effort', 'intensity of linkage', etc (Weiß and Maedche 2002).

In Figure 13 an excerpt of fingerprints of two network companies are shown and compared. Company **a** for example is looking for a co-operation with medium time horizon, whereas the network company **b** prefers to co-operate in long-term. The companies share the same conceptual model therefore the values are comparable. A matchmaking environment of a b2b integration technology architecture can process this information and may have discovered and selected business partners **b**. The iep of both companies is 'strong', the preferred network

Figure 13. Excerpt business partner profile (BPP) as "fingerprint" of a network company



structure is 'heterarchical' and the trust-level is 'average', intensity of linkage rated as 'medium' (see Figure 13).

Matching component shall retrieve those cases which show highest similarity with values of the profile of the querying organisation. In the following we look at the matchmaking component. Looking at the vision shown in Figure 1 (stages on the way to the digital business ecosystem) a possible solution retrieves data from BPPs centrally stored. On the advanced stage 2 and 3 we intend to expand the existing boundaries through application of information retrieval techniques.

As an advantage of using an explicit information model in form of ontology based model, it proposed approach enables using semantic discovery to identify best fitting partners based on the selected search criteria and applied weightings. Use of ontology brings service provider and service requestor to a common conceptual space and supports to realise semantic matching of collaborative information stored in the BPP.

Currently, we are investigating the application of different available semantic discovery mechanisms. Particularly, the matchmaking module still requires specifically further investigations and research efforts. However, researchers of different disciplines especially those working in the fields of SOA, electronic markets as well as Web services and business process modelling and management are currently looking into the possibilities to determine the degree of similarity of applied meta models. Therefore, it can be likely taken for granted that a variety of approaches and solutions will emerge soon and will add enhanced functionalities to an adequate matchmaking environment. The task is to search for an existing offer or offers that match each received search query. A central element of a matchmaking environment is the aspect of symmetry (Field and Hoffner 2003). Both sides send a profile that contains relevant data concerning description of the own entity and requirements that the other party must satisfy. According to Field and Hoffner (2003) the customisation of a related service of the ICT infrastructure results from coupling the availability of information from both parties with the ability to update some service properties dynamically.

In the current version of the demonstrator the similarity of profiles A and B is measured as sum of the distances measured of the normed values a_i and b_i of a specific theme i. For each query, themes can be selected from a list of available concepts that can be queried. Each theme i can be weighted in the range of 1 to 5 to enrich the query with individual preferences of the searching entity. The computation of similarity of profiles is described in detail in (Weiß, 2005, pp. 242). Related work of interest is the current developments in the field of Semantic Web services and matchmaking on electronic markets (Veit 2003).

Information Retrieval

As mentioned before, information retrieval techniques offer a huge field for analysing social networks (Klink et al. 2006) and for managing business information (Klink 2006) (Klink et al 2007). Discussing all bits would blast the scope of this chapter. But in particular, the fields of gathering and storing all kind of information and retrieving relevant information are still interesting topics in research which are discussed in various journals (e.g., IJDAR, *Journal of the American Society for Information Science*, etc.) and conferences (e.g., SIGIR, ECIR, ECML, CSCW etc.) and will be touched in the following.

Before a system is able to retrieve relevant information and thus becoming useful, specific information must be gathered from various sources. Especially in business environments collecting information/data and delivering relevant task- and context-specific information is vital (Holz 2005).

In our scenario of b2b environments the collected data is stored and distributed in BPPs. In the case of structured information with known semantic model, BPPs are created using a questionnaire and with the help of a Web-based self-auditing component. This case is described in paragraph 3.4.

In the case of unstructured information and unknown semantic model, BPPs have to be of such expressiveness that information retrieval techniques allow to gather information from unknown network entities (Klink 2006). In this way, network boundaries are expanded and we are able to establish business relationships with new business partners. Recently, business partners are hosting illustrative and informative Web-sites and it becomes a popular way to use Internet search engines for gathering information of potential business partners (Bergman 2000). But also for creating BPPs this is an elegantly way.

Using business Web-sites for gathering information has the advantage that these Web pages contain recent information because business Web pages are updated regularly. But the disadvantage is that Web pages contain unstructured and much information – mostly in textual form. Thus, the problem of information overflow arises (Klink 2004).

An interesting approach for handling the information overflow problem is summarisation. The huge amount of text is shortened and summarised to some paragraphs or some pages, respectively. Summarisation is one of the emerging fields of information retrieval and is a helpful tool for indexing huge amount of data in Internet search engines (Larsen and Aone 1999). In classical information retrieval summarisation is based on full-text data but recently research is more and more based on structured information and is using XML.

Weigel (2006) presents new structural summaries that enable highly efficient and scalable XML retrieval in native, relational and hybrid systems. The work shows that structural summaries significantly improve the efficiency and scalability of XML retrieval systems in several ways. Former relational approaches have largely ignored structural summaries. The results show that these native indexing techniques are equally effective for XML retrieval in relational database systems. Unlike some other labelling schemes, this system achieves high retrieval performance with a fairly modest storage overhead (see Figure 14).

Another interesting retrieval technique which is relevant to our approach using BPPs is called Case-Based Reasoning (Bergmann and Stahl 1998), (Bergmann et al. 2003). Case-based reasoning (CBR), as a sub-area of the field of knowledge-based systems, focuses primarily on problem solving by experience. It provides techniques for representing, storing, indexing, and adapting experience. CBR contributes a rich set of techniques which are highly relevant for experience management, particularly for the activities modelling, storing, reusing, and evaluating (Bergmann 2002).

The general procedure when applying CBR, is commonly described by the classical Case-Based Reasoning cycle introduced by (Aamodt and Plaza 1994) (see Figure 15).

The starting point of a new problem solving-process is a given problem for which a solution is required. This problem can be characterised as a new case for which the solution part is still unknown. This new case—often also called query—is then processed in four consecutive steps: retrieve, reuse, revise, and retain. The advantage of using CBR technologies is the learning ability of the system. The more the system is running and the more BPPs and ties to partners are created, the better and the more "intelligent" the system becomes.

Using CBR vocabulary, the cases in our scenario are the BPPs, the problem is finding an appropriate business partner and the solution is the best fitting business partner. More precisely, if some business is searching for appropriate partners then the BPP of this business is used as the new case. In the retrieve phase, previous cases (in our scenario similar BPPs) are searched in the (general) knowledge database. In the reuse

Figure 14. +Three-Level Model of XML Retrieval relates queries (top level) to their matches in the document tree (bottom level) and the corresponding hits in the schema tree (intermediate level) (Weigel, 2006)

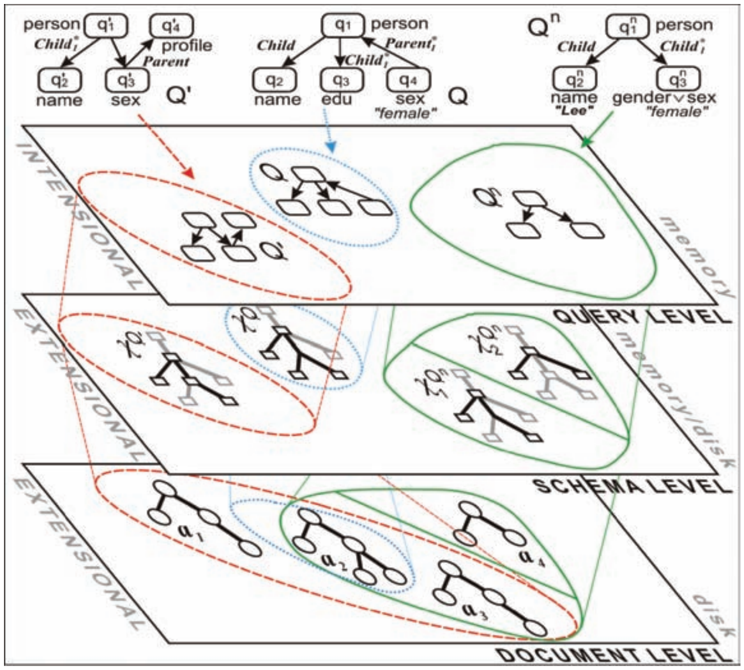


Figure 15. The Case-Based Reasoning Cycle by Aamodt & Plaza

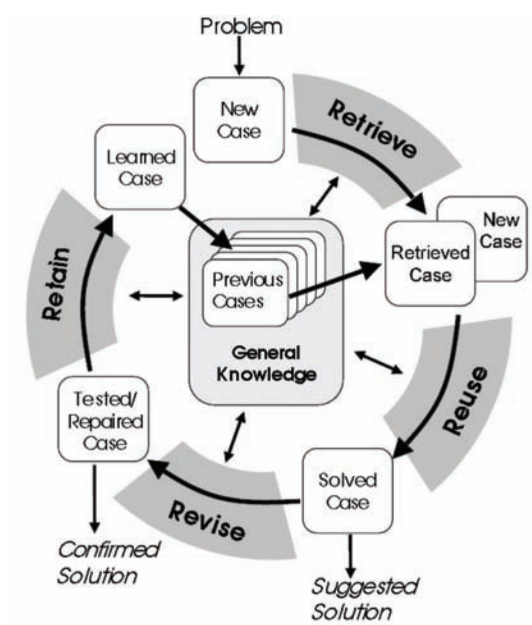

phase, the solutions of retrieved cases are used, i.e. each stored appropriate partner is given as a suggested solution. If the solution is confirmed, then these partners are stored as the solution of the new case and the new (learned) case incl. the solution is stored as an additional previous case in the knowledge database.

Implementation

ODAMY is implemented using KAON infrastructure (KAON Dev. Guide 2003). KAON is an open-source ontology management infrastructure targeted for semantics-driven business applications. It includes a comprehensive tool suite allowing easy ontology management and application. Important focus of KAON is on integrating traditional technologies for ontology management and application with those used typically in business applications, such as relational databases. KAON consists of a number of different modules provid-

Figure 16. KAON tool overview (Gabler et al. 2004)

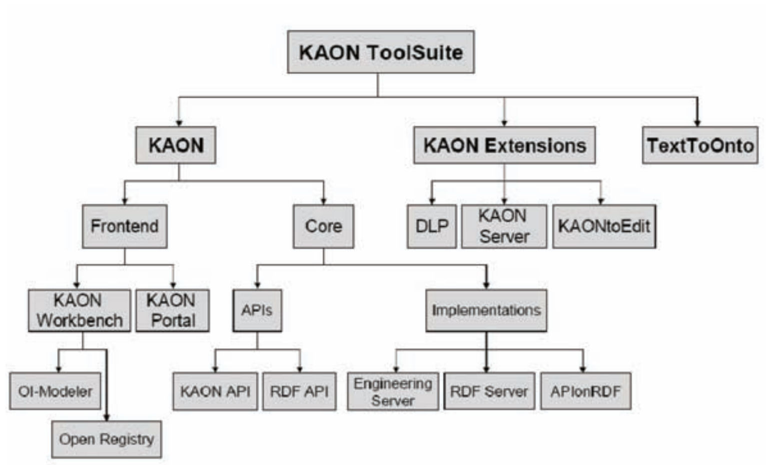

Figure 17. Concept "Questionnaire" and its subconcepts in OI Modeler

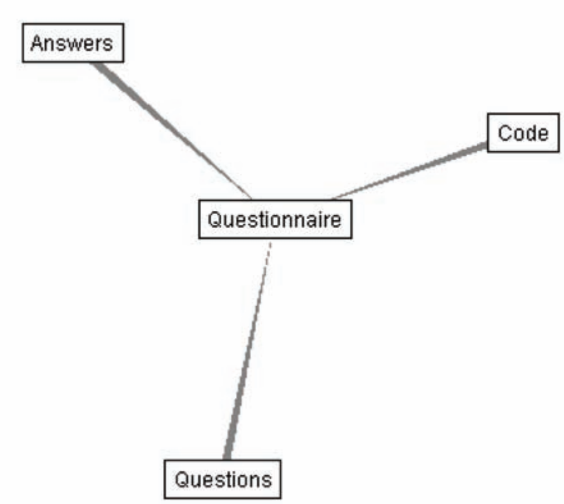

ing a broad bandwidth of functionalities centred around creation, storage, retrieval, maintenance and application of ontologies (Gabel et al. 2004). Typical model elements of KAON OI-Model are concepts, properties, property ranges (property-centric, several ranges), attributes (of type string). Min-max cardinalities are a feature but are depending on API implementation. In the following, we do not consider cardinalities for the modelling. Further features are lexical layer, modularization, evolution and meta-modelling. Main feature used for conceptual modelling is OI-Modeller (ontology editor). For implementing the self-auditing tool KAON portal is used. Figure 16 shows diagrammatically the KAON toolsuite.

BPP are created using a questionnaire which assesses the entry values for different variables. The value of these variables are then computed and aggregated according to predefined rules to values for the aggregated factor values. Figure 16 shows diagrammatically the three subconcepts which shall store assessed data set for each network entity. Concept "Answers" stores the response value for each question (variable). "Questions" contains the questions of the questionnaire. Concept "Code" assigns each value entry a classification code as class identifier.

Figure 17 shows parts of the ontology-based model: the concept "Questionnaire" and its subconcepts "Answers", "Code" and "Questions". This part of the model stores important information to deal with the life-cycle of a BPP. Entering the inter-organisational network corresponds to filling in the questionnaire and producing a BPP. Entities which do not possess a profile are not seen as part of the (electronic) network consisting of latent and activated network relationships. Once a

BPP is created collaborative services can be used to establish and maintain business relationship management electronically. In the light of steady increasing number of network nodes humans are no longer able to deal with resulting complexity. We see future networks according to (Krystek et al. 1997) as open, many inter-organisational relationships and of high reciprocity.

Referring to concept "Questionnaire", dealing with dynamics is an important feature in the given context. As already mentioned our work aims to develop a conceptual model which allows to design and develop collaborative services which are able to process the collaborative data stored in the BPPs.

In the following we explain how the model stores assessed collaborative data, and how this information shall be processed through services.

A Web-based self-auditing component supports a network entity in describing its profile. The auditing component consists of a questionnaire. The component has been realized using Java Server Pages and tag libraries which are directly connecting to the API of the KAON-Toolset. The created profile is directly stored as a set of instances into the ontology structuring the network (case base).

Having a look at following example which displays a typical data entry taken from the questionnaire. As shown, the topic is "intensity-of-linkage" as already described in previous section. "102053" documents the origin of the data entry and is stored as cross-reference of the questionnaire.

For each data entry (answers of respondent) an instance is produced in concept "Code" and stored in the ontology structure. For the instance a link or relationship is established with the concept "Answers" (number of the question within a topic in the concept and the concept "Questions". The stored answer is referencing to the respondent (in our case the network entity). In addition we have a concept "Rule" which stores information how the stored qualitative data has to be processed in order to achieve "qualitative" values. Typically, these values have the range low, medium or high (see Figure 7).

As our implementation is realised with KAON-Toolset, each data entry has a URI which provides the object with a unique identifier. As we have as well defined a respective namespace, the discovery of data entries is not restricted to borders of the regarded network.

Example:

```
<rdf:Description rdf:ID="102053">
  <rdfs:label xml:lang=
    "en">102053</rdfs:label>
  <rdf:type rdf:resource="#Code"/>
  <entry-with rdf:resource="#3"/>
  <entry-in-topic rdf:resource=
    "#intensity-of-linkage"/>
  <entry-in-question rdf:resource=
    "#Question5"/>
  <entry-in-complex
    rdf:resource="#typology"/>
</rdf:Description>
```

(Excerpt BPP of concept "intensity-of-linkage" in OWL: value entry of question 5 of the inter-network analysis).

CONCLUSION AND OUTLOOK

In this chapter we elaborated the conceptual basis for establishing and maintaining electronic business relationships. We overlooked current state-of-the-art of business networks and motivated future scenarios of digital business ecosystems. Growing popularity of business communities indicates a noticeable change and openness of business partners to publish information and data (far more than just contact details, comprising career steps, competences, and business interests).

Prominent communities are, e.g., LinkedIn, Plaxo or Xing, the latter with daily up to 30,000 users online. We highlighted that collaborative services supporting business networking and the management of business communities and networks, respectively, are demanded and are expected to have tremendous social impact on how electronic business will be conducted in the future.

The chapter motivated a development path towards digital business ecosystems comprising three distinct development stages. In particular, the scenario shown at stage 3 imposes interesting questions and challenges such as gathering unstructured and textual information from business Web sites.

Furthermore, we introduced business partner profiles (BPP) as an appropriate concept to overcome existing barriers of electronic networks. Limitations currently exist primarily with problems related to gathering and storing of all kinds of business and collaborative information. With the emergence and fast growing of business communities on the Internet, available amount of collaborative information is exploding and challenges current retrieval and analysis techniques. We highlighted some of these challenges and looked at how networks can be analysed from an inter-network perspective.

Additionally, we looked at information retrieval techniques, namely case-based reasoning and gathering of unstructured information. Ontologies are able to describe underlying data structures and semantics of data stored in BPP. Retrieval techniques allow gathering and storing information from unknown network entities and in this way enable supportive collaborative services to maintain electronic business relationships.

We presented a use case which highlighted a possible application scenario in the context of cluster management. Finding business partners and gathering information from business partners is an important task.

Business Web-sites are used for gathering information as they contain relevant business data in unstructured or textual form (typically in HTML or XML-format) but are updated regularly. However, businesses are hosting informative Web-sites containing plenty of information about competences, offerings, products and capabilities of a company. Thus, search engines have become a popular way to use the Internet as an infrastructure to maintain business relationships and to collect information about potential business partners. Ontologies provide required meta data to make information stored on business Web-sites more expressive and self-descriptive. Nevertheless, standards (such as NACE, UNSPSC, eCl@ss, etc.) and reference models (e.g., competence grids such as the European e-Competence Framework) shall be used to structure and reference contents of profiles. Besides, frameworks should be transformed by means of XML-based ontology languages as, e.g., OWL ontologies to serve the needs of our application scenario.

The use case at hand used existing classification systems for structuring and describing this information and data. Besides classification systems we used an empirical model to assess collaborative information from business partners. This information is stored in BPP to support emergence and postulated ability of business networks to be self-descriptive in order to distinct themselves from their environment (an ability called "self-referencing"). Both characteristics are foundations for self-organised systems. Collaborative services primarily aim at supporting self-organisation as it can be seen as one of the key drivers of digital business ecosystems.

Another strand we looked at is case-based reasoning. Case-based reasoning provides techniques required for implementing our collaborative services. It provides the ability to learn from daily experience and to induce intelligence in collaborative services not exclusively related to business relationship management by building required knowledge-bases.

The chapter provided answers primarily on conceptual basis but was at this stage not yet able to provide a proof of concept. For implementation of the presented approach we use KAON infrastructure. Ontology development tool sets have matured during the last years. KAON tool set is used to build BPP by means of a self-auditing tool which uses a standardised questionnaire. With regard to implementation of a software prototype, we envision in a next step further implementing the use case "cluster management" referred. For this purpose BPP profiles have to be build and implemented in a lab environment to apply state-of-the-art query and retrieval techniques. State-of-the-art techniques of information retrieval and Semantic Web have to be combined with methods of social network analysis.

The chapter described and discussed necessary foundations for discovery and matchmaking services. Fast growing acceptance and maturing of business communities will offer interesting use cases for analysis and further research activities. One of the biggest challenges ahead is to learn and to substrate necessary theories and methods from real life cases.

At the beginning of the chapter we have introduced a framework structuring the research area. The framework highlights required interdisciplinary nature of our future research design. Next step to be done is to use the self-auditing tool to build BPP. This will allow working with real life data and to set up a lab environment to analyse, explore, and validate presented concepts.

Chapter 5.8

The Use of Social Media by Nonprofit Organizations:
An Examination from the Diffusion of Innovations Perspective

Richard D. Waters
North Carolina State University, USA

ABSTRACT

Nonprofit organizations are an essential part of the social, political, and economic landscape of contemporary society. Social media provide ample opportunities for these organizations to increase their community presence, impact, effectiveness, and efficiency. A qualitative study of 39 nonprofit leaders explored how nonprofits are utilizing the potential of the social media technologies to carry out their programs and services. Thematic analysis revealed that nonprofits are slowly embracing the possibilities offered by the new social interaction technologies. Most nonprofit organizations lag behind and wait to see how other nonprofits incorporate these new communication outlets into their budgets and daily operations. Paralleling Rogers' diffusion of innovations theory, innovators and early adopters are using social media to revitalize their fundraising and volunteering efforts while the majority lags behind.

DOI: 10.4018/978-1-60566-368-5.ch042

INTRODUCTION

Nonprofit organizations are an essential part of the social, political, and economic landscape of contemporary society. They provide a way for individuals to connect to their communities, effectively participate in the democratic process and ultimately to "make a difference." Currently, there are more than 1.9 million nonprofits in the United States (IRS, 2006). Though it is difficult to generalize about what nonprofit organizations are or what they do, most of these organizations share similar experiences, for example, raising funds or attracting volunteers.

Despite widespread interests (e.g., healthcare, economic development, religion, political, and social issues), a nonprofit organization can be defined as a voluntary association of a group of individuals bound together to pursue shared missions or goals (Lohmann 1992). In such mission-based organizations members are neither forced to relate nor enticed by the prospect of personal profit or gain, while their operation is facilitated by an endowment of resources. Through their mission-oriented work, nonprofits generate social capital—the attitude and willingness of people to engage in collective activity to address issues on the basis of shared values and beliefs, which in turn reinforce trust, confidence, and commitment of the participants (Hall, 2005).

Although nonprofits vary enormously in scope and scale, ranging from informal grassroots organizations with no assets and employees to multibillion-dollar foundations, they are facing new challenges as technological advances change the way nonprofits carry out their missions. Moreover, external stakeholders increasingly influence nonprofit organizations to adopt new technologies, including social media. The present chapter introduces a qualitative study of 39 nonprofit leaders designed to explore how nonprofits are utilizing the potential of social media to carry out their programs and services. During the study, twelve one-on-one interviews and three focus groups were conducted with nonprofit organization communicators.

BACKGROUND: NONPROFITS AND WEB 2.0 TECHNOLOGIES

Accountability and Transparency

Topper (2007) encouraged nonprofit organizations to consider all types of social media to help spread the word about their programs. Whether it be through RSS (Really Simple Syndication) feeds, Twitter updates, or podcasts, increasing the awareness of a nonprofit's activities will ultimately benefit the organization in terms of increased donations, volunteer hours, and participants in their programs and services. "It's pretty simple really. My job is to do anything I can to help educate people about what we do. Technology is helping me reach more people than our newsletter and brochures ever could," said one senior communications officer for a nonprofit research organization participating in the interview.

RSS feeds, podcasting, and making pictures or videos of the nonprofit's events available through sites similar to Flickr or YouTube are still mainly a one-way distribution of information. Albrycht (2004) encourages nonprofits to truly become interactive with their stakeholders by blogging about their successes and failures. Blogs can be useful in spreading word about a nonprofits' programs or services, but they can also be used to address an individual's questions and concerns (Wasserman, 2005).

Increasingly, nonprofit organizations are being challenged to demonstrate their accountability to donors, their operating community, and their clients and program participants. Blogs provide a channel for open communications. Individuals can openly question an organization's practices in front of their virtual peers, and the organization's answer (or lack thereof) is available for everyone to scrutinize. Marken (2005) argues that an organization's blog can provide a powerful strategic and tactical communications tool because it offers an organization the opportunity to respond to inquiries directly. This direct communication works to solidify relationships the organization has established with its stakeholders. When organizations fail to respond to comments or delete them from their blog, they risk damaging the trust they have built with their stakeholders.

Finally, blogs allow individuals to discuss a nonprofit's events in a manner that brings people together. "Last summer, we wanted to hold rallies to draw attention to the harm (a company's) operations were causing to the local watershed. We posted an announcement on our blog and had a lot of replies within 24 hours," explained one of the participants during the focus group discussion.

"The connections we made online resulted in a large turnout at our rallies." For this nonprofit organization the virtual connection resulted in a unified voice addressing an environmental concern in the physical world.

Fundraising

Social media are also helping considerably with nonprofit organizations fundraising efforts. As it was noted in the previous research (Waters, 2007b), nonprofits organizations incorporate blog management into their online fundraising, efforts because blogs offer an effective and economic means of two-way communication with potential donors. One study participant in charge of fundraising said: "We had one donor say he gave to our organization because of our blogging. We answered his questions about our programs in a timely manner, and he wanted to see us continue to advance our cause."

Recently, new websites have been created to facilitate charitable donations to nonprofits in lieu of birthday and wedding gifts. Sites, such as ChangingthePresent.org, allow individuals to register their special occasions online and have invitations sent to family and friends. These invitations encourage the recipients to donate to a specified nonprofit organization instead of purchasing a gift for the event's host.

Cybervolunteering

One new aspect of nonprofit organizations has emerged because of social interaction technologies. *Cybervolunteering* is similar to traditional volunteering in that an individual gives time and effort to work for an organization, except the work is done remotely through an Internet connection rather than being required to be onsite to complete the tasks. Online volunteers perform a variety of tasks, including: translating documents, proofreading and editing reports, designing logos and communications materials, moderating online discussion groups, and even database management. Virtual volunteering has helped many smaller nonprofit organizations attract volunteers with highly technical skills because the volunteers are able to perform work on these complex projects on their own time rather than having to work only when the nonprofits are open (Cravens, 2000).

Virtual volunteering has helped increase awareness of some nonprofit organizations' services because of *vlogging (*or *video blogging*). Similar to text-based blogs, vlogs provide regular updates and commentary on a topic through online videos. "We simply don't have the resources to produce our own videos, but one of our virtual volunteers videotapes our events and activities then edits them down to short videos that we can distribute to our donors and government officials," emphasized an interviewed communications officer from a nonprofit focusing on substance abuse recovery.

Volunteers are able to develop sophisticated videos that can be presented on YouTube, Google video, or the organizations' own websites. While these video presentations can be helpful, many organizations wish to have more control over their content. The organizations may record their own footage, upload the files to the Internet, and relay them to their cybervolunteers, who work remotely for a nonprofit organization to edit the video clips down into a clip ready for widespread Internet distribution.

Online Scheduling and Internet Conferencing

Previous research has found that nonprofits use websites, such as Meetingwizard.com and other online meeting scheduling services, to arrange meetings for their boards of directors (Lipnack & Stamps, 2000). These scheduling services offer for those who are invited to the meetings the ability to reserve a seat at the meeting or state that they would not be attending. One of the study participants, a communications director for a healthcare nonprofit said: "We use a scheduling system online that allows our board members to tell us whether or not they're coming to the meeting. The system also lets them read the minutes from the previous meeting and also lets them discuss the agenda before the meeting starts."

Internet conferencing has also helped nonprofits reach a larger number of constituents. A public information officer for a nonprofit educational institution who participated in the focus group noted, "Instead of just looking at people in our city, we're now able to reach out and help people across the country. Our local research and planning efforts are now having an impact on communities all over the U.S." By taking advantage of the boundary-free reach of the Internet, nonprofit organizations are able to increase the magnitude of their training and strategic planning efforts by reaching larger populations while reducing the costs of holding sessions on-site (Mitschke, 2008).

Whereas some scheduling software allows individuals to offer comments about a meeting's agenda or minutes from past meetings, one participant volunteered that his organization was actively incorporating a *wiki* - a social software application that allows multiple users to add and edit content collaboratively. Another focus group participants said, "It took some convincing but now that our wiki is up and running, we're getting great feedback. It lets our senior staffers share their knowledge about organization procedures in a non-threatening manner." Fitch (2007) felt that wikis would be a valuable institutional resource since content can be updated and maintained by all users and can be instantly updated as the organization's environment changes.

Technical Assistance

One final area where social interaction technologies are used by nonprofits involves the organizations reaching out to one another for technical assistance in implementing new technologies. Nonprofit organizations, large and small, have embraced the Internet Relay Chat, instant messaging and most commonly online forums so that the sectors can turn to one another for help in designing and evaluating programs and services. One such forum hosted by TechSoup.org is dedicated to nonprofit sector employees and volunteers who have an interest in helping others working in the nonprofit sector to solve information technology problems. TechSoup.org and other similar forums are also used to help develop coalitions and grassroots movements within the nonprofit sector so that societal issues can be brought to the forefront of the public's attention (McNutt & Boland, 1999). The Nonprofit Technology Network (NTEN), a membership organization of nonprofit technology professionals, helps the nonprofit sector utilize the latest technology resources to enhance community outreach and pursue effective fundraising, including online fundraising campaigns.[1]

THE USE OF SOCIAL INTERACTION TECHNOLOGIES BY NONPROFIT ORGANIZATIONS: A QUALITATIVE STUDY

Nonprofit organizations often face operational and technical challenges in carrying out their missions due to the financial constraints. However, one recent survey revealed that public relations practitioners in nonprofit organizations were not laggards in the adoption of new technologies (Porter & Sallot, 2003). Instead, they were found to be advocates for new technology. The purpose of the present study was to explore how nonprofit organizations use social media and for what purposes.

Prior Research

Review of literature on the topic of the use of technology by nonprofit organizations shows that they have slowly come to adopt new interactive online applications and services (Porter & Sallot, 2003). Employees of nonprofit organizations mostly use the Internet for productivity, efficiency, research, evaluation, and issues management (Sallot, Porter, & Acosta-Azuru, 2004). Nonprofits are generally successful in giving their organization a professional virtual presence and have been encouraged to capitalize on the interactive nature of the Internet to reach out to like-minded individuals when focusing on advocacy efforts (McNutt & Boland, 1999; Waters, 2007), but they often fail to incorporate interactive elements and two-way communication into their websites (Kang & Norton, 2004).

In part, their reluctance to incorporate the elements of interactivity has been based on their lack of sufficient resources to maintain sophisticated websites (Hill & White, 2000). Nonprofits often have minimal staff to monitor communications efforts, such as web traffic and Internet requests (Guo & Acar, 2005). Instead, they are more likely to dedicate their time, energy, and financial resources to carrying out their programs and services, rather than their communication efforts (Markam, Johnson, & Bonjean, 1999).

Ryan (2003) raised additional concerns. A survey of nonprofit communicators showed that most practitioners have the skills needed for effective web communication. However, they struggle with teaching others the components of good websites. Training in concepts and technical skills were also shown to be problematic. Yet, nonprofits recognize the beneficial nature of web-based communication, and they are making efforts to increase their competencies especially as they see how the medium can benefit their organization's programs and services.

Corder (2001) indicated that nonprofit organizations are more likely to use interactive technologies and emerging social media if their external stakeholders, such as donors or volunteers, are using them. With the expansion of social interaction technologies, nonprofits quickly have to learn how to use different applications, or they risk being viewed as behind the technological curve (Var, Chon, & Doh, 2001). Increases in web-based inquiries, the exponential growth of e-philanthropy (or Internet-based fundraising) and new developments in social media have led nonprofits to become more engaged with the Internet.

Theoretical Perspective

It takes time for innovations to diffuse within a system, and organizations go through several phases while implementing an innovation. These stages begin with identification and move through experimentation and rationalization before widespread technology transfer occurs (Raho, Belohlav, & Fiedler, 1987). Lundvall (1992) argued that technological change is gradual and cumulative in nature.

For more than six decades, scholars have studied how innovative technologies expand throughout social groups. The diffusion of innovations theory by Everett Rogers examines "the process by which an innovation is communicated through certain channels over time among the members of a social system" (2003, p. 5). Research has shown that innovations are largely spread through interpersonal channels and networks. The first adopters of technology are *innovators*, enterprising individuals who imagine the possibilities of the new technology and are eager to try it.

As innovators test the new technology and discuss their experiences, *early adopters* take mental notes based on the evaluations of the innovators to confirm their decision to either adopt or reject an innovation. Early adopters are known for their well-informed decision making abilities, and they often represent the opinion leaders in a community. When the early adopters share their experiences, it creates a domino effect throughout the rest of the social system as the *early majority* group adopts the innovation. After the majority of a social group adopts an innovation, the *late* *majority* catches on. Rogers labels the last few members of a population to adopt a technology, *laggards*.

Research Questions

The diffusion of innovations theoretical perspective discussed above informed the following research questions:

RQ1: How are nonprofit organizations using social interaction technologies?

RQ2: How often are nonprofit organizations incorporating these technologies into their efforts?

To answer these exploratory questions, twelve in-depth interviews and three focus group discussions were conducted. Although the findings cannot be generalized to the entire nonprofit sector because of the qualitative nature of the study, the researcher used a purposive sampling design to ensure that the participants were selected with a variety of experiences in adopting social interaction technologies. The interviews and focus groups were conducted outside of the nonprofit organizations so that the participants felt comfortable to discuss their organizations' use of technologies openly.

Participants

The participants in this research study represented the diverse composition of the nonprofit sector. They came from a variety of cultural backgrounds: Caucasians (41 percent), Black or African Americans (26 percent), Hispanic/Latinos (13 percent), and Asian/Pacific Islanders (10 percent), and Native Americans (10 percent). More than half (62 percent) of the participants were female. Slightly more than half worked at nonprofits with budgets larger than $1 million, and 38 percent worked at organizations with annual budgets under $300,000. All six of the Association of Fundraising Professionals' nonprofit subsections were represented: namely, arts/culture, education, health, human services, public/society benefit, and religious organizations.

Sampling Technique

Snowball sampling was used to recruit active users of social software in the nonprofit setting after three individuals responded to an initial online invitation posted on the TechSoup.org discussion board. During the interviews, participants were asked about their motivations for using the technologies, how they used social software, and what were their successes and failures with incorporating social media into their organization's communication practices. At the conclusion of the interviews, the participants were asked if they knew any other nonprofit organizations that were actively using Web 2.0 technologies or specifically individuals who might be willing to discuss their organizations successes and failures with the new technologies.

Focus Groups

For the three focus groups, participants were contacted based on their membership in professional communication associations, such as the Public Relations Society of America, the International Association of Business Communicators, and the American Marketing Association. All of these associations have nonprofit organization divisions. These individuals were informed that there would be no financial compensation for their participation; however, they would be exposed to others' views on the benefits and challenges of incorporating social software into their communication efforts. Refreshments were served at the beginning of the focus groups, and an experienced moderator was used to ensure that all focus group participants had the opportunity to speak about their experiences with social software whether they were experienced users or had not implemented the strategy into their programming.

Interviews

For the one-on-one interviews and the focus group sessions, both audio and video recordings were made to maintain accuracy in the participants' meaning. Following an approved institutional review board protocol, participants were required to sign a form indicating that they consented to be recorded. In-depth interviews and focus groups were chosen for this project since these methods allow researchers to openly explore the issues without trying to classify them into predetermined categories (Creswell, 1997).

Thematic Analysis

Thematic analysis involved reading the transcriptions and comparing each statement with the others while looking for similarities and grouping them together by category (Lindlof, 1995). Once the data stopped providing new insights into the subject being examined, the process ended. However, the researcher had to take the findings back to the participants for a member check phase to make sure that their words and experiences were interpreted correctly. Validity checks prevent the researcher from coming to faulty conclusions based on the analysis. Member checks were conducted within ten days of the final analysis.

RESULTS AND DISCUSSION

The first research question sought to determine how these nonprofit organizations were incorporating social media into their daily operations. Thematic analysis revealed that social interaction technologies were used to facilitate virtual meetings, to boost fundraising efforts, to demonstrate an organization's accountability and transparency, and to reach out to a new group of volunteers.

Though the results of this qualitative study cannot be generalized to the entire nonprofit sector, they highlight some major points of emphasis that parallel Rogers' diffusion of innovations theory. The three participants of the in-depth interviews who responded to the initial posting on TechSoup.org were clearly innovators, using diffusion terminology. Throughout the interviews, they spoke proudly of what the new technologies were allowing them to do with their organizations in ways that the organizations' management and board of directors had not imagined. One female participant (communications officer) said: "My [executive director] knew that web conferencing was a possibility but she had no idea how easy it was to use. It has increased our efficiency tenfold, especially with conducting our board meetings. We're not tied to having a monthly meeting in a location that requires members to drive to and from the meeting every month. They're happier, we're happier, and our work is being done more effectively."

Another public relations officer said that they had begun using web conferencing as a way to connect their affiliate branches throughout the Southeast. "Social media are helping us reduce the amount of money we spend on overhead. We can meet virtually, get the same amount of work done, and not run up travel expenses."

As the number of Congressional hearings (e.g., 2005's "Charities and Charitable Giving: Proposals for Reform") and public scrutiny intensify, nonprofit organizations have had to work harder to demonstrate their social and fiscal accountability. In 1999, the Independent Sector - a coalition of corporations, foundations, and nonprofit organizations that work together to strengthen America's nonprofit sector - conducted research and found that public confidence ranged from 28 percent to 72 percent for different types of nonprofit organizations (Saxon-Harrold, 1999). A Gallup Poll from May 2005 found that only 15 percent of the American public has a great deal of confidence in charitable organizations (Light, 2005).

The falling levels of confidence were due to the increasing number of questions the public has about the effectiveness and efficiency of nonprofit organizations. Light (2005) maintains that the public is less concerned about nonprofit organizations' ability to "show us the mission" but instead is more concerned with how nonprofits can demonstrate their impact and reduce the amount of overhead they spend on their programs. As the use of social media advances through the stages of the diffusion of innovations process, more nonprofit organizations will come to see that social media can help them demonstrate their financial and social accountability to audiences that are becoming increasing more web savvy.

Of all the advances the Internet has brought to nonprofit organizations, they seem most receptive to how it has changed their fundraising efforts. A representative of the Harvard Business School commented that nonprofit management officers who fail to recognize the power of e-philanthropy will find their organizations falling behind the curve. Organizations seem to be receptive to incorporating web-based fundraising; however, they have not truly grasped the benefits of social media yet. Increasingly, nonprofits are recognizing how blogs can be used to maintain a two-way communication channel with their donors and like-minded individuals. They also have begun to explore the impact of YouTube, Flickr, and other video and photograph sharing sites as vehicles for spreading information about their programs.

Interestingly, the results of this research contradict the findings of previous nonprofit organization studies. Often, changes stem from the nation's largest nonprofits and trickle their way down to smaller, local nonprofit organizations. For example, the national headquarters of the American Red Cross was one of the first organizations to conduct official fundraising campaigns online after the 1999 Kosovo relief crisis. Their successes led other larger, established nonprofits to experiment with online fundraising (Wallace, 2003). Waters (2007b) documents the rapid expansion of Internet fundraising from large nonprofits and notes how they expanded to smaller community-based organizations.

The participants in this study indicated that a reverse effect might be present. Perhaps because of the strong connectivity involved with social media, smaller nonprofits tend to be innovators and early adopters of social media technology. One participant said: "Smaller nonprofits are at greater risk for falling by the wayside because they don't have a huge financial endowment to fall back on during tough times. They need to reach out to their donors, volunteers, and everyone else however they can reach them. Facebook, YouTube, and all the other websites give us more channels to reach people."

Reflecting the diffusion stages, one public information officer from a large national nonprofit admitted the following: "We lag behind others in how we use technology. We have to follow the guidelines from our national office. We can't take advantage of Facebook or YouTube with local efforts because of the possibility of risking the national brand." For this individual, there was a desire to explore social software within the local organization; however, a bureaucracy prevented the organization from pursuing this option.

For others, they seemed to fall into the late majority, or laggard cycle, simply because they were unsure of how to use social media to advance their causes. "I really would love to be able to record a video and send it out to people when we have good news to share, but I just don't know how," said one participant dealing with fundraising. Still for others, the current success level using traditional communication channels has prevented their organizations from reaching out to new communication technologies: "My boss says if it's not broken, why fix it. I think we could benefit from seeing how other nonprofits are using the technology, but a strong resistance to change is keeping us from moving forward."

As the *Chronicle of Philanthropy* and other nationally recognized nonprofit trade publications highlight the successes of organizations that use the social media, increasing numbers of individuals will recognize the potential the software has for their organizations. Though it may take time for nonprofits to truly incorporate social media into their communication practices, the exponential growth of the use of these technologies by the entire American public—not just the "Millennial generation"—will result in greater understanding of social media and how it can be used effectively.

The second research question sought to determine how often nonprofit organizations were using social interaction technologies. Even though the study participants offered several different examples of how social media helped them advance their missions, several nonprofit communicators expressed concern about the implementation. "I see the benefit of these strategies, I really do. But, I simply don't have the time or resources to dedicate to using them," said a public affairs director for a large religious nonprofit. Another communications officer asserted, "If I had more time, I would really like to see [my organization] produce some podcasts or videos to help get our messages out beyond our core supporters." Finally, one public relations director stated, "People who use the Internet a lot get annoyed when they don't get immediate replies. I wish I had the time to be able to sit in front of a blog and monitor it all day, but I don't."

Another concern that nonprofit organizations had involved the training necessary to maintain the social media functions. Reflecting Hill and White's (2000) results, several nonprofit communicators said they simply did not know how to incorporate these strategies into their efforts. "It took me forever to figure out how to design web pages and that was with one of those *Web-Sites for Dummies* books. I wouldn't even know where to begin with RSS feeds or podcasting," said one senior communications officer at a science and technology museum. Another summed up her feelings by saying: "Even though I blog regularly on my personal website, I'd be scared to represent the organization. I'm not sure I'm prepared to be the sole voice of my organization online, and I certainly don't want others to chime in on certain topics."

Reflecting the diffusion of innovations, several individuals said that they had been using social media sites, such as Facebook and MySpace, for some time, and others had mixed experience levels with Flickr and other social interaction technologies. One focus group participant summed up her experience saying, "I think I was one of the first of my peer group to use Facebook. I'm totally comfortable using it for me. I'd have to see how other organizations used it before I tried it with (my agency)."

Several nonprofit organizations represented in a study appear to be in the early majority phase. They are waiting to see how the innovators and early adopters incorporate these technologies into their daily work especially since they have experience with them in their personal lives. The question that must be asked with future research, then, is who are the innovators and early adopters of the social media technologies for the nonprofit sector. One might expect that the larger nonprofits (e.g., those with annual budgets greater than $1 million) would be the technology leaders because of the increased availability of resources.

However, based on the results of this study, smaller nonprofit organizations appeared to be the innovators of the social media. Despite the lack of resources, smaller organizations have created a sense of community and the social media have brought them further together to work towards the organizations' missions. A volunteer in charge of communications for the nonprofit with the smallest budget said, "[Our organization] doesn't have the resources to create an expensive marketing or public relations campaign to compete with other nonprofits in town, but using social media lets me reach a lot of people without spending a lot of cash."

FUTURE TRENDS

As virtual presence becomes even more important for an organization's day-to-day operations, nonprofits are beginning to learn how to use Web 2.0 technologies to reach the stakeholders. The new approach is gaining support from donors, volunteers, and nonprofit organization clients. Technologies such as podcasting, blogging, microblogging and vlogging, RSS feeds and tagging, photo and video sharing, and social networking services, have created a promise for a nonprofit sector with greater outreach and interactivity. This trend in using social interaction technologies for strategic communication is resonating with many nonprofits as the interactivity offered by social media channels offers a unique ability to cultivate and develop a two-way communication relationship with the stakeholders rather than maintaining a one-way information conduit.

Incorporating blog management into their communications efforts allowed, for example, a Seattle-based environmental nonprofit organization Oceana to increase donations and interest in volunteering at the organization (Waters, 2007b). Shortly after this news spread through TechSoup.org, many larger organizations began expressing interest in how they could successfully blog with their stakeholders. Social software allows these smaller organizations to demonstrate their fiscal and social accountability to external and internal audiences, and the software is frequently used to help foster a greater sense of community within the nonprofit sector (Bach & Stark, 2004).

Even though some nonprofits are still resisting the integration of new technologies into their strategic communication efforts, other nonprofits (mostly smaller organizations) are serving as the harbingers of change. It is reasonable to assume that as their success stories spread, more nonprofits will be inclined to adopt social interaction technologies in the future and their influence will be felt across the entire nonprofit sector.

CONCLUSION

Nonprofit organizations are carrying out vital work to address the nation's social, economic, and political problems. Social interaction technologies are slowly changing the way nonprofits perform their work allowing nonprofits to reach out to the community in effective, open and transparent ways. Most importantly for nonprofits, social interaction technologies allow users to share their thoughts and opinions and give feedback on how the operation of an organization can be improved (Finin, Ding, Zhou, & Joshi, 2005). It may be of interest that communication consulting companies that work with nonprofit organizations have started to distribute guides to teach how to use blogs, RSS feeds, podcasts, wikis, virtual worlds, and online social networking to advance the organizational missions in an Internet-driven world. Fichter (2007), for example, encourages nonprofits to start using new technologies and learn about them first hand.

Social interaction technologies offer a rich, participatory, and collaborative experience for the user—the type of experience shown to result in enduring relationships between an organization and its stakeholders (Tyler, McGirr, & Stanley, 1998). These technologies allow community members to participate and collaborate in a nonprofit organization's efforts in a meaningful and gratifying way (Needleman, 2007). Whether through posing questions to the organization's discussion forum or blog or receiving updates about programs and services through microblogging, social media allow nonprofits to become more open and attractive to their stakeholders.

Based on the results of the interviews and focus groups conducted for this research project, it appears that currently the use of social software by the nonprofit sector still is still in the early adopters stage. However, to extrapolate findings of this study to the nonprofit sector, more research should be undertaken. The rapid growth of the usage of social media by nonprofit organizations parallels how the social interaction technologies are being used by individuals in a larger society. Early adopters of social media are encouraging their organizations to pursue the strategy of innovations, and take the possible risks that are paying off with increased fundraising results and volunteer recruitment efforts. As the adoption of the existing social software tools and applications continues to progress through the diffusion of innovations stages, the nonprofit sector can only wonder what is beginning to emerge on the horizon for the innovators to explore.

KEY TERMS AND DEFINITIONS

Cybervolunteering: Contributing time and effort to a nonprofit organization through an online connection, rather than, or in addition to, an on-site service.

Diffusion of Innovations: The study of how, why, and at what rate new technologies and ideas spread through a social system or organization.

Early Adopters: The second (after the innovators) wave of adopters of new technologies, who represent opinion leaders in a social system because of their decision-making skills.

E-Philanthropy: The cultivation and management of relationships with key stakeholders of nonprofit organizations using the Internet.

Early Majority: The third wave of adopters of new technologies, who represent the group that adopts a technology just before the "average" person based on the actions of opinion leaders in their social system.

Innovators: The first adopters of new technologies who are willing to face uncertainty and risks as they interact with new technologies and ideas.

Laggards: The fifth and final wave of adopters of new technologies, who want to maintain the status quo by refusing to purchase or accept new technologies or ideas because they are very skeptical.

Late Majority: The fourth wave of adopters of new technologies, who represent a group that generally adopts new technologies to stay even with their peer networks even though they are often cautious of change and sensitive to prices.

Vlogging: Blog authoring that contains video clips to assist in relaying messages; vlogging is becoming more common as equipment becomes more accessible and distribution channels, such as YouTube and Google Video, increase their storage capacity.

Chapter 5.9
Situating Social Identity through Language Convergence in Online Groups

Scott L. Crabill
Oakland University, USA

ABSTRACT

According to social identity theory, individuals create and maintain their social identity through group membership. During face-to-face interactions within a group, people assess various verbal and nonverbal cues to influence the perceptions of themselves by others. However, in the context of online communication these cues are not as readily available. A screen name can be viewed as part of an individual's "social identity creation": a message that members of online discussion boards interpret and react to while trying to situate themselves within the group. This chapter explores how language convergence can function as a cue that facilitates situating social identity within online in-groups. Results of a content analysis of 400 screen names suggest that the screen names of discussion board members serve as an organizing variable for participants to situate themselves socially within the context of online interaction.

INTRODUCTION

In spite of original visions for the Internet, it has moved beyond the constraints of impersonal and task-oriented interactions. Scholarly research has acknowledged a trend in increasing interpersonal elements within computer-mediated communication (e.g., Pena-Shaff, Martin, & Gay, 2001; Spears, Lea, Corneliussen, Postmes, & Haar, 2002; Tanis & Postmes, 2003; Walther & Burgoon, 1992; Walther, 1992, 1993, 1994, 1996; Walther, Anderson, & Park, 1994; Walther & Tidwell, 1995). Within face-to-face interactions, individuals rely upon nonverbal "cues" and interpersonal rules to guide interaction. However, computer-mediated communication (CMC) does not allow for immediate or visual assessment often relied upon to reduce uncertainty and form impressions in face-to-face settings. Yet, according to Walther and Tidwell (1995), "CMC is not bereft of the cues needed to make varied social judgments" (p. 372). The researchers contend that previous approaches limited the scope of cues to body language and tonality, failing to recognize cues that are inherent within CMC. Giles and Coupland (1991) define language convergence as a "strategy whereby individuals adapt to each other's communicative behaviours in terms of a wide range of linguistic/prosodic/non-vocal features including speech rate, pausal phenomena and utterance length, phonological variants, smiling, gaze and so on" (p. 63). The present study explored how language convergence can function as a cue within computer-mediated communication that facilitates creating and situating social identity within online in-groups.

BACKGROUND

The Internet is a truly powerful technology that enables numerous opportunities for identity construction. It allows us to think about our identity, and if desired, change ourselves to who we want to be (Chandler, 1998) and construct images of ourselves through various types of self disclosure. Research has argued that the Internet technology is limited to impersonal and task-oriented interactions. Referring to a "cues-filtered out model", Kiesler, Siegel, and McGuire (1984) state: "In traditional forms of communication, head nods, smiles, eye contact, distance, tone of voice, and other nonverbal behavior give speakers and listeners information they can use to regulate, modify, and control exchanges" (p. 1125). Such a "reduced cues" perspective suggests that CMC lacks nonverbal cues necessary to substantiate interpersonal communication amongst CMC interactants (Connolly, Jessup, & Valacich, 1990; Hiltz, 1975, 1981; Hiltz, Johnson, & Agle, 1978; Hiltz, Johnson, & Turoff, 1986; Hiltz, Turoff, Johnson, 1989). Within this perspective, CMC is viewed as somewhat inadequate, with the capacity to harm and to keep people from "real" relationships (Thurlow, Lengel, & Tomic, 2004). This stands in contrast to the optimistic claims that the Internet can foster new relationships across social and geographical boundaries and create friendships and communities rooted in common interest and concerns (Thurlow et. al., 2004).

Reactions to the "reduced cues" perspective lead to a diverse body of research exploring interpersonal relationships created, maintained, and utilized in cyberspace (Soukup, 2000). This research attempts to identify the social dimensions of interactions mediated through computers (Amaral & Monteiro, 2002; Braithwaite, Waldron, & Finn, 1999; Douglas & McGarty, 2001; Kleinman, 2000; Muramatsu & Ackerman, 1998; Pena-Shaff, Martin, & Gay, 2001; Ramirez, Walther, Burgoon, & Sunnafrank, 2002; Spears, Lea, Corneliussen, Postmes, & Haar, 2002; Tanis & Postmes, 2003; Tidwell & Walther, 2002; Walther & Burgoon, 1992; Walther, 1992, 1993, 1994, 1996; Walther, Anderson, & Park, 1994; Walther & Tidwell, 1995). As such, it is apparent that communication on the Internet has moved beyond the constraints of impersonal and task-oriented interactions into interpersonal interactions. The cues by which individuals are assessed within CMC may vary. Zhou, Burgoon, Twitchell, Qin, and Nunamaker (2004), contend that we evaluate language choices and make attributions about another's social status, background and education. Despite the surmounting research within this trend, there is a lack of known socially contextual cues within CMC interactions (Tanis & Postmes, 2003). According to Spears et. al. (2002), the exact nature of the interpersonal implications of CMC is still under debate and not well understood.

Situating Social Identity

Our identity is in continuous flux from the time we are cognizant of social realities throughout the remainder of our lives (Hall, 1990). According to social identity theory it is these social realities that shape and form our social identity (Tajfel & Turner, 1986). It is through our membership into various social groups that we discover and experiment with social identities in the hope of creating an image of ourselves that is acceptable to the social realities we are invested in (Tajfel & Turner, 1986). Furthermore, it is assumed that we will strive to remain a member of a group and seek membership to new groups if the group of interest has some degree of positive influence on our social identity (Tajfel, 1978b).

Research on impression management has concluded that a large portion of this process is conscious; individuals rely upon context to determine how they will represent themselves (Andrews & Kacmar, 2001; Berzonsky & Adams, 1999; Yoder, 2000). Within the context of CMC, Walther (1993) concluded that in a zero-history group experimental setting, "CMC users formed increasingly developed impressions over time, presumably from the decoding of text-based cues" (Walther, 1993, p. 393). Hence it is conceivable that individuals interpret text-based cues (such as a screen name) as a means of evaluating individuals within an interpersonal framework, enough so that they can make decisions/judgments about interactants.

Minority status groups, such as white supremacists groups, tend to have higher in-group identification (Brown, 2000). People who have a high identification with the group tend to see both the in-group and the out-group as more homogenous than people who have a low identification with the group (Brown, 2000). Thus, the feeling of belonging to a group places one in a social category that defines who one is in terms of the defining characteristics of the category (Hogg, Terry, & White, 1995). As such, social identities have self-evaluative consequences (Hogg, 1996); since "white supremacists" views their ideology as superior, they will take the necessary steps to maintain that perception. In accordance with this tenet of social identity theory, any display or action that will tie group, in this case "white supremacists", to their cause will result in greater identification with that group (Tajfel, 1978a). In short, individuals will know the intra-group communication thereby tying them to that social identity. Subsequently, people who feel that they are "white supremacists" will exhibit the characteristics of "white supremacists"; they will strive to situate themselves as "white supremacist" and will know and utilize language patterns and symbols that pertain to the group. The current study explores the possibility that the construction of a pseudonym utilized as the screen name within a white supremacist discussion board can serve as a means of identifying with the group. In addition, an individual screen name can function as a marker of identity and this marker is germane to white supremacist group membership. There are a vast number of cyber communities that rely mostly upon CMC as a means of maintaining contact with one another and recruiting new members (Thurlow et. al., 2004). Among them, white supremacist groups have recognized the value of CMC as a means of substantiating and maintaining communities; in fact, CMC has become their primary means of surviving and expanding during the last decade (e.g., Bostdorff, 2004; Burris, Smith, & Strahm, 2000; Duffy, 2003; Preston, 2003). According to the Anti-Defamation League (2001): "The high-tech revolution that has altered our domestic, educational, and workplace routines and habits has brought the same informational and communications opportunities to the organized hate movement" (p. 2).

As a result, the number of hate groups operating in the United States is steadily on the rise. Various watchdog organizations have noted a 78% increase in the number of hate groups and group chapters involved in racially prejudiced behavior between 2000 and 2006 (Media Awareness Network, 2000; Southern Poverty Law Center, 2008). According to the Southern Poverty Law Center (SPLC) there are currently between 450-500 "hard core" hate sites and as many as 1,500 – 1,750 hates sites that are potentially problematic on the Internet.

The discourse of white supremacy is abundant and easily accessible; in fact, white supremacy has had a long history in America and has maintained its ideologies throughout the course of this nation's history (Blee, K. 2002; Ezekiel, R. S., 1996; Daniels, J., 1997; Dobratz & Shanks-Meile, 1997; Quarles, 1999). The Internet has availed white supremacists the ability to reach a much more focused audience than their predecessors ever imagined (Anti-Defamation League, 2001). Discussion boards have become an important tool for establishing and maintaining group identity and thus are a primary source for white supremacist discourse (e.g. Bostdorff, 2004; Burris, et. al., 2000; Duffy, 2003; Preston, 2003). In essence, these discussion boards function as a community resource center that allows those interested to gather information about local events or discuss ideas with those of similar dispositions. This has become just one of many ways that white supremacist group's commune and share their identities with others for the purpose of grouping themselves. Hence, the Internet has provided a social space in which white supremacists have an opportunity to create a social identity within the context of CMC.

A STUDY OF SOCIAL IDENTITY AND LANGUAGE CONVERGENCE IN ONLINE GROUPS

An underlying assumption exists regarding the nonverbal cues exchanged and gathered in face-to-face settings which suggests that individuals treat most nonverbal behavior as intentional and designed to communicate information to others (for example, Allen & Atkinson, 1981; Buck & Van Lear, 2002; Manusov & Rodriguez, 1989; Richmond & McCroskey, 2004). In mediated contexts individuals may assume that the usernames utilized in cyberspace contain purposeful clues as to the personality or identity of the sender, which is a unique identifier since screen names cannot be duplicated within a specific discussion forum. Therefore, an individual's perceptions of volition should influence the impact that username has on perceptions. According to Heisler and Crabill (2006), screen names perceived as selected and designed by their users offer more information related to situating social identity (and greater predictability) to others.

The potential for screen names to vary, while not infinite, is substantial. With the ability to combine any number, letter, or symbol, the emergence of uniformity within a discussion board membership list would suggest convergence within their creation. Furthermore, a type of structure functions in their construction. Hence, the creation of a screen name is a process of self-identification, a message that members of online groups interpret and react to within their discussions. The current study aimed to explore whether screen names can serve as an organizing variable within participants' attempts to situate themselves socially in the context of discussion boards. Consequently, it was hypothesized that:

$H_{1:}$ Screen names of an online white supremacist discussion board will contain cues to the social identity of the group.

Method

The flow for a typical content analysis was adapted from Nuendorf (2002) and used to guide data collection and analysis. Due to the nature of the study and the data, percentage frequencies of the variables were reported. The initial form of analysis of the data was to determine and report the frequency of the coded variables. Once the frequencies were determined, mean scores of each variable were compared using independent sample *t* tests with significance at $p<.05$.

Group Selection

To address the research hypothesis of the study, it was deemed necessary to compare the group of interest to a similar group. It was important that the researcher identified an online white supremacist group and control group that utilized a discussion board as the primary means of interacting. The lack of available demographic information poses a methodological complication that required the use of a purposive sample. Review of the literature of white supremacist discourse revealed a prominent theme of music (see Crabill, 2006). Therefore, the researcher selected the website of a prominent white supremacist recording label, "Resistance Records", which is dedicated to the production and promotion of white supremacist music. Selecting a comparison group was done systematically by searching the Internet for music genres similar to that produced by "Resistance Records." The researcher identified another record label, "Plan-it-X Records", which produced a similar genre of music and maintained a comparable website design and membership. The missions of the two groups are comparable as well; both sites are interested in motivating others to take action against an oppositional entity and as such motivate others to act as social agents for change in our society. In addition, the groups maintained sufficient membership for adequate sampling.

Sample

A member list of screen names was collected from each discussion board. Since screen names are unique identifiers for members of each discussion board within the forum, it is not be possible for duplicate names to occur. However, it was possible, but not likely, that a screen name would be duplicated between the discussion boards, as the same person could belong to both groups and use the same screen name for each. Had such phenomena occurred, the screen names would have been removed from the data set. There were a total of 2,127 screen names identified from "Plan-it-X Records" and 8,045 from "Resistance Records." To ensure that coding of screen names included members who were most invested in the respective groups' social identity, posting statistics garnered from the websites were relied upon to identify the top 200 posters from each list. Screen names were rank-ordered based upon the number of posts each member made within the discussion forum. Thus, the final data set consisted of a total of 400 screen names.

Content Classification

The coding categories were inductively derived from the review of the literature and pretested in a pilot study for intercoder agreement. With the goal of finding categories pertinent to white power identity in particular, a discussion thread "What inspired your screen name?" from a prominent white supremacist website, Stormfront.org, was used for the pilot analysis. The researcher created a coding structure and a code book with supplemental content by reading 575 replies posted for the discussion thread (Crabill & Smith, 2005). The resulting codes are described below.

- *Anti-Other* included any slanderous reference to nonwhite ethnicities. This included the presence of specific references to a white supremacist organization, band, slogan, or expression commonly used by white supremacist.
- *Ethnicity* included any reference to a specific race, ethnicity, or nationality. Derogatory references about other ethnicities are not included in this category and should be coded in the "Anti-Other" category.
- *Personal Name* was defined to include names that use a formal personal name as the screen name.
- *Other* included any screen name that was not coded in the other categories.

Coding

The researcher and a trained assistant coded all the data. The second coder was provided with an in-depth description of each category along with examples taken from site content. Coders were to classify each screen name using the code book and a coding sheet. Each screen name was coded individually and placed in one of the four catego-

Table 1. Inter-Rater Reliabilities

Category	Percent Agreement		
	Overall	**Resistance Records**	**Plan-it-X Records**
Ethnicity	69.76%	68.29%	100%
Anti-Other	89.29%	91.25%	50%
Personal Name	86.36%	73.08%	91.57%
Other	87.11%	79.73%	91.67%

ries. To establish reliability of coding, Holsti's method of calculating the percent of agreement was used. According to Neuendorf (2002), this method is recommended when two raters assign codes to the same units. Reliability coefficients were calculated for each of the categories (see Table 1), ranging from 69.76% to 89.29%.

Study Results

As anticipated, the categories of *Ethnicity* and *Anti-Other* had the greatest frequency within the screen names of the white supremacist group, while the categories *Personal Name* and *Other* had the greatest frequency in the control group. Frequency distribution of the data and the means is reported in Table 2.

Two-tailed independent sample *t* tests were conducted using SPSS. The level of significance was set at $p<.05$ prior to analysis. Some variables were significant beyond this confidence interval. It was anticipated that the social identity of the white supremacist group would manifest in the codes for ethnic references and *Anti-Other* declarations within the construction of screen names. In addition, it was anticipated that the control group would have greater frequency of the coding categories for personal name and other content not included in the code book.

Results of the independent sample *t* test revealed a significant difference in the coding of screen names between the white supremacist group and the control group. There was statically significant difference of the categories *Ethnicity* (t=-8.308, df=798, $p<.05$) and *Anti-Other* (t=-14.653, df=798, $p<.05$) within the white supremacist group's screen names compared to the control group. While, there was statistically significant difference of the categories *Personal Name* (t=9.851, df=798, $p<.05$) and *Other* (t=7.093, df=798, $p<.05$) within the control group compared to the white supremacist. These results support the research hypothesis as the white supremacist screen names were constructed with distinct cues that reflect the social identity of the group.

It was anticipated that the analysis of the screen

	Overall			Resistance Records			Plan-it-X Records		
Category	**Coder 1**	**Coder 2**	**Mean**	**Coder 1**	**Coder 2**	**Mean**	**Coder 1**	**Coder 2**	**Mean**
Ethnicity	34	39	36.5	32	37	34.5*	2	2	2
Anti-Other	79	80	79.5	77	76	76.5*	2	4	3
Personal Name	101	104	102.5	23	23	23	79	81	80*
Other	186	177	181.5	69	64	66.5	117	113	115*

Note: *Indicates statistical significance.

names of two comparable groups would be beneficial in understanding the process of constructing social identity within an online white supremacist group. Results of the analysis suggest that the screen names of discussion board members do provide information about the social identity of group membership. The majority (55%) of screen names of the white supremacist group were coded as having content inclusive of the *Anti-Other* and *Ethnicity* codes, while only 2.5% of the screen names of the control group were coded in these categories. These findings are particularly relevant and useful in understanding how social identity is constructed online through the creation and use of online screen names.

DISCUSSION

The potential of screen names to vary is substantial, which makes it challenging to create a comprehensive coding structure that captures the full extent of possible content under investigation. However, it was anticipated that the screen names of the white supremacist group would include content that was specific to an argot that reflected group membership of white supremacist groups. Therefore, categories were created that would encompass content included within the specific argot of the white supremacist group, which were *Ethnicity* and *Anti-Other*. It was not surprising to find that the screen names of the control group had very marginal frequencies for these categories. Instead, it was anticipated that the control group would exhibit statistically significant frequencies for the categories *Personal Name* and *Other*. Thus 97.5% of the screen names for the control group were coded in these categories. There was no reason to assume that the control group would include the argot specific to white supremacists within the creation of their screen names.

Overall, the findings revealed interesting patterns in the white supremacist screen names that reflected group membership. The results suggest that the white supremacists rely upon maintaining a systematic group code, which is similar to the use of colors and symbols by street gang members to indicate membership. With the ability to combine any number, letter, or symbol, the emergence of a distinct pattern for the white supremacists screen names suggests convergence within the creation of screen names and furthermore a type of structure functions in their construction. In particular, the pairing of numbers and letters was a common feature of the screen names for the white supremacist group.

FUTURE TRENDS

The proliferation of the Internet has created an explosion in the variety of reasons people are taking the journey into cyberspace. Current trends by Internet service providers to offer affordable pricing have made the cyberspace available to even the most casual of computer users. Hence, the Internet has seen unprecedented growth and continues to emerge as a dominant form of mediated communication: for example, by 2008 the Internet penetration in the U.S. has reached 72.5% of the population (Internet World Stats, 2008). Internet discussion forums, online interest groups, and online identities are increasingly becoming ubiquitous. It is of vital importance for researchers engaged in an emerging interdisciplinary field of studies of online behavior to follow these new developments to provide an accurate scholarly analysis of the potential societal implications.

CONCLUSION

It can be concluded that the creation of a particular screen name in an online setting is part of a complex process of social self-identification, self-categorization, and enhancement. A screen name is a message that members of online discussion boards communicate, interpret and react to while trying to situate themselves within the social identity of the group. Consistent with social identity theory assumptions, screen names converged within variables that were relevant to the social identity of the white supremacists. The findings of the present study are consistent with the research by Heisler and Crabill (2006) which investigated a similar phenomenon within perceptions of e-mail usernames: the ability for participants to choose their e-mail name had implications upon the impressions that participants developed about the username. Participants acknowledged that creating e-mail usernames, opposed to assigned names, provided an opportunity to reveal information about themselves. Within the context of the current study, all screen names were created by the participants and therefore, participants had the opportunity to convey information which situated them as members of the white supremacist group by relying upon an argot specific to the group's social identity. In this regard, it seems that screen names serve as an organizing variable for participants to situate themselves socially in the context of discussion boards. It is apparent that CMC contexts do offer enough information about members to influence mediated perceptions, although it should be noted that the accuracy of such information is reliant solely upon the volitions of participants.

KEY TERMS AND DEFINITIONS

Computer-Mediated Communication (CMC): Any form of human interaction across networked computers. Although the term has traditionally referred to those communications that occur via computer-mediated formats (i.e., instant messages, e-mails, chat rooms), it has also been applied to other forms of text-based interactions.

Reduced Cues: The "reduced cues" perspective suggests that CMC lacks nonverbal cues necessary to substantiate interpersonal communication amongst interactants.

Screen Name: A pseudonym constructed for the use of participation in an online discussion group or chat.

Social Identity Theory: A theory originally conceived and formulated by Henri Tajfel, a British social psychologist, in his early research of social perception.

White Supremacy: Broadly generalized, the term "white supremacy" can refer to a number of ideologies. The term itself is often used as a blanket label to identify individuals with perceived prejudiced or racial bias toward minorities.

Chapter 5.10
Building Social Relationships in a Virtual Community of Gamers

Shafiz Affendi Mohd Yusof
Universiti Utara Malaysia, Malaysia

INTRODUCTION

The explosive growth of the Internet has enabled virtual communities to engage in social activities such as meeting people, developing friendships and relationships, sharing experiences, telling personal stories, or just listening to jokes. Such online activities are developed across time and space with people from different walks of life, age groups, and cultural backgrounds. A few scholars have clearly defined virtual community as a social entity where people relate to one another by the use of a specific technology (Jones, 1995; Rheingold, 1993; Schuler, 1996) like computer-mediated communication (CMC) technologies to foster social relationships (Wood & Smith, 2001). It is further supported by Stolterman, Agren, and Croon (1999) who refers to virtual community as a new social "life form" surfacing from the Internet and CMC. There are several types of virtual community such as the virtual community of relationship, the virtual community of place, the virtual community of memory, the virtual community of fantasy, the virtual community of mind/interest, and the virtual community of transaction (Bellah, 1985; Hagel & Armstrong, 1997; Kowch & Schwier, 1997). These types of virtual community all share a common concept, which is the existence of a group of people who are facilitated with various forms of CMCs. With the heightened use of CMCs, people begin to transit and replicate the same sense of belonging through meaningful relationships by creating a new form of social identity and social presence. As emphasized by Hiltz and Wellman (1997), people can come from many parts of the world to form "close-knit" relationships in a virtual community.

The purpose of this article is to understand how online gamers as a virtual community build social relationships through their participation in online games. Empirically, several aspects in the context of virtual community are still not fully understood, such as: (1) What types of rules, norms, and values are grounded in virtual community? (2) How do people institutionalize their members in a virtual community? and (3) Why do they create social relationships in virtual environment? The identified gap thus explains why studies have produced inconsistent findings on the impacts of online game

DOI: 10.4018/978-1-60566-014-1.ch024

play (Williams, 2003), in which many studies in the past have only looked at aggression and addiction. A more detailed understanding of the social context of in-game interactions would help to improve our understanding of the impact of online games on players and vice versa. Therefore, this article will present a case study of a renowned online game, Ever Quest (EQ), with the aim of understanding how players establish and develop social relationships. In specific, the Institutional Theory was applied to examine the social relationships among the players, and a hermeneutic-interpretive method was used to analyze the data in order to address the following general research question, "How is the social world of EQ constituted in terms of building social relationships?"

BACKGROUND OF EVERQUEST

The virtual community of gamers' environment investigated in this study is Ever Quest (EQ). EQ is the world's largest premier three-dimensional (3D) "massively-multiplayer online role-playing game" more commonly referred to as MMORPG. People are becoming more attracted to this new type of online game, which is a subset of a massively-multiplayer online game (MMOG) that enables hundreds or thousands of players to simultaneously interact in a game world where they are connected via the Internet. Players interact with each other through avatars, that is, graphical representations of the characters that they play. The popularity of MMORPGs have become evident with the introduction of the broadband Internet. MMORPGs "trace their roots to non-graphical online multiuser dungeon (MUD) games, to text-based computer games such as *Adventure* and *Zork*, and to pen and paper role-playing games like *Dungeons & Dragons"* (Wikipedia, 2004, para. 2). It is expected that online gaming will grow from a $127 million industry in 2003 to a $6 billion industry by the year 2006 (ScreenDigest, 2002).

EQ is a game that attracts an estimated 400,000 players online each day from around the globe and, at peak times, more than 100,000 players will be playing EQ simultaneously (Micheals, 2004). The game's players interact with each other inside and outside the game for game playing, game-related and non-game-related interactions, and for buying and selling game-related goods. EQ, as a game, is characterized by well-defined social structures, roles, interaction rules, and power relations. EQ, as a virtual community, encompasses all of the different kinds of virtual community. EQ is a virtual community of relationship, a virtual community of place, a virtual community of memory, a virtual community of fantasy, a virtual community of mind/interest, and a virtual community of transaction.

After its launch in 1999, EQ became a worldwide leader in massively-multiplayer online games, and it is North America's biggest massively-multiplayer online game (Micheals, 2004). Since then, EQ and its expansions[1] have sold over 2.5 million copies worldwide, and it has been translated into seven languages. EQ is one of the largest and most dynamic online fantasy worlds ever created (Stratics, 2004). The reason for choosing to study EQ is because of the incredible popularity of online gaming, which has numerous economic and societal implications.

CASE STUDY OF EVERQUEST ONLINE GAMING

The method used was a single case study to examine the unique social world of EQ. There were, altogether, 157 respondents chosen from the game, discussion forums, and Web sites. They were invited through emails to participate in the study. The case study took six months to complete. Within this approach, multiple modes of data collection were utilized, including online questionnaires, semi-structured interviews, interactions through discussion forums, analysis of documentation such as game manuals, monitoring of Web sites, and non-reactive observations/recordings of chat sessions in the game. It is useful to note that the interview protocols for the semi-structured interviews, online chats, and online questionnaire were all the same. The only difference was how it was carried out—through face-to-face interviews or through the use of information communication technologies (ICTs).

The respondents were interviewed using an established semi-structured protocol. The interview protocol began with some general questions. First, information elicited from each respondent was on how they got to know about EQ. Answers included: through friends, magazine article or gaming press, word of mouth, coworker, came with computer, family members, store display, online Web site or from Internet, and so forth. Second, further probing questioning was carried out, for example, how long have they played the game? Most of the respondents have played EQ from 1 – 6 years. Third, they were asked what attracted them to playing EQ. The answers were classified into four thematic categories: (1) the social aspects of the game; (2) the game play: (3) the characteristics of the game; and (4) generalized recreation. After asking about the general questions, the main issues on social relationships were raised for them to answer. Once saturation was reached in the answers given by the respondents, the interview efforts were halted, and the answers (in text) obtained from the interviews and online questionnaire were analyzed.

BUILDING SOCIAL RELATIONSHIPS IN A VIRTUAL COMMUNITY OF EQ

In essence, many of the respondents described the social aspects of the game, such as friendships, interaction rules, socialization, leadership skills, relationships, sense of belonging to a community, teamwork, and the different cultures. Below are examples quoted from two respondents:

Friends first and foremost. When I first arrived in (the) game, I was completely amazed at how far gaming has progressed, and continue to be amazed even still. I am a gamer to the core, playing on every platform since Atari.

I enjoy the interaction with my fellow players. I have long been a role player (pen and paper style), and EQ allows me to enjoy that same kind of group camaraderie and fun at my computer. I also am a big fan of the high fantasy genre of games.

Moreover, some of the respondents were attracted by specific elements of the game play such as questing, exploration, player versus player (PvP) combat, raiding, competition, killing, advancement, role playing, and trade-skilling. One informant even talked about progression as being an attraction:

Progression. Seeing my avatar get better skills, weapons, armor. Seeing new monsters, zones, attempting and overcoming difficult challenges and encounters.

A third attraction is the characteristics of the game itself. Respondents mentioned various features that attracted them to the game, such as graphics, atmosphere, fantasy setting, colors, storyline, immersiveness, virtual world, virtual economy, and many more. Here is a response from one informant:

The fantasy setting attracted me first...I have always been a fan of RPG (role playing game) type games because of its storyline.

Last, but not least, are the generalized recreation reasons: relaxation, addiction, escapism, self-satisfaction, ego-building, time-wasting, and others. Here is an example of a comment that was found amusing:

It's better than TV and the social aspect. Also, a compulsive competitive streak that's hard to control. I WILL beat this game damn it!

And another informant just simply had this to say about what attracted him to EQ:

Fun…fun…fun…fun!

In the subsequent questions, players were asked, "What do relationships mean in the game?" Respondents gave a variety of answers such as:

It can have so many different meanings, depending on the people involved. There are, of course, friendships, partnerships, professional relationships, mentoring. There are also people who find deeper friendships in game and have gone on to marry or move in with each other, (and so forth). Many people have found people who live near them and have in-life real relationships. Others have long-distance friendships that carry on out-of-game. Others still are manipulative and try to form "false" relationships and jump between "friends" in game.

Many of the respondents (34.1%; 31 from 91 responses) interpreted relationships to mean "friendships." According to respondents, friendships: (1) develop over long periods of time without having directly meet the other people; (2) develop with someone who enjoys your company as much as you enjoy theirs; (3) mean helping each other out; (4) mean sticking together through the hardships; (5) involve people who share the same motivations and get along well; (6) may result in friends that could feasibly last a lifetime; (7) provide good friends in the game with whom you do stuff often; (8) develop when there is something in common such as interests or goals: (9) are made up of people that you trust; many respondents just defined relationships as "friends."

Occasionally, friendships progress to the point where two people finally end up getting married. The next closest meaning given by respondents (16.5%) on relationships is "marriage." As such below is an illustration of such phenomenon,

Relationships in a game are the same as in life. Some people go as far as to get married (both in game and in life). I was a best man for my bro's wedding in EQ, then the next day he got married (in) real life (and yes, he got married (in) real life to the same girl he got married to (in) EQ life… it was cool:D.

Most "marriage" relationships remain in-game, however. Some marriages in EQ are purely for role-playing purposes, like a Paladin marrying a Druid. They serve no in-game benefit, and no one looking at the character would be able to tell he/she is married. Usually the two people plan the role-play event like a real marriage. They will find allocation for all guests can get to, get someone to officiate (the GM's or the Guides or friends can play the role of the priest/civil authority) the marriage, and multiple people bring party supplies, cake, drinks, food, and fireworks. Finding and choosing a location for guests is always important; it has to be scenic, and attendable by all races. In the game, it is perfectly legal for players to have same-sex marriage and polygamy. The process of getting married, changing names, and getting divorced is the same as a normal relationship. As one player admits:

I know of at least one pair of female toons (characters) that were married, because I was half of that pair. As with others, that marriage fell apart due to, as was said, "role-playing differences". I petitioned to have my surname changed.

Continuing with relationships, it can also mean a variety of things in the eyes of the respondents. For example, relationships can represent: (1) people you love (9.9%); (2) acquaintances (6.9%); (3) social interaction (5.5%); (4) people you met in the past (5.5%); and (5) people that keep coming back to you (3.9%). The quote below encapsulates two respondents' definitions of relationships:

They run the gamut. There are people in game whose character name I know and that's all. There are other people who I meet whenever I travel to their part of the country for coffee. There's one person who I was romantically involved with for quite a while. EQ is a social environment. Being familiar with the people you group with and comfortable with how they play their characters is important when facing new encounters. I've been lucky to meet players whose company I enjoy and prefer to be around while in game.

A few respondents (14.1%) avoided giving a definition of relationships. They felt it was not important and have not paid much attention to it, while on the other hand the game demands and rewards cooperation. Here is a quote from an informant that captures this attitude:

I avoid "relationships". It appeals to some people, but I draw the line at forming in-game friendships.

In a massively-multiplayer online gaming like EQ, there is a group of people who are "loners" or people that do not have relationships with other people, even though EQ fosters community-building and socialization among the people in it. This is not a surprise, because about 12% (15 out of 122 responses) of respondents said that they like to play solo instead of being in a guild (group). In order to succeed in the game, people have to build relationships because the tasks ahead of them required a large number of people to kill huge monsters in the game. These people cannot avoid being a loner inside the game at higher levels, but they can definitely be a loner when they are outside the game in the Web sites which do not require them to do so.

Although the following answer is amusing, the ambiguity that the respondents pointed out could do some harm in the long run for relationship-building. His response was:

But I don't get involved in things like that, because the person you think is a girl could be an old guy.

According to the players in the discussion forums, this is quite true, since many players choose to play the opposite sex for their characters instead of their true gender. It is nearly impossible to identify the true gender of a player unless you communicate with him or her through a telephone and can hear their true voice. Even then it can be uncertain, because a male voice can sound like a female voice and vice versa. Obviously in the long run, if the relationship continues, the truth will be known at least to the two parties involved.

Tolerance in this social world is demonstrated by the fact that players are allowed same-sex marriage and polygamy, situations that, while perfectly legal in this social world, are not the norm and are indeed taboo in much of the real world. Tolerance is also extended to players running a character or characters that are not their real-life gender (for example, a female elf could be played by a man and vice versa). As pointed out by Thompson (2004), video games have long allowed players to experiment with new and often taboo identities.

In online games such as EQ, almost half of the women characters are actually men—"guys who prefer to cross-dress when they play" (Yee, 2001, para 3). Motives for playing the opposite gender vary. Some of the players think that it will benefit them tremendously inside the game, as women characters are more likely to be treated better and given more help by other players. But they can also be treated like second-class citizens; when both a male and a female character have equal strength in terms of fighting and experience, the male character will usually win the hearts of the other group members to lead a raid. Yee (2001) also found that women who play male characters often "say they didn't realize how cold, hierarchical, and impersonal a lot of male-male bonds can be" (para. 6).

In summary, this study attempted to find out what players thought of the "social relationships" in the game. The players were asked about what relationships meant in the game, especially "in-game marriage", and how relationships would improve their status or performance in the game.

FUTURE RESEARCH

In specific perspective, it is useful to note that the concept of leadership has been fully established in fields such as management, psychology, sociology, and social psychology. Yet empirical investigation on the concept of leadership in the online or virtual environment is still under research and deficient (Avolio & Kahai, 2003; Cascio & Shurygailo, 2003; Kayworth & Leidner, 2002; Zigurs, 2003), and even more on the concept of emergent leadership (Yoo & Alavi, 2004). Hence, it would be fruitful for future research to examine the issue of emergent leadership in the virtual community environment in general, and also to focus on this type of leadership in the online gaming perspective by addressing question such as: "What styles and types of leadership emerge in online gaming?"

In order to develop virtual communities, it is also crucial to focus on processes, rules, and procedural formation. The formation of virtual community is based on a collective concept or group orientation. Questions such as, what purposes does it serve, how is it set up, and what rules are in place, would be equally interesting to explore. For example, if the future versions of the game will be oriented more towards powerful raiding guilds, will the category of people between guilds disappear, or will they have to make a choice to belong to one of the guilds? As the game progresses, it is anticipated that the family guilds will have similar questions to answer; they may feel that they are not valued as much, and may walk out of the game. They may join a game in which family guilds are given equal weight, or where every guild is considered as a family guild. Hence, some key questions are: (1) What are the factors that make a guild successful, and what happens to the family guilds in the future if the game is about raiding? (2) What is the future of the guild? and (3) Does it affect the social structure of EQ?

CONCLUSION

The emergence of the "online game" virtual community has enabled hundreds or thousands of players to simultaneously interact and build a relationship in this new, interesting virtual world. What is more intriguing to discover is the fact that people have developed their own rules and regulations to facilitate the structure of their social relationships among and between the players. Players as communities are simply connected and interacted via the Internet, although they may be thousands of miles apart from each other. Thus, in this social world of EQ, many players felt that *relationships* mean the "friendships" that they build inside the game. Many players acknowledge that by knowing other players, it would help them progress to a higher level in the game. In fact, players stated that by reaching a higher status in the game, it had no effect on the relations that they have established. The second meaning of *relationships* given by players is "marriage." Astonishingly, there are many couples that started their relationship as friends, got married in the game, and then moved on to real-life marriage and families outside the game. But there are cases where the marriage is only built inside the game and for the fun of role playing, thus not realistic in that sense. In a nutshell, all these findings have essentially addressed the proliferation of virtual communities in online gaming environment.

KEY TERMS AND DEFINITIONS

Case Study: A research design that employs an in-depth or rich investigation of a phenomenon; the unit of analysis can be a single or several person/individual, organizations, or environment/ context to be examined.

Computer-Mediated Communication (CMC): Process of human communication via computers involving people, situated in particular contexts, engaging in process to shape media for a variety of purposes (December, 1997)

EverQuest: EQ was one of the world's largest premier three-dimensional (3D) MMORPG. It is a game that attracts an estimated 400,000 players online each day from around the globe and, at peak times, more than 100,000 players play EQ simultaneously (Micheals, 2004).

MMORPG: Massive(ly)-multiplayer online role-playing games or MMORPGs are virtual persistent worlds located on the Internet. They are a specific subset of massive(ly)-multiplayer online games in which players interact with each other through avatars, that is, graphical representations of the characters they play.

Online Gaming: A game that requires a connection to the Internet to play; they are distinct from video and computer games in that they are normally platform-independent, relying solely on client-side technologies (normally called "plug-ins"). Normally all that is required to play Internet games are a Web browser and the appropriate plug-in (normally available for free via the plug-in maker's Web site).

Social Relationship: Involves dynamics of social interactions, bounded and regulated by social and cultural norms, between two or more people, with each having a social position and performing a social role

Virtual Community: A virtual community is primarily a social entity where people relate to one another by the use of a specific technology (Rheingold, 1993).

ENDNOTE

1 There are, altogether, 14 expansions of EQ since its debut in March 16, 1999. The first expansion, *EverQuest: The Ruins of Kunark,* was released April 24, 2000. Since then, it has become a part of the basic *EverQuest* package, giving players more than twenty new zones, a new playable race of lizard men called the Iksar, and selling over 400,000 copies to date. The second expansion, *EverQuest: The Scars of Velious*, was released on December 5, 2000. It provides 19 more zones of content designed for level 30 characters and above, and has sold more than 300,000 copies since its release. The third expansion, *EverQuest: The Shadows of Luclin*, sold over 120,000 copies on its first day at retail, and takes players to the enchanting moonscape of *Luclin*. It offers over 28 new adventure zones, all-new items, creatures, and spells, a new playable char-

acter race, and rideable horses. The fourth expansion, *EverQuest: The Planes of Power,* launched on October 21, 2002, and unlocked the door to the most powerful deities in Norrath. It sold more than 200,000 units in its first three weeks. *The Planes of Power* introduces players to an arching storyline and epic adventures. The fifth expansion, *EverQuest: The Legacy of Ykesha,* launched on February 24, 2003. This extension broke new ground by offering numerous technical advances and improvements to game play via digital download. The sixth expansion is *EverQuest: Omens of War,* launched in September, 2003. The seventh expansion is *EverQuest:Gate of Discord,* launched in February, 2004. The eighth expansion is *EverQuest: Omens of War,* launched in September, 2004. The ninth expansion is *EverQuest: Dragons of Norrath,* launched in February, 2005. The tenth expansion is *EverQuest: Depths of Darkhollow,* launched in September, 2005. The eleventh expansion is *EverQuest: Prophecy of Ro* (February, 2006); the twelfth expansion is *EverQuest: The Serpent's Spine* (September, 2006); the thirteenth expansion is *EverQuest: The Buried Sea* (February, 2007); and the latest expansion is *EverQuest: Secrets of Faydwer* (November, 2007).

ABSTRACT

This chapter addresses awareness support to enhance teamwork in co-located collaborative environments. In particular, the authors focus on the concept of situational awareness which is essential for successful team collaboration. Mutual situational awareness leads to informal social interactions, development of shared working cultures which are essential aspects of maintaining working relationships. First, an overview of the studies on team coordination and situational awareness support is presented. Second, a collaborative working environment is described for scientific teams in a molecular biology omics experimentation domain. Then, the results of practical case studies are discussed, as well as situational awareness support for scientific teams in collaborative environments. Finally, the authors discuss practical challenges in design and evaluation of group support systems for collaborative working environments and our multi-level analysis approach. The chapter gives new insights into how shared displays support group awareness, and how to design and evaluate interactive systems and visualisations that afford awareness in order to stimulate existing and new forms of collaboration in advanced working environments.

Discovery is seeing what everyone has seen, and thinking what nobody else has thought

—Albert Szent-Gyorgy

INTRODUCTION

The diversity of multiple disciplines in teams positively impacts collaborative problem solving (Coughlan and Johnson, 2006; Shalley and Gilson, 2004). It is essential to analyse how such collaboration takes place in daily work practices. Team collaboration can be supported by providing an appropriate environment and a certain context (Coughlan and Johnson, 2006). However, introducing a new environment and new technologies, like multiple visualisations on a large display, may increase the cognitive load of team members and influence the way they collaborate (Varakin et al., 2004). Awareness information in such shared workspace environment is always required to coordinate team activities (Dourish and Bellotti, 1992).

The overwhelming amount of visual information on multiple displays, and the multitude of personal and shared interaction devices in new collaborative environments lead to a lack of awareness of team members on ongoing activities, a lack of understanding of shared visualisations, and a lack of awareness on who is in control of shared artefacts. The focus of our research is on the awareness support of co-located teams working on long-term scientific projects in collaborative working environments. Understanding who you are working with, what is being worked on, and how your actions affect others, is essential for effective team collaboration (Dourish and Bellotti, 1992). Such shared awareness helps getting jobs done that cannot be done by a single expert, or by experts that only have a limited range of disciplines covered. Moreover, shared awareness also leads to informal social interactions and development of shared working cultures which are essential aspects of maintaining good working relationships in a team.

Situational Awareness

Situational awareness (SA) concerns "knowing what is (and has been) going on", basically being aware of what is happening around you in the environment and having a shared understanding of the information. Before giving the extensive definition, we will first explain the importance of SA for team collaboration.

Situational awareness is expected to be an important determinant of team performance (Bolstad et al., 2005; Endsley, 1995). Especially in multidisciplinary settings situational awareness information is affected by abilities of individual members, their interaction with other team members, and the environment in which they collaborate (Bolstad et al, 2005). Various factors affect individual situational awareness formation: context (physical location, display arrangement and size, system capabilities etc.) and group aspects (communication, use of collaboration tools, team processes etc.). In order to assess SA during evaluation of collaborative interfaces or awareness displays, specific factors need to be identified relevant to a particular domain.

Situational awareness is critical in such complex multi-display environments that change rapidly and that provide a lot of information to keep up with. Recent studies (Borchers, 2006; Brad et al., 2002; Huang, 2006; Rogers and Lindley, 2004) clearly point out that people are less aware of their visual surroundings than they think they are. Data overload, fatigue and other stressors can undermine the development and maintenance of situational awareness (Boltstad, 2006). The phenomenon of change blindness shows that even if people have an accurate representation, they may still fail to notice changes (Martens, 2007; Varakin et al., 2004). Actively capturing attention at the location of the change by means of spatial cues improves the detection of the information and detection of changes. Therefore, it is of a great importance to design systems that support situational awareness and sharing of SA between team members in order to ensure that a collaborative environment supports efficient and effective team coordination and decision making.

Endsley's (1993, 1995) theory of situational awareness suggests that SA can be achieved by linking an objective state of the world to its mental analogue on three main levels: perception, comprehension and projection. Level 1 of SA—is perception of relevant elements in the environment. It is an active process whereby individuals extract salient cues from the environment. Level 2- embraces comprehension of the meaning of these cues. It involves integration of information in working memory (Salas et al., 1995) to understand how the information will impact upon the individual's goals and objectives. In this way an individual develops a comprehensive picture of the world in this way, or of that part of the world of concern to the individual. Level 3, projection, consists of extrapolating this information forward in time to determine how it will affect future states of the operating environment (Endsley, 1993). The third level of SA combines what the individual knows about the current situation with his or her mental model of similar events from previous experience, to be prepared for what might happen next.

In our research, we define SA as based on the three main aspects:

1. a person's previous knowledge and understanding of the situation, which contributes to identifying the source and nature of issues and problems;
2. detection and comprehension of the relevant perceptual cues and information from the environment, which supports comprehending multiple visualisations in their context;
3. interpretation of these and reconfiguration of understanding and knowledge in a continuous process during the group collaboration effort. This allows awareness of changes in the environment, knowing what team members do and have done regarding current events in the environment, and keeping track of work progress.

Henceforward we refer to *shared situational awareness* as to the amount of communality of the individual SA of team members on the three aspects defined above. Our research investigates the following questions: What does situational awareness mean in team collaboration? How can we support situational awareness in collaborative working environments? How can shared displays support shared situational awareness in practice? How can we design and evaluate interactive systems and visualisations that afford situational awareness in order to stimulate existing and new forms of collaboration?

Team Coordination

There have been a series of studies investigating group processes in real world situations. However, the tasks used in these studies did not address scientific teams. Still, one can be just as creative in science as in design (Johnson and Carruthers, 2006). A recent empirical study by Johnson and Carruthers provides a good overview of the relevant theories on creative group processes. Results of this work are requirements for software tools to support specific creative tasks (Johnson and Carruthers, 2006).

Other empirical studies, although conducted in real work environments, focus only on team coordination in extreme collaboration scenarios (Blandford and Wong, 2004; Manser, 2006; Wilson 2006). *Extreme collaboration* refers to collaboration within *warroom* environments where teams work together synchronously in all phases using a variety of computer technologies to maximize communication and information flow. For instance, Manser et al. (2006) investigate coordination needs of cardiac anaesthesia teams in an operating room environment. The result of their study is a conceptual framework for the analysis of multidisciplinary team collaboration in complex work environments. A qualitative study by Wilson et al. (2006) reports the impact of a shared display on small group work in a medical setting.

Applying a human-centered approach, we need to analyse the actual context in which the collaborative system will be deployed (Carroll et al. 2006; Varakin et al., 2004). An understanding of the work context will help us to design technology that supports team members in their primary task at hand, and thus leads them to communicate and interact in a collaborative environment with prolonged involvement and, hopefully, better results. It will also help us to find out how new computing technology in collaborative environments, such as large shared displays, influence scientists' work and team coordination (Hallnass and Redstrom, 2002).

AFFORDING SITUATIONAL AWARENESS IN SCIENTIFIC COLLABORATION

In contrast to domains such as aircraft or plant operation control, emergency dispatch or crisis management (Mark, 2002; Sharma et al., 2003), scientific teams are not working in life-threatening situations and are not under constant strong time pressure. However, long-term scientific projects involve high costs and therefore it is hard to recover from any errors. Shared visualisations on large displays have proven to be helpful to support group discussions because the support situational awareness (Borchers, 2006; Huang, 2006; Rogers and Lindley, 2004). Other examples of teams using a large display to enhance awareness of their activities are programming and design teams (Biehl et al., 2007).

Evolving technologies in molecular biology produce vast amounts of data. Scientists in this domain are confronted with the problem of applying methods from different disciplines when analyzing and interpreting their data, such as statistical, mathematical and machine learning techniques. Moreover, integration of the results from heterogeneous information sources is a difficult but essential part of the analysis of experimental results. Current omics experimentation in molecular biology, for example in drug discovery and cancer research, is a complex, highly dynamic and multidisciplinary task that requires teamwork (Rauwerda et al., 2006; van der Vet et al., 2007). It is essential for life scientists to design the experiment precisely and accurately to ensure the statistical validity of the data. Timely spotting outliers and abnormal patterns in a huge amount of data is crucial for experimentation (see Figure 1). Recent studies showed that there is a strong need for visualising the omics datasets on a shared display for comparing and discussion among multidisciplinary scientists (Kulyk et al., 2007; Li et al., 2005).

Presenting visualisations on a shared display in a collaborative working environment can support group discussions (Borchers, 2006; Huang, 2006; Rogers and Lindley, 2004). Looking at the statistical representations of the same data on a shared large display enables scientists to assess the quality of the entire omics experiment at a glance (Kulyk et al., 2007). The visualisations on the various parts of the display are implicitly related, in the sense that they refer to the same experiment, but currently it is not always evident what this precise relation is. To prevent team members from getting lost and to support situational awareness, the relations between various statistical representations have to be explicitly visualised. In order to afford detection of changes in visualisations and to avoid change blindness, it is important to draw team members' attention to current changes without distracting them from the discussion.

Multiple visualisations can be closely related, and therefore a change in a visualisation on one display will have to be related to visualisations

Figure 1. Scientists interacting with multiple visualisations in e-BioLab, MAD/IBU, University of Amsterdam

on other displays in a manner pioneered by the Spotfire[1] system. In our case, however, the situation is more complex. Scientists in multidisciplinary teams use discipline-related visualisations. For example, in microarray experimentation, spotting the outliers and abnormal patterns in the large data set can be done only by an expert in both statistics and in molecular biology, by analysing a combination of various statistical representations and microarray scans. Another example is when, at the microarray experiment design stage, a statistician needs to establish confidence intervals and statistical power of an analysis. However, only molecular biologists and microarray experts can assess whether it is experimentally possible in the wet-lab to increase statistical power or to avoid confounding by choosing a different experimental setup.

Molecular biology in general is a highly visual discipline (Campbell and Heyer, 2006). Visualisations play a large role in the analysis and interpretation of *omics* experiments (van der Vet et al., 2007), Figure 2. In the next section, the issue of collaborative working environments is addressed. We discuss how visualisations can support group discussions in such environments. We will also report our own experience on situation awareness support of scientific teamwork in a molecular biology context (Kulyk et al., 2007).

We argue that situational awareness can be supported in such environments by bringing relations between various visualisations in the focus of attention at any particular moment.

VISUALISATIONS AND SITUATIONAL AWARENESS IN COLLABORATIVE ENVIRONMENTS

Until recently, most of the studies in scientific visualisations mainly address the design of integrated software visualisation tools, with "single user—single visualisation" interaction. However, as a study on collaborative scientific visualisations illustrates (Li et al., 2005), the picture becomes more complex in situations in which groups of users will be interacting with multiple visualisations and communicating with each other at the same time. In genomics research, there is a strong need for visualising the large genomics datasets during multidisciplinary collaborative discussions for comparing and sharing data among scientists (Li et al., 2005). Designing visualisations for multiple use to enhance exploration of heterogeneous information is a new challenge in cooperative work.

Much of the work on situational awareness cited before is relevant but has to be adapted to

Figure 2. A scenario in which a life scientist is interacting with multiple visualisations

the specific needs of the multidisciplinary teams in omics experimentation: molecular biologists, microarray experts, bioinformaticians, and statisticians. The practitioners of the various disciplines involved in our research bring with them rich and often implicit background knowledge, as was found for scientists in general by Dunbar (1995).

The *e-BioLab* is a collaborative environment that aims to facilitate multidisciplinary teams during project meetings on molecular biology omics experimentation, with an initial focus on *microarray experiments* (Rauwerda et al., 2006). The goal of a microarray experiment is to simultaneously examine the expression level of all genes of a specific organism, in a cell type in a specific growth or stress condition. Microarray technology is currently one of the most important methods in genomics and is usually applied to unravel complex cellular mechanisms or discover transcriptomics biomarkers: genes whose expression profile can be used for diagnostic purposes or to monitor and predict cellular processes (Stekel, 2003).

In interpreting a microarray experiment in the e-BioLab, both the results of the experiment itself and those of statistical data analysis can be displayed in the form of visualisations on the large display, as in the example in Figure 2. In this way, team members can assess an entire microarray experiment. Moreover, in a multidisciplinary setup a large high-resolution display connected to online genomics resources can be used to construct models of biological mechanisms, thus enhancing omics experimentation and collaborative interpretation of the results. The largest tiled display is split into a number of displays, Figure 1 and 2. Visualisation of various statistical representations of the data on the tiled display enables scientists to assess the quality of the entire experiment at once. The visualisations on the various parts of the display are obviously related in the sense that they refer to the same experiment, but currently it is not always evident what the precise relation is. To prevent users from getting lost and to support situational awareness, the relations between various statistical representations have to be explicitly visualised. In order to enable detection of changes in visualisations and to avoid change blindness, current changes have to be put in focus of attention.

The complexity of multiple displays showing often complex visualisations can, as mentioned earlier, be reduced by employing attentive and proactive interfaces, also called notification services (Crowley, 2006). Such interfaces have to anticipate the context and provide an appropriate feedback without distracting the users from their main task. An example of such an interface for awareness and collaboration support is the persuasive displays environment designed by Mitsubishi Research Lab (Dietz et al., 2004). Such an environment can also include a *peripheral awareness display*: an information system or a graphical representation that resides in the user's environment and provides information within the periphery of user's attention (Plaue et al., 2004). Monitoring the peripheral display should cause minimal shift from the user's current focus of attention, allowing users to garner information without being distracted from their primary task. Most current peripheral display approaches use visual, auditory and tactile modalities for conveying the information. Our primary focus for this chapter is on the visual modality, since this is the main source of information in state of the art E-BioLabs. The information can be generated on the basis of multimodal cues sensed by the sensors embedded in the environment (Iqbal et al., 2005). The evaluation of such an awareness display is mainly focused on effectiveness and unobtrusiveness: the ability of the visual representation to communicate information at a glance without overloading the user (Plaue et al., 2004; Kulyk et al., 2006).

The next section gives an overview of various practical case studies on team coordination support in collaborative working environments. Our own case studies in different subdomains of bioinformatics are presented as examples (Kulyk and Wassink, 2006). We also introduce the assessment model of team situational awareness in collaborative working environments that can be used for human-centered design and evaluation during practical case studies. Finally, we discuss practical challenges in the design and evaluation of group support systems for collaborative working environments and our multi-level approach for the analysis of technology-mediated interaction. We end with a conclusion and discussion.

SITUATIONAL AWARENESS IN OMICS EXPERIMENTATION

The support of multidisciplinary scientific teams in collaborative environments is centrally addressed within our BioRange project. As in any user-centred approach, user studies and task analysis are a core activity in our research (Bartlett and Toms, 2005; Javahery et al., 2004; van Welie and van der Veer, 2003). Contextual observations and interviews are conducted to find out how such collaboration takes place in daily work practice between biologists, bioinformaticians, and biomedical researchers and how we can support them (Kulyk and Wassink, 2006). The results of our studies underline that multidisciplinary collaboration is essential in molecular biology and bioinformatics. Visualisations of experimental and biological data are used for discussing the experimental results and for assessing the progress of an experiment. Scientists expect they will profit from multiple visualisations in a collaborative environment. At the same time, they point out the danger of overwhelming the viewer with too much information. They strongly prefer to collaborate face-to-face. This is also confirmed in studies for other user groups (McCowan et al., 2003; Nijholt et al., 2006; Rienks et al., 2006) and for scientific teams (Dunbar, 1995). The results of our exploratory study have been translated into requirements for the support of collaboration and multidisciplinary teamwork in bioinformatics, as well as into profile descriptions of novices, experts and scientific teams (Kulyk and Wassink, 2006).

In order to identify the key aspects and user requirements for collaboration support in the context of a scientific collaborative environment, we also perform an extensive task analysis of the current microarray experimentation practice, based on contextual interviews and observations (van Welie and van der Veer, 2003). Use case scenarios for empirical studies in microarray experiments are provided by our project partners (Rauwerda et al., 2006). Scientists from various disciplines: molecular biologists, microarray experts, bioinformaticians and statisticians, closely collaborate during such experiments. In particular, we aim to build a detailed task model of microarray experiments. A task model of the current work situation describing phases of a microarray experiment is currently being validated with domain experts.

As the literature confirms, creative problem solving in scientific collaboration can be supported by providing an appropriate environment and a context (Coughlan and Johnson, 2006). However, introducing a new environment and new technologies, as for example presenting multiple visualisations on a large display (see Figure 1,2), may increase scientist's cognitive load and influence the way project team members collaborate (Varakin et al., 2004). Awareness information in such shared workspace environment is always required to coordinate team activities (Dourish and Bellotti, 1992). We believe that situational awareness is a very important aspect of co-located team collaboration in complex environments, as other research confirms (Manser et al., 2006) (see section 2). Especially in the multidisciplinary settings, situational awareness information is affected by individual team members' abilities, their interaction with other team members, and the environments in which they collaborate (Bolstad et al., 2005). It is essential to provide situational awareness support in collaborative environments in order to support team's coordination needs and creative problem solving.

On the basis of our current findings from conceptual studies and requirements analysis, we are performing a series of practical case studies. We are conducting a series of real-life observations during the project discussions of multidisciplinary scientific teams in the e-BioLab (Rauwerda

et al., 2006; van der Vet et al., 2007). Our aim is to get insight into how shared displays affect teamwork, and to contribute to the development of novel concepts to support co-located situational awareness in a scientific collaborative environment. In particular, we are investigating the effect of the large display visualizations on both individual and team situational awareness. We are also evaluating new designs to enhance the awareness by making relations and changes between different visualizations more explicit. For instance, during project meetings relevant visualizations on a tiled display will be highlighted and other ones will become faded. In this way, a presenter can draw the attention of other team members to visualizations relevant to the expertise of particular scientists, Figure 2. In addition, a notification of the annotations made on visualizations is essential to make all team members aware of the changes.

Concepts for SA Support in Scientific Collaboration

We are currently exploring various alternative solutions for SA support in collaborative environment for scientific teams (van der Vet et al., 2007).

For instance, a *Highlighting on Demand* interface enables the team member who is currently controlling the tiled display to draw attention of the team by highlighting a certain visualisation using a slider on a personal interaction device (for instance, TabletPC or a WiiMote controller).

Another concept is a *Memory Board* interface, which automatically stores and visualises the history of changes on a shared display, allowing team members to go back in time and retrieve a certain annotation made on previous slides or visualisations. This board serves as a peripheral display, affording memorability. It supports level 2 of situational awareness, comprehension.

We expect a supporting effect of visualisation of status information about who is in control of a display or another shared artefact on a personal interaction device. This would make every member of a team aware of who is making the changes and what changes are made. We also intend to visualise the *control interface* on a shared touch display, as well as displaying it on a personal interaction device (e.g. tablet PC). Such an interactive interface enforces sharing and thus supports coordination mechanisms and group awareness on who is currently manipulating and annotating the visualisations. It also partially resolves the potential control negotiation conflict about the annotation of visualisations and about manipulation of the shared display.

ASSESSING SA SUPPORT IN COLLABORATIVE ENVIRONMENTS

The complexity of communication processes in the co-located team and the use of a collaborative environment require the combination of a methodological approach to support situational awareness for team collaboration and a practical method to capture and analyse the dynamics of technology-mediated interactions in context. The nature of the interfaces as well as physical characteristics and affordances of the environment influence the way in which interactions occur (Fruchter and Cavallin, 2006). Therefore our approach for data analysis includes a combination of behaviour, interaction and environment analysis.

We will assess shared situational awareness of team members when we provide supportive visualizations on a shared large display. We aim at reducing disturbing factors that are considered distraction from the primary task. We intend to establish an indication of the relations between Situational Awareness, team satisfaction, group processes like decision making, and the perceived task performance. In our case multiple data collection techniques are used: direct observations to assess user behaviour based on a validated coding scheme (Biehl et al., 2007), screen capturing, video recordings, a validated post-questionnaire (Kulyk et al., 2006; Olaniran, 1996; Paul et. al., 2004), and a post-interview. Video recordings from several viewpoints combined with screen capturing of multiple displays, enables us to analyse several simultaneously ongoing interactions. In addition to the observations, post-interviews and questionnaires are carried out to obtain subjective judgements of the team members, e.g., on group satisfaction, awareness and distraction from primary tasks (Cadiz et al., 2002; Kulyk et al., 2006; Olaniran, 1996; Paul et. al., 2004). Group satisfaction will be assessed by a combined validated post-questionnaire featuring the group process and decision making (Olaniran, 1996; Paul et. al., 2004). We apply these questions to assess the perceived usefulness and impact of new *Highlighting on Demand* and *Memory Board* concepts on shared situational awareness of team members, on distraction from the primary task, and on team satisfaction with the group process and decision making process.

The three aspects of situational awareness described earlier, as well as recent related studies (Biehl et al., 2007; Blandford and Wong, 2004) are used to identify relevant factors of SA to design our questionnaire. We are adapting a computational model of shared situation awareness (Bolstad et al., 2005) to the context of our case studies. This model uses the Situation Awareness Global Assessment Technique (SAGAT)—an objective measure of situation awareness mainly based on work of Endsley (1995).

Our current observations and video analysis show that scientists tend to walk to the tiled display to inspect a specific detail of a visualisation, which indicates that they are treating the display different from a movie screen or a static projection. This points to the dynamic nature of interactions as reported in other studies (Tan et al., 2006). High resolution of the displays allows them to zoom on fine details. This indicates a high immersion, though possibly partially due to the novelty of the large displays.

Applying user study techniques and a multi-level method for data analysis will allow us to identify interaction patterns: natural ways in which team members interact with each other (behaviour patterns) and with the shared displays in the environment. Thus we may iteratively improve the design of SA support and construct a framework for the evaluation of how shared displays influence scientists' work and team collaboration.

FUTURE WORK

We will perform controlled comparative case studies on the impact of the Highlighting on Demand and Memory Board SA concepts. Our target groups for the first study are small multi-disciplinary teams (3-5 members) working on joint projects and scientific omics experiments in life science domain. We will assess shared situational awareness of team members, providing supportive visualizations on a shared large display. We aim at reducing the distraction from the primary task, and establishing relations with team satisfaction, group process, decision making process, and with the perceived task performance. Analysis of user behaviour allows us to define interaction patterns.

In the second case study we aim at assessing the long-term influence of large shared displays on team shared SA in other domain(s) and different collaborative environment(s). We will apply the adjusted measurements of shared SA from the first study. Cross-culture and cross-organizational differences might show different effects compared to the first study. The first target group for the second study are software engineering teams.

CHALLENGES IN MERGING COLLABORATIVE WORKSPACES

Although our primarily focus is on co-located collaboration in which situational awareness plays a crucial role, we also consider remote collaboration scenarios for future case studies in which *social awareness* (Röcker and Magerkurth, 2007) and *presence* (Bystrom, 1999) concepts are also of great importance. The study of Röcker and Magerkurth (2007) on the Hello.Wall display shows that people are apparently not always willing to publicly display their presence in the collaborative environment and prefer to set their own activity status. In our vision, this can be easily resolved by the abstract representation of the general current level of activity in the collaborative environment based on the level of activities of present members. Such an activity representation can provide awareness for the remote project members, and may raise curiosity and encourage them to join the team discussion remotely or even to walk to the building and take a look what is going on in the lab.

One of the future extensions on the e-BioLab environment is real-time teleconferencing in order to collaborate with other e-BioScience labs across the Netherlands. New challenges arise when we attempt to merge physical and virtual workspaces in collaborative environments. Figure 3 shows how 3D teleconferencing and natural documents sharing concepts[2] that were once presented for the future office vision, have been partially realised during the official opening of the e-BioLab.

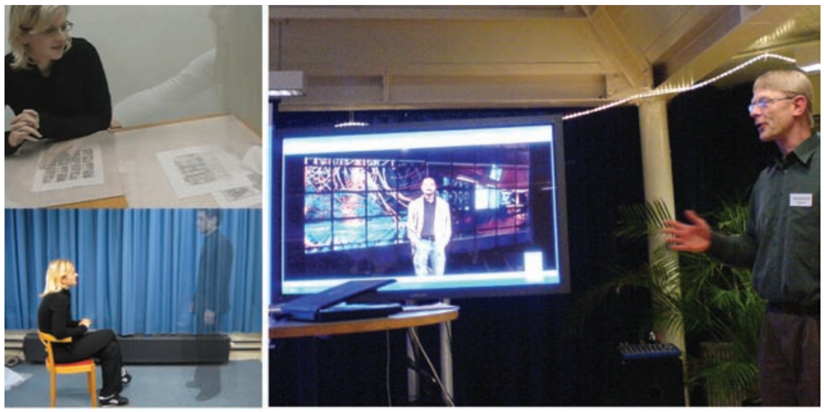
We have to explore the transfer of information between different types of displays, between the virtual workspace and the real one. Control of the shared display remains a potential problem to tackle. Our expectation is that, just as in the physical environment, team members will develop their own coordination mechanisms, negotiating about the control over the central largest shared display. The shared visualisation of the control interface on a plasma touch display currently remains the optimal solution. Sharing enforcement is shown to positively impact coordination strategies, and therefore should work for the team better then several personal controllers. Furthermore, refined evaluation techniques and measures are needed in order to adequately address these aspects of collaborative work in such hybrid workspaces.

CONCLUSION AND DISCUSSION

A new wave of advanced collaboration environments, such as collaborative interactive environments (Borchers, 2006), multiple display environments (Huang, 2006; Rogers and Lindley, 2004) and our collaborative working environment (van der Vet et al., 2007) requires new methods for design and evaluation in order to adequately address all aspects of collaborative work. This chapter presents the research on group awareness support to enhance team collaboration in the co-located working environments in the context of molecular biology omics experimentation.

This chapter aims to provide new insights into how to design and evaluate systems that afford awareness in order to stimulate existing and

Figure 3. 3D teleconferencing and natural documents sharing concepts[2] affording presence (left); official opening of the e-BioLab at the University of Amsterdam by Dr Jason Leigh from the University of Chicago (right)



new forms of collaboration in advanced working environments, as well as insights into how team members of various levels of expertise and backgrounds interact with new technologies in collaborative working environments. We present an overview of the state-of-the-art studies on team coordination and situational awareness support.

Furthermore, we discuss how visualisations can support group discussions and describe the collaborative environment for scientific teams in a molecular biology context. As a result we show that situational awareness is of a crucial importance in co-located team collaboration. We argue that SA can be supported in such environments by bringing changes and relations between multiple visualisations more in the focus of attention. We also report our results of an empirical case study and domain analysis translated into user requirements for the support of multidisciplinary collaboration of scientific teams. Finally, we discuss practical challenges in the design and evaluation of group support systems for collaborative working environments and hybrid workspaces, and present our multi-level approach for the analysis of technology-mediated interaction.

Practical case studies bring new insights into how new technology, in particular large shared displays, affects teamwork and contributes to the development of novel concepts for group awareness support. The main contribution of this chapter is the conceptual framework for studying situational awareness of multidisciplinary teams in collaborative working environments, as well as requirements and guidelines for new collaborative technologies to support situational awareness of teams based on the practical case studies. This work aims to inform the theory and practice of human computer interaction and design for collaboration support.

ACKNOWLEDGMENT

We would like to thank our collaborators Han Rauwerda, Wim de Leeuw, Timo Breit (MAD/IBU, University of Amsterdam), Tijs de Kler and Jorrit Adriaanse (SARA, Amsterdam) for their helpful feedback and for allowing us to use their lab and equipment in our studies. We also thank reviewers and other colleagues for their helpful comments and ideas inspiring this research. This work is part of the BioRange program of the Netherlands Bioinformatics Center (NBIC), which is supported by a BSIK grant through the Netherlands Genomics Initiative (NGI).

KEY TERMS AND DEFINITIONS

Awareness: is the ongoing interpretation of representations of human activity and of artefacts (Chalmers, 2002).

Collaborative Working Environment: is a co-located shared workspace that facilitates groups during meetings. The workspace is enhanced with multiple collaborative systems and media, such as private and shared displays, tabletops, touch screens, cameras and other devices.

Extreme Collaboration: refers to working within *warroom* environments where teams work together synchronously in all phases using a variety of computer technologies to maximize communication and information flow.

Group Awareness: is the understanding of who you are working with, what is being worked on, and how your actions affect others, is essential to effective collaboration (Dourish and Bellotti, 1992).

Microarray Experiment: examines simultaneously the expression level of all genes of a specific organism, in a cell type in a specific growth or stress condition. Microarray technology is currently one of the most important methods in genomics and is usually applied to unravel complex cellular mechanisms or discover transcriptomics *biomarkers*: genes whose expression profile can be used for diagnostic purposes or to monitor and predict cellular processes (Stekel, 2003).

Omics Experimentation: is a research area in molecular biology that deals with *omes*: large or complete arrays of cell components, such as the genome (all genes) and the proteome (all proteins). For example, studies that encompass the whole genome are in general referred to as *genomics* studies, and studies that examine the expression level of all mRNAs (messenger RNA, which directs the synthesis of proteins) in a given cell population are called *transcriptomics*.

Peripheral Awareness Display: is an information system or a graphical representation that resides in the user's environment and provides information or visual feedback in the periphery of the user's attention. Monitoring the peripheral display causes minimal shift from the user's current focus of attention, allowing users to garner information without being distracted from their primary task (Plaue et al., 2004).

Situational Awareness: is the perception of the elements of the environment within a volume of time and space, the comprehension of their meaning, and the projection of their status in the near future, and the prediction of how various actions will affect the fulfilment of one's goals (Endsley, 1995, p.36).

Shared Situational Awareness: is a reflection of how similar team members view a given current environmental situation. Thus, if a team has a high degree of shared situational awareness, we can assume they are perceiving, comprehending, and interpreting the situation's information requirements in a similar manner (Bolstad et al., 2005, p.1).

Task Analysis: is a domain-specific analysis of the current work situation, which combines such classical HCI techniques as contextual interviews, field observations, ethnography and interaction analysis (Jordan, 1996; van Welie and van der Veer, 2003).

Chapter 5.12
Developing Social Skills through an On-Line Learning Environment: A Qualitative Study

ABSTRACT

The rapid pace of social change deriving from technological and financial revolution and globalization, effects greatly people's lives. Adults nowadays need to stay relevant with their environment, to be proactive and to take important decisions that affect their personal and professional future. Thus, they need to be equipped with advanced social skills such as time management, leadership, communication, teamwork, problem solving, flexibility etc. Such skills can be developed through training programs, designed and delivered upon the Adult Education and Experiential Learning theories and principles. A central aim of this chapter is to highlight the methods through which e-learning can contribute to the development of social skills, implementing at the same time the above mentioned principles, in the context of a large organization.

DOI: 10.4018/978-1-60566-830-7.ch014

INTRODUCTION

The general goal of this chapter is to pinpoint the essentiality of social skills development through training programs which are designed and delivered according to the adult learning theories. It will also present a case study in which on line training seems to respond successfully to the learning needs of the employees working in today's demanding environments.

The chapter's specific aims are:

1. To bring out the necessity of social skills development for adults working in contemporary and complex environments.

2. To elaborate on the preconditions demanded in order for social skills to be developed in the context of large organizations.
3. To explicate the emerging obstacles during social skills development.
4. To analyze a case study which shows that e-learning can enforce and ensure most of the Adult Training and Experiential learning principles.
5. To present results demonstrating the effectiveness of developing a collaborative and creative on line learning environment.

A. The Necessity of Social Skills Development in Contemporary Complex Professional Environments

Contemporary social conditions and constant change are greatly and variously influencing adult lives, often resulting in professionals´ difficulty to stay relevant and meet their career demands. Caffarella & Lewis note that: "*In a society of constant change, like ours, learning and preparing for new challenges has become an industry targeting to all citizens and ages. Furthermore, and contrary to previous times, adult lives and choices are far more complicated and of a broader range*." (in Brockett & Knox, 1994, p. 1)

According to bibliography[1] such changes concern three major areas: social structure, financial globalization and rapid technological progress.

Constant *sociological* changes create the need for ongoing adult training and development so that citizens can face contemporary demands. Goleman (2000) supports that in times of employment instability, where the term of "labor" is replaced by the term "transferable skills" such skills are becoming of great importance allowing adults to ensure their present and future employment opportunities and progress. This means that members of the society should be armed with advanced skills in order to manage changes – both voluntary and involuntary – and must be flexible and fast learners. Furthermore, adults need to own such skills not only for surviving in today's society but also in order to lead a creative life, feeling content, utilizing a wide range of employment and personal development opportunities, and successfully encountering potential threats.

Equally the increase of competition and institutionalization of *globalization* affect the world economy. Organizations aim at decreasing costs and increasing the quality, as well as the variety of their products. Achievement of such aims can be pursued through human resources who can undertake multiple and complex roles and duties and thus should be characterized by self motivation and creativity, flexibility and problem solving skills, in order to overcome crisis and demanding work conditions (Phillips, 2006).

Last but not least, *technology* catalytically influences knowledge, entertainment, employment, economy and government. The necessity for technological conversance and new information technology practices daily entering working environments as well as the continuous data creation lead to rapid depreciation of existing professional skills and knowledge, (Meriam & Caffarella, 1999, p. 15).

Due to the above mentioned changes new working conditions are being created leading to the necessity of Social Skills for various employment roles. The term Social Skills refers to a group of skills – excluding knowledge, qualifications and work experience – that each professional should be armed with in order to meet the demands of his/her role and duties. In an attempt to clearly define the term Social Skills through Bibliography research, one often detects an indisputable core of skills containing abilities such as communication, teamwork, leadership, time management, flexibility etc. (Brookfield, 1986).

Goleman, (2000) reports some quite distinct examples in order to show the necessity of Social Skills in contemporary society:

- "In a modern technology company the group of employees dealing with the feedstock storage should carry skills such as active listening, comprehension, flexibility and cooperation within a team.

- In a medical centre, technical training and analytical skills are considered to be invaluable. However, emotional skills such as interpersonal abilities, innovation, effective leadership and cooperation with various institutions within a broader context surrounding the medical centre, are also quite important.
- In a large petrol industry, analysis and expertise are considered essential skills in order to succeed in the fields of mechanical engineering or information technology. Equally important are skills such as self-confidence, adaptability, goal setting, provision of quality service, teamwork, exerting influence, and personnel development." (p. 59).

Training and development can highly contribute in the exploitation of new opportunities and the successful encounter of potential threats. Jarvis, (1999) remarks that training can aid adults in achieving a more creative relationship with modern reality, enhancing their lives and eventually conquering the above mentioned social skills. However, which kind of training is considered to be more effective in the development of social skills? What kind of training techniques, principles and preconditions will assist adult trainees in developing social skills and consequently coping with their demanding career roles?

B. Basic Preconditions for Social Skills Development (Adulthood and Experiential Learning)

The previously described essential social skills that a professional must demonstrate in the workplace cannot be developed through the mere reading of a book or the participation in a relevant lecture. Carefully designed training should be delivered in order to cover the special training needs of the participants. Research reveals that personnel's training has not always been appropriate for the accomplishment of the above aims. Corporate training programs often target in plain knowledge acquisition using traditional learning techniques and thus their effectiveness is considered low. Sometimes organizations train their employees in leadership, creativity, change management and active listening, with seminars that are completely based in theory and lack of practice. It has been proven that such seminars have actually a negative effect rather than a positive one (Goleman, 2000).

On the other hand, the difficulty of the social skills development is a given fact, since it involves changes in a person's attitudes and behavior. It has pinpointed that laborers often participate in well designed training programs and courses, while employees working in an office environment dealing mainly with people rather than products, rarely participate in training. This is due to the fact that their development is considered difficult since it involves skills instead of technical knowledge. Their social skills are developed mainly though "trial and error" rather than the participation in a series of training events (Argyle, 1998).

Many scholars in the Adult Education field recognize that the social skills development itself as well as the nature of adulthood and the characteristics of adult learners, dictate a specialized training approach. It is noted that in order to develop social skills through training, student centered techniques must be adopted. Such techniques promote the active participation of the trainees and provide them with the opportunity to discover and mainly experience change before they are asked to put it in practice. Experiential learning and the training techniques involved in it seem to be quite effective not only in relation to the social skills development but also in regards to the profile of the adult trainee himself (Phillips, 2006).

The following factors and characteristics signal adulthood and create the need for a training design (either in classroom or through e-learning) that will satisfy its specialized conditions.

Adults participating in training have often recognized the need for it. Thus adults come in training with *particular goals*. If they don't manage to cover their goals, sooner of later they will terminate training (Rogers, 1999). Another characteristic of adult trainees is their *desire for action*. Thus, in adult training programs the trainer should share the responsibility of the training process, training goal setting and methodology with the trainees (Jackson & Caffarella, 1994). Another factor impacting the training process is the adult learner's demanding life and its *exigent obligations*. The training programme they are participating in is not their major activity. Thus they exhibit concentration difficulties especially if the training process seems uninteresting or does not require their immediate participation. When the trainer treats them as passive receivers they quite easily loose concentration and are more likely to reflect on their following day's concerns (Jackson & Caffarella, 1994).

The more important characteristic of adults that seems to mainly affect their training is their accumulated *experience*. Rogers (1999) mentions that trainees´ experiences can have a motivational function in the training process. The trainer can easily associate any matter with their personal experiences in order to maximize their interest in the training process and subject matter. In fact, such experiences should not be ignored since they depict the trainee's lives, in which they have sentimentally invested, and when disregarded they feel that their personality is being questioned.

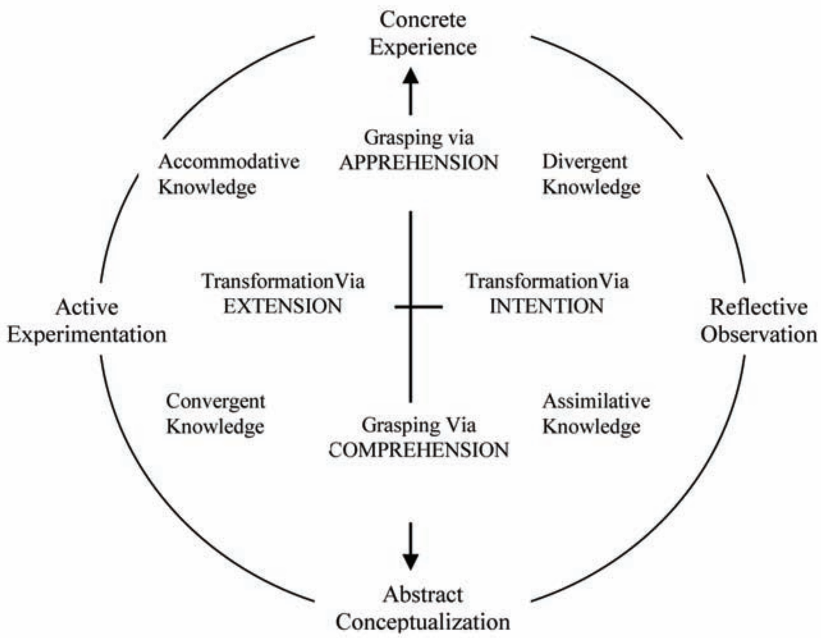
The above mentioned characteristics are immediately related to the imperativeness of the trainees´ active participation in the learning process, either by exploiting existing experiences or by creating new ones. Courau, (2000) describes active participation as one of the seven preconditions in adult learning. Noyé & Piveteau (1999) also support this position adding that the more participative the process the more effective the development and knowledge acquisition. Likewise, Piaget (in Merriam, & Caffarella, 1999) mentions the importance of the trainee's active role in the construction of his/her personal knowledge and abilities.

Freire, (in Kolb, 1984) also supported the necessity of *praxis* in the training and learning process. According to him action means reflection and participation in the real world in order to succeed personal transformation. Such learning and transformation can only be achieved through action (Merriam & Caffarella, 1999). Experiential learning seems to greatly meet the above mentioned preconditions of adult learning, since it is defined[2] as learning through experience or learning through action. Trainees are firstly exposed to an experience and then are encouraged to reflect upon it in order to develop new skills, behaviors or ways of thinking. Under these circumstances, trainees are mainly asked to act instead of listen and are motivated to analyze and reflect on their actions (Jackson & Caffarella, 1994). According to Dewey, (1997) - one of the first scholars to intensively research the importance of experience in learning – experience is created through interaction between the person and the environment. The experience obtained shapes, enriches and reconstructs the person's sentimental world.

Kolb, (1984) created a theoretical model on experiential learning known as the "Experiential Learning Cycle". According to this model the experiential learning process can be described as a cycle encompassing four learning functions: (a) concrete experience, (b) reflective observation, (c) abstract conceptualization and (d) active experimentation (p. 42). The main idea of this model is that learning results from the combination of grasping experience and transforming it into a form of knowledge. Kolb's (1984, p. 42) theoretical model is depicted in the following schema:

Experiential Learning's substantial difference from other types of active training is that all four

Figure 1. Kolb's Learning Cycle



stages should be implemented during the training process. Also, the stage of critical reflection is considered to be of great importance and if omitted the training event can not be characterized as experiential. Mintzberg (2005) studied the input of training programmes in the development of managerial staff and reached the conclusion that "although managers cannot be created in a classroom, existing managers can further develop there. Their experiences can turn the classroom into a rich arena for learning. Thus, through experiential training techniques such as Case Studies, for example, can help managers see their experiences in other contexts, while theory can help them generalize from their experience" (p. 243).

According to Jarvis (1999) developing skills– in the sense of someone being able to do something - can not be identified with memorizing theory but with an active nature of training. He supports that in order for someone to be able to do something in the workplace, she/he must have the experience of trial and error during his/her training, and to be able to experience its practical implementation. If a trainee just observes someone practicing a skill or listening to his instructions of how to go about it, it will not ensure its successful practical implementation from the trainee. Mintzberg (2005) comments that "“Transmission” is not the most important part of training but just a part of the process. Learning does not flow like electricity. And learners should no more be seen as "recipients" than trainers should be seen as "senders" " (p. 242). He also remarks that developing competencies – training for skills – is not a straightforward business. It can be difficult and time-consuming, requiring learning the basic idea, experimenting, being coached, receiving feedback and carrying that learning on (Conger 1992 in Mintzberg 2005 p. 257).

It is therefore concluded that both the nature of adulthood, which requires an active participation in the training process, as well as the importance of critical reflection upon experience, make experiential learning appropriate for social skills development. For this reason, many organizations worldwide have adopted experiential learning techniques during their in house training processes.

Extensive work has been carried out by the scholars of experiential learning, regarding its preconditions of effectiveness and the techniques which serve best its intentions.

A very important element determining experiential learning's effectiveness is *content*. Silberman (1998), argues that experiential learning programs should be selective, choosing the "need to know" before the "nice to know". They have a lean curriculum since they concentrate on the critical learning areas – those elements of the subject that provide the essential basis for building later. When the content level is kept moderate, the trainer has the time to design activities that introduce, present apply, and reflect upon what is being learned (p. 13).

A next precondition refers to the *variety* of learning techniques and approaches and the *balance* between them (Silberman 1998, p. 13). Using different learning approaches is likely to be more effective than a single approach that may work for some but not for others. Also, the trainer must design a balanced program allowing time for reflection. A program full of activities but no time for reflection will tire the trainees and will not give them the opportunity to consider how these techniques have worked for them and their skills development.

The techniques used in the program e.g. Role plays, case studies, simulations and games need to be *relevant* to the participants´ factuality and interests (Silberman, 1998, p. 128). Real experiences are deeply felt by the person who has lived it and yet easily shared with other trainees who have lived similar experiences (Mintzberg, 2005, pp. 266-267). The design and delivery of training techniques and the aims achieved by them should be closely related to the specific training *goals*. In order for experiential training techniques to be successful they should meet specific training purposes (Jarvis, 1999).

Negative feelings or conflicts may emerge during a training event, due to the experience of new situations or the relive of existing ones. Thus, the trainer should be fully *informed* of the trainee members. This will assist him/her in choosing experiences and activities that will not make participants feel uncomfortable or create an unpleasant situation for them. At the same time, the trainer should be armed with skills that will help him/her handle such situations and manage crisis within the training team (Phillips, 2006).

Another precondition for effective experiential learning concerns the *directions* given prior to a learning activity. They should be carefully though out in order to have the desirable impact on the participants (Silberman, 1998, p.131). Experiential Learning involves the effort of change and fear for such change may affect negatively the trainees. Therefore, they should be absolutely certain of the task they have to complete in order to feel confident and safe.

Due to all of the above preconditions the *learning environment* should be carefully chosen. Its role is important and should ensure an atmosphere of creativity and teamwork in order to avoid traumatic experiences. Studies showed that learning was greater and more effective within organizations with a positive environment characterized by autonomy and development opportunities (Kolb, 1984). Contrarily, when the environment is not encouraging many learning barriers emerge. Kirkpatrick (1998) clearly pinpoints the importance of the environment: "In order for change to occur, four conditions are necessary:

1. The person must have a desire to change.
2. The person must know what to do and how to do it.
3. The person must work in the right climate.
4. The person should be rewarded for changing." (p. 21).

Under no circumstances should the *reflection* upon experience stage be omitted. When reflection is ignored, the trainees cannot define what they have actually learned and achieved through the activity they have experienced (Merriam & Caffarella, 1999). T.S. Elliot writes in one of his poems "We had the experience but missed the meaning" (in Mintzberg, 2005, p. 254).

After the completion of the program trainees will return to their work place and will be asked to put into practice the knowledge and skills acquired from training. Silberman (2005) suggests the creation of an *action plan* regarding the "steps taken by participants and the obstacles they will face as they implement new ideas and skills" (p. 15). Thus the trainer should involve them in such future planning at the end of the training program.

C. E-Learning for the Development of Social Skills: How Successful Can It Be?

Although Information and Communication Technologies (ICT) were not particularly developed for the enhancement of learning, their potential over time shows that in the near future learning will be closely associated with the "e" prefix (Cedefop (a), 2001, p. 3). E-learning emerged in the early years of ICT development, in the form of Computer Based Training (CBT) or stand-alone multimedia Cds. Nowadays, many different types and approaches of technologies, tools, and ideas have arrived on the scene. Researchers are trying to identify models and theories in order to reach excellence and best e-learning practices (Ehlers et al., 2005, p.12). However, this is not an easy task. Even when examining "conventional learning" one finds a variety of theories each one attempting to explain the process of learning from its different point of view.

As far as e-learning is concerned, even the definition of the term is a controversial effort. Moreover, when researching relevant bibliography one finds more than one term: computer based training or computer assisted learning, blended learning, virtual learning environments, online learning and internet based learning, learning packages, learning management systems, are only few of them that may be connected (Coulon et al., 2004, p. 15-18). In the current chapter the e-learning term is associated to the use of technology for the support and enhancement of the learning practice during any stage of the learning experience and with the usage of any e-tool (Mayes & de Freitas, 2004, p.5).

Many e-learning implementations and designs were originally developed by computer experts and not by learning specialists. This led to the creation of non pedagogically-based learning practices, which in turn arouse many difficulties to the development of the new emerging discipline. Although such practices were not supported by educational and training principles, the field was technologically innovative and hence developed rapidly. However, after several decades of inquiry and research there now seems to be an effort to frame the several models of e-learning within certain educational principles. Such effort allows e-learning to mainly serve the "learning" part of the term, rather than the "e" part (Coulon et al., 2004, p.14; Ehlers et al., 2005, p.31, 71). More specifically, there are three basic perspectives that generate different e-learning strategies according to the assumptions about what is crucial for understanding learning. These are:

- the associationist perspective (learning as activity),
- the cognitive perspective (learning as achieving understanding) and
- the situative (learning as social practice).

The above perspectives have been respectively connected with relevant learning theories (Mayes & de Freitas, 2004, p. 7-10). The first perspective is connected with Associationism, Behaviourism and Connectionism research traditions, which are mainly based on a bottom-up approach where learning starts from small and logically ordered chunks and moves to more complex and interconnected meanings. The second perspective is based on Information Processing theories where learning takes place when new forms of understanding are built through activities. New experiences help the learner to construct new meanings and understanding upon already framed structures. The last one is connected to a Social perspective and is based on communities of practice and situated learning that is created amongst groups of people. According to Mayes & de Freitas (p.10) these perspectives are not necessarily contradicting. However, the important fact here is that every e-learning design should be characterized by one (or more) of the above mentioned perspectives. This will assist the alignment of the e-learning strategy with the specifically designed learning outcomes which can be achieved through learning practices and processes.

As mentioned previously, the development of social skills in the contemporary professional arena is of great importance; however certain limitations and boundaries can lead to non effective training interventions. Such boundaries can be of practical nature (time, place) and may create substantial difficulties during the learning experience (lack of or limited participation, training effectiveness etc). Important obstacles such as distance between the seminar room and the working environment may be aroused. Such obstacles may be overcome with the exploitation of e-learning tools and their particular training advantages (flexibility of time and place, collaborative constructed knowledge, development of best practices in real-life cases etc.). The approach of the research presented in the current chapter, has mainly adopted the Cognitive and Situative perspective, and at the same time it attempts to incorporate the adult characteristics and experiential learning principles and preconditions described earlier, in order to overcome the mentioned barriers.

The program design proposed in the current research embraces the theories of adult education and experiential learning, wishing to support more effectively our learners and provide them with suitable learning experiences. More specifically, the fulfilment of the adult characteristics and the effective learning principles mentioned in the chapter's earlier stages is succeeded through the following:

1. **Adult learners come in training with *particular goals*.** In the proposed design of the e-learning program trainees are asked to clearly and openly state their personal training needs to the rest of the team. These statements are marked on a separate discussion board accessed at any time during the learning event. At the same time the board with their mentioned needs help participants assess their progress during training.
2. **Adult learners have a *desire for action* (praxis) related to their real life context that will provide them with new experiences to reflect upon.** Their training program has been enriched with several practical ideas for implementation in their everyday working place. Participants are asked to share, discuss and reflect upon these ideas. The added value of an e-learning environment is that even if trainees being in their own environment they can simultaneously participate in a learning event. Thus, they do not experience the gap between real life and training which makes their contributions more specific and their discussions more effective.
3. **Adult learners live demanding lives and have *exigent obligations***. Although the training program has a weekly curriculum, flexibility is assured through the absence of definite deadlines. Also, group discussions amongst trainees are arranged on certain times; however, opportunity for feedback is given, even for the latest submissions, allowing them to work at their own pace.
4. **Adult learners come to training with accumulated *experience* and existing beliefs**

and ideas. The designed activities are based on their personal structured concepts and give opportunities to reflect upon their assumptions and life decisions. The e-learning environment allows them to think and rethink over their assumptions and observe their progress.

5. **The training process should refer to the participants' real life events.** The learning activities require participants to share personal working experiences and events, and propositions regarding best working practices, processes etc.
6. **Experiential learning needs extended duration to contribute effectively to ones personal development.** The e-learning environment gives the opportunity to participants to keep in touch with the subject matter, their tutor and their colleagues for as long as they wish.
7. **Experiential learning should be followed by an action plan for implementation in the work environment.** The e-learning environment gives the opportunity to participants to prepare an action plan on a calendar and stay in touch with it and with their personal learning goals, even when they return to their workplace.

The principles analysed above and the related actions taken into account in the design of the course are clearly connected with the socially mediated constructivist perspective to e-learning (Muirhead, 2002). According to Mayes & de Freitas (2004) the cognitive perspective views learning outcomes as an interaction between new experiences and the structures for understanding that have already been created (p. 9). This is connected with several of the above principles (2, 4, and 5). Also they state that new forms of understanding are gained though activity, which is also reflected in the experiential learning principles we tried to turn to advantage in our design. Participants work to discover broad principles and construct meaning through their experiences. All these can be achieved in a collaborative environment where trainees share what they gain during the learning process.

Moreover, some of the basic principles of this overall design derived from Anderson's ideas on freedom and social presence. To succeed and gain the participation of employees to a project with no extrinsic motivation, we should give them maximum freedom and flexibility and at the same time offer them the greatest opportunity for learning, participation and communication (Anderson, 2005, p.1). With the e-learning method participants obviously gain flexibility of space and time. With lack of fixed deadlines they also have freedom of pace. As far as freedom of media is concerned, many usability constrains can appear that may hinder the learners. Yet, a significant effort to find new and flexible ways to learn is possible, using alternative tools. Freedom of access was an important success of the presented e-learning project mainly due to the fact the banking organization in which it took place, made the application available through the internet, meaning that no extra cost was added to neither the participants, nor the organisation. Freedom of content can also be achieved. Although participants in this project, did not have the opportunity to change the instructional style, they had alternative choices over where to post (blog or discussion forum) and if it should be public or not. They also had several opportunities to enrich the content by adding some of their favourite material relevant to the subject matter. Finally, freedom in creating relationships was an immense benefit for the learners. New and close friendships were generated amongst participants and partnerships initiated in order to perform stress-release activities, followed by briefing to the non participant members of the team, regarding their experience. Some of the trainees chose to be more discreet in creating relationships and opted for posted messages in discussion forums restraining from closer contact.

D. The Case Study: A Collaborative E-Learning Environment in the Context of a Banking Organization

D1. Description of the E-Learning Course Provided within the Organization

The designed e-learning course presented here is provided to the employees by the banking organization they work for. The course theme is "Stress Management" and is available to all staff occupying clerical and non managerial positions. Most of them are graduates of management or financial university degrees and have a good level of ICT skills. However, they have limited prior e-learning experiences. They are positioned in quite demanding posts, with many customers to serve and need to deal with multi tasks simultaneously.

The e-learning course's goals are to:

- Understand the definition of stress and how it affects their lives.
- Realize their stressors and symptoms of stress that they personally experience.
- Develop their self-awareness in regards to stress.
- Identify the stress release techniques that suits them best and implement them in their everyday professional and personal lives.

The duration of this e-learning course is four (4) weeks. Each week deals with a particular subject matter (**Week 1**: Defining stress, **Week 2**: Basic stressors, **Week 3**: Fundamental stress symptoms and **Week 4**: Effective stress management techniques).

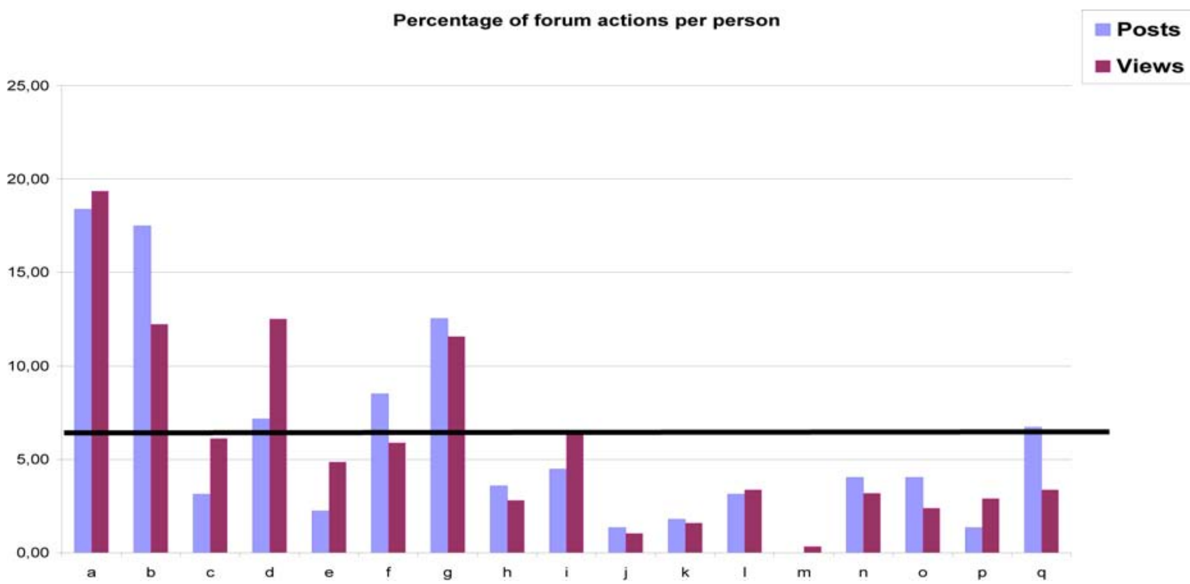
The structure of the program and the main area where the activities are held is a Moodle Virtual Learning Environment[3]. The main technologies used for the set of activities proposed are: Discussion Forums, Wikis and Blogs. The Moodle site provides a unifying accessible space which learners can visit in order to be informed about the program, the activities and the study resources. Through the same space they can access discussion forums, the wiki application and a blog facility. Especially for the blog facility, which is embedded in the Moodle application, its affordances are bounded if compared with usual blog providers, and it is preferable to use a more convenient one for related activities. Moodle also provides a suitable place for building communities with several communication facilities (one-to-one, one-to-many, many-to-many) and content management tools (building wikis, databases, glossaries etc.) that can serve fully the socially-mediated constructivist approach (Moreno, et al., 2007, p. 893).

Some other key issues that have informed the design derived from Goodfellow's report on Computer Mediated Communication and the lessons that were learned about it in the OU (Goodfellow, 2006). The main purpose of this e-learning project was to give an opportunity to participants to work together and stay in touch with the subject studied in a more interactive and long-term way, than the one-day classroom seminars. A major issue that also arose was the amount of workload that would be added to their existing demands of their personal and professional lives[4].

D2. Data Collection

The data presented and analysed was collected during a pilot phase of the course. In this phase 20 participants were randomly selected and invited. The data collected by Moodle and used in the analysis below were the logs of the group's actions (views and posts) regarding resources and forums. Also, an open-ended questionnaire was distributed at the end of the program, which participants anonymously filled out. This aimed in evaluating their learning experience. Lastly, all the discussions held in the forums were available for analysis.

Figure 2. Percentage of forum use (posts, views) per participant



D3. Data Analysis

Analysing data gathered from a case study is a difficult task and many pages of information and remarks can be collected. In the current case study focus is given on analysing the users' log files and on cross examination of these findings with the statements of participants presented in their evaluation questionnaires.

a. Forums

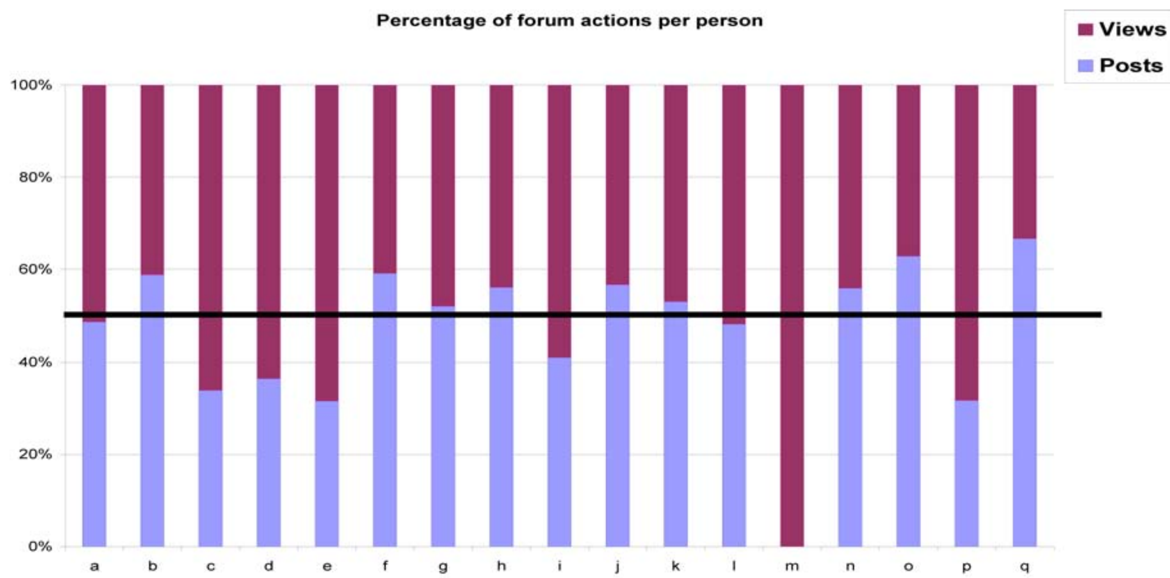
The use of forums was one of the most interesting and indicative aspects of the study. The forums' log files where processed in two different categories as shown in Chart 1.

The horizontal line in the Figure 2 indicates the average forum use. Amongst the group members one can find participants with very high activity, as well as participants with average or low activity. However, the following interesting point is detected: there is a great variety of behaviour when comparing percentages of posts and views. More explicitly, there are participants with similar patterns of access and postings, others with similar patterns only and those that have either a higher preference in access or others with a higher preference in postings. Even though one would expect the percentage of views to be higher or similar to postings, this is not the standard case. Moreover, those with the greatest difference (higher percentage of postings compared to views) are those who are employed in the bank's branches. This fact could be an indication that participants who are branch employees accessed the site in a more "effective" way. On the other hand, those participants that are occupying positions outside the bank's branches (e.g. Headquarters, administration and support positions), have a more frequent access record, even though such access was made just to check out whether other participants were posting something or to just browse the site.

The above results are depicted in Figure 3. The horizontal line indicates the dominant behavioural pattern for each participant.

The most frequently accessed forums were the ones serving introductions amongst participants. The forums created by the participants themselves in order to include information they personally gathered in relation to stress, were also, frequently

Figure 3. Percentage of forum use comparing post actions and view actions per participant



accessed. The highest activity was reported during the fourth week's forums. Such finding could be predictable since during the fourth week the most valuable and interesting topic was discussed and analysed: the basic techniques used to manage stress. However, this high level of activity was not focused on accessing the fourth week's relevant recourses and advices on stress management provided by the training programme itself. Instead, participants entered forums in order to discuss their personal experiences and methods that worked best for them in their stress management pursue.

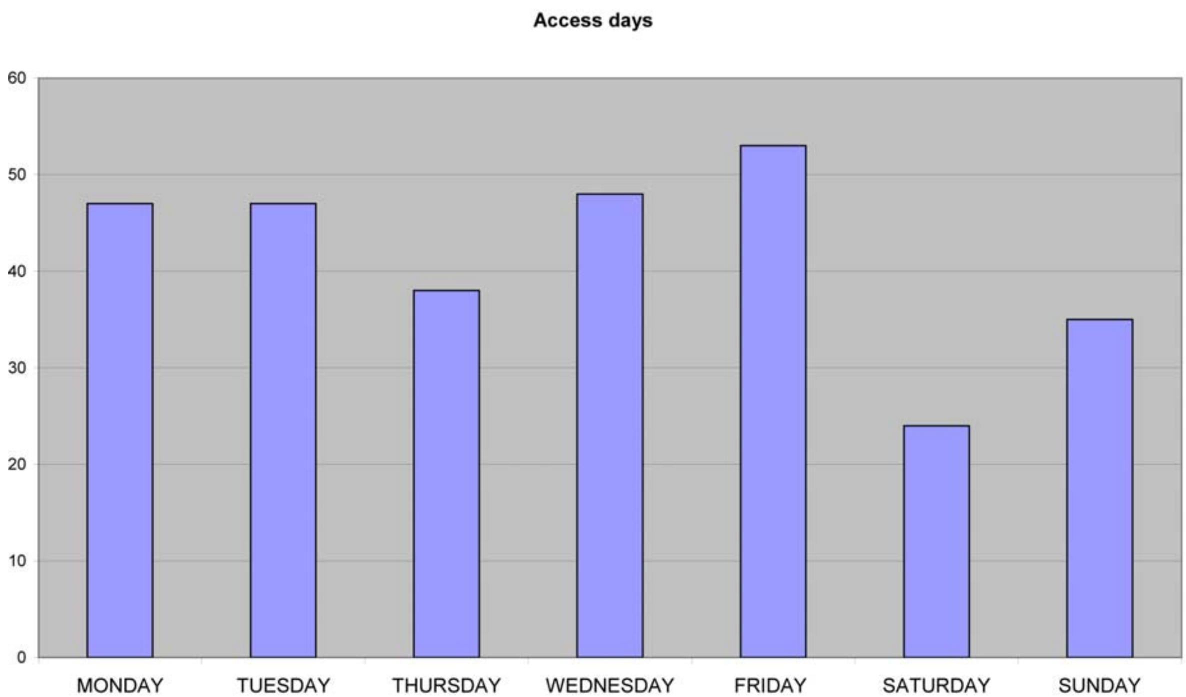
b. All Actions

An interesting finding concerning the evaluation of log files is that the actions taken from participants occupied in positions other than the bank's branches (e.g., headquarters, support and administration) are of greater quantity than the actions taken by frontline employees positioned in branches. Such finding could indicate that work pressure and work load is greater in frontline positions, thus hindering participants' learning process and progress. Moreover, the average site use by female participants was double in quantity compared to use by male participants.

It is worth mentioning that even though the most interesting and important recourses (articles etc.) provided by the training programme, were available during the fourth and last week of the learning event, they were least accessed by the participants. However, the forums of this particular week were the most accessed ones (as mentioned earlier). On the other hand, the most frequently accessed recourses were those of introductory remarks, first theoretical approaches to stress and the database with advices and ideas to managing stress.

A description of access in relation to each weekday is presented in the following graph. One can see that weekends are the least popular regarding the participant's preferences. It is also indicative that trainees with children never accessed the site during weekends. This may be interpreted that the course is considered by them as strictly professional concerning solely their

Figure 4. Percentage of participants' access in weekdays



career, while weekends are dedicated to personal interests and family members.

c. Questionnaires

One of the findings emerged from the questionnaire[5] analysis is that participants need to see adult education and experiential learning principles and techniques implemented in e-learning training.

More specifically, all of the participants mention (directly or indirectly) that the main benefit gained from the course was the opportunity to interact with colleagues. They also report that their greatest payoff was their active participation and the substantial role given to them in the construction of knowledge through the learning process. An example supporting such evidence is that the first question, dealt with the course content and the trainees' views regarding it. Participants' answers did not focus on evaluating the content provided in the internet but on the fact that they had many opportunities to contribute to learning, to create their personal knowledge and to taking action (praxis).

Their answers regarding details about the actual knowledge gained include peer learning as one of the greatest course advantages and they consider interaction as a main factor of developing their self-awareness. Only one third of participants mention details regarding actual knowledge gained. It seems that their main criteria for measuring the course success is the attitudes developed towards themselves, other participants and the subject of stress.

Additionally, in the second part of the questionnaire, participants opt for even more praxis and communication opportunities amongst them. This is also indicative of their priorities, especially if their answers are associated with the many drawbacks of the system's usability and efficiency.

It is also important to analyse their answers given to those questions concerning the differences participants detected between this e-learning procedure and other more traditional classroom courses attended in the past. Their answers can be classified in three categories. The first category is related with the opportunities given for experiential learning. The second category is related to access and flexibility of the course that gave them the opportunity to involve themselves in further critical thinking. Finally the third category is related to the opportunities given for interaction amongst participants. These three categories of answers are aligned with we described earlier as important preconditions for adult learning, and from their answers it is obvious that the program succeed in providing them.

Answers to the question relating to problems and difficulties participants faced during the training event, are associated with two major barriers: a) lack of time and plurality of professional or personal obligations, and b) system difficulties regarding access or limited experience on dealing with similar technologies. These answers completely agree with the adult learner's profile prescribed earlier in the chapter (high level of obligations, limited time, difficulty with changes and new technology etc).

D4. CONCLUSION

Change in practices come real slow in large organisations, due to the fact that the work environment learners return to is not supportive enough to help them retain their progress (Mintzberg, 2004, p. 242, 257). In this framework we tried to present a case study in which e-learning seems able to enhance the learning processes and to help adults overcome obstacles restraining them from effective training. The necessary prerequisites for the design of the e-learning course derived from the Adult Education and the Experiential Learning theory.

The necessity for employees´ social skills development, whether they are working in a large or a small organization, has been proved to be a critical factor for a company's advancement. However, such skills development is a quite demanding project. Contemporary rapid financial changes do not allow for a student centered training culture, when it comes to personnel's development. Hence, it is accustomed to encounter poor and superficial learning practices in order to manage more efficiently budgets regarding human resources training.

Through the case study presented in this chapter one may conclude that such difficulties maybe overcome by the implementation of e-learning practices which seem to greatly support the social skills development of a company's human capital. The current research findings have shown that the appropriate exploitation of e-learning tools, along with a student centered approach, may assist substantially the field of adult education.

The most innovative element of the programme presented is considered to be the fact that participants were given the opportunity to meet colleagues from various posts within their banking organization and to develop precious relationships and rapport with them by exchanging personal thoughts, experiences and critically reflect upon their fears and barriers. What was mainly constructed is a supportive community.

For trainers, the benefits can also be great. For example as it is referred in Goodfellow's report it is itself an opportunity to radically alter conventional distance-teaching relationships (Goodfellow, 2006). It is obvious that such an effort can contribute positively to the organisation and its training results, to the people and the strengthening of relationships and finally to the educational practices adopted and developed.

Assuredly, the restricted scale of this case study allows ample room for future research. A larger scale investigation should be performed in order to gain sound proof of its actual efficiency, especially in regards to the trainer's work load. At the same time the trainees' working conditions should be further examined preparative to the discovery of whether their participation is regular and effective. Even though the research showed that both front line and administrative personnel intensively participated, their in between average gap was considerable. Finally, the creation of standardized activities will greatly assist in the exploitation of the current research's findings.

ENDNOTES

1. Jarvis, P., 1999, Merriam S., Caffarella, R., 1999, Goleman, D., 2000, Brocket, R., Knox, A., 1994, European Committee, 2000
2. According to Jarvis, P., (2004) "Experience" is defined as the subjective cognition of a present situation, cognition which is generated only though reflection of previous experiences.
3. Available at www.moodle.org
4. At the Appendix of the chapter a part of our design is described according to Salmon's e-tivity model
5. The questionnaire is available in the Appendix

APPENDIX

Name of e-tivity	**Stress- actuation or disease?** ***Explore what stress really is, what hidden or not stresses you.***
Purpose	Participating in this e-tivity you will have to opportunity to explore the different ways researchers have interpreted stress and how it works in your body, mind or behaviour. Identifying the stressors that affect you, you will increase your self-awareness. You will have the opportunity to exchange views, ideas and experiences concerning stress and self-test your personality.
How many participants	15-20 participants
Structure	The activities will run over tow weeks and will have the above time plan **Week 1: introduction and understanding of stress** 2 hours – self introduction and orientation towards stress 3 hours – three theories concerning stress **Week 2: stressors** 1 hour – the main stressors 3 hours – personality type 1 hours – stressors at work
Associated media and other resources	Moodle platform will be used as single a access point for discussion forums and resources to read. Also as a wiki application provider. Vox will be used as a blog provider, because of its flexibility on levels of privacy. Using it participants can choose which will view their posts. Thus, it is possible for a group to make blogs and write posts that can be seen only among them. This fact will serve the purposes of the course. Short readings concerning 3 different approaches to stress (300-600 words each), personality type A-B (300 words) and work-related stressors (300 words). Two embedded self-tests, created with Moodle tools, to give the opportunity to participants identify their personality type and try the Holmes & Rahe inventory concerning stress (Ross & Altmaier, 1994, p.138-139). Wikipedia, as a recourse of contradicting theories and views over a single thing (in this case personality type).

Student actions	**Week 1** **Introduction**: Students are expected to introduce themselves in a specific discussion forum, intended for it. They will be asked to introduce themselves by saying their position in the organization, anything they want to say about themselves that will help others know them better, and if stress was a person-hero, object or animal, what exactly would it be. Also they would be asked to comment at least two others introduction messages. (1 hour) **Orientation to the course**: Students are advised register to Vox blog provider and announce their url to the course team in order to make their blog available to them. A group of blogs which can be seen only among them is created. Then participants are asked to read the course learning intended outcomes and write a post on their Vox blogs a stress experience they had in the past and their thinking when they decided to register to the course. Finally they should write their own aims for the end of the course. In the end they will have the opportunity to read back and see whether they have succeeded their goals. (1 hour) **Approaches to stress**: Participants are asked to read short texts that present three different approaches to stress (Ross & Altmaier, 1994, p. 1-7). Then in separate discussion forums they are asked to find an example of their stress experiences and try to interpret it through these three different approaches. Also, concerning the second approach they are asked to fill in an inventory and discuss their results. (3 hours) **Further reading:** a set of resources are available to participants if they wish to find more about these approaches and they are asked to add any more information or articles they have found and are related to the discussion. **Week 2** **Basic stressors:** Participants are encouraged to “brainstorm” on a wiki what stresses them. After several contributions a discussion concerning the categories of stressors begins in a discussion forum. (1 hour) **Personality type:** Participants are asked to fill in a self-test to find out which personality type they are. Then they read a short article concerning the basic characteristics of A-B personality types and discussion concerning their results begins. Because personality types are a subject under much controversy, after the discussion, they are asked to access wikipedia and the find related article. They are asked to read the discussion tab of the article and discuss their findings. (3 hours) **Stressors at work:** Participants are asked to re-read the wiki, where the e-moderator should have organized their contributions to different categories of stressors (physical, social and occupational) and have added some notes concerning occupational stressors. Participants are also asked to add any information they have found on their searches concerning stressors at work and discuss their findings (optional) (1 hour). During the 4 weeks of the course they are encouraged to keep posts in their blogs (either public or private), about their thoughts and behaviour concerning stress and evaluate their own progress.
E-moderator actions	The e-moderator during these two weeks should: • Help participants with any technical problems they face. • Respond in queries concerning the subject of study whether they are expressed publicly or individually. • Give clear guidelines during the activities concerning the intended outcomes ad encourage participants’ involvement. • Participate in discussions, comment blogs and moderate the wiki activity, in order to show participants the affordances of communication tools and strengthen the sense of being important. • Give feedback to discussion forums and pose more questions in order to help participants broad their views on the subject they discuss. They should be challenged to reveal their assumptions concerning stress, their personalities, their position etc. The above actions could occupy him-her 1-2 hours everyday of the course, according to students’ participation.
Evaluation	To evaluate the activities above three main directions are taken: • Evaluation of participation, in terms of quantity and quality. • Assessment of broad conceptual understanding: qualitative content analysis on their contributions in discussion forums and blogs • Assessment of participants’ interest and view: Feedback from participants concerning the several parts of the activity, which of them were helpful, difficult, interesting, etc.

Evaluation Questionnaire

Questions concerning the content of the course:

1. Which part of the course content you found most interesting? Explain why.
2. Which part(s) of the course you found most tiresome? Explain why.
3. Were there any parts of the course that needed more clarification? If yes, describe them.
4. What have you learnt from this course?

Questions concerning the training method:

1. Which characteristics of the course were mostly effective in helping you learn the subject matter?
2. Which characteristics of the course you consider to be the most difficult?
3. In which ways this course was different compared with other conventional seminars you have attended?
4. Which of the above differences you consider difficult in regards to your personal learning experience?
5. What is your opinion of your tutor? Did she have a positive or negative role regarding your personal learning experience? Was she inconsistent in any way?
6. Did you find any limitations in relation to your participation and contribution to the course in general? If yes, please explain the reasons.

Questions concerning the implementation of the system:

1. Do you consider any future difficulties in regards to the participation of other colleagues or the implementation of the system? If yes, plese describe them.
2. According to your personal experience from the participation of the program, do you have any suggestions regarding changes on future implementations?

Please add any comments you may have:

Chapter 5.13
Social Networking and Schools:
Early Responses and Implications for Practice

Chris Abbott
Reader in e-Inclusion, King's College London, UK

William Alder
Sixth Form Student, Trinity School, UK

ABSTRACT

Although social networking has been enthusiastically embraced by large numbers of children and young people, their schools and colleges have been more cautious, and often concerned about the implications for online safety. Social networking used by young people is considered here as part of a trajectory of online practices which began with personal Web sites in the mid 1990s and continued through the use of interactive services to the networking sites familiar today. The response of the education system is examined through interview and anecdotal evidence, and with reference to a growing body of research in this and allied areas. It is concluded that social networking has initiated a series of practices which cannot now be abandoned, and that the challenge for the education system is not control or abolition but the inclusion of social networking appropriately within teaching and learning.

INTRODUCTION

If the placing of a research tender can be seen as indicative of the maturity of a topic for study, then the recent award of a contract by Becta, the UK government agency for ICT in education, to research current in-school and out-of-school Web 2.0 experience is an indication that social networking is a relevant area of study for those seeking to understand educational practices in the UK. The researchers at the three Universities involved (www.lsri.nottingham.ac.uk) will be faced with a range of responses from the education system to the social networking sites that form a key part of current Web 2.0 practice.

Young people of school age frequently use social networking sites in the way that their counterparts of ten years ago used personal Websites: to provide an online representation of themselves and their views and interests, and to communicate with others who may share these preoccupations. Schools and other educational institutions have responded in different ways to this; often by banning such activity but occasionally in a more enlightened way. This chapter will describe how this has happened, outline the positive affordances of social networking for education, and will then suggest a more constructive response from schools and colleges.

SOCIAL NETWORKING AND YOUNG PEOPLE

Social networking has developed rapidly since 2003 and its use by young people has been characterised by successive waves of enthusiasm and ever-changing allegiances. Early alliances with MySpace have given way, for the most part, to institutionally-based networks such as Bebo or culturally-marked sites such as Facebook. At the time of writing, MySpace is seen by many young people in the UK as being more appropriate for younger children, with Bebo having a strong presence within youth in educational institutions and Facebook mostly catering for the late teen and young adult middle class user. This breakdown should be seen as a snapshot in time, however, and, during the period in which this chapter was written, the increasing take-up of Facebook by young professionals has led to a slowing down of its adoption by school-age youth.

It is interesting to note the differing degrees of anonymity in these systems, with the early and largely-anonymised MySpace giving way to Facebook and its supposed use of real names at all times. The youngest children of all have only recently begun to use social networking through systems such as Club Penguin, recently purchased by Disney in a sign of the financial potential of this area of the online market.

Making assumptions about the relative standing of different social networking sites can be a difficult process. Sites which are seen as of great importance and are sought-after one year can then be demoted the next, as is to be expected with a medium which is closely linked with other areas of youth interest such as music and fashion. One of us is an experienced social networking user and explains further, taking issue with some of the assumptions in the popular and academic press.

I'd say MySpace has a particular type of teenage interest, not younger. Also, it focuses on more arty people to a certain extent – ...[there is a] music function, and there are video and other places to display your own work. It also lets you modify your page to make it look how you like, …but personally I find that extremely annoying. I don't like how you cannot read information about people, because it's in a ridiculous font or too small, or because of the photo behind it all due to someone's bad coding. That's what I like about Facebook, you can easily read what people have written about themselves. The day that Facebook changes that is its downfall!

Also, Facebook is much more institutionalised. It used to be the case that you had to have a school, college or university email in order to have an account on it. They've changed that now. It's based around schools, colleges and Unis and where you come from, different networks. (Alder, 2008)

In addition to these wide-ranging general social networking sites, users have the opportunity to align themselves to owned social networks such as Friendlink.

Friendlink is a place for young Quakers (members of the Religious Society of Friends) to meet and greet. It is a forum for discussions, with sections for general chat, creative writing, poetry, role play and so on, and an online forum-based games area. Most of the members know each other outside of the forum in real life, but some are from across the world, and are attracted to meeting other young Quakers.

Friendlink differs from Facebook as it is aimed at a specific group, young Quakers, though it does accept others. It is worth examining further not because of any intrinsic importance in itself but as an example of a different style of social networking site, and to which one of us (Alder) belongs. It is also forum based, and although there are places for socialising and putting photos of events and so on (all screened from the public eye), there are many heated discussions about topics that would not be as greatly fought out on places such as Facebook. Although almost all participants come from a Quaker background, there is no common theme in what is believed, and diverse views are represented: Quakerism varies greatly in different countries, having no set beliefs or ways of worshipping. In a sense, where Facebook is more about the individuals and their lives, and is the impression that they wish to give to others (by the use of profiles with photographs, background information, personal profiles and so on), Friendlink is much more about the individual person's beliefs and what they think about particular issues. Although there are spaces to catch up about people (such as *Something that made you smile today* or *Things to love and hate today*), much of Friendlink is about events or current issues that people want to ask about, and apart from groups on Websites such as Facebook, there is no other counterpart to this activity, at least not within a focused community such as Quakers.

In addition to the social networking sites themselves, users have the possibility to add functionality through add-ons. In many cases these are merely intended to amuse, such as the wide variety of virtual gifts possible on Facebook or the aquarium to which friends can contribute fish bought with virtual currency. In other cases, the add-on may add real information, such as the various maps that show cities visited by the site owner, or new communicative possibilities as in the chat add-ons like Twitter.

Unlike many previous online activities, such as personal Website ownership, there seems to be little evidence of gender or indeed sexuality bias in uptake of these facilities. It is striking to note the rapidity with which change has taken place in this area, as is evident from a reading of a New Scientist article published as recently as September 2006. In this article (Gefter, 2006) the emphasis is still mainly on blogging, an activity which seems increasingly arcane and outdated just a year or two later. The essential stance of the article is that, for young people, blogs have replaced diaries, Flickr has replaced photo albums (but did young people ever have photo albums?) and social networking sites have replaced email. The latter is perhaps the most contentious statement, and others might argue that social networking site conversation is more likely to have replaced instant messaging and that email continues on parallel tracks, but data for this supposition is almost impossible to obtain without large-scale research, and these speculations must therefore remain just that.

Gefter notes in particular the acquisition by News Corporation of MySpace, at the time "ranked number one Website among US internet users, receiving more hits in a one-week period than even Google" (Gefter, 2006: 46). Gefter characterises blogging as essentially a female occupation, although no data is given to justify this apart from the fact that the majority of LiveJournal users are female (or claim to be). As Gefter recognises, the aspect of blogging that comes closest to later social networking sites is the ability to link blogs together into communities of readers and writers. She also makes the key point that, unlike previous communicative online practices such as chatrooms and gaming, the use of social networking sites is not usually anonymous. Gefter's assertion that online and real-life friends are the same is unproven but can be supported anecdotally.

...young people on social networking sites are interacting for the most part not with strangers, but with friends from their real life. Thus their online social life doesn't detract from their real one, as the two are simply different manifestations of the same network of friends. (Gefter, 2006: 47)

Most young users would agree and would stress that their Facebook interactions build upon and enlarge their face-to-face social activity, and may indeed support these real-life meetings.

Not everyone lives online, but most of my immediate friends have Facebook. Certainly it could never replace a real life social life, though in some cases use of the Internet does replace actual going out. However in the majority of cases, it's a great place to arrange events or meeting up with friends. It's very easy to keep track of how many people can come to a particular event, and who you have invited – you can also keep complete tabs on who knows what about the event. Another great use for it I and others have found is that through the networks and also the groups, I've got back in touch with people I was friends with in primary or middle school, and also people that I've met through different things. I find it much easier to find people there than by, [using] say, MySpace or Bebo. (Alder, 2008)

It is also striking to notice how quickly users can change patterns of uptake and social networking practices. Gefter asserted in a conveniently neat turn of phrase that "MySpace connects individuals through friends, Facebook through schools, LinkedIn through professions, and LibraryThing through books" (Gefter, 2006: 48). While such a division seems attractively tidy, it is also unconvincing and has not stood the test of time. In the UK, Facebook, for example, has become the social networking site of choice for young working middle class adults, with LinkedIn more used among formal consultancy partnerships.

Other writers have presented a more nuanced picture of the gendered dimension of social networking. Research by Danah Boyd at the University of California-Berkeley indicated what she termed the "significant cultural resonance" (Boyd, 2007) attached to social networking sites, even though their impact had lessened among the group she studied. Exploring the implications of these sites for youth identity formation, Boyd locates them in what she terms networked publics.

I argue that social network sites are a type of networked public with four properties that are not typically present in face-to-face public life: persistence, searchability, exact copyability, and invisible audiences. (Boyd, 2007: 2)

This is a useful theoretical framework for an area where theory is largely missing. Persistence and searchability are certainly relevant to the comments of the user quoted earlier, although evidence for what Boyd terms a complication of the ways young people interact and for the ability of social networking to "fundamentally alter social dynamics" (Boyd, 2007: 2) is harder to come by. Boyd reminds us that the persistence of online discourse permits not just asynchronous communication but also the extension of the life of a discourse without limit. Searchability is one of the key drivers of online communities, but replicability is a more hidden aspect which Boyd reminds us about: by use of the ability to copy an original identically, there is no visible difference between the copy and the original. Boyd's concept of invisible audiences inter-relates with her other factors, since persistence, searchability and copyability are all open to these unknown participants.

Boyd's main data came not from Facebook but from the earlier market leader: MySpace. Her two year ethnographical study focussed mainly on urban youth, the majority of them aged from 14 to 18 years. Among her target group, Boyd found users and non-users of MySpace, but almost all had an opinion about it and knew of it, making it, she says, "the civil society of teenage culture" (Boyd, 2007: 3). Her early users were characterised by a high degree of technical knowledge, exploiting their capabilities with CSS or HTML to do more with their MySpace pages than was intended by the site developers. In this way, these early pioneers echo the practices of many of the first young Website owners in the mid 1990s, who have been described by one of us as "technological aesthetes" (Abbott, 2001). The practices of these early MySpace users, and their tendency to help each other and copy and paste code from tips sites, bears remarkable echoes of the Website owners of ten years earlier.

Boyd's main emphasis is on young people's use of the social networking site, the creation of their digital identity – or digital body as she describes it – but she also considers the effect of these practices on home life. Interactions with formal education are less relevant to her research, although she relates a telling story of the reaction of one school to a student applicant whose MySpace profile seemed to present a different picture than that presented by him at interview. Boyd sees school as the structure from which young people seek to escape by creating online spaces and representations, at a time when young people seem to less likely to be outside away from parents than were previous generations. Much of this discussion is US-centric, relating as it does to problems of mobility in a context where public transport may be non-existent or perceived to be unsafe, but a degree of the same concerns exists in UK and European cultures.

Boyd's conclusions include reference to the dilemma facing educational institutions that seek to decide whether to control, support or ignore social networking.

…we need to figure out how to educate teens to navigate social structures that are quite unfamiliar to us because they will be faced with these publics as adults, even if we try to limit their access now. Social network sites have complicated our lives because they have made this rapid shift in public life very visible. …They are learning how to navigate networked publics; it is in our better interest to figure out how to help them. (Boyd, 2007: 23)

Beer (2006) has suggested that Boyd's networked publics can also be seen as part of a second media age (Poster, 1996) and sees the demise of artefacts such as Top of the Pops as part of the same process. Beer's central focus of interest is music and the extent to which it is now mediated through social networking, but his discussion of issues such as ownership versus free access or the tension between "various capitalist interests and localised interfaces" (Beer, 2006: 4.3) can be seen as a variant on the education system's concerns about parallel issues.

It is worth considering in passing the extent to which social networking can be accurately seen as youth-oriented any longer, especially as this chapter is being written as Saga Online is launched, in order to offer social networking for the over 50s. It can be a risky business to suggest that social networking is mainly for young people, as BBC Technology Correspondent Rory Cellan-Jones discovered after he described what happened when he suggested in an online article (Cellan-Jones, 2007) that social networking was not for over 30s. He received a great deal of response, including suggestions that the important thing was to have lots of friends – not to know who they were – and someone else set up a *Befriend Rory Cellan-Jones* group. Other more thoughtful responses suggested that Facebook was being used, for example, by lecturers to keep in touch with students overseas. He surmises that "it seems that the virtual worlds… are just a way of managing a thriving real world social life" (Cellan-Jones 2007), a conclusion very much in line with that of Boyd quoted earlier.

Tentative taxonomies of this use put forward in the 1990s included the division of personal Website owners into Technological Aesthetes, Community Builders and Professional Activists (Abbott 1999; 2001). Later work on the use of guestbooks and interactive fora on Websites has highlighted many of the issues that have now come to the fore in the use by young people of social networking sites (Abbott 2005). This developing line of research has highlighted some key methodological and ethical issues associated with this phenomenon, and these have also been explored by one of the current authors (Abbott & Seale 2007).

THE RESPONSE OF THE EDUCATION SYSTEM

Much of the response from the educational system to social networking has related to the real or perceived risks. These risks may relate to current dangers from online predators or be related to concerns for the future of young people who are inadvertently creating a permanent record of youthful indiscretions (Rosenblum 2007), much as the student quoted by Boyd did when his MySpace page came close to causing his rejection by a prestigious school.

Rosenblum titles his article *What anyone can know* and this is in many ways a summary of the concerns of authority figures and institutions. He indicates in some detail the risks associated with posting personal data online in this way, although he recognises that a more guarded approach to sharing information will inevitably result in "some chilling effect on the fluid, no-holds-barred ethos of these sites" (Rosenblum, 2007: 40). In addition to his recognition of the ways in which Internet-based information is both persistent and accessible, Rosenblum also notes the increasing trend for "prospective employers, government agencies or businesses collecting market data" (Rosenblum, 2007: 41) to have the right to view and make use of this information.

Some social networking sites have responded to these concerns by offering extra privacy options. For example, on Facebook users can choose to let people see only their limited profile, so they are unable to view more personal information such as phone number and address, or even photos. It is possible to control how much anyone sees, even if they are designated friends. These privacy controls, however, are fairly low-profile on the site and do not seem to be widely used, even after the recent announcement that Facebook sites would be searchable with Google (BBC News, 2007).

Schools have been more concerned about online safety than identity theft, probably in reaction to the scale of public and perceived concerns. Discussions with young people who use Facebook, especially those of Sixth Form age, have shown that some have teaching staff in their online friends group and vice versa. However, it seems more common for staff to not accept friend requests and to keep their social life separate from their work. This is no new issue of course; there has always been a difficult line to draw between older students and staff at social events such as graduation celebrations. Identity theft, however, or inadvertent revealing of information that may in future cause problems, is an issue that seems little recognised by schools or by many students.

…an entire MySpace generation could realise, when it is much too late to intervene, that the cyber personae they spawned in adolescent efforts to explore identity have taken on permanent lives in the multiple archives of the digital world. (Rosenblum, 2007: 49)

Early responses to social networking from schools have been negative for the most part and have revolved around control or prohibition. Many schools have used their filtering systems to block access to sites such as MySpace, Bebo and Facebook. Others have reacted punitively towards pupils found referring to their schools or teachers on these sites. Some educational institutions have ensured that use of social networking sites has led to dismissal or expulsion, but others – although not many - have supported the practice and incorporated it into their pedagogy.

As understanding of the potential of these networks develops, there are signs of a more mature and enabling attitude on the part of a growing number of educational institutions. There is evidence for this in the increasing understanding of the interactive possibilities of institution-based online networks which aim to link together learners, teachers and carers/parents. Although some use of these systems is low-level and mechanical and involves for the most part the maintenance of records, management of homework and registration of attendance, in other cases real interactivity and discursive use is beginning to be recorded. These developments take place against a policy shift in the use of digital technologies by schools, with current Government diktat favouring the "harnessing" of technology (DfES 2005) over its use to free learners to learn, despite the parallel focus on personalised learning.

A number of short anecdotal case studies arising from the personal experiences of both authors of this chapter may go some way to giving examples of the range of responses of educational institutions to social networking.

- Two years ago, a part-time Masters student chose to write a dissertation about the uses of social networking by students at the independent school where he was employed. He began by interviewing his students and discussing the topic with them, but his efforts were overtaken by events when his school featured in a national Sunday newspaper. It transpired that some students had made comments on Bebo which were highly derogatory about some members of staff at the school. The Masters student himself was relieved to note that he featured in only benign descriptions.
- A student at a prestigious music college set up a Facebook site which included discussion of the college and comments from other students. The next time that the student arrived at the college, he was escorted from the premises by security guards, on the orders of the college administration.
- At least one educational institution in the UK has threatened staff with dismissal after they commented on their place of work in postings on their own and their friends' Facebook sites.
- The social dynamic between teacher and students is changing, as both may appear in the same Facebook group. Whilst some institutions and employers would see this as acceptable, others would be most concerned and would consider it to be an example of unacceptable informality between staff and student. In many ways, this is merely the latest manifestation of a developing pattern, and submission of homework by email has sometimes led to an informalising of teacher-student dialogue as would be expected on that medium. In many schools, the decision for these contacts to occur via school email accounts is seen as keeping the discourse within a professional arena. Text contact via mobile phone between teacher and student is likely to be proscribed, but this may need to be reconsidered as handheld and mobile devices become more accepted in schools and colleges; and e-learning environments have bought online informal discourse practices into the virtual classroom.
- Some school systems have adopted a more open approach. In Denmark, the national schools network also involves parents, and all parents are allocated email usernames by the schools that their children attend. Progress reviews are held twice a year and these can be held online and are always summarised on the network. In this way, social networking has been made part of Danish educational practice.
- Researchers are beginning to explore the potential of avatar-based sites such as Second Life, where social networking can take place either at one remove or through the assumption of an online identity. There is particular interest in the potential of this approach by those working with children who have become disaffected by

school. One example of this is the Open University-supported Schome ("not school – not home"). In a depressing example of the difficulties of establishing new practice, Schome was funded firstly by NESTA (National Endowment for Science, technology and the Arts), then by the National Association of Gifted and Talented Youth and then by Becta (UK government agency), but has no current funder (www.schome.ac.uk). Of course, one aspect of the enabling of third-party add-ons for Facebook has been the opening up of dynamic links to other environments, including Second Life.

This mixed picture indicates a range of practices which highlight possibilities as much as constraints, although the unifying factor for the positive uses described is their adherence to a perspective which recognises the socially-constructed nature of most learning. A recent example of Facebook use to facilitate collaborative real-life activity arose during the making of a film during the summer vacation period. Alder explains how Facebook facilitated this activity, and demonstrates the socially collaborative nature of the process.

We used Facebook to initiate the project by creating interest, and are still continuing to do so. A lot of my immediate friends are involved with Drama, Music, and/or technical work, and I thought that I was in the best place to facilitate such a project. I started by advertising it, and laying down specific dates when we would be filming, and asked people to contact me. This wasn't the sole way of casting, obviously – I had some people in mind for certain characters! We then kept updating the group we had made to try and get extras, crew and musicians to record the soundtrack. One of the co-writers of the initial plot I had only discussed over the internet, and was a friend of a friend – I didn't meet him until after the majority of the filming was over!

I've now created another group to do with the project – the main one is for all the people that may want to be involved in being extras, musicians, or are just interested in the project as a whole, or indeed seeing the final product as their friends are involved. The other for the production crew and cast to discuss when we are going to be filming, analysing the poster campaign I'm making as part of my A2 photography work, and the trailer we have produced. We keep this group closed so that the public, as it were, don't know when/where we're filming or what is going on. All of the cast, and most of the crew of the film are on Facebook, so I can send out mass messages to all of them. Clearly we keep in contact by phone and email, but it's a good way of sorting everyone into one place and sending messages about filming and the suchlike. (Alder, 2008)

It seems likely that one of the next phases in the development of social networking will be the integration of geographical location information within handheld devices, enabling real-life meetings to take place serendipitously. Early services such as Dodgeball, owned by Google since 2005 but still only available in certain US cities, have made this possible, as has the Bluetooth capability of many mobile phones. This is perhaps what Gefter had in mind when she talked of her belief that the various sites will in the end become conjoined.

"…a meta-network linking together all the various social networking sites will emerge – and an individual's full identity, shown from all sides, will live online. …We will be more autonomous and mobile than ever, and at the same time discover an unprecedented form of collectivism."(Gefter, 2006: 48)

CONCLUSION

Social networking offers an unparalleled opportunity to education, although this is not without concomitant risk and concerns. To ignore social networking and what it has to offer to education would not only be short-sighted but would also indicate a basic failure to understand the impossibility of returned to a pre-Internet world. Social networking, like its precursors email, instant messaging and mobile phones, has changed communicative practices permanently. It is now essential that the educational establishment grapples with the implications of that change: the genie is well and truly out of the bottle and no wistful longing will put it back again.

Chapter 5.14
Peer Learning and Social Interactions in an Asynchronous Learning Environment

Angela T. Ragusa
Charles Sturt University, Australia

ABSTRACT

This chapter explores how Internet-based asynchronous communication forums utilized in teaching undergraduate courses affect social interactions and student satisfaction. Drawing from an analysis of qualitative data, such as student and teachers' perceptions, this case study reveals four key factors that affect learner satisfaction: (1) trust of people and technology, (2) awareness of how technically-mediated interactions differ from face-to-face interactions, (3) peer-based learning opportunities, and (4) integration of relevant learning materials and opportunities for social engagement. The findings suggest that when asynchronous forums are used as the principle vehicle for communication and learning, students feel less socially isolated, report a sense of belonging, and positively evaluate learning outcomes. The case study identifies asynchronous electronic forums as an effective tool for peer learning and social interactions among upper-level distance education students in Australia.

DOI: 10.4018/978-1-60566-368-5.ch017

INTRODUCTION

Electronic communication has irrevocably changed the way learners and educators approach education. Internet-based communication forums are one specific venue in today's network society enabling and facilitating dialogue across cultures, geographies and generations. This chapter explores some key issues facing developers, users, and evaluators of software for distance education. Drawing from distance education learning and teaching experiences in Australia and conceptualised within a global learning environment, this chapter emphasizes advantages and disadvantages of incorporating asynchronous electronic forums as educational technology in teaching advanced sociology subjects.

By presenting empirical qualitative data, informed by the social theory of Symbolic Interactionism, this chapter demonstrates how Internet-based social interaction technology can enhance learning and communication among undergraduates by creating a shared purpose and awareness among otherwise isolated users. The study presented here is contrasted with recent e-learning research that questions both the utility of specific communication technologies as well as the pedagogical appropriateness of their application. The overarching objective of this chapter is to provide an alternative perspective. Distance education technologies are often characterized as mediocre and supplemental tools whose primary purpose is to augment traditional classroom-based learning. In contrast, this chapter reveals how the adoption of asynchronous forums as the principal learning and communication vehicle in a senior-level correspondence-based distance education course resulted in enhanced student satisfaction. It is argued that high-quality social interactions pursued for the purpose of higher education can be attained virtually, without face-to-face interaction, although the interactions experienced may differ in a number of ways. Ultimately, while identifying and acknowledging the complexity of virtual communication, this research questions the fundamental assumption that virtual classrooms are *a priori* inherently inferior to those occurring face-to-face.

BACKGROUND

Social interactions exist and are understood from both lay and professional vantage points. In this section a sociological definition of social interactions is offered to inform and conceptualise the ensuing analysis of student-student and student-teacher interactions occurring in asynchronous subject forums. The present case study seeks to offer researchers, practitioners, and users theoretically grounded, yet concrete and tangible advice, on users' and designers' perceptions and experiences in a distance education environment. The research purpose is to inform users and planners of distance learning courses about asynchronous forums as communication, interaction and networking tools to facilitate learning and student engagement.

Social Interaction and Knowledge Society

From a sociological perspective, social interaction involves tacit knowledge, shared meaning systems and negotiated agreements about the norms, purpose and process of communicating. Classical symbolic interactionists, such as George Herbert Mead and Erving Goffman, provide a useful theoretical framework to understand social interaction as fluid, mutable and subjective. According to Goffman (1967, p. 9), "the definition of the situation" is both contingent and social. By using this theoretical approach to frame contemporary communication technologies, such as asynchronous forums, we may improve our understanding of how individuals and institutions "do" education.

Historically, learning in the modern era was a passive activity (Palloff & Pratt, 2001) where students attended geospatially "real" schools to learn objective facts, histories and skills necessary to participate in society. Today, knowledge-based economy (OEC, 1996) is redefining the purpose and focus of education specifically, and knowledge production, or epistemology, more broadly. In our new knowledge society, knowledge is no longer handed down but rather exists as an interaction between learner and environment which subsequently reconfigures both (Semple, 2000). In contrast with modernist science, which was resolved to operate under the constraints of the natural world, post-modern science and technology "is not concerned with discovering 'laws of nature', as it is [seeking] the reinvention of nature itself" (Holmes, Hughes, & Julian, 2007, p. 66). Contemporary educators, particularly in higher education, occupy social roles demanding flexibility and cultural awareness in addition to disciplinary and trans-disciplinary expertise.

"Revolutions" in communications and information technologies (Aronson, 2001) have fundamentally altered the structure of our global world economy and its social institutions. Education is one such institution. Global communication technologies have permitted the growth of global and virtual classrooms. Virtual classrooms, upon which distance education increasingly relies, transcend the national and physical boundaries of traditional classrooms (Ragusa, 2007) and create learning environments mediated by computers and reliant on global telecommunications systems.

Virtual Classrooms and E-Learning Debates

Despite the initial use of e-learning for distance education students, virtual classrooms are increasingly being used to supplement traditional learning environments. Learning environments utilizing blended, or hybrid, teaching styles incorporating traditional lectures supplemented by virtual learning have been found to be both productive and appropriate (DeCastro, Munoz, De Freitas, & El-Hani, 2008). However, lack of research on "purely" distance education delivery appears to be leaning to perhaps premature generalizations, such as the assertion that successful distance learning requires both synchronous and asynchronous communication modes in order to be successful (Yucel, 2006). A persistent theme in debates is the notion that distance education is an inferior, albeit perhaps necessary, mode to reach non-traditional and rural students who otherwise are unable to access higher education (E-Learning, 2007). According to Maeroff,

> Online learning seems to be still living down the early days. Those who thought that this was going to be a whole revolution with everybody moving courses online were so wrong. People who saw piles and buckets of money at the end of the rainbow were just misguided. It is clear now that, more than anything, e-learning benefits people who are mature, self-motivated, and looking for classes that teach various aspects of career and professional development….Also, e-learning will never, and probably should never, be the dominant method of educating students. But it will be a fixed part of the delivery system of higher education. (cited in E-Learning, 2007)

Although this may characterize perceptions about higher education in the U.S., in Australia there is a continuing trend among universities to not only move components of courses to electronic delivery, but moreover for electronic/distance learning to be the dominant method of education particularly at a number of specific universities. Statements such as, "e-learning will never, and probably should never be the dominant method of educating students" reveal deep-seated values and beliefs about the role, (in)adequacies and purpose of technology in higher education. Such values and beliefs are fundamentally connected to societal norms regarding social interactions.

Distance education implementing forums generally relies upon two types of communication: synchronized and/or asynchronised (Yucel, 2006). Synchronized forums are characterized by real-time/simultaneous communication where dialogue occurs at the same time yet is mediated by technology. In contrast, asynchronous forums utilize a static form of communication, akin to posting a message on a billboard and then awaiting others to view and/or reply.

In Australia, the introduction of asynchronous forums has enabled academics to create learning and assessment tasks that transcend traditional correspondence-based tasks characteristic of distance education. This technology has dramatically changed the structure of distance education, from a passive to an interactive learning experience (Anderson & Garrison, 1995) permitting the fostering of critical thinking skills if appropriately structured (Yang, 2005). Despite changes in practice, little research explores the use of asynchronous forums in Australia and virtually none comes from the discipline of sociology. Traditionally, distance education students independently read and completed written assignments, submit them for marking and wait for written feedback. The process relies heavily on introverted characteristics and independent work. Consequently, distance education students identify isolation as one of the principle barriers they struggle to overcome (Ragusa, 2006). Jorgensen (2002) articulates that active involvement in collaborative online learning is key to equalizing quality, cautioning "when individuals are simply receiving posted material and sending back individual work, the results are poorer then in traditional classrooms" (p. 9). Indeed, recent research shows variation in preference for online forum interaction is associated with perceived isolation (Ragusa, 2006). In sum, historically shaped structural and subjective factors work to influence the social interactions and communications of asynchronous forum managers and users both overtly, via concrete technical systems, and more subtly, via socialization and normative expectations.

Previously, research on asynchronous forums has focused on: netiquette and didactic guidelines (Buelens, Totte, Deketelaere, & Dierickx, 2007), the timing, rate and role of instructors and student perception and participation (Mazzolini & Maddison, 2007; Yang, 2005), discourse and content analysis (Beuchot & Bullen, 2005; Perrotta, 2006; Schrire, 2006; Zhu, 2006), flaming (Lee, 2005), professional development (Barnett, 2006) and meta-analyses of research methodologies to assess discussion forums (Marra, 2006). This research is mainly conducted in North America and Europe. Only van Aalst and Chan (2007) ask how collaborative computer-supported learning can be assessed, although their research focuses on portfolios of graduate and Grade 12 students in Hong Kong and Canada. The present study examines student satisfaction with learning using asynchronous forums.

Asynchronous Forums as Social Interactive Communication Environments

Surveys of large introductory courses (N=100-350 students) demonstrate inconsistency in student endorsement and satisfaction in distance education broadly and asynchronous forums specifically (see Ragusa, 2006). Differences in support services offered by Australian Technical and Further Education (TAFE) and high school environments, compared to universities providing distance education, is one element augmenting first year students' reservations about virtual forms of learning. To explore student experiences with communication technologies, this research prioritizes senior students' perceptions assuming that they have over time adapted to tertiary environments. Due to attrition rates and disciplinary specialization, advanced courses contain far fewer students than first year subjects. As such, this research offers an in-depth, case study of final year experiences and does not seek broad extrapolation from the experiences of 22 students in their senior year ("third-year" in Australia) enrolled in social theory courses (in 2006 and 2007).

The insights presented are derived from learner/educator communications whereby the only mechanisms for social interaction available were virtual, either via e-mail or through accessing the subjects' asynchronous forums. Data were gathered via surveys for two consecutive years (with a 30% response rate in 2006 and 88% rate in 2007) and student reflections (100% response rate in both 2006 and 2007) designed to explore communication and isolation issues raised by the introductory student surveys more deeply.

Students' only contact with the lecturer was by written comments returned via the post on essay assignments. Student dissatisfaction with non-interactive correspondence-based learning is expressed in a number of survey comments: such as, (1) "It was great to have to work more closely/directly with other students. This was such a nice change, especially as a distance education student" (Student R, 2007); (2) and "The online format made the subject easier to understand increasing my enthusiasm for the learning environment" (Student Q, 2007); and, (3) "The sub-forum design is excellent and I would like to see this used in other subjects. This also helped to build relationships with classmates - a rare opportunity for distance students" (Student U, 2007).

Sixty-three percent (2007) and 100% (2006) of the students agreed they would like to see the same online forum approach used in other subjects; all agreed responses to their subject forum postings helped their learning. In both cohorts, asynchronous forums were used for assessment. Unlike the predominant use of electronic communication for the distribution of information, this subject used asynchronous forums as a virtual classroom enabling students to prepare and conduct class presentations, lead and manage formal discussions with their peers and reflect on how the "tyranny" of distance may be mitigated by technology.

Four Key Lessons to Inform Virtual Interactions

To understand the pedagogical implications of electronic communication and interaction, students in both cohorts were asked to reflect on their experience of using technology to coordinate an assessment item with their peers, use asynchronous forums to lead and participate in virtual classroom discussions, and learn social theory. From these reflections, four key lessons about the complexity of virtual social interaction emerge:

1. Electronic Communication Requires Trust - of People and Technology

Identified as one of the greatest challenges was developing a working relationship "with an unseen partner and impression management, which was tentative and gradual on both sides" (Student A, 2007). To accomplish this, students "worked hard at communicating to each other, establishing and re-establishing guidelines continuously over the time committed" (Student A, 2007). While for some establishing communication norms and guidelines proved challenging, for others the limitations of technology posed greater complexities and was frequently contrasted with face-to-face interaction. Asynchronous forums possess temporal drawbacks and advantages different from traditional classrooms:

A compounding factor was the difficulty for XX in contacting her fellow team member due to circumstances beyond the control of both of us. These included technological difficulties and complications. Although we finally managed to get in touch, it should also be noted, that as distance education students, communication was somewhat slower than what it may have been had we been able to communicate face to face. For example, if one of us had an idea or a problem that needed to be discussed with the other then we would have to e-mail the other person and wait for a response, which usually wouldn't be until the following day. As such a simple question, or idea, which may usually only take minutes or a couple of hours to work through face to face, took at least a day. (Student O, 2006)

2. Interactions Mediated by Technology are Different in Kind

Interacting with people via the Internet remains different from face-to-face interactions for a number of reasons. Communication, cognitive, literary and technical skills are thrust into a public arena for viewing causing some personal discomfort: "This presentation brought my predominantly private studies, interpretations, and academic ability into the public sphere, with the potential of judgement by peers, which I felt to be the most daunting aspect of the exercise" (Student G, 2007). Second, that one may never meet those with whom one is working/conversing is an unusual reality for some:

One of the challenges of this project was to work with another person who lives too far away from me to meet face to face…the distance factor was definitely a challenge. This was resolved by my partner and I contacting each other by phone, *but this was still a challenge for me. (Student B, 2007)*

…juggling a full time job and then a second shift as wife and mother, followed by a third shift as student. I was often very tired by the time the books came out; The challenges faced once the presentation was launched were entirely different, now it was a race against the clock to check the forum for a response, formulate a reply and have it posted in order that there was time for other participants to respond and develop a dialogue. I feel that my partner and I were able to overcome the problems of distance and timing to coordinate a comprehensive presentation that facilitated the learning of our fellow students (Student F, 2007).

The main challenge is distance, not knowing the audience I am addressing and not being provided with the knowledge gained through non-verbal communication. Not being able to sit down and communicate thoroughly. Found it difficult to communicate effectively over phone and net. Nothing beats real life one on one formal communicating. As responses are not instant you as a student and a worker have to juggle work and study, sometimes they don't correlate as well as you like and have to wait for an answers or other students have to wait for your reply, which doesn't always lend itself to effective communicating (Student N, 2006).

On the positive side, I met a new person from a totally different world who was similar in age with similar commitments trying to better her life. Having two people work on the same subject is positive as it gives different perspectives and ideas. This assessment was definitely an achievement in that I have never done one with this format (i.e. a forum discussion). Having positive input from fellow students and the lecturer was also encouraging. (Student M, 2006).

Holding logistical issues constant, interaction and communication norms themselves become subject to review. As one astute student deduced:

This project has enabled us to gain an insight into both Symbolic Interaction and electronic forms of communication. The greatest difficulty encountered in this activity has been, ironically, interpretation. Electronic communication is a difficult medium in which to express ideas and concepts. It is made harder when comprehension is not equal amongst participants…Examples are good, if used academically and with a full understanding…Symbolic interaction concerns the negotiation of shared meanings, and, as the discussions emphasised, such a negotiation is often a very precarious business. This is the greatest assistance of these discussions: it has been made patently clear that people use their past to interpret their present and future…Distance and communication issues have made writing and contributing to a joint venture a difficult undertaking. Different approaches to work and time constraints have been equally constricting. However, it has been a positive experience.

As a peer of this student identified, often being challenged can be daunting: "I felt with the discussion that everyone knew a lot more than me which challenged me to read more...this exercise emphasized the difference between distance education and face to face – there are definitely negatives!" (Student M, 2006).

3. Electronic Communication Technologies hold Potential for Making Distance Education less Individualistic

As noted, isolation, both physical and social, is a prominent barrier to distance education students' success. This research shows communication technologies hold great potential for substantially altering distance education experiences: "It [the asynchronous forum] was a different method of studying from my prior experiences and it was nice to feel like the class was learning together instead of just individually" (Student C, 2007). The creation of virtual classrooms that prioritise meaningful interactions offers an example of how technology can facilitate peer-based collaborative learning. As Student D (2007) notes:

I believe that the sheer ability to work with a 'distant' partner…has been a success as life tends to get in the way of doing things like this. XX and I had some excellent exchanges and discussions via e-mail, instant messaging and telephone and I believe we communicated and coordinated this assignment as well as we possibly could. I am pleased that when I couldn't understand something – I was able to consult with XX and with other classmates via the forum.

The multiplicity of technologies available, combined with a positive approach, can assuage demands facing distance education students who also are employees, parents, etc: "Interaction with my project partner held some challenges as we quickly found out that we worked different hours which allowed us to rarely work jointly, however, this was overcome by constant daily e-mails and openness" (Student E, 2007). This experience proved to be common as nearly every student mentioned competing life demands and put forth their opinion about the flexibility, or inflexibility, of communication technologies.

4. Electronic Communication Forums hold much Potential for Greater Perceived Relevance and Engagement in Learning Tasks

A common question from students is the relevance of subject material to their lives and careers. In this subject, learning and practicing PowerPoint software offered a tangible skill for use beyond the classroom. Surprisingly, although only a minority of students had past experience and some approached the task with trepidation, not one negative comment resulted. Student E (2007) stated, "It provided me with an opportunity to present an assignment in a unique style, one that I am not familiar with, instead of another long winded essay." By listing the achievements gained ("allows recounting of subject material; allows structured interaction; maintains a high level of precision and accuracy; always encouraging trying something new and succeeding (hopefully); putting together a comprehensive power point presentation; overcoming communication difficulties"), Student N (2006) shows us how learning outcomes from AOF compare with those of traditional classrooms. As Student S (2006) commented, "I found that the online discussion was really helpful - most times when I was unclear of an aspect of a topic somebody online was able to clarify and give examples - very good way to learn this topic." Yet, to achieve successful outcomes, electronic interactions require different strategies:

Being used to working in isolation requires adjustments when asked to work with another person, and I don't believe that we allowed ourselves enough time to cover the 'space and time' aspect, given that we are both in the workforce. The greatest achievement was that we managed to present one presentation, which I believe appeared interesting, and on time. The exercise showed me that I am capable of undertaking new ventures (learning Powerpoint), and work under pressure, rather better than I had previously thought. (Student H, 2007).

Along with learning technical skills, electronic interactions permit the exchange of different types of social engagement. Specifically, written dialogue has potential to be far more detailed and personal than traditional classroom communications: "The discussions gave me a much better understanding of sociological theory and enabled me to apply the theories to everyday life" (Student W, 2007). While in some cases this has negative consequences (Ragusa, 2007), it also holds great potential for developing deeper learning and critical thinking:

I actually got more out of the group forum discussions than I thought I would. I was apprehensive *initially about a group assignment and hosting a forum, but found the support of my peers, their willingness to participate and their honesty so rewarding…I felt I received the support I needed from my peers on the forum" (Student I, 2007).*

Learning to work in a discussion group and being totally fascinated how a project can come together via e-communications. The amazement that questions you created can create such thought provoking material from people all over the country – not because they have to but because they were genuinely interested…I feel creating this is a gratifying achievement" (Student L, 2006).

All participants of the 2006 cohort strongly agreed they were "encouraged to think critically about the subject." Still, the key to fostering a nurturing environment lies in the structure and management of technology. Asynchronous forums themselves do not create positive communication environments. Comparing this subject to another, Student J (2006) notes, "I made the point to another student that this is the first "discussion forum" that I have had the opportunity to debate/discuss issues at length." Student T (2007) states, "The forum leadership and discussion was thoroughly enjoyed as it assisted in learning the various themes involved and compared our learning with others."

According to Student K (2006), "Of particular use is the discussion format. It is only there that we can see whether our statements have been clear, or if we have a correct understanding of the topic." Structuring asynchronous forums as "safe" environments to explore the complexity and multiplicity of ideas is particularly suitable for social sciences and areas where ethics and "facts" demand analysis and critical thought. Student O (2006) notes this learning objective was best achieved through academically guided peer discussions:

Both of us found the varying opinions of all of the discussion participants somewhat fascinating and even more enlightening. The discussion was extremely beneficial to our learning in that it gave us a clearer perspective of the varying viewpoints of our fellow students. Having this interaction with them allowed both of us to ponder many issues in relation to the theory which they otherwise may not have considered. We gradually gained more confidence to participate in the discussions with our peers…We both found it a little challenging and intimidating when we attempted to respond to the opinions of classmates, without sounding condescending or too light-hearted. As it turned out many of the participants were able to apply life experiences to the responses, and this in turn meant that the discussion was led into other aspects that were surprising.

Continuing the practice of offering situated "knowledges" (Harding, 1992), whereby researchers let "the researched" speak on their behalf, this final student quote echoes well the main points:

Some students made insightful and fascinating comments that had not been raised in any book I had read. It was good to learn Powerpoint, I found that once I started putting in pictures and messed about with settings, it was hard to stop… Another thing that really impressed me was how well the class was able to discuss the subject with maturity and manners. Distance education was possibly of great assistance as the passionate few did not dominate a verbal discussion and there was no authoritative presence 'correcting' students with different opinions. Most students submitted different, sometimes very different opinions on the forums… Receiving a forum posting was rather like getting a personal e-mail, and gave me a rather revelatory sense of fellowship or community with my classmates which I have not otherwise experienced in distance education. Distance education is quite an isolated experience with most interaction of ideas occurring between oneself and the reading materials rather than with other people.I found that some who may have known the subject the best *were not the most effective communicators. The two skills (understanding the subject and being able to communicate ideas about the subject) were neither inclusive nor exclusive to each other, just totally separate skills. I concluded from this that it is more important to be able to communicate clearly a little of what you have learned, than to learn much and not to be able to communicate any of it. (Student P, 2006)*

Comparative Evaluation of Learning Outcomes

Overall, experiences of the two cohorts show that asynchronous forums are valuable learning tools. Empirically, on a scale of 1 (very strongly disagree) to 7 (very strongly agree), subject evaluations confirm this finding. Evaluations for the 2007 cohort are presented in the charts in Figure 1 on the left and exist in contrast with the 2006 cohort evaluations for the same or similar items depicted in the charts on the right hand side. As the charts demonstrate, all students completing the evaluations reported they agreed, strongly agreed or very strongly agreed that the subject, learning materials and assessment tasks utilizing asynchronous forums were beneficial to their learning.

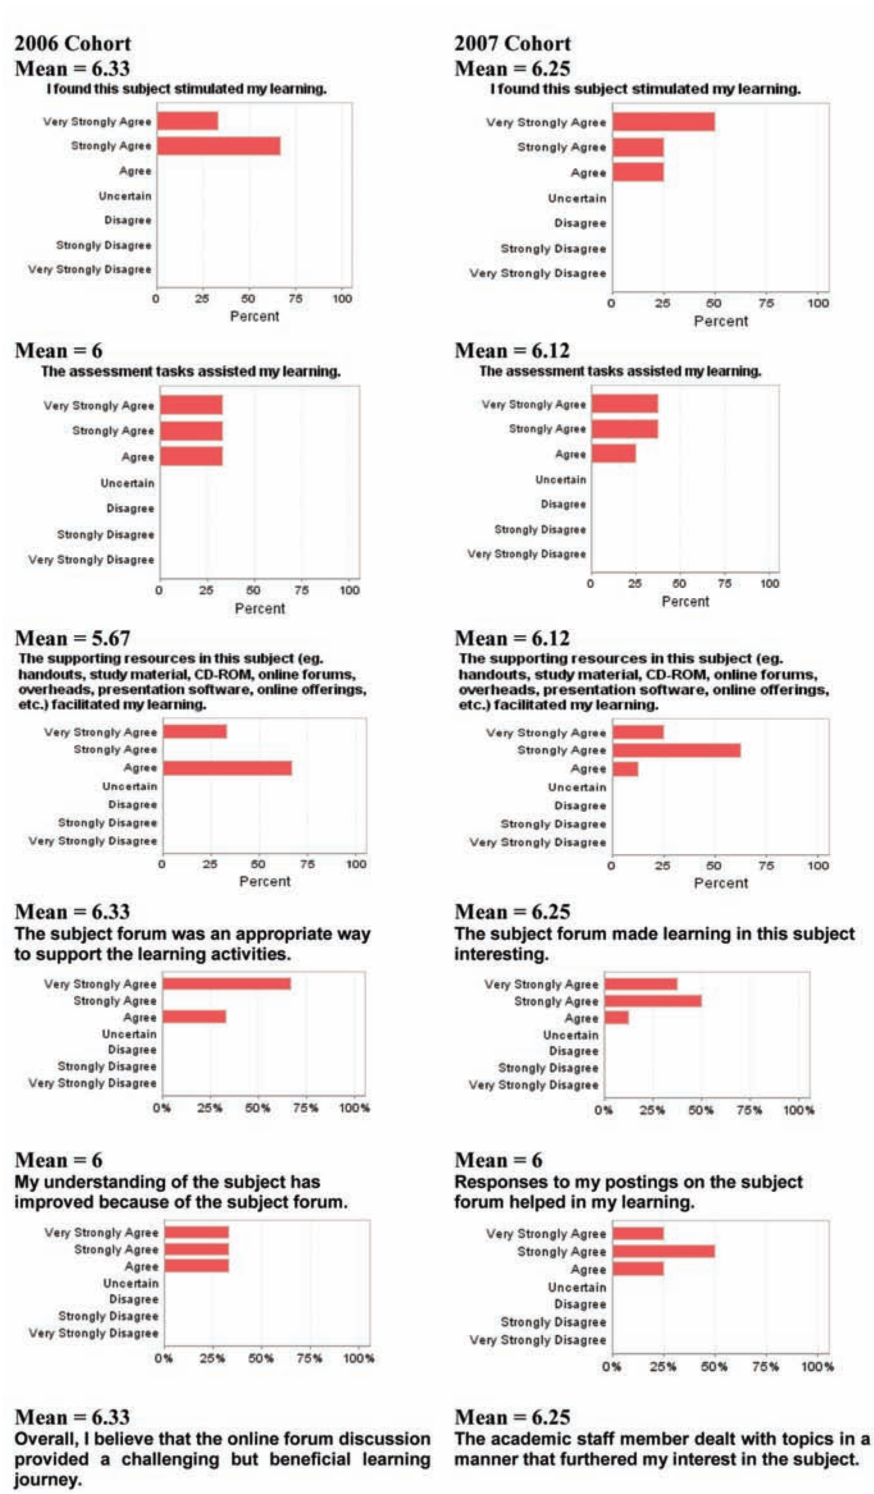
These evaluations demonstrate widespread support of asynchronous forums in these two cohorts where they were used for both supporting and assessment tasks. However, as detailed in the next section, the qualitative nature of this research warrants caution in generalizing the findings. Still, the general lessons learned are noteworthy and may serve as guidelines for future users and developers of asynchronous forums for distance education students.

FUTURE TRENDS

In discussing what it would take to have an education revolution in the U.S., Robert Zemsky, a member of the U.S. Department of Education's Commission on the Future of Higher Education, asks: "How many distance-education courses do exactly online what we do on the classroom? We did not want it to be that way. E-learning was supposed to be the different space, not the replicated space" (cited in E-Learning, 2007). Although the research results presented in this chapter cannot endeavor to explain Australia's progress towards an education revolution, it does contribute evidence towards viewing virtual learning as indeed a "different space." However, what appears to remain the same at this point in time are some educational institutions' stereotypes and norms about what constitutes quality education. In Australia, as elsewhere, social change is occurring in relation to the nature and praxis of education. Future research should focus on the parameters of this social change, noting resistance as well as adoption of educational technologies while paying close attention to how social expectations impact interactions.

Despite distance education students' embracement of social interaction technologies, such as asynchronous forums, and request for them to be more widely adopted as noted in this research, uptake by individual academics has been exceedingly low in parts of Australia over the past several years due to perceptions of heightened workload. In response to changing student needs in a technologically-driven society, some Australian universities have institutionalised interactive technology by requiring all subjects to operate using a Sakai platform. The imperative for all teachers and learners to socially interact using communication technologies demonstrates a distinct change from correspondence-driven learning and supports Lynch's (2002) identification of communication cues and interaction opportunities as key criteria differentiating traditional classrooms from online

Figure 1. Evaluation items comparable across two cohorts



learning environments. Large-scale change points to the need for new methods of planning, evaluating and altering how distance education delivery is conducted and affected in this new social structure and raises many questions including: What new skills are required by learners, administrators and teachers? How does electronic learning differ from face-to-face? What equity and social justice issues accompany different communicative abilities and technical access? These and other questions highlight ethical considerations about ownership of ideas, privacy, identity and the infiltration of personal lives into public spaces which all require further exploration.

CONCLUSION

Electronic communication forums, specifically asynchronous forums, are arguably better planned and executed when communication norms and expectations are made explicit. This research has provided firsthand accounts of asynchronous forum users from two senior courses an Australian university. Conceptualised within a sociological framework prioritising users' perceptions and experiences with asynchronous forums as a vehicle for peer learning and social interaction, the findings support the claim that asynchronous electronic forums can be used effectively in among upper-level distance education courses. By focusing less on the technical structure of electronic communication forums in favour of analysing users' experiences with asynchronous forums as social interaction tools, with potential to bridge demographic and socio-cultural divides (multigenerational, multinational, multicultural, geospatially disparate, etc.), this chapter identified and evidenced four key lessons for future users, planners, and evaluators. These lessons reveal asynchronous forums hold potential for generating positive learning experiences, particularly among small cohorts of senior students. Incorporating well-structured asynchronous forum assessment tasks into distance education develops life skills: such as, greater technological competence, leadership and critical thinking, making abstract theories and subject information relevant by encouraging application and connection to everyday life, and working to assuage the social isolation some students experience by fostering group solidarity, integration, and dialogue with peers.

KEY TERMS AND DEFINITIONS

Asynchronous Forums: An Internet-based electronic communication environment, which permits users to post messages for some or all of the members to view. Messages remain posted until a forum moderator removes them. *Asynchronous* refers to the static nature of the environment. Postings are done one at a time, anonymously or not, and offer a written electronic record of the communications conducted.

Knowledge-Based Economy: A phrase used to describe economies in which information and knowledge hold greater contributing power to the economic welfare of nations than in industrial societies.

Network Society: A term used to characterize the changes in a society brought about by the Internet communication technologies and in which individuals and groups organised around digital information networks.

Peer-Based Collaborative Learning: A teaching and learning strategy which places emphasis on group work and interactions among students in contrast to traditional teacher-centered learning.

Social Interaction: The exchange of verbal and nonverbal communication in a society. Within the social sciences *Symbolic Interactionism*, stemming largely from the works of George Herbert Mead and Erving Goffman, is a theoretical tradition that studies the relationship between "self" and society.

Situated Knowledges: A view of social reality put forth by the feminist social philosopher, Sandra Harding, which argues that our social position in the world affects, and creates, the types of "knowledges" and worldviews we experience. In other words, what we think and believe is "socially situated" and socially constructed.

Sub-Forum: An online communication environment that exists as a subset to a larger electronic forum.

ABSTRACT

We present an empirical study investigating how interactions with a popular social tagging system, called del.icio.us, may directly impact knowledge adaptation through the processes of concept assimilation and accommodation. We observed 4 undergraduate students over a period of 8 weeks and found that the quality of social tags and distributions of information content directly impact the formation and enrichment of concept schemas. A formal model based on a distributed cognition framework provides a good fit to the students learning data, showing how learning occurs through the adaptive assimilation of concepts and categories of multiple users through the social tagging system. The results and the model have important implications on how Web 2.0 technologies can promote formal and informal learning through collaborative methods.

INTRODUCTION

The World Wide Web (WWW) gained extreme popularity during the late 1990s due to its simple architecture and design (Millard & Ross, 2006). The 1990s version of the WWW, now dubbed as Web 1.0 (O'Reilly, 2005), is characterized as "read-only" Web. Web 1.0 efforts included content management systems, fixed directory structures and portals that used client-server architecture. In stark contrast, Web 2.0 is characterized by user-generated content (e.g., blogs, photos), communities of users (e.g., social networks), peer to peer networks (e.g., Napster), and content syndication (O'Reilly, 2005). While the exact definitions of Web 2.0 is open to debate, it is important to note that web applications have evolved into collaborative user-centered rich internet applications (RIA). The implication of this evolution is significant considering its possible impact in a variety of domains ranging from healthcare (Kaldoudi *et al.*, 2008), marketing (Parise & Guinan, 2008), e-Science (Fox *et al.*, 2007) and education (Ullrich *et al.*, 2008).

The traditional WWW has been a strong medium for development of the e-learning tradition. The use of traditional web as a teaching and learning medium has led to the development of traditional learning management systems (e.g., WebCT and Blackboard) and also more adaptive intelligent tutoring systems. But, research on the use of Web 2.0 technology for teaching and learning is limited (Ullrich et al., 2008). The features afforded by Web 2.0 are in line with educational theories such as constructivism, exploratory learning, and connectionism, making it extremely interesting instructors, learners and designers. Ferdig (Ferdig, 2007) describes four theoretical aspects of Web 2.0 that make it suitable for pedagogy. He argues that Web 2.0 technologies: (a) provide an environment for scaffolded learning (with teachers, peers or an intelligent system), (b) support collaboration, cooperation and shared work resulting in active student participation learning, and (c) provide constructivist learning environments by encouraging students to actively publish, revise and comment on others' content. Alternatively, (Ullrich et al., 2008) provide technical, social and cultural characteristics of Web 2.0 that make it useful for pedagogy. These include the support for individual creativity and exploratory behavior, usability aspects such as desktop-like interactions, technological aspects such as the use of light-weight architectures and easy modifications, and multiple modes of access (e.g., PC, mobile devices).

Though researchers have claimed the potential usefulness in using Web 2.0 technologies for educational purposes, there are very few studies that explore how Web 2.0 technologies can be effectively incorporated into the public education milieu. One possible reason could be relative newness of these technologies. But, it is interesting to note that several for-profit companies have strongly encouraged their employees to write blogs and develop internal wikis (Ajjan & Hartshorne, 2008). Another reason could be the instructors' lack of knowledge or interest in using these technologies or tools in the classroom. Ajjan and Hartshorne (Ajjan & Hartshorne, 2008) use a survey based study to investigate faculty interest in using Web 2.0 technologies in the classroom in a large public university. They found that faculty members are generally aware of the pedagogical benefits of using Web 2.0 technologies. But, more than half of the respondents did not plan to use any Web 2.0 technologies in their classrooms.

Researchers have explored the development and use of Web 2.0 technologies in a variety of domains and tools. One domain that has received attention for Web 2.0 technologies is e-Science projects. Pierce et al (Pierce *et al.*, 2008) developed outreach tools as a means of creating communities of like-minded researchers. This is an e-Science venture aimed at outreach activity of broadening the participation from minority institutions. Fox et al (Fox et al., 2007) examine the usefulness of tagging and social bookmarking for identifying and building keyword-based profiles that can be used for "collaborator match-making services". The system, called Minority Serving Institution-Cyber Infrastructure Empowerment Coalition (MSI-CIEC) incorporates online bookmarking and tagging for researchers. Mason and Rennie (Mason & Rennie, 2007) report on the development and use of a range of Web 2.0 technologies that supported the development of a community in Scotland. The social software helped in community interaction, ownership and pride about the local landscape and learning about the local tourist locations.

With respect to the use of Web 2.0 technologies for education, most research reports have focused on design and development of tools. Others have argued about the opportunities for using these tools (Alexander, 2006). Kaldoudi et al (Kaldoudi et al., 2008) describe a problem-based learning approach using wikis and blogs for supporting medical education. The authors contrast the lecture-based tradition in medical education with the active, exploratory learning approach that is afforded by Web 2.0 technologies. The authors describe a wiki-blog based system that supports collaboration among medical experts, support strong instructor presence, helped in continuous monitoring of student activities and provided tools for student inquiry. Takago et al. (Takago *et al.*, 2007) describe the ineffectiveness of their e-learning system designed for teaching engineering design. The original design was assembled from independent software components and provided static web content. The new Web 2.0 based redesign is based on analysis of students' learning activities and helps students publish revise and exchange information. It also helped instructors (and peers) track the progress of the students to give them constructive feedback. Synchronous Learning Environment with Web 2.0 (SLEW) is another application developed with AJAX technology. SLEW is a synchronous distance-learning application that supports dynamic interaction, knowledge sharing and interaction between teachers and learners (Lin *et al.*, 2007). SLEW uses Web 2.0 technology and YouTube API to develop instructional courses for distance learning.

Web 2.0 technologies also face several potential disadvantages. One of the more explored aspects is the challenges Web 2.0 technologies pose for security and privacy (e.g., (Ahern *et al.*, 2007); (Lam & Churchill, 2007)). Recent studies have shown that users are often not sure about the available privacy choices and often are not in a position to make well-informed decisions (Ahern et al., 2007). The openness of Web 2.0 systems is also another potential disadvantage for new users. Bhattacharya and Dron (Bhattacharya & Dron, 2007) discuss the challenges of effectively integrating Web 2.0 technologies for pedagogy. They organize the challenges into the following categories: technical challenges confronting the instructor and students, devising effective mechanisms for monitoring the students within and outside the classroom, and learner assessment processes. The authors do not provide any insights about how to overcome these challenges.

The possibilities for using Web 2.0 technologies for pedagogy are endless. But as we can see from the literature, these technologies are still new and there is limited research on how they can be applied to improve context-aware learning. More empirical studies are required to evaluate the challenges in using Web 2.0 in the classroom or at home on a longer-term basis. In this chapter, we will focus on a popular Web 2.0 technology called social tagging. We will first briefly discuss its history and characteristics, followed by a description of an empirical study that investigates how social tagging systems may directly impact concept development. Finally, implications to long-term learning are discussed.

SOCIAL TAGGING SYSTEMS

Social tagging systems are major Web 2.0 technologies that have gained popularity in recent years. A popular social bookmarking Web site is called del.icio.us (http://del.icio.us). Users register and personalize their own collection of bookmarks in their own page. Each bookmark is accompanied by a short description, or tags, of the contents of the site that the bookmark leads to. Users can also see the tags that other users create, search for bookmarks with certain tags, or browse the collection of bookmarks created by other users. Social bookmarking web sites therefore allow a new form of collaborative information discovery and sharing. Users can quickly set up a social bookmarking page for a topic of interest; learn from others who have similar interests, and discover new topics or subtopics and their connection to other users.

Alexander (Alexander, 2006) describes the increasing role of social bookmarking in pedagogical applications. He explains their importance in information search and discovery, acting as an "outboard memory", helping in finding collaborators with similar interests and self-reflection on patterns by evaluating one's own tag clusters.

Additionally, it also provides interesting opportunities for evaluating student (or group) progress by tracking their bookmarks and tags. In addition to publicly available social bookmarking systems such as del.icio.us, specific applications have been developed to support user needs in different environments. Examples include the PennTags project (http://tags.library.upenn.edu/) and the Harvard H2O project (http://h2o.law.harvard.edu/index.jsp). The PennTags project helps online library users at University of Pennsylvania to tag and organize their favorite library resources. The H2O project at Harvard law school creates an online venue for communities to create and exchange ideas through online interaction and discourse.

One major reason why social tagging becomes popular is that people are becoming less satisfied with the Internet being used as a large information database, from which users can retrieve facts easily through powerful search engines. Instead, people are increasingly relying on the Internet to explore and comprehend information, and to share experiences and socialize among other users. The major difference is that Web 1.0 aims at deriving powerful algorithms to index massive amount of information, but Web 2.0 aims at deriving semantic structures among these information that are pertinent to real-world information tasks imposed to real users. For humans, this distinction is not particularly prominent because the human cognitive system naturally conjoins the two functions as we process information. As we will elaborate later, when a person learns to index a new object, such as when learning that a four-leg animal is a cat, the person tends to naturally encode contextual information and classify the object in certain mental categories. When the person encounters an object in the future that is known to be a cat, he or she can then infer only that it has four legs, but also that it meows, has fur, etc. The formation of these mental categories therefore not only allows the cognitive system to capture the structure of the contextual information related to the object, but also allows the cognitive system to capture the similarities and differences across structures in the environment. This is arguably the process that humans can perform much better than computers, and the reason why Web 1.0 fails to satisfy the needs of users. We address this point later in the chapter.

Instead of relying on mental concepts and categories to exploit contextual information, search engines, on the other hand, often rely on automated indexing software to determine the information content of web pages. For example, software such as web crawlers will visit hyperlinks in multiple web sites on the Internet and develop a list of keywords that appear on each of the web pages to which these hyperlinks connect. Eventually, a large database consisting of a master list of these keywords is created. When a user enters a query in the search engine, the words in the query are compared with those in the database. The results of the search are all of the web sites that have been listed under the keywords in the database that match the query words, and the links to these web sites are returned in the order that is determined based on frequency of visits, certain usage histories in the past, location of keywords in the documents, number of other sites that link to each of these web sites, or other features that are believed to increase the likelihood that the information returned from the search engine will match the information goal of the user. Information accessed by this kind of indexed retrieval is often just an *ad hoc list*, with no internal organization at all. Therefore, the fundamental problem with this kind of simple indexing and retrieval is that it does not capture the natural structural relationship among these web sites based on their information content. Although many online systems do provide classification information such as subject headings in book-selling web sites such as amazon.com, or topics or directories links in search portals such as Yahoo.com, one has to keep in mind that these categories are created by the humans, presumably someone who believe these classification is general enough that they could help users to find information more efficiently. Search engines by themselves, are not very good at generating these classification. In other words, the major drawback of the simple indexing and retrieval in Web 1.0 is that it does not allow users to directly learn the context under which the information naturally appears, thus preventing users to develop the natural structural relationship and classification of information based on the informational structures that naturally exist in our environment.

Social tagging systems, on the other hand, allow collective indexing of the massive information space based on the subjective interpretation of the information in the web pages by different users. Human indexing not only allows better representation of semantics at the level that other humans can easily understand, it also allows multiple interpretations by people with different knowledge background and information needs. The major drawback, compared to automated indexing, is the lower speed of processing. However, this drawback seems to be well compensated by the massive volume of users as they provide metadata to the web sites that they find useful and are happy to share with others with similar interests. Indeed, results show that although users may have diverse backgrounds, the dynamics of tags are found to stabilize quickly as the number of users increases (Cattuto *et al.*, 2007; Golder & Huberman, 2006). This is perhaps one of the most fascinating aspects of social tagging as well as other Web 2.0 technologies, as demonstrated by the success of Wikipedia and other similar open-source projects.

With the increasing popularity of social tagging systems, many are hopeful that they can potentially promote learning about social events, beliefs, or concepts that go beyond knowledge acquired from textbooks or formal instructions in classrooms. Although many are hopeful that Web 2.0 technologies may provide a revolutionary way of learning, some researchers question whether this kind of informal learning may only lead only to superficial knowledge acquisition – accumulation of bits and pieces of facts by collective indexing without necessarily developing the deep structural networks of knowledge acquired in formal learning environments. Indeed, most recent studies on social tagging systems have focused on user motivation for contributing to different web sites (Sen *et al.*, 2006)or aggregate usage patterns in specific web sites across a specific period of time (Cattuto et al., 2007; Golder & Huberman, 2006). To a certain extent, many of these studies have treated social tagging systems as a form of technology that provides more meaningful indexing of information than automated indexing by search engines. To our knowledge, no empirical study has been done to investigate how the interactions with social tagging systems may potentially influence higher-level cognitive structures and promote "real" learning beyond indexing of information. To illustrate this point, we will first review the ideas of distributed cognitive systems before we present our study that directly test how social tagging systems may directly influence learning.

Social Tagging Systems and Distributed Cognitive Systems

Social tagging systems are excellent examples of distributed cognitive systems (Fu, 2008; Hollan *et al.*, 2000; Hutchins, 1995; Zhang & Norman, 1994). In contrast to the traditional definition of cognition, a distributed cognitive system encompasses all flow of information among individuals and the resources in the environment. The idea is that when one examines the outcome from the distributed cognitive system, one cannot easily attribute the outcome to any isolated component of the system. In fact, the basic premise of a distributed cognition framework is that behavior arises out of the interactions of the components of the system. The functional unit of analysis of behavior in a distributed cognitive system should include all elements that bring themselves into coordination to accomplish some tasks, and any isolated analysis of its parts is insufficient to understand how the system works. A classic example is the demonstration of distributed memory systems in the cockpit by Hutchins (Hutchins, 1995), who showed that the encoding and retrieval of critical information by pilots rely on various displays inside the cockpit as much as individual memory. In addition, information from the external environment provides more than simply a cue to internal memory, but provides opportunities to reorganize the internal and external representations in the distributed cognitive system.

Under the distributed cognitive systems framework, the current analysis of social tagging systems will focus on the intricate interactions between internal and external representations of concepts, tags, and documents as a user is engaged in as they interact with the system. Figure 1 shows a notational diagram of this theoretical framework. Multiple users have their internal representations of the world, as they interact with the social tagging systems and consume information on different web pages. These internal representations partially reflect the different background knowledge of different users, as well as differences in their information needs. These internal representations will influence how they interpret the information in different web pages, the tags created by others, as well as the tags they will create to associate with the web pages that they visit. To a certain extent, these internal representations are shared among others through the external representations (tags) of the information content of the web pages. It is not only the case that users may contribute tags to different web pages, but the interpretation of tags created by others may also influence their own internal representations as some forms of knowledge adaptation. The major characteristics of this distributed cognition framework is that: (1) both internal and external representations may influence the search and interpretation of the web document, and (2) the understanding and interpretation of the web document may influence both the internal (concepts) and external representations (tags).

Tagging, Schemas, and Knowledge Adaptation

Researchers in cognitive science have proposed different representational structures to capture the properties of our general knowledge of objects around us, and one prominent representational structure is called a schema (Rumelhart & Ortony, 1976). Schemas represent our concepts of objects such as their attributes and their categorical relationship. For example, we know that houses have rooms, can be built of wood or stone, serve as human dwellings, and are a type of building. The importance of the category information is that it stores predictable information about instances of a category, such that when someone mentions a house we have a rough idea of the object being referred to. Note that schemas represent knowledge at an abstract level, in the sense that they encode what is generally true rather than what is true about specific instance.

One important property of schemas is that there are default values for certain schema attributes, which are presumably developed from our past experiences. This provides schemas with a useful inferential mechanism. Many studies have been conducted to confirm the psychological reality of schemas. For example, Brewer and Treyens (Brewer & Treyens, 1981) conducted a study in which participants were told that they were in an office. After a short period of time, participants were asked to recall objects in the office. Results showed the participants were much better at recalling objects that can typically be found in an office than those that are not. In addition, participants mistakenly recalled objects (such as books) that can typically found in an office, but were in fact not in the specific office that they were in. These studies show that when given a hint to what the object belongs to, people will utilize their existing knowledge to infer the other "hidden" attributes of the object.

As people interact with their environment and acquire more experiences their schemas may be

Figure 1.A distributed knowledge representations framework in a social tagging system (reps = representations).

modified to make sense, or used to make sense of the new experiences. This process of knowledge adaptation can be traced all the way back to the Piaget's (Piaget, 1975) developmental model of equilibration of cognitive structures in children. According to Piaget, there are at least two processes through which new experiences interact with existing schemas. When new experiences are modified to fit existing schemas the process is defined as assimilation. In contrast, accommodation is an adaptation process of knowledge acquisition that changes the schemas in order to fit the new experience, or the person creates an entirely new schema in order to accommodate new data that does not fit any of their existing schemas. Through the process of assimilation and accommodation, people can adapt to new experiences that they obtain from their interactions with others, such as when they discuss, share, or exchange information.

Consider the case when a user is browsing for information related to a broad topic of interest, such as when one is interested in knowing more about facts or events related to the independence of Kosovo. We called this kind of *exploratory learning* an ill-defined information task (as opposed to well-defined task in which a specific piece of information is needed such as looking for the address of a hotel, see Chin, Fu, & Kannampalil, 2009; Fu & Pirolli, 2007), in which one only has a rough idea about what they are looking for, and the information goal itself will be refined throughout the search process. During the search, social tags created by others can be utilized as useful cues to select and navigate to the documents pertaining to the topic of interest (Marchionini, 2006; White *et al.*, 2007). Through this process of *exploratory search-and-learn*, the user gains a better understanding of the topic through the enrichment of internal representations of concepts relevant to the topic (either assimilation or accommodation, or both). The user may then create their own tags for the web documents based on their own understanding as well as the existing social tags, and may choose to perform another cycle of exploratory searching and learning, refinement of concepts, and so on. *In other words, through iterative exploratory search-and-learn cycles, the interactions between internal concepts and external tags gradually lead to sharing and assimilation of conceptual structures as more and more people assign social tags to represent ideas* *or concepts that they extract from the massive amount of web documents.*

Applying the above framework of knowledge adaptation to social tagging, we have three specific predictions on how social tags may influence knowledge development. First, the ability to predict based on category membership is presumably the major utility of tags that are assigned to a bookmark. Tags invoke certain internal schemas of the user, and these schemas allow the user to predict what information is "hidden" in the web page that the bookmark leads to. It follows that the higher the "quality" of tags (in the sense that they allow better prediction of the underlying schemas), the higher the efficiency of the user in finding the right information. Second, given an information goal, when there are more high-quality tags that match the existing schemas of the user, the existing schemas of the user will be richer through the process of assimilation. Third, when information content is more diverse, more distinct schemas will be developed through the process of accommodation. We will formalize these processes in the next section.

A Formal Model of Social Tagging under the Distributed Cognition Framework

To formalize the analysis of social tagging, we will present a probabilistic model of exploratory learning behavior as users interact with a social tagging system. The formal model allows not only allows precise predictions on behavior, but also provides clear characterization of how different components and processes influence behavior. The model assumes that people will naturally categorize web documents as they go through and comprehend them (with the tags helping by adding additional features), and *the reason why mental categories (schemas) are formed is that this is an adaptive response to the inherent structure of the stimuli from the external world to our minds that allow humans to predict features of new objects better*. Tags assigned to documents are just another set of features that allow us to predict the unobserved contents of the documents, and with the formation of mental categories, the tags will not only inform the user what they literally refer to, but also other unobserved features of the documents.

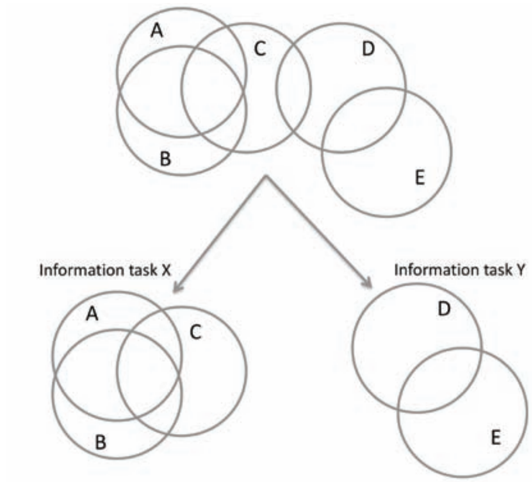
Assume that a user has a set of schemas *S* and a set of semantic topics *T*. The information goal is to predict whether topic T_j (some useful information) can be found by following a link with tags *G*, i.e., the user is trying to estimate this probability: $P(T_j|S,G_k)$ when deciding on links, which can be broken down into two components based on the distributed cognition framework. One component predicts the probability that a particular topic can be found in a given schema, and the second component predicts the probability that a given set of tags are associated with a given schema:

$$P(T_j \mid S,G) = \sum_m P(S_m \mid G)P(T_j \mid S_m)$$

(*Equation 1: Likelihood of finding topic T_j given schemas S, and tags G*)

In other words, to predict whether topic T_j can be found in a particular document, one can first estimate $P(S_m|G)$: the probability that the document with tags G belongs to a particular schema Sm. This estimate depends on how much the internal and external representations match each other: The higher the match, the better is the model able to predict to which categories the document belongs. It also provides a measure of the "quality" of tags, as it indicates how much the tags may help invoke the set of schemas in the user. The second estimate $P(T_j|S_m)$ is the probability that topic T_j can be found in schemas S_m. This estimate therefore depends on the relationship between the topics and the schema. The overall probability $P(T_j|S,G_k)$can then be estimated by enumerating the product of these two probabilities over all mental categories.

Figure 2.Notational diagrams showing the original information space (top), and the information space for relevant topics for information task X (left) and Y (right). Each circle represents a topic.



Assimilation: Enrichment of Mental Categories

If we assume a set of schemas that people may have, one can first estimate the prior probabilities for each of these schemas, and calculate how likely a tag created by a user is created based on a particular schema by the Bayes theorem. Specifically, if $P(S_m)$ is the prior probability of schema S_m, and $P(G|\ S_m)$ is the conditional probability that tag G belongs to S_m, then we can obtain $P(S_m|G)$ by:

$$P(S_m \mid G) = \frac{P(S_m)P(G \mid S_m)}{\sum_m P(S_m)P(G \mid S_m)}$$

(*Equation 2: Probability that a document with a tag G is created from schema S_m*)

To estimate the prior probability, one can assume that there exists a prior probability for any two random objects (e.g., documents) to belong to the same schema in a particular (informational) ecology. The higher the value of this prior probability, the lower the likelihood that any two objects will belong to a new schema. For the current purpose, we assume that a prior probability that any two web documents belong to the same category for a particular information task. The prior probability therefore depends on the general structures of the information distribution and the information goal. For example, the top of Figure 2 shows a notational diagram of 5 topics (A, B, C, D, & E) in a given information space, and these topics have some levels of overlap in their information contents. Assume that for information task X, topics A, B, & C are relevant. The information space becomes highly overlapped (bottom left of Figure 2). However, for information task Y, topics D and E are relevant, and the information space contains topics that have low overlap. Therefore given the same information space, information task X will have a higher prior probability that any two relevant documents will belong to the same schema, but for information task Y, the same prior probability will be lower.

The conditional probability $P(G|S_m)$ can simply be estimated by the ratio of the number of members in schema S_m that contains G and the total number of members in G, i.e.,

$P(G|S_m)=n/n_m$

(*Equation 3: Probability that a tag belongs to mental category m*).

When the user is browsing different documents and their corresponding tags, estimates of how these tags may come from any of the existing schemas can be derived by calculating the value of $P(S_m|G)$ for each m. The schema that has the highest value of $P(S_m|G)$ can then be selected, and refined based on Equation 3. As more and more documents are processed, the new experiences will be assimilated with the existing schemas of the person and the existing set of schemas will be enriched through this process.

Accommodation: Formation of New Mental Category

It is possible that a person may encounter a new piece of information that does not fit into any of his or her existing schemas. In that case, the existing schemas need to be adjusted to accommodate for the new piece of information. This decision was based on the value of $max[P(S|G)]$, where G represents the contents and tags of the document and S represents the set of existing schemas, and the max operation is performed in the set S. Specifically, a new category will be created only if

$$P(R_{new}) > max[P(R|S)]$$

(*Equation 4: New mental category*)

i.e., the probability that the document belongs to a new category is larger than that for it to belong to any of the existing schemas. If this condition is met, a new schema will be created. The accommodation process therefore allows new schemas to be formed from new experiences.

Assigning Tags to a Bookmark of a Web Document

Given an existing tag G_k, the model will calculate the value of $P(G_k|S_m)$, where S_m is the category to which the current document is assigned according to Equation 3 & 4. The model will assign this tag G_k to this document only if

$$P(G_k|S_m) > \tau_{threshold}$$

(*Equation 5: Assigning an existing tag*)

Where $\tau_{threshold}$ is a free parameter to be estimated from the data. A new tag is created only if any of the tags associated with the documents in category S_m is larger than the maximum of $P(G|S_m)$ for all existing tags, i.e.,

$$P(G_{new}|S_m) > P(G_{max}|S_m)$$

(*Equation 6: Assign a new tag*)

Note the model does not predict which particular tags will be used, it only predicts how likely existing tags will or will not be used based on the relationship between the tags and the predicted mental categories formed.

EMPIRICAL STUDY

The main purpose of the empirical study is to test to what extent interactions with a social tagging system will directly impact knowledge adaptation. In addition, precise protocol data was collected to verify the predictions made by the model, which specifies both the assimilation and accommodation processes that underlie knowledge adaptation. A set of exploratory learning tasks was chosen. In all tasks, undergraduate students were given a rough description of the topic and gradually acquired knowledge about the topic through an iterative search-and-learn cycle. Students were told to imagine that they wanted to understand the given topic and to write a paper and give a talk on the given topic to a diverse audience. Two general topics were chosen: (1) "Find out relevant facts about the Independence of Kosovo" (IK task), and (2) "Find out relevant facts about Anti-aging" (AA task). These two tasks were chosen because the

IK task referred to a specific event, and therefore information related to it tended to be more specific, and there were more Web sites containing multiple pieces of well-organized information relevant to the topic. The AA task, on the other hand, was more ambiguous and was related to many disjoint areas such as cosmetics, nutrition, or genetic engineering. Web sites relevant to the IK task have more overlapping concepts than those relevant to the AA task. The other characteristic is that because the AA task was more general, the tags tended to be more generic (such as "beauty", "health"); in contrast, for the IK task, tags tended to be more "semantically narrow" (such as "Kosovo"), and thus had higher cue validity than generic tags.

Participants

4 participants were recruited from the University of Illinois. Participants were undergraduate students and all had extensive experience with general information search and the del.icio.us Web site. Participants were randomly split and assigned to one of the tasks. From their self-report it was obvious that they were unfamiliar with the given topics. Participants were told that they should explore all relevant information to learn about the topic using either the search function in del.icio.us or any other Web search engines, and should create tags for Web pages they found relevant to the topic and store them in their own del.icio.us accounts. Participants were told that these tags should be created for two major purposes. First, to allow them to re-find the information quickly in the future; second, to help their colleagues to utilize the relevant information easily in the future for their search purposes.

Procedure

Each student performed the task for eight 30-minute sessions over a period of 8 weeks, with each session approximately one week apart. Students were told to think aloud during the task in each session. All verbal protocols and screen interactions were captured using the screen recording software *Camtasia*. All tags created were recorded manually from their del.icio.us accounts after each session. Students were instructed to provide a verbal summary of every Web page they read before they created any tags for the page. They could then bookmark the web page and create tags for the page. After they finished reading a document, they could either search for new documents by initiating a new query or selecting an existing tag to browse documents tagged by others. This exploratory search-and-tag cycle continues until a session ended. All tags used and created during each session were extracted to keep track of changes in the shared external representations, and all verbal description on the Web pages were also extracted to keep track of changes in the internal representations during the exploratory search process. These tags and verbal descriptions were then input as contents of the document.

One week after the last session, participants were asked to come back to perform a sorting task. Participants were given printouts of all web pages that they read and bookmarked during the task, and were given the tags associated with the pages (either by themselves or other members in del.icio.us). They were then asked to "put together the web pages that go together on the basis of their information content into as many different groups as you'd like". The categories formed by the participants were then matched to those predicted by the assimilation and accommodation processes in the rational model.

RESULTS

Participants on average created 88.5 bookmarks (IK1=93, IK2=84) and 379.5 tags (IK1=392, IK2=367) for the IK task, and 58 bookmarks (AA1=52, AA2=64) and 245 tags (AA1=256, AA2=234) for the AA task. Participants in the IK task created more bookmarks and assigned more tags than those in the AA task, but the average number of tags per bookmark is about the same (4.3 tags per bookmark) for the two tasks. As expected, finding relevant information for the AA task is more difficult, as reflected by the fewer number of bookmarks created. Given that distribution of information was more disjoint in the AA task (e.g., there is little overlap of information between web sites on skin care and genetic engineering), the results were consistent with the assumption that the average rate of return of relevant information was lower for the AA task then the IK task.

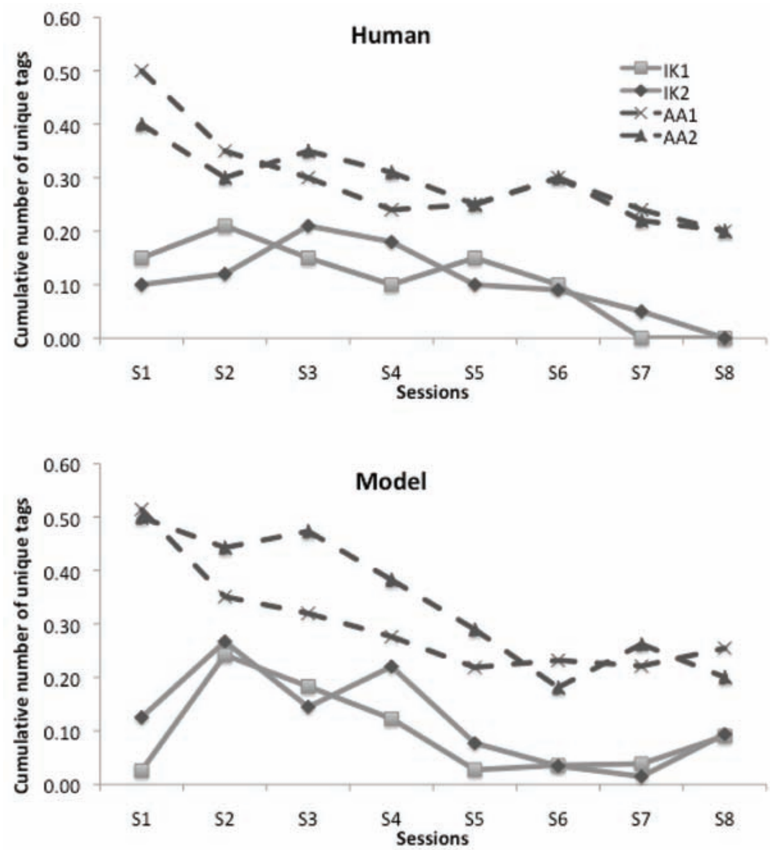
Figure 3 shows the proportion of new tags created by the participants (left) and model (right). Perhaps the most interesting pattern was that even though participants assigned fewer tags, but the *proportions* of new tag creation over total number of tag assignment were higher in the AA task than in the IK task. This was consistent with the lower rate of return of relevant information in the AA task, and this lower rate was likely caused by fact that the existing tags on del.icio.us was less informative for the AA task. Indeed, concepts extracted from the documents by the participants in the AA task were more often different from the existing tags than in the IK task, suggesting that the existing tags did not serve as good cues to information contained in the documents. The general trends and differences between the two tasks were closely matched by the model (R^2=0.75). Again, the major mismatches were found in the first sessions, where the model tended to under-predict the creation of new tags, especially for the IK task. A model that randomly assigns tags was created and compared to performance by humans and model. Chi-square tests show that both human and model performance was significantly different from the chance model ($p<0.01$), showing that they are significantly above the chance level.

Formation of Mental Categories

One core assumption of the rational model was that the assignment of tags and the selection of links were both based on the set of mental categories formed from observing existing tags assigned to documents that they processed. It is therefore critical to verify that the set of mental categories formed by the model match those formed by the participants. To do this, correlations between the mental categories formed by the model and the participants were calculated by constructing "match" tables for each participant and model. Items that are in the same category will be given a value 1, otherwise a 0. For example, two possible categorization for the set {a,b,c,d,e} are {ab}, {c,d}, {e} and {a,b,c}, {d,e}. In that case, their correlation can be calculated as r=0.102 based on the match table.

The major determining variable for mental category formation in the model is the value of the coupling parameter, *c* (see Equation 6). This was set to 0.6 for the IK task and 0.3 for the AA task to best fit the data. Because the information distributions are more disjoint for the AA task, the value of the prior probability of P(S) was set to a higher value. Table 1 shows the number of categories formed by each participants and model, as well as their correlations. As predicted, participants formed more categories in the AA task, reflecting the structures of the information sources. However, as shown earlier, participants in the AA task had lower rate of return in their information search, suggesting that they spent more time looking for relevant information. Although the number of categories formed was higher in the AA task, the quality of these categories (in terms of how much they help in finding information) was lower than those in the IK task (results shown next). The correlations between the participants and the models were high in both tasks, suggesting that the model roughly formed similar mental categories as participants, even though the inherent information structures were different between the two tasks.

Figure 3. Proportions of new tags created over total number of tags assigned across the 8 sessions by the students (top) and models (bottom).



DISCUSSION

From our knowledge, the current study is the first that shows social tagging systems not only can facilitate dissemination of information, but can also induce cognitive changes such as concept formation and knowledge assimilation. The current results also show that social tagging systems have the potential to facilitate not only collaborative indexing of the massive amount of information, but also as a means for social exchange of knowledge structures, and thus has the potential to promote formal or informal learning of diverse topics and the development of common schemas

Table 1. Number of categories formed by each participant and model, and the correlations of the partitions of the categories of the models and the students calculated using the match tables.

	#categories (Students)	#categories (Models)	Correlations of the partitions
IK1	6	6	0.71
IK2	5	6	0.68
AA1	12	13	0.59
AA2	10	11	0.67

or understanding within or across different communities. Given the direct impact on the development and refinement of mental schemas, it is not hard to imagine that social tagging systems could also impact collaborative activities that involve higher-level cognitive processing, such as problem solving, decision making, or creative designs. Indeed, many innovative ideas were generated by the sudden realization that knowledge structures in disjoint domains are relevant. It seems that we have only started to harness the potential of socio-technological systems, especially in the area of education.

The formal model was developed under the assumption that humans adapt their knowledge schemas through the assimilation and accommodation processes as they explore the Internet and comprehend knowledge extracted from web documents. The model, developed under the distributed cognition framework, was successful in providing good quantitative predictions on the emergent behavior of four different individuals across an extended period of time. The model shows how internal representations slowly assimilate to the external informational distribution through the processing and assignment of social tags, and how individuals create new tags based on their internal representations. The dynamic interactions between internal and external representations captured by the model has also highlighted the value of the distributed cognition framework, as they imply that isolated analysis of either the distributions of external tags or cognitive mechanisms of the user will unlikely lead to good characterizations of the dynamics that emerge from socio-technological systems.

The formal model also provides direct design guidelines for future social tagging systems. For example, the formal analysis of the current distributed cognitive system can be implemented as software tool that facilitates extraction and exchange of mental categories for different groups of people who have different expertise in different domains. Can tags, for example, be organized by mental categories extracted from experts in different fields in ways that facilitate knowledge transfer? Will transfer or exchange of knowledge at the fact, concept, and category levels facilitate innovation because they encourage re-structuring of existing knowledge structures? The del.icio.us system in this study was a general-purpose social tagging system. The current results suggest that social tagging systems can be specialized for different purposes. For example, to facilitate context-aware learning, perhaps the systems can be combined with knowledge engineering software that extracts and classify knowledge according to top-down domain knowledge to facilitate knowledge adaptation.

Chapter 5.16

Entering the Virtual Teachers' Lounge:

Social Connectedness among Professional Educators in Virtual Environments

Randall Dunn
Liberty University, USA

ABSTRACT

As communication and connection are essential instruments for professional educators, this chapter seeks to examine the effectiveness of an online "virtual teacher's lounge" in the framework of offline communities. Essentially, an online discussion forum for educators is evaluated for the purpose of determining whether the forum provides a "space" conducive for the development of a community of professional educators as benchmarked against an understanding of offline community formation and existence. The foundational works of Ferdinand Tonnies, James Coleman, and Ray Oldenburg are used to develop 12 characteristics of community—as understood in the context of social communities. The study finds that online communities closely resemble offline communities in structure and interaction, but only for select participants. The participants observed demonstrating or facilitating the characteristics of community comprise around 10% of the total number of users participating in the analyzed discussions.

DOI: 10.4018/978-1-60566-826-0.ch010

INTRODUCTION

As globalization continues to bring more individuals to computer-medicated communication (CMC) of interaction as found in the phenomenon of the Internet, the education community must continue to embrace the technologies that exist to better address social, pedagogical, and professional needs. The United Kingdom has looked to technologies as cornerstones of recent educational reforms (Selwyn, 2006). It is only reasonable for the educational community, speaking in general terms here, to purposefully explore the latest technological innovations as possible means of assisting in communication for the purposes of professional development, collaborative support in pedagogical and social contexts, and for the discovery and connections of important content expertise. These tools can prove to be the connecting points between education professionals on opposite sides of the globe and around the literal corner. The challenge is to properly determine the most important and effective methods to allow educators the opportunity to effectively use resources and time to best meet the needs and demands of the 21st century.

This chapter examines significant developments in the specific context of the communication needs of professional educators as met by naturally-forming virtual environments. The primary question asked is whether virtual environments can serve the social needs of educators – essentially becoming virtual teacher's lounges, or more generally educational "third places" (see Oldenburg, 1991). This question is addressed through a primarily qualitative study, examining a single naturally forming educational community in an online environment.

The included background section creates a framework in which to evaluate an online discussion forum and its efficacy as a social community of professional educators. This chapter will review the sub-questions of the research –12 characteristics – in terms of analytical findings and synthetical conclusions. Conversational analysis and general observational techniques are employed to accomplish this study's goals. Further analysis of context illuminates other areas of interest as part of this study's execution.

BACKGROUND

The true nature of community promotes copious debate; or specifically, debate centers on whether community exists today as it once did, whether it will ever exist as it once did, and whether community has dynamically evolved and has therefore adopted a new meaning (Bauman, 2001; Putnam, 2000).

As the 1998 edition of the Dictionary of Sociology notes, "the concept of community concerns a particularly constituted set of social relationships based on something which the participants have in common — usually a common sense of identity" (Marshall, 1998). Identity is an important component of the formation of and participation in community. The perception of self, the subsequent behavior, and the juxtaposition of self with others all are vital concepts to understanding community (Bauman, 2003; Turkle, 1995). Community really can be considered a relationship between identity and the formed relationships with that identity.

George Hillery notes in Definitions of Community: Areas of Agreement in Rural Sociology (1955), "there is one element, however, which can be found in all of the concepts . . . all of the definitions deal with people. Beyond this common basis, there is no agreement" (Marshall, 1998). So communities are built upon relationships among individuals, aside from specific interests, geographical proximity, or necessity. None of these elements are present in agreed-upon definitions. This is particularly important for the pursuit of an understanding of computer-medicated communication (CMC)-based community formation.

Offering a different perspective, Zygmunt Bauman (2001) argues that the sense of community depends upon a community not knowing it is a community. This community must evolve "naturally" and not be artificially manufactured. Once realization occurs, then community is no longer pliable and that real community becomes something entirely different (Bauman, 2001, pp. 10-13). Grossman et al. actually attempted to fabricate such a community in an urban educational environment (2001). However, forced construction does not a community make.

Turning to an analysis of community, Bauman separates communities into two basic types: aesthetic and ethical. Aesthetic communities are formed as temporary, often based on an "idol." Membership in these communities remains noncommittal. Ethical communities, on the other hand, are communities that are based on rules, allowing members to experience security, safety, and certainty (Bauman, 2001, pp. 59-73), thus creating stronger ties.

Marshall's (1998) focus is on the distinction between community and society, which is important in this discussion. This distinction is made through sociological terms, coined by Ferdinand Tönnies in 1893, Gemeinschaft and Gesellschaft (Harris, 2001). The former denotes community — focusing on relationships based on family and close face-to-face ties. Elements in such a community are an attachment to place, concern over ascribed social status, and elements of homogeneity. Gesellschaft refers to society and general association, denoting the concepts of urbanism, industrial life, mobility, heterogeneity, and impersonality (Marshall, 1998).

For the purpose of this discussion, this study looks at communities as self-forming informal units of interaction – of the more ethical community type as Bauman defines them – where individuals have social connections on multiple levels in a stable and securely established conduit of communication. This can be best summed up by Ray Oldenburg's description of the "Third Place." This is the pub house, the bar, the bowling alley, the church meeting hall, or any place where informal relationships are continually reinforced. The Third Place exists outside of family and work (the first and second places, respectively). And for the purpose of this discussion, the Third Place can actually not be an actual place at all.

Oldenburg, in the *Great Good Place* (1997), describes the problem of place in America as manifesting in "a sorely deficient informal public life." He argues that America must revitalize its informal connections — dubbed "The Third Place" — a generic designation for a great variety of public places that host the regular, voluntary, informal, and happily anticipated gatherings of individuals beyond the realms of home and work." This Third Place is community, the informal connection among individuals on personal common interests and issues. Home and work are the first two "places," according to Oldenburg. These first two places remain a large factor of a person's identity. The existence of the Third Place is in decline (Oldenburg, 1997).

Oldenburg describes the Third Place as having the following elements: escape/ time-out from daily duties, neutral ground, "leveler," conversation, accessibility/accommodation, regulars, low profile, playful mood, and a home away from home. These aspects are implied to be unique to the third place. Oldenburg sums up that "(t)hird places that render the best and fullest services are those to which one may go alone at almost any time of the day or evening with assurances that acquaintances will be there" (Oldenburg, 1997). The Third Place is the home away from home (and away from work) – the place where people know they are accepted, feel comfortable, and interact informally with those they care about.

Another relatively recent concept in the realm of community, and relevant to this study, is the concept of Social Capital, focusing on beneficial relationships (mutual and singular).

Social capital has been defined as "features of social organization such as networks, norms and social trust that facilitate co-ordination and co-operation for mutual benefit" (Putnam, 1995). As individuals and as groups, people desire interaction with one another for specific benefits, whether these benefits are economic, social, political, cultural, psychological, physical, or even educational.

The actual formation of the social capital theory arose out of a need to reconcile the differing approaches of economists and social theorists with regard to individual motivation – one explaining it in terms of gain and the other in terms of complying with norms (Coleman, 1988; Bourdieu, 1983). A theory was necessary to demonstrate the effects both social expectations and individualistic drive have on an individual's choices and actions (Coleman, 1988).

The informal third place becomes very important in light of social capital. The benefits are not merely confined to Putnam's list of characteristics (escapism, neutrality, playfulness, conversational, community-feel, etc.), but rather may directly rely upon more social advancement-related reasons. People need interaction that indirectly or directly has positive effects on their development. They gather valuable tools, form valuable relationships, and establish long-lasting relationships to their benefit.

Talja Blokland found that those socially less advantaged could glean much from the "urban elite," provided there exists "informal rather than institutional relationships" and that success depends on "specific characteristics of reciprocity and mutuality of neighborhood networks across race and class" (Blokland, 2002).

This is a challenging time concerning informal connectedness. Putnam sees the great influence of the Baby Boomer generation as changing the way people interact in American society. There is a debate of which came first: the decline in community and subsequent use of technology or the use of technology in lieu of more traditional means of connecting with others. This issue has a great effect on this paper as the question arises as to whether people can experience connectedness — the macher/formal or schmoozer/ informal types as Putnam describes — in a seemingly disconnected environment (Putnam, 2000). However, as Lerner notes and Oldenburg reiterates, there still exists a "Problem of Place in America" where the small town (informal) cannot be revitalized, so a new community structure must evolve to take on integrated community needs in the "quest for community" (Lerner, 1957).

This research has established concepts surrounding community, community formations and the relationship to a third place (as defined by Oldenburg) and social capital (as defined by Putnam and Campbell). This study now turns to Etienne Wenger's Communities of Practice.

In the last two decades, Wenger (with the help of Jean Lave) developed a theory set exploring the concepts of learning and organizations and their convergence. He rooted this theory-set in a concept called communities of practice. In short, these particular communities contain "members (who) regularly engage in sharing and learning, based on their common interests" (Lesser & Storck, 2001). The theory's application travels from the commercial/ business world to the world of education as it looks at learning as a social process (with deep roots in John Dewey). Community members seek to learn from social groups in addition to collectively developing the social rules for engagement as pertaining to practice among its membership.

Grossman et al. (2001) looked at the semi-natural formation of an educators' community in a secondary school among history and English teachers. This project sought to put these groups of teachers together to accomplish two primary activities in the context of professional development: the development of pedagogical practice and of professional content knowledge in view of the two disciplines. While seeing some success in the discussions that developed, the researchers noted that the discovery of constructed professional communities saw less success than was initially anticipated. Merely providing time and resources does not meet the basic needs of community formation among professional educators. There is a mysterious element, very social or intellectual in nature that addresses this gap in effective formation.

The classical examination of social learning theories includes primarily face-to-face communication methods as the necessary component. More recently, a re-examination of this theory set has allowed for the discussion to expand to include other media such as e-mail and discussion forums. In fact, not only do these technologies provide a means to grow communities of practice but these media can actually be the primary facilitation for the development of entities (Lesser & Storck, 2001).

Regardless of medium or method, the initial development and further cultivation of communities of practice are directly related to the exchange of social capital. Members exchange social capital in the form of trust, mutual obligation, and language. Through structural (connections between members), relational (connections among networking processes), and cognitive (shared context and codification of meaning and processes) dimensions, communities of practice evolve.

This is the primary benefit of an examination of communities of practice: to examine as how a group of teachers develop methods and means to improve their practice as teachers (Wenger, 1998). In the context of informal social exchanges, researchers can use the relational dimension as discussed above to further solidify discussions on social capital and Oldenburg's work. The above is provided to develop a framework for teacher communities, but the use of the communities of practice model (or the work of Grossman) is primarily devoted to exploration of professional communities as they develop the practice pertinent to them. This research explores the nature of the social exchanges of participants in communication avenues and whether these exchanges support the construct being applied of communities (yes, professionally labeled but social in nature).

Concerns have arisen over the direction of community (see Bauman, 2003, and Giddens, 2002, for discussions on negative aspects of the globalization of community) with the advent of the Internet. The Informational Revolution is here (see Putnam, 2000). So how effective can virtual environments be in helping to establish or progress community?

Manuel Castells (1996) notes that the technological innovations that brought into being the Internet and virtual networking were conceived to solve a problem concerning connecting individuals. Suddenly, the world is connected and geographic boundaries are no longer impeding the formation of global communities.

Virtual communities as Castells defines them are "like Howard Rheingold('s) self-defined electronic network of interactive communication organized around a shared interest or purpose, although sometimes communication becomes the goal in itself." He notes that virtual communities may be formalized systems (like Bulletin Board System (BBS) or hosted conferences) or be spontaneously formed. In either case, the communities are ephemeral from the point of view of the participants —where users can move in and out as necessary. Virtual community participants are described as either transitory or electronic "homesteaders" (Castells, 1996; Ward, 2002),

What is unusual about CMC in general, and virtual communities specifically, is there exists a many-to-many relationship (Castells, 1996). This provides for many touch points for interests and individualism. It also makes it difficult to account for the many different informal virtual communities in existence as individuals can pass casually from one informal community to another without completely attaching.

Howard Rheingold, like Hammon (1998), has suggested that virtual interactions and relations overlap in to the real/physical lives of those participating. Face-to-face meetings were common among Rheingold's compatriots in the 1980s, spending their evenings sharing information and experiences in online environments and some weekends gathering for picnics to see who actually was the individual behind the virtual identity (Rheingold, 1994).

Some studies show that more than half of participants in newsgroup discussions not only begin long-lasting relationships in online environments but also continue off-line relationships with these online friends. Other avenues of communication are employed (postal service and telephone), and over time these develop into long-lasting personal relationships. Social bonds become redefined. Thomsen et al. sums up that newsgroup relationships "typically serve as catalysts for long-term and meaningful relationships" (1998).

Furthermore, evidence demonstrates that physical co-presence is not necessary for "intimate quality interactions" (Thomsen et al., 1998). As he also notes — as do Steven Jones (1998), Ray Oldenburg (1997) and Howard Rheingold (1993) —the various CMC technologies "have sprung out of the need to re-create this sense of community that participants join and become involved with the express purpose of re-establishing social bonds.". Suddenly virtual communities become Oldenburg's "Third Place," where bonding relationships can be established through the exchange of informal social capital.

The cyber-community becomes the connection to the real world for the Web-surfer. As Steve Jones surmises, Internet users have strong attachments online (1998, p. 5), thus it is a real experience. As Markham (1998) notes, "All experiences are considered real so therefore virtual is a misnomer." The gravest of subjects becomes a real exploration using online community tools to interact with other real participants through virtual communication lines.

Research on virtual communities in the context of professional educators has been limited. This is likely due to the fact that the world of virtual communities is completely reliant upon the only recently birthed CMC modes, such as the Internet. Obviously, because it is recently formed, there is a small window of time for exploration.

Selwyn (2000) provides one such exploration into the world of teacher-based virtual communities. This study examined the SENCo community (a communication group of Special Educational Needs Coordinators for schools in the United Kingdom). As a result of the government's push for the use of "virtual communities" as part of its educational reform practices, the researchers began to question if these virtual communication avenues truly accomplished the goal of connecting educators in communities from geographically disparate locations. The format of these communications followed what has been called discussion forums but also can be called e-mail list-servs (or e-mail groups that get archived in online environments).

Selwyn (2000) found that participants certainly did exchange in three of the four communication purposes (information exchange, empathetic exchanges, virtual respite), but the deep connectedness of community (the fourth) was not as prevalent. One more note here in this study is the emergence of some 24 participants who essentially became the hard-core users. These participants contributed some 50 percent of the message analyzed.

A distinction in this community formation is the imposition of the creation of community (as in Grossman's study above) by external forces as opposed to the natural evolution of community.

As discussed earlier, Coleman, Oldenburg, and Tonnies provide the foundation of what is understood about social communities (close-knit, naturally forming, and homogenous). An understanding of online communities can be found in works by Howard Rheingold, Steve Jones, Sherry Turkle, Robin Hammon, Stephen Doheny-Farina, Nathaline Bowker. Wenger's work moves toward understanding the formation of professional communities, but his work focuses on how communities of professionals share meanings so as to articulate, develop, and refine processes and knowledge to assist in practice. Selwyn attempted to look at the viability of these communities in the context of government-identified educational groups (identified with a job function), but does not see the arrival of communities online in that form or under those conditions. What is missing here is an understanding of teacher social communities and specifically teacher social communities online.

Taking these findings, one may synthesize a full picture of the potential of educator communities in online environments. Research notes communities are naturally forming, often informal, social groups. These groups are built on conduits of communication and social connections. Norms for behavior are established as part of a collaborative process, where individuals agree through negotiation on proper processes for group functioning. Participants gain membership – and thus are enveloped into the system of trust – in the group. Community is strengthened by the participation and efficiencies developed.

The development of understanding as related to problems, the contributive nature of participants, characteristics of movements of information, the development of tools, and professional language features all are uniquely identified in the communities of practice theory set (Wenger, 1998). The study here looks at the social exchange features of Coleman, Tonnies and primarily Oldenburg. These comprise the main drives of design for the study as the informal social and non-professional purposes of community formation of these (and primarily Oldenburg) present the type of community attempting to be analyzed/ identified.

This synthesis of understanding of community is the foundation for proceeding in this study, where in the section following, the study investigates online interactions for efficacy of community.

RESEARCHING ONLINE COMMUNITIES

The research, undertaken as part of this project, works to answer the question of whether online social communities created and maintained among professional educators constitute an informal community as earlier defined.

This is the construction of the design of this project: a positivist approach employed in a simple research question accompanied by interpretations/ analysis of the gathered textual data for attaching deeper meanings to the associations. Simply put, the analysis of unsolicited textual submissions proves to be too complicated for a simple quantitative mode of enquiry. A more inductive approach is necessary for such meaning-rich data that employs analysis of numerical representations of social phenomena (Kuikin & Muill, 2001).

To determine the nature of exchanges among professional educators in virtual spaces, these exchanges must be analyzed in light of a model for an off-line, informal community. The study uses Ray Oldenburg's descriptors of the *Third Place*, Ferdinand Tönnies' *Gemeinschaft*, and the discussion of social capital as the basis of this benchmark off-line community (and thus the impetus for the identified categorizations to be used in the study). These together form the necessary picture of informal community: close-knit, supportive, mutually beneficial, and connected. Deliberately excluded from this group is Wenger's notions of community in the context of professional communities. These chosen sets used for constructing a model for interpretation comprise an image of exchanges of the purely informal variety for the purposes of social interactions, not for the development of professional practices.

In order to gauge the community existence in this project, the study employs the 12 community characteristics gleaned from the works of Oldenburg, Coleman, and Tönnies, to create the following questions and guide conclusions.

- Is the virtual space a location for participant escapism?
- Does the locale provide an area of neutral ground for all participants?
- Do all members have equal access to participation?
- Does conversational-style communication dominate the environment's discussion patterns?
- Are there "regulars" in this environment?
- Is there evidence of playfulness in this virtual space?
- Does this place act as a "home away from home" for the membership?
- Is there an obvious attachment to place among the place's membership?
- Is there evidence of a concern over ascribed social status among the place's membership?
- Are there elements of homogeneity – via beliefs, interests, or backgrounds – among the space's membership?
- Does the "community" exert self-regulation? Is there evidence of a contract (explicit or understood) for membership governing behavior and participation?
- Is there evidence of an exchange of ideas for the development of individuals?

These questions then are transformed into the coding-based categories for examining the relationships and the interactions contained within the chosen community.

To answer the outlying question of what types of exchanges occur in virtual communities of professional educators, the study selected an online teacher community (primarily consisting of a cost-free discussion board area so as to remove boundaries of limited access). A particular weekday was selected, and every electronic discussion (and preceding discussions with the same attached date) active on that particular weekday was then gleaned for analysis. In essence, a random sample of discussions was then used for answering the basic questions posed as part of this study. The participants in this online community are primarily educational professionals or para-professionals.

The sheer volume of the available discussions led to the consideration of limiting the analysis. However, all discussions were included, with the one exception of limiting very long threads to no more than 100 posts. This limited the ability to analyze previous discussions, but many of these proved to be the "game-like" discussions and appear to not have impacted the study.

The other limitation to note here is elaborated upon and developed further later. This relates to the notion of what has been categorized as the "regular user." The limitation of this study identifies a group of users in such a category, but the number identified here and its relevance does not speak to the actual occurrence of "regularness" in quantifiable terms. In other words, the 30 identified "regular users" do not speak to how many users are actually represented by this group. In some respects, this is an intrinsically focused number and categorization so as to identify further characteristics and understandings of those more identifiable as regulars in an online forum.

In consideration of the above, this study's primary approach for data collection and analysis are now described.

All discussions posted to or created within the 24- hour period (12 a.m. EST to 12 a.m. EST of the following day) are saved as text files. Some of the actual discussions contain multiple pages (possibly as many as 30 pages). If so, then all discussion posts within the most recent 100 posts are gathered. On average, some 10 topics are "active" (i.e., have been active on any given day) per a forum. The resulting discussion threads from the 25 discussion forums were imported into QSR International's NVivo 7's software interface for organization and analysis. At this point, the coding of the data proceeds.

The following categorizations provide the guiding aspects for the coding of the data gleaned from the forums (based on the guiding theoretical discussion questions as noted above): participant escapism, neutral ground, equal access to participation, conversational as dominant style, "regulars," playfulness, home away from home, membership attachment to place, social status a concern?, homogeneity (as in identified perceived like-ness in areas of interest, professional or vocational identification, ethnic affiliation), self-regulation/ contracts, and idea exchange for individual development.

The number of occurrences and the level of adherence to these concepts are examined. Further in this phase, the additional peripheral statistics are gathered to develop contextual understandings of the posters. Finally, additional information on posting policies, FAQs and other Web site provided information on the forums are gathered to use toward answering the questions posed. This document review is used to complement the interpretation of the gathered data from participation.

All data gathered is used to form an analysis of the actual interactions contained within these randomly selected in the study. Primarily, the method of analysis involved the specific examination of these discussion threads in isolation and the collection of additional peripheral information as related to the governance and structure of the forum and general data on users.

PARTICIPANTS AND PLACE

Below is a provided background of both nature of the "place" where these discussions occurred and the participants in this study.

The forums pre-created, as repositories for organizing potential discussions, can be divided into three primary types: those as related to professional needs, those as related to social needs, and those as related to the management of the discussion forum itself. For example, the forum has established sub-areas for each broad level of education (elementary, secondary, etc), for types of activities (classroom penpals, postcard exchanges, behavior management, etc.), and for specialty areas (like Montessori education, special education, pre-service teachers). The other areas range from exam preparation to general game and chatting sub-forums. Some of these areas remained quite professionally focused (like the exams area) while others were exclusively non-professional (like games and chitchat). Others oscillated between these two general characterizations depending on the specific subject/ topic.

The greatest number of active threads took place in the TeacherChat forums on the day of collection (comprising discussions geared toward social and professional needs). What is misleading here is that we arrive at this conclusion because of an accounting of the amount of threads active, not the actual amount posted in each thread. This point is revisited and further elaborated upon below. Regardless, we can draw some conclusions.

The highest number of active discussions occurred in the Elementary Education sub-forum of the TeacherChat Forums (with 16). The next highest number of active discussions in a sub-forum appeared in the New Teacher Sub-Forum of the TeacherChat Special Interest Forums. Following closely behind are the Games and the ChitChat sub-sub-forums (both of the TeacherChat Forums/ Teacher TimeOut Sub-Forums) and the Teacher TimeOut Sub-Forum main area itself. These discussions will be examined in more detail below. The ChitChat area proves to be the most active area during the discussion analysis period.

These users are primarily participating in discussions about a specific professional need (like Elementary Education) or they bear participating in social engagements (like ChitChat and Games). This very differentiation – a divide between the professional and the social - becomes a hallmark of the analysis of this forum *world* in the following sections.

As the nature of this study remains quite observational where interaction is intentionally minimal, all data illustrative of the participating users' backgrounds is gathered from public sources, primarily from the users' member profiles. Here, the location, the age, the overall posting record, and the particular vocational (or personal in some cases) interest of the poster (with some other background details) can be gleaned. With the exception of the posting history, all details remain optional for the forum members, thus only a sampling can be provided of the types of users posting to this forum. The count of non-responders is included with each demographic below. This sampling still remains illustrative and enlightening.

Out of the 301 users who participated in the discussions, around 86% of the users listed a location (a specific state, a province, or a country). Primarily users reside in the USA, with Canada and Australia representing much smaller segments. Within the United States, California clearly is the most common origination point for users (with 22% of the total United States-based users living their offline lives here). Other states with relatively high counts of participants include Florida, Michigan, New York, New Jersey, and Texas.

The next piece of data involves age of the participants. This piece of data is not used to draw specific conclusions, as there are some issues with this piece. First, users may not be honest about their ages when listing this in a public forum. Next, the users who reported ages may be more inclined to do so as these users may be more representative of the younger segment of the user group. With these caveats, reported ages are examined. The users who chose to include a birth date in their profiles comprise 22% of all users, with users including birth date in their profiles tending to be younger (with those aged 30 and below comprising 71% of the total). The oldest recorded was 66 while the youngest was 20.

Next, an understanding of vocational and professional pursuits or personal interests can be quite helpful in understanding the users posting to this forum. The data gathering process identified 50 different types of professions or affiliations. Several users noted in-between affiliations ($4^{th}/5^{th}$ grade, for example). Even with these in-between affiliations, a clear pattern emerges. The first, second, and third grade teachers (not counting in-betweens) comprise 18% of the overall user group. Also interesting to note, 22 (or 7%) of the users identified themselves as students (or college students in teacher education programs).

Elementary Education rises to be the most identified profession. This is corroborated through an examination of the actual postings and active discussions (discussed below and above respectively).

With general understandings of the place and the participants, the below sections detail the analysis and synthesis of this research undertaken and the constructed broad categories of results:

The Participant Divide: Regulars and Non-Regulars
Regulars and the Role of Expert: Professional Assistance
Regulars and the Online Playground: Social Interaction

The Participant Divide: Regulars and Non-Regulars

This research discovered a distinct divide between two groups of individuals: the Regulars and the Non-Regulars. The question of "regulars" really relies on the notion that there exist those who frequent and feel attachment and affection for this "place" — enough to participate in the discussion, enough to be present more than a few times, enough to move from a new member to a prodigal member to a fully engaged member (Oldenburg, 1997).

A small portion of the posting community was responsible for a large portion of the actual posts analyzed. This aspect is a reinforcement of Selwyn's findings (2000). The selected group (a group of 30) became the identified "regulars." These regulars (as coded by the schema "Regular_(number)") acted as experts, asked questions of one another, enjoyed each other's company during reflections, during hard times and stressful situations, and through silly and nearly meaningless conversations. These regulars embraced new and relatively unknown members graciously.

While this might seem to be an obvious conclusion, the questions surrounding this could multiply. Before we assume many conclusions, we must be skeptical and honest about this particular study. The very restrictive nature of this study – in initial and natural structure and the specific employment of methodological approaches in research design and execution, limits our generalization of findings. This study has identified that there is clearly a separation between regular and non-regular, but it cannot be so easily relied upon quantifiably as reported. Keeping this limitation in mind, we can draw some tentative conclusions – to be explored in other studies employing other approaches.

Posting rates overall proved high in this group of regulars – both in the posts in the analyzed documents and in the overall posting rates in each of the regulars' board histories. Additionally, two of the essential components of becoming a regular are to establish trust and to act decent. These 30 live up to this set of standards (Oldenburg, 1997).

The challenge in this question is that 30 users became regulars in this virtual space. Two hundred eighty one did not. The specific numbers can be held in suspect but the actual comparison should be accepted. The types of discussions in which these two groups participated are illustrative of the needs being met for each. The regulars participated heavily in light discussions while the non-regulars did not and chose rather to participate in those discussions that proved serious and focused often on professional questions and issues. This is further elaborated upon in other questions below.

Further reflections should be made, referring back to Soukup's criticisms, of whether the actual nature of these interactions (among Regulars) can be considered along line with off-line interactions. Would the nature of the actual discussion forum actually impact the results of these interactions? In addition, would these take place in MOOs, MUDs, MMPORGs, etc as noted by Soukup? What role does the nature of this forum (asynchronous, textual posting) play in the development of these interactions between Regulars? In short, would these Regulars still be the same type of "Regular" we see here and how would the environment impact that? This impact could only be gauged by revisiting this study in other technological settings (in Second Life for example).

Another note to make here is the further unknown group that participates in this forum to some extent: that of the lurker. This individual explores content – presumably personal and professional – potentially to answer not only questions (like in the case of licensure questions, issues on behavior management or on the organization of instruction) but also to merely enjoy the conversations (in a potentially a voyeuristic way) of the participants. Can this group – the great unknown – be considered part of the "community?" Is their undefined benefit making them any less as compared to their Regular comrades? Do they feel that they are part? Moreover, potentially, could we even say that some Regulars actually could function in this role

Regulars and the Role of Expert: Professional Assistance

Social status as a component of Tonnies' Gemeinschaft (Marshall, 1998) plays a large role in this discussion. The complexities have yet to be revealed, but the different approaches are clearly discernable. Users enjoy visual and textual notations of status in the community (based on chosen identities, expressions of professional affiliation, and posting counts). Further, some of the regulars (and even some of the non-regulars) gain notoriety in their various roles – such as a math expert, an expert on certification issues, etc. This is status and this provides identity in a world where identity is often masked.

With a large number of participants (generally speaking in terms of the life-time of the forum) never exiting "new member" status, the question arises again – what pushes one user to leave the group of thousands of nearly unknown users with monikers to users with reputations in a group of elite posters? And what pushes the lurker to a new member status?

Tonnies' Gemeinschaft (Marshall, 1998) again provides direction useful in this analysis. This group of users and this virtual space provide opportunity for users of like interests, backgrounds, or identities to congregate and share. This is the nature and often the primary purpose of online discussion forums – and this forum proves to be no different.

The affiliations of a professional nature clearly point to like mindedness in interests. The elementary contingent (self-identified in profile creation in the forum) is notable among the groups with others trailing close behind. Further, the structure of the forums themselves attracts members to specific areas for specific query types (or general discussion types). With discussions ranging from similar interests in math, music, and fashion trends to similar jobs, teaching practices, and geographic locations to level in pursuing certification, and stage in applying for a teaching job, the level of homogeneity is clear. The data confirms that the users share similar interests and congregate according to these. The similar backgrounds are often identifiable through profiles.

What would prove interesting is an exploration of the level of connected-ness (to place or to one another) experienced by these various types of homogeneity. Our understanding of community in general dictates assumptions of homogeneity. How these homogenous identities play in virtual worlds may change that further. The simple existence of these types of relationships was observed in this context.

Further in this context of professional identity enters the concept of idea exchange. The exchange of ideas (and its presence in a community) deals directly with the concept of Social Capital (Coleman, 1988). The users primarily use this forum for exchanging ideas – ideas for classroom management, ideas for projects, lessons and activities, ideas for gaining employment, ideas for studying for exams, or ideas for a nonsensical game or notion. These are all exchanges that others benefit from in one way or another.

The presence of some experts, the regulars self-identifying in these roles, provides a basis for providing the exchange of ideas. The notion that the receiver then becomes the giver is not easily discernable in this data, as the scope of analysis is limited to a specific set of discussions and time frame for many of the discussions. The four primary types of exchanges noted in the analysis include teacher practice assistance, teacher application assistance, personal advice, and teacher certification assistance. The obvious exchange for benefit exists in this environment. The true nature of the exchanges and their adherence to the understanding of social capital needs more study.

Regulars and the Online Playground: Social Interaction

While Oldenburg's Third Place has no place for "serious conversation" (Oldenburg, 1997), the online teacher community embraces such conversation. Many of the discussions center on serious questions of a personal, professional, or even pedagogical nature. This does not mean that the playful discussions do not exist; they are merely relegated to their own home in a forum entitled the Teacher TimeOut Sub-Forum.

This area is set aside for the casual discussions of light-hearted remembrances of years past, word and get-to-know-you games escapist in nature, and general social discussions that enter the realm of laughter as participants play games of who would be kicked out if this were a reality television show. The playfulness of discussions is present, just often contained in where it is meant to be. This is an interesting natural separation – and almost naturally occurring phenomena in online discussions. This discussion forum takes time to be sure that participants know what can be posted where. Some of these understandings are explicit and some are implicit. This actually can be likened to Social Learning Theory and in the Community of Practice construct as those participating – and the more they participate – develop and build understandings of where it is appropriate to discuss X and where it not appropriate to do Y.

Oldenburg's Third Place (1997) experienced a feeling of a "home away from home" – espousing the gift of regeneration, at-easeness, and hints of possessiveness from its occupants. One of the most important roles this forum plays is that of a means for teachers to come together to regenerate. Many of the teachers (or educationally-minded participants) seek others to share frustrations and joy, but also to escape (as discussed above) and to recuperate. Discussions seeking a result of regeneration included personal issues, disappointment with students, and frustrations with parents and the profession in general. Participants note that they cannot find the answers and comfort in their workplaces that they can find in the virtual space of this forum.

These participants are at ease possibly simply because they remain anonymous. However, to be sure, these regulars also know one another and must take comfort in identity and status on the forum. These participants joined as members of this board, and they return as they find the answers they need or meet the needs they have. This is their forum and they found it.

The regulars (the 30 heavy posters) comprise a group who fit into Tonnies' Gemeinschaft (Marshall, 1998) — one where they feel an attachment to this virtual space. They have developed an identity here (and it is interesting to note that this identity is in terms of actually who they present themselves to be and how they see themselves apart from presentation in the context of the virtual space). These 30 posters return (many daily) to the forum to gain the answers they seek or the comfort they need (or maybe just because it is fun). The unrepresented group here is the vast number of people that register and post a few times or less and never return. The attachment does not appear to exist for them. They gain the answer they need and move on, possibly to never return. The difference between these two types of users proves to be the interesting question that needs to be explored.

Regardless, the regulars – the ones who return to this home away from home – possess this virtual space as theirs. What has not been clearly examined in the nature of membership in this group in the context of personal identity. This can only be determined by getting behind the screen instead of interpreting discussions. There would need to be more examination of the nature of this community formed as an exclusive community of an inclusive one.

This notion of identification and attachment with place is more definitively identified as such as compared to Selwyn's work (2000) that found little evidence of attachment to place. The difference between these two studies appears to be in motivation. In Selwyn's examination, the users were provided space with a very specific set of content to be explored and shared (very professional in nature and following a mind-set of a community of practice – sharing practice, etc) whereas this community studied is completely naturally forming and the ideas and topics have developed form the users participating. More work is needed here.

The non-regulars, the vast majority of the users in the study, obviously do not attach in the same way as the regulars identified. This is a crucial finding – these regulars have entered a different phase of interaction in this virtual environment.

In conclusion, how does this analysis answer the research question posed:

The research, undertaken as part of this project, works to answer the question of whether online communities created and maintained among professional educators constitute a community, as we understand them in the context of off-line communities.

Using the benchmarks as formed from the literature reviewed for this project, the analysis points to a complex answer. While this community of users strongly feels an attachment to place, self-regulates through informal contracts, exchanges ideas for the benefit of the individual, are homogenous in interest, have the opportunity to express social status in the context of the environment, play (at times), converse and escape the realities of the world in a neutral environment; they do this if they have moved to a status of regular (or near-regular). The challenge is in the statistic: 83% of all of the forum users have posted less than five times. This is sobering statistics that demonstrates a large number of users exist who definitively do not feel a connection in this environment. Is this environment a community for virtual members? Yes – but only for some.

The basic construction of online discussion forums for professional educators contain two primary targets of content – the discussions centered on issues of a professional nature and those discussions centered on a personal/ social nature. While the discussions themselves are organized as such, the people participating in these and moving from one to the other behave and interact in different ways according to the discussion content.

In those discussions centered on content of a professional nature – those that focus on certification issues and questions, on job applications and hiring questions and advice, on level-specific teaching methods and approaches, and on general pedagogical and professional issues – the participants contributed in very professional ways. The process here involved the query/ problem stated, the contributions of those in positions of authority on the subject (or even those that empathized) and a synthesis (or confluence of ideas) to form a best approach for the participant/initial poster. Many of these discussions proved shorter in nature, very focused, and many of those who were frequent posters acted as the subject matter experts.

In contrast, those discussions focused on more social interactions – those that focused on game-like discussions, on personal issues and celebrations, on funny stories, on past reflections, and on home life and its trials and fun – proved more interactive (as to the types of interactions), more long-lasting, containing higher levels of participation, and the presence of those that are more participatory in the forums as a whole.

These two types of interactions constitute the gamut of types of discussions on these boards. The question remains: Do these types of discussions (the process, the content, and the outcomes) effectively create environments of community for those who participate?

FUTURE RESEARCH DIRECTIONS

This study (as Selwyn's before) serves well as a frame of reference for other studies on the efficacy of community for professional educators. Selwyn's work relied heavily on government-created communities whereas this study worked with communities that arose naturally among the participants (at least one).

Further studies should examine the actual nature of these "regulars" and why they moved from the new status to member (and beyond). What is the mysterious factor that pushed the social experience from casual participant/ lurker to "regular?" Additional research into the motivations and needs of these users would prove useful in understanding the potential use of online environments for teacher interaction and community-building. Working on illuminating more details on who these participants really are and what skills they have acquired and what lives they lead would greatly expand the understanding of this mysterious factor. Specifically, more should be done on following users – if possible – through these phases of online existence. In addition, work and examination in areas of professional identification and personal and social identification as juxtaposed with this notion of "regular user" should be worked into future research in this area.

This study sought to understand informal social exchanges, but in the process found the professional development potential for such online environments (pedagogically and subject-specific). This area could be further explored as its potential for addressing the time issue and the definitive need for professional development for today's educators is undeniable. Important here is the understanding of potential policy implications – can we develop effective online professional development modules AND online avenues for professional communities (as envisioned in the Selwyn study). If so, do our notion of Regular user and our eventual understanding of the nature of the Regular user's evolution as an online persona have an impact in this venture design and implementation?

In addition, how does the impact of these lurkers – the silent observers – change the way this community should be considered? Do we then conceptualize the nature of community based on what is present (surface-level) and what is potentially possible based von assumed lurkers? Does the presumptive presence of these lurkers have implicit impacts on the types of participation or the level of personal (or professional) interactions in these environments? In addition, of course, does the actual venue of the technology have an impact here?

Other questions arise concerning the true nature of the exchange of social capital among these educators online and if the differences exist between non-regulars and regulars. Additional research in the nature of the discussions – i.e., more of a topical analysis going much further than the scope of this paper – would also bring to light an understanding of these communities.

Much works needs to be done here. This study has pointed to an unknown gap between those who participate and those who do not. This phenomenon could result in real impact on how we design and develop online communities (or online spaces for interaction) for professional educators.

CONCLUSION

This chapter, at its core, examined the development of understanding of virtual communities (based on understandings of off-line communities), established benchmarks for analysis, examined an existing community for adherence to benchmarks, and used conclusive results to further the discussion of the reality of, the importance of, and the benefits of virtual communities in the professional educational sector. This has been an untouched area heretofore and is ripe for the examination.

Upon analysis of the gathered conversational data, this study initially concludes that a select few individuals self-identifying as professional educators form communities of users in online environments much in the same fashion as off-line communities. This conclusion is based on the existence of a body of individuals (identified as "regulars" and numbering 30) who exemplify the general nature of the sought-after characteristics of informal, social off-line communities.

The limitations of this research and the restrictions on collection and data types make this a tentative conclusion that needs further solidification through other modes of data analysis. This formulation of a community appears to be anomalous as compared to the entire body of potential and registered users. Admittedly, an unknown lingers in this discussion that bears heavy weight upon the conclusions – the 30 identified regulars represent a larger body of individuals and that number is not known. The individual purposes and the self-established meanings and significances of these individuals' participation in this community was not established in this study, but would be an obvious next step for understanding the nature of the transformation persons experience in moving from casual disconnected participant to fully participating and involved member of an online community.

KEY TERMS AND DEFINITIONS

CMC*:* Computer-Mediated Communication

*Third Place***:** The informal aspect of community, as identified Ray Oldenburg, not related to concepts of Home and Work (the first two places)

Newsgroup*:* A communication venue found in CMC where users can post messages related to actual news and general information of interest.

Regulars*:* In the context of this study, the users who posted most frequently, numbering about 10% of the total analyzed posters

Non-regulars*:* In the context of this study, these are the other 90% of users who posted in this forum who did not post frequently

Chapter 5.17
Trust Modeling in a Virtual Organization Using Social Network Metrics

Grzegorz Kołaczek
Wrocław University of Technology, Poland

ABSTRACT

One of the most important factors in human interaction and communication is trust. Each organization performing its quotidian tasks use intentionally or involuntary established trust relations to estimate the probability of achieving the expected results or the level of confidentiality. As in societies that evolved from real world relationship (e.g. school, office, sport activity, etc.) also in virtual communities (e.g. chat rooms, Web boards, mailing lists, etc.) trust is one of the most fundamental type of binding among the group members. In this article the trust relation establishment and evolution in virtual communities has been investigated. The presented model uses some typical parameters like node degree and centrality coefficient related to social network description and analysis. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

Trust and reputation of subjects has been typically assessed as a function of the quality of their response to requests coming from other members in the community. This approach is used in some organizational learning systems as, for example, *Answer Garden* (Golbeck,2005) or knowledge communities (Golbeck& Hendler, 2005; Schillo, 1999). Discussion about the different ratings that can be obtained by analyzing response quality is to be found for example in (Grzonkowski, 2005). These systems rely on ratings provided as a feedback from the subject receiving the response to a previous demand. Subsequently these ratings are combined and finally each subject calculates its own trust value. Trust and reputation measure gives an idea of the confidence one can have on the quality of a subject's responses. The disadvantage of this type of mechanism is that it needs the explicit and frequent involvement of users that issue ratings. This implies that a good reputation calculation and maintenance depends on the involvement of users and continued contribution of ratings. Less intrusive and less demanding in terms of users involvement methods are more interesting. The problem is how reputation and trust level can be measured in the absence of any user feedback for subject's responses.

The main idea presented in this work is that some information about the dynamics and formation of the virtual community network can be used to evaluate the trust and reputation values. The Internet, the electrical power grid, the transportation network as well as the social networks can be viewed and analysed as the examples of complex networks. Two important properties displayed by many of these networks are the small world and scale-free properties (Ehrlich, 2006). Small-world networks can be characterized by the clustering coefficient and the average network distance. The clustering coefficient is the probability that any two nodes are connected to each other, given that they are both connected to a common node. The average network distance measures the average minimal number of links connecting any two nodes in the network. Many regular networks have high clustering coefficients and large network distances. Random networks, on the other hand, have small network distances and low clustering coefficients (Watts, 1999). Small-world networks fall somewhere in between these two extremes as they have large clustering coefficients and small average network distances (Garton 1997). The scale-free property is defined by an algebraic behaviour in the probability distribution $P(k)$ of the number k of links at a node. When we consider virtual community all these parameters describing small-world or scale-free networks can be used to analyze the position and relations among community members.

In the article a novel concept of a trust modelling and management that addresses above mentioned problems by using the some universal measures for complex networks is presented.

In the next section the main ideas dealing with how trust can be modeled within online communities have been presented. Next, some background describing social networks analysis has been described. After that, methods for constructing community-aware trust levels assessment that enables automation of the trust level calculation process and to establish trust relations between users of a social network. This methods use a novel trust model that takes advantage of complex networks. Finally, in the last section a discussion about the presented model and directions of future work has been presented.

TRUST MODELS

Trust is a very important aspect of our life because trust is the fundamental for all bilateral and multilateral activities in human society, especially when results of our own actions are highly dependent on the actions of others. The most frequently quoted definition of the trust seems to stress the following aspect related to this notion (Gambetta, 1990; Marsh, 1994):

- Trust is subjective. Trust is the social knowledge that is derived from personal observation and serves for future personal decision-making.
- Trust is affected by some actions that cannot be monitored
- Trust is context dependant. Trust can have different meaning dependently from the context. For example, one can trust TV news when it has been prepared by X but not when it has been prepared by Y.
- Trust level strictly depends on how our actions are affected by the others.
- Trust is directed.Trust relation is always composed by two entities: trustor and trustee, so

the relation is asymmetric. A trust B does not implies that B trust A.

- Trust is measurable belief. Trust is usually associated with a value that represents the strength or degree of trust. A can trust B more than it trust C.
- Trust is conditionally transitive. When we consider trust as the recommendation factor it is partially transitive.
- Trust has a temporal dimension. Trust is derived from the past observations and trust values evolve with a new observations and experience. The behavior of B may force the A to recalculate its trust
- Trust between collectives does not distribute automatically to trust between their members. If a state A trust the state B it does not imply that all state members trust state B.

The other important idea related to trust is reputation. The most typical real life context of reputation application is when someone need to work with a new, unknown person. Then, the typical practice is to ask people with whom one already has relationship for the information about such person. Based on the obtained information one can form an opinion about the reputation of the new person. Further, a positive reputation leads to confidence or trust in the person while negative reputations to the other leads to lower confidence or social status. It is worthy to mention, that the reputation propagation in real life societies works well and it is true even in cases of large societies. The mainspring of this is related to the structure of societies where members tend to be highly interconnected and the topological distance between society members is small. This propriety is know as the Small World effect and it has been proved to be true for a many different real and virtual communities.

Trust is also very important feature of security engineering. In this context it is related to risk management, surveillance, auditing and communication. Extensive knowledge on security engineering has already been collected and analyzed by Taipale (Yen, 2005) and has been studied in the Trusted Systems (Shoillo, 1999) project, which is a part of Global Information Society Project (Shoillo, 1999) lead by the World Policy Institute (Marsh 1994). It investigates systems in which some conditional prediction about the behavior of people or objects within a system that has been determined prior to authorizing access to system resources.

Another research area related to this topic is the concept of "Web of trust" systems. This concept emerged in applications related to cryptography and is an element of such technologies like PGP, OpenPGP-compatible (PGP) or public key infrastructure (PKI). They have been defined to support the trust endorsement of the PKI generated certificate authority (CA)-signed certificates.

Finally, the most popular research area in the context of trust is called a trust metric. The aim of it is to propose a measure of how a member of a group is trusted by other members. An exemplary overview of such metrics has been prepared on the Internet community at (TrustMetrics Wiki) and it presents a brief classification and provides many examples.

There are many different metrics that are diverse in many aspects. For example TrustMail (Golbeck,2003) or FilmTrust (Golbeck 2006) propose to take advantage of a Semantic Web-based social network. Other different approaches are based on graph walking or use subjective logic to express trust level (Josang, 1999). In the PeerTrust Project (PeerTrust) a decentralised Peer-to-Peer electronic community has been considered and a proposed trust model considers only three factors: the amount of satisfaction established during peer interaction, the number of iterations between peers and a balance factor for trust. At the other hand, the EigenTrust (Kamvar 2003) algorithm has similar ideas to PageRank (Page1999) but has been used in the context of file-sharing systems. This method computes global trust for peers, where the value is based on the history of uploads. It is dedicated to support the system to choose the peers with a history of reliable downloads and to exclude the malicious peers from the network.

Although much of the previous related work presented in this article is related to trust metrics, the proposed approach differs from this work with regard to several aspects. The described in this article trust model for virtual communities takes advantage of the capabilities of the social network analysis.

SOCIAL NETWORK METRICS

The basic idea of a social network is very simple. It could be understood as a social structure made of actors which can be represented as network nodes (which are generally individuals or organizations) that are tied by one or more specific types of interdependency, such as values, visions, idea, financial exchange, friends, kinship, dislike, conflict, trade, Web links, etc. The resulting structures are often very complex (Jin, 2004). Social relationships in terms of nodes and ties among them could be used in various types of analysis. A number of academic researches have shown that dependences form social fields play a critical role also in many other fields and could be used in determining the way problems could be solved.

Better understanding of social networks requires a complete and rigorous description of a pattern of social relationships as a necessary starting point for analysis. The most convenient situation is when we have complete knowledge about all of the relationships between each pair of actors in the population. To manage all pieces of information related to social network the mathematical and graphical techniques have been used. This formal apparatus allows us to represent the description of networks compactly and systematically. In this context, social network analysts use two kinds of tools from mathematics to represent information about patterns of ties among social actors: graphs and matrices.

Network analysis uses one kind of graphic display that consists of nodes to represent community members and edges to represent ties or relations. There are two general types of situation when there are a single type of relations among the community members and more than one kind of relation. The first one can be represented by simplex graph while in the second case we use multiplex graphs. Additionally, each social tie or relation represented by graph may be directed or undirected (tie that represents cooccurrence, co-presence, or a bonded-tie between the pair of community members). Another important feature related to the social networks and their graph representation is the strength of ties among community members. In a graph it may be one of the following types: nominal or binary (represents presence or absence of a tie); signed (represents a negative tie, a positive tie, or no tie); ordinal (represents whether the tie is the strongest, next strongest, etc.); or valued (measured on an interval or ratio level).

Other basic network proprieties that can be formally described and so can constitute a good background for analysis of community dynamics and also trust modelling are as follows (Hanneman 2005):

- Connections
  - the number of immediate connections may be critical in explaining how community members view the world, and how the world views them, so it could be also important factor while modeling trust relations within community
  - the number and kinds of ties are a basis for similarity or dissimilarity to other community members
  - the direction of connections may be helpful to describe the role of the community member in the society, it can be “a source” of ties , “a sink”, or both.
- Size

    - the size of a network is indexed simply by counting the number of nodes,
    - critical element for the structure of social relations because of the limited resources and capacities that each community member has for building and maintaining ties
    - in a bigger groups more likely it is that differentiated and partitioned subgroups will emerge
    - the size of a network also influences trust relations while in bigger group it is easier to preserve anonymity and its more difficult to evaluate trust values
- Density
    - the proportion of all ties that could be present to that actually are
    - the number of logically possible relationships then grows exponentially as the number of actors increases linearly
    - in communities with greater value of density parameter it should be easier to maintain trust relations as we get more information about the other community members
- Degree
    - it tells us how many connections a community member has
    - *out-degree* - the sum of the connections from the community member to others
    - *in-degree* - the sum of the connections to the particular community member from others
    - community members that receive information from many sources may also be more powerful
    - community members that receive a lot of information could also suffer from "information overload" or "noise and interference" due to contradictory messages from different sources
    - impact for the trust relation is similar to that described in a case of density, dependently from in/out-degree when an individual has more or less information about its neighborhood
- Reachability
    - a community member is "reachable" by another if there exists any set of connections by which we can find link from the source to the target entity, regardless of how many others fall between them
    - if some community members in a network cannot reach others, there is the potential of a division of the network
    - disconnected community members could have more problems to evaluate trust value
- Transitivity
    - the transitivity principle holds that, if A is tied to B, and B is tied to C, then A should be tied to C.
    - the triadic relationships (where there are ties among the actors) should tend toward transitivity as an equilibrium condition
    - the trust relation is not strictly transitive and so this propriety not necessarily influences trust evaluation process
- Distance
    - an aspect of how individuals are embedded in networks,
    - two actors are adjacent when the distance between them is one
    - how many community members are at various distances from each other can be important for understanding the differences among community members in the constraints and opportunities they have as a result of their network location
    - community members located more far apart from each other in the community have more problems with trust evaluation than the members which are close
- Geodesic distance
    - geodesic distance is defined as the number of relations in the shortest possible walk from one community member to another

- many algorithms in network analysis assume that community members will use the geodesic path when communicating with each other
- it could be useful to find the exact trust value between two community members
- Diameter
  - the *diameter of a network* is the largest geodesic distance in the connected network
  - tells us how "big" the community is, in one sense quantity in that it can be used to set an upper bound on the lengths of connections that we study
  - the diameter value could be an important coefficient while calculating trust value
- Cohesion
  - the strength of all links as defining the connection
  - count the total connections between actors
  - more strong connection between community members should determine grater trust values
  - Centrality, Power, Betweenness
  - centrality, closeness, betweenness describe the locations of individuals in terms of how close they are to the "center" of the action in a network – though there are a few different definition of what it means to be at the center
  - the more important community member is, the more important its opinions should be, it should be also reflected while establishing new trust relations
- Eigenvector of the geodesic distances
  - an effort to find the most central community members in terms of the "global" or "overall" structure of the network, and to pay less attention to patterns that are more "local"
- Cliques
  - a sub-set of community members who are more closely tied to each other than they are to community members who are not part of the group.
  - idea of cliques within a network is a powerful tool for understanding social structure and the embeddedness of individuals
  - cliques reflects the groups of community members with strong relationship so in natural way it also influences trust relations between them

As it was depicted here above most of the typical parameters used in social networks description has more or less strict relation with trust modelling problem. The basic assumption of this work trust model is also that some of these typical for social networks parameters can be used to model some aspects of the trust.

Figure 1. Simple communication network in virtual community

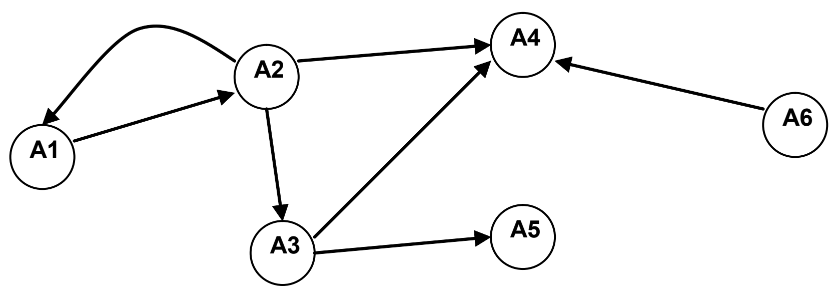

Figure 2. Example of the communication vectors for the network form Figure 1

	A1	A2	A3	A4	A5	A6
A1	-	5	?	?	?	?
A2	4	-	10	24	0	0
A3	?	0	-	?	?	?
A4	?	0	?	-	?	?
A5	?	0	?	?	-	?
A6	?	0	?	?	?	-

The numerical value of clustering coefficient can be calculated using for example following formula:

$$C_i = \frac{\left|\left\{e_{jk}\right\}\right|}{k_i\left(k_i - 1\right)} : v_i, v_k \in N_i, e_{jk} \in E$$

where:

- v_i – nodes,
- N_i – neighborhood of the node v_i ,
- e_{jk} – link between v_i and v_k,
- k_i – degree of the node v_i

SOCIAL NETWORK–BASED TRUST MODEL

In this section the framework of the novel trust model will be presented. The basic assumptions of it explain how trust and reputation have been defined in the model and how they can be used by the members of virtual community during their operations.

The general assumption for the model is that the trust value assigned is bilateral relation (A_x, A_y) between community members X and Y and its value is evaluated using three following components:

- *S* – subjective belief
- *C* – context related value
- *O* – other community members opinions

Where: *S, C, O* $\in$ <0,1> and

- $T(A_x, A_y)$ – trust level value between X and Y
- $T(A_x, A_y) = S+C+O \in$ <0,1>

Trust is explained in terms of a relationship between virtual community members. There are trustor and trustee. Where trustor is that community member who holds a belief for trust in another community member, and trustee is the trusted community member.

The model distinguishes two levels of trust modelling:

- Level 1: the trust is evaluated locally, using only knowledge of a single community member
- Level 2: the trust is evaluated using global knowledge about all community members activities

Trust model at Level 1 uses communication vectors to evaluate the context related component of trust. These vectors are a direct source of knowledge about the character of community member communication.

It should include such information like:

- a source and a destination of the communication – it is equivalent to the information about *out-degree* and *in-degree* parameter
- type of the communication (e.g. http, ftp, ping, …)
- intensity of the communication

The values from the table presented in the Figure 2. can be interpreted e.g. as the number of kilobytes of data transferred during last period t_i from the community member A2 to other entities.

Correspondent tables can be created in the context of e.g. number of ftp sessions, number of packet send between community members.

Level_1 Trust evaluation algorithm

Given:	Identifier of the trustee (A_x) and trustor (A_y), Communication vector for a trustor, V={v_1, v_2,… v_k,} Opinions about trustee obtained from other community members (T(A_x,A_1), T(A_x,A_2), … T(A_x,A_n)). Where opinions may be trust relation values send to the trustor by other community members.
Result:	T(A_x,A_y) – trust value of relation between trustee (A_x) and trustor (A_y).

The following algorithm for trust evaluation at the Level 1 has been proposed.

BEGIN:

1. Assign the subjective belief value to the parameter *S*
2. Calculate *T'* value in the following way: *T'* = 1 – *S*
3. Assign a value to the context related component *C*

$$C = \frac{v_y * T'}{\sum_{\forall i} v_i}$$

4. Calculate *T''* value in the following way: *T''*=1-*S*-*C*
5. Evaluate *O* opinion component value

$$O = \frac{\sum_{i=1}^{n} T(A_i, A_y) * T(A_x, A_i)}{n} * T''$$

6. Return final trust value for trustee A_x and trustor A_y (see Box 1).

END

Trust model at Level 2 uses some external knowledge from a point of view of a particular community member. It is assumed that there is an entity that monitor all communication within the virtual community. Let it call Social Network Monitor (SoNeMo). In relation to its observations SoNeMo can pass information about values of some global parameters describing virtual community. For example SoNeMo can calculate a centrality coefficient, eigenvector of the geodesic distances or other social network related parameter. SoNeMo has a similar role in the proposed trust model as Certification Authority in the Public Key Infrastructure has got.

Because, as it was mentioned earlier, the centrality parameter reflects the importance of the community member within its local society, centrality was selected as the main factor for context related trust component. The more important community member is, the more important its opinions should be and this will be also reflected while establishing new trust relations.

The level 2 trust model uses the communication matrixes to evaluate the context related component of trust. These matrixes are a direct source of knowledge about the character of communication of all community members.

The following algorithm for trust evaluation at the Level 2 has been proposed in Box 2.

BEGIN:

1. Assign the subjective belief value to the parameter *S*
2. Calculate *T'* value in the following way: *T'* = 1 – *S*
3. Assign a value to the context related component *C*
4. Calculate *T''* value in the following way: *T''*=1-*S*-*C*
5. Evaluate *O* – opinion component value

$$O = \frac{\sum_{i=1}^{n} T(A_i, A_y) * T(A_x, A_i)}{n} * T''$$

6. Return final trust value for trustee A_x and trustor A_y

Box 1.

$$T(A_x, A_y) = S + C + O = S + \frac{v_i * T'}{\sum_{\forall i} v_i} + \frac{\sum_{i=n}^{n} T(A_i, A_y) * T(A_x, A_i)}{n} * T''$$

Level_2 trust evaluation algorithm

Given:	Identifier of the trustee (A_x) and trustor (A_y), Normalized centrality value of the trustee I_x Opinions about trustee obtained from the other community members ($T(A_x,A_1)$, $T(A_x,A_2)$, … $T(A_x,A_n)$). Where opinions may be trust relation values send to the trustor by other community members.
Result:	$T(A_x,A_y)$ – trust value of relation between trustee (A_x) and trustor (A_y).

Box 2.

$$T(A_x, A_y) = S + C + O = S + I_x * T' + \frac{\sum_{i=n}^{n} T(A_i, A_y) * T(A_x, A_i)}{n} * T''$$

Figure 3. Example of the communication matrix for the network form figure 1

	A1	A2	A3	A4	A5	A6

A6	0	0	0	34	0	-

END

CONCLUSION

The proposition of the trust modeling in virtual communities using social network analysis method has been described and discussed in this work. Integral element of cooperation within any kind of community is trust, so there is a special need for some adequate tools and models for trust management in virtual communities. Cooperation within virtual communities is very often characterized by the lack of earlier experience in a context of real world interactions. This is why it is so important to support virtual communities members with another kind of premises to build and manage trust. The several trust modeling concepts was presented. Also the basic related to social network analysis parameters were described with a special stress put on their usefulness while considering trust modeling.

An interesting possibility for future analysis will be addressing relationship between Level 1 and Level 2 trust models. Another important area of research is the comparison of impact of different social network measures on trust modeling. The comprehensive studies including experiments of trust evolution and propagation are intended as the continuation of the theoretical work described in this article.

Chapter 5.18
Trust in Social Networking
Definitions from a Global, Cultural Viewpoint

Max Kennedy
University of Kentucky, USA

Toru Sakaguchi
Northern Kentucky University, USA

ABSTRACT

This chapter attempts to understand the trust in social network services, where users post their personal information online to everyone with or without any specific relationships. Many definitions of trust were examined through a literature review in electronic commerce and virtual community areas, and it was found that most of them were based on a specific relationship, such as a buyer-seller relationship. However, one concept of trust—generalized trust, also known as dispositional trust—was found to best fit the situation of social networking. Generalized trust in social networking is further discussed from a cultural viewpoint. As an example, a Japanese SNS, Mixi, was analyzed in detail. Future research direction on trust in social networking is discussed as well.

DOI: 10.4018/978-1-60566-104-9.ch012

INTRODUCTION

Trust has been conceptualized by previous research in a variety of ways ... and researchers have long acknowledged the confusion in the field. (Gefen, Karahanna, & Straub, 2003, p. 55)

There have been many studies done on the issues surrounding trust online. In a global environment, much of the recent research concerning trust has dealt with e-commerce and collaboration efforts occurring over the Internet (e.g., Ba & Pavlou, 2002; Dellarocas, 2003; Gefen et al., 2003; Backhouse, Hsu, Tseng, & Baptista, 2005; Salam, Iyer, Palvia, & Singh, 2005; Chow & O, 2006). These studies tend to define trust in the context of reliability and the predictability of the business or person to perform as expected (Gefen et al., 2003). In these definitions, the object of trust is an interpersonal relationship with either a specific person or a specific business.

Social networking refers to a category of online applications, also known as social network services (SNSs), that help connect friends, business partners, or other individuals together (Alabaster, 2006). With the relatively recent rise in popularity of social network services, such as MySpace, which currently has over 100 million accounts, users of social networking are giving out personal information to the public at large with little, if any, expectation of the future performance or predictability of another person or business. Although users seem to trust something, the definitions of trust mentioned above do not seem to be applicable to SNSs.

This study will examine trust literature for the different types of trust mentioned and see whether the current studies are applicable for studying trust in social networking. Additionally, since what seems to be being trusted by someone who posts their own personal information online to a SNS is the public at large, this study will examine if there are some differences between cultures on how much and what type of information a person is willing to share in this type of situation.

This study is important because there is not enough research involving trust in social networking or research that takes into account cultural differences in social networking. With the rapid rise of SNSs, trust is of interest to: 1) users of such applications because they may want to know more about the issues of information disclosure to the public; 2) marketers who are preparing to mine SNSs for data, because they may want to know about cultural differences in the type and quality of the data they mine; 3) academic researchers examining SNSs, because they may need a new perspective of trust.

BACKGROUND

Social Network Services

The term "social network" originates from Barnes' work in the 1950s in Sociology, and originally referred to an informal system of personal contacts that cut across organizational boundaries (Barnes, 1987). In recent times, the term is being used to refer to online applications that connect individuals with family members and friends. Using blogs, chat rooms, e-mail, or instant messaging, users of social network services (SNSs) can communicate, either within a limited community, or with the world at large (Alabaster, 2006). One of the most popular SNSs today, MySpace, had 2.4 million members in November 2004 and 26.7 million a year later (Kornblum, 2006). One and a half more years, as of May 2007, when this chapter was written, the number is 192 million (Wikipedia, 2007). This popularity, especially among teenagers, is also drawing the attention of parents and schools who are concerned about the nature of some of the pages on the site and the safety of young users who give too much information about themselves (Kornblum, 2006). MySpace prohibits users under 14, but kids sometimes lie about their ages. Still, they have probably learned a long list of important safety and privacy lessons already: buckle up; do not talk to strangers; hide your diary where your nosy brother cannot find it, and so forth, yet they have not probably learned another lesson: Do not post information about yourself online that you do not want the whole world to know (FTC, 2006).

There are certain degrees of trust involved in giving out information to the public, but as a review of the literature will show later in this study, the trust when applied to social networking is seemingly different from those types of trusts used for e-commerce and other traditional collaboration activities online. Like e-commerce sites, SNSs are a new phenomenon with limited bandwidth available for knowing or learning to trust the other party. However, unlike e-commerce sites, users of SNSs do not give out information to any specific entity, nor expect any future performance or predictability from a specific party in return. Since the core of SNSs is the fact that the contents of the sites are generated by the users, everybody in the network can view the user-generated contents; the user-generated content is the basis for the success of the sites like Wikipedia or YouTube (Brown, 2006). Therefore, it can be said that SNSs are broadcast networks broadcasting the information to the "perceived" members of the network, but unlike the broadcast medium of old, everyone can be broadcasters of the information and unlike Web pages of old, all the broadcasters are "perceivably" linked together in a network of users. Problems occur when those perceived network of close friends include agents who have less-than-friendly intentions (FTC, 2006). Knowing such, why do users of SNSs trust other users and broadcast their personal information?

Trust Online

Trust has been studied as a central aspect of e-commerce and other transactions online. There are many definitions of trust and expectations of trust available (Gefen et al., 2003). Gefen et al. (2003) have analyzed the various types of trust in creating their model for trust and TAM in online shopping. They consider that trust may be: at the heart of all relationships, or the defining attribute of relationships; a reducer of risk and social uncertainty; based on familiarity; raised by seals of approval and affiliations; and crucial in many economic activities that may have undesirable outcomes in which one party can take advantage of another party. They also provide a summary of the various types of trust studied dating from 1971 to 2002 in their article (Gefen et al., 2003).

There are many new studies of trust in e-commerce since their work (e.g., Gefen & Straub, 2003; Pavlou, 2003; Chow & O, 2006). The summary of these studies (in progress) are presented according to Gefen et al.'s (2003) categories in Appendix, Table 1. Besides e-shopping, other online issues related to trust have been studied including reputation and online buying on auction sites, word-of-mouth buying networks and feedback, privacy statements and expectations, certification services and many other things, tending to show a uniqueness of the online environment for such studies (Ba & Pavlou, 2002; Dellarocas, 2003; Salam, Iyer, Palvia, & Singh, 2005; Backhouse, Hsu, Tseng, & Baptista, 2005; Chow & O, 2006). The issue of limited bandwidth through which information can be known between the seller and the buyer and the newness of the phenomenon are often mentioned as the reasons for the interest in studying trust in e-commerce (Ba & Pavlou, 2002).

Paul and McDaniel (2004) consider how trust reduces complexity in a complex world and enable parties to collaborate on virtual collaboration teams. They consider trust as enabling complexity reduction, as aiding collaboration, and determining the effectiveness of relationships, reducing transaction costs, and facilitating learning and innovation. They further mention that trust is part of directing people that you do not see. These things come closer to the type of trust that is involved in posting on a SNS online, as they involve people you do not see.

The rest of their study focuses on interpersonal trust. Interpersonal trust includes: calculative trust, based on forming ideas about trust in an economic relationship; competence trust, whether the other party is capable of performing as said; relational trust, also called benevolence trust, or how much one party feels the other intends to do good regardless of economic incentive; and integrated trust, which is all of these forms of trust integrated and mixed together in various ways depending on the circumstance.

Table 1. Newer conceptualization of trust

Study	Trust Conceptualization	Trust Object	Measures
Anderson (2005)	Transactional Trust: A unilateral trust in the system governing the transaction, not the other party (bilateral trust). Similar to trusted computing initiatives.	System governing transaction	Conceptual
Caziera, Shaob, and St. Louis (2006)	Willingness to be vulnerable and characteristic-based trust	Buyer-seller relationship. E-business differentiation through trust	Adopted from Zucker et al. (1986)
Chow and O (2006)	Ability, benevolence, and integrity	Buyer-seller relationship before and after first-hand experience of e-shopping	Adopted from Jarvenpaa et al. (1998)
Everard and Galletta (2006)	How presentation flaws affect perceived site quality, trust, and intention to purchase from an online store	Buyer-seller relationship on Web site	Adopted from McKnight et al.(1998)
Flavián, Guinalíu, and Gurrea (2006)	Construct of honesty, benevolence and competence	Buyer-seller relationship on Web site	Perceived Web site honesty, benevolence and competence
Gefen and Straub (2003)	Willingness to depend Display honesty and willingly fulfill its commitments	Buyer-seller relationship in e-services	Adopted from Gefen (2000)
Gefen, Rose, Warkentin, and Pavlou (2005)	Trust in adoption of new IT system (eVoting)	Trust in seller/administrator of e-voting system, cultural diversity	Adopted from Gefen et al. (2003)
Geng, Whinston, and Zhang (2004)	The sustained competitive advantages of honest members over cheaters throughout the evolution of a community.	E-communities (trust-health in whole community)	Mathematical model: Trust is a function of punishment and time
Hung and Fox (2006)	Expectancy, belief in expectancy, and willingness to be vulnerable	Trust in transitiveness from a social network	Adopted from Mayer et al. (1995)
Ho and Weigelt (2005)	Personal relationships, embeddedness	Trust building game (trust creation between strangers—i.e., anonymous eBay relations with specific others	Adopted from Granovetter et al. (1985)
Jøsang, Keser, and Dimitrakos (2005)	"Reliability trust and decision trust"	Directional relationship between trustor and trustee in trust management	Reliability trust: Adopted from Gambetta et al. (1998; 1990); Decisiontrust: McKnight et al. (1996; 1998)
Jøsanga, Ismailb, and Boydb (2006)	"Reliability trust and decision trust"	Buyer-seller relationship and reputations online	Reliability trust: Adopted from Gambetta et al. (1998; 1990); Decision trust: McKnight et al. (1996; 1998)
Stewart (2006)	Trusting beliefs (similar to portal affiliation, with both sides of link examined)	Relationship between hyperlinks/Web sites as viewed by user (p. 3)	Adopted from McKnight et al.(1998)
Keat, and Mohan (2004)	Degree to which person perceives trust	E-commerce: perception that technology is trustworthy; and disposition to trust other party.	Conceptual model development
Kim, Xu, and Koh (2004)	Trust: other party will behave in a dependable manner	Buyer-seller relationship.	McKnight et al. (1998)

Table 1, continued.

Study	Trust Conceptualization	Trust Object	Measures
Lim, Sia, Lee, and Benbasat (2006)	Cognitive-based trust	Buyer-seller relationship online	Adopted from Mayer et al.(1995) McKnight et al.(1998) Jarvenpaa et al. (2000)
McKnight, Kacmar, and Choudhury (2004a)	Dispositional trust: tendency to believe in the positive attributes of others in general Alt: willing to depend or become vulnerable to general other people	General others (advice giving Web sites in this case) as opposed to specific others in interpersonal trust.	Operationalized as 1. Faith in humanity-general, 2. Faith in humanity-professionals, 3.Trusting stance
Mcknight, Kacmar, and Choudhury (2004b)	Dispositional trust (propensity to trust)	A specific Web business.	Adopted from McKnight et al. (2002)
McKnight and Choudhury (2006)	Trusting beliefs and trusting intention	-seller Relationship	Adopted from Mayer et al. (1995), McKnight (1998)
Metzger (2006)	Trust: the expectation that an exchange partner will not engage in opportunistic behavior	Relationships between buyer/seller.	Adopted from Jarvenpaa et al. (2000)
Mutz (2005)	Social trust: generalized trust in people	Buyer-seller economic behavior	Social trust is manipulated in experimental design and manipulation check questionnaire
Paul and McDaniel (2004)	Interpersonal trust, including: calculative trust, competence trust, relational trust, and integrated trust	Virtual collaborative relationship	Comparative case studies: Trust was operationalized as self-interest, ability, empathy, and integrated interpersonal trust
Pavlou (2003)	The belief that the other party will behave in a socially responsible manner, and, by so doing, will fulfill the trusting party's expectations without taking advantage of its vulnerabilities	Traditional (in a specific party), and in integrity of transaction medium (infrastructure)	Adopted from Jarvenpaa et al. (1999)
Pavlou, and Dimoka (2006)	Benevolence (goodwill trust) and credibility	Buyer-seller relationship in online marketplaces	Adopted from Doney et al. (1997)
Ratnasingam (2005)	Technology trust: derived from the security mechanisms and standardized routine business processes embedded in the e-commerce technologies Relationship trust: the subjective probability with which organizational members collectively assess that a particular transaction will occur according to their confident expectations	Relationships buyer-seller in e-commerce, technology trust in e-commerce	Conceptual
Ratnasingam, Gefen, and Pavlou (2005)	Institutional trust in electronic marketplaces	Trust of institution in buyer-seller relationship in online market	Situational normality, structural assurances, facilitating conditions Adopted from Pavlou et al. (2003)
Uslaner (2004)	Strategic trust: based on our experience with people doing specific things, Moralistic trust: a generalized humanity trust	Buyer-seller relationship	Conceptual

TRUST IN A VIRTUAL COMMUNITY

Another field of study, which deals with trust, is "virtual community." A virtual community is a group of people that primarily or initially communicates or interacts via the Internet. In a sense, a virtual community is a larger, generalized concept of social network services, which includes Usenet, IRC, chat rooms, and electronic mailing lists, among other things. A few recent studies

Table 2. Conceptualization of trust in virtual community

Study	Trust Conceptualization	Trust Object	Measures
Castelfranchi and Tan (2002)	Willingness to rely on the other party's internal (ability, knowledge, motivation, commitment, morality, social disposition) and external environment and circumstances	1. Environment and infrastructure 2. Agent and mediating agent 3. Potential partners 4. The authorities	Conceptual
Leismeister, Ebner, and Krcmar (2005)	Adopted from Gambetta (1990), and Abdul-Rahman et al. (2000): 1. Interpersonal trust 2. System trust 3. Dispositional trust	1. Another agent 2. System or Institution 3. General 'others'	Empirical: 1. Perceived Competence 2. Perceived Goodwill/benevolence
Mainelli (2003)	Trusting information given, trusting others to understand information provided, trusting individuals to act as expected, trusting others to make decisions on your behalf, entrusting others with your assets	"Financial" community	Conceptual
Radin (2006)	Derived from Putnam (2000), Thick trust: deep trust, including the assurance that the other side will not give away critical information Thin trust: a thinner trust in the generalized other	Thick trust: within dense networks of business associates, relatives, friends and neighbors Thin trust: Generalized other	"laboratory" case study
Ridings, Gefen, and Arinze (2002)	Derived from Gefen (2002): an implicit set of beliefs that the other party will refrain from opportunistic behavior and will not take advantage of the situation	The collective entity of others (generalize)	Adapted from Jarvenpaa et al. (1998): the scales reflect the multiple interdependencies that exist in a group
Shubert and Ginsburg (2000)	(Trust itself is not defined)	Buyer-seller relationship	Conceptual

on trust in virtual communities are summarized in Table 2 using the same format.

Some of the literature about virtual communities is still about buyer-seller relationships (Shubert & Ginsburg, 2000; Castelfranchi & Tan, 2002), since that is what businesses care about the most. "Leisure-Time Communities" like SNSs may not be as interesting yet for business researchers as "Virtual Communities of Transactions" (Shubert & Ginsburg, 2000) currently are. However, Leismeister, Ebner, and Krcmar (2005) suggest that the term "trust" can be classified into three types: interpersonal, system, and dispositional. Interpersonal trust is a type of trust in a specific person or organization on a personal level. System trust is not based on the trustee (the other party) but on the perceived property or reliance on a system or institution, such as a monetary system. Dispositional trust is the general attitude of a person seeking trustworthiness toward others. Radin (2006) refers to this generalized trust in people as "thin trust," and Mutz (2005) as "social trust." According to McKnight et al. (1998; cited in Leismeister et al., 2005), this type of trust has two assumptions: one presumes that others are normally trustworthy; and trusting others leads to better outcomes regardless of whether the others are really good or bad.

We will now examine the definitions of trust commonly used in these studies, and how these definitions may relate to that of the trust inherent in SNS actions such as posting personal information to the virtual community or sometimes literally to the world.

DISCUSSION

Definition of Trust in SNSs

There are many varied definitions of trust. Most of these definitions are based on a relationship that is implied in the trust. In the case of SNSs, users post personal information presumably to the members of the community, yet in most cases it is actually broadcast to everyone: friend and foe; neighbor and stranger; known and unknown. Therefore, the definition of trust dealing with a specific relationship, such as a buyer-seller relationship, is hard to use to explain the trust the users of SNSs have toward the group of people who visit their sites and read their postings. However, there are some studies dealing with more generalized trust.

Uslaner (2004) distinguishes between two categories of trust: a strategic trust based on our experience with people doing specific things, and a generalized trust that he further sub-defines as moralistic trust. The first type of trust, strategic trust, is widely found in business/economic literature since it occurs in buying and selling relationships. The second type of trust, generalized trust is also found in the literature (e.g., dispositional trust in McKnight et al. (2004a) and Leimeister et al. (2005); and thin trust in Radin (2006); and social trust in Mutz (2005)). Uslaner's (2004) moralistic definition of trust revolves around an optimistic viewpoint. According to him, "A handful of bad experiences should not withdraw us from social connections" (p. 29). In Uslaner's viewpoint, the future of the Internet may require faith in humanity, a moralistic trust. In general, Uslaner's view can be subsumed under generalized trust definitions.

The sources of trust Ba and Pavlou (2002) mention, that is, familiarity, calculativeness of costs and benefits, and values, and the types of trust, that is, benevolence and credibility, generally apply better to trust toward specific parties rather than toward the general public. Calculativeness, that is, the calculation of risk of revealing some information versus the chance of gaining other information or acquaintanceship, could explain some sources of trust on a SNS. For some users, a SNS is a place they may gain something. Carter (2005) reported at least two-thirds of the users of Cybercity she interviewed said meeting friends or creating new friends was their most important reason for joining the community. Those users may have provided their personal information to attract new people of interest to them, weighing the risks and benefits of doing so.

Paul and McDaniel's (2004) view of trust as a reducer of complexity and enabler of collaboration on virtual collaboration teams may be another aspect of trust in SNSs. Since it is almost impossible to examine all the participants of a given social network, users cannot help but trust them. According to Gefen et al. (2003), trust is the expectation that others will not behave opportunistically and take advantage of the situation, that they will be dependable, behave appropriately, and fulfill commitments, even in cases when they are dependent and vulnerable. According to Gefen et al. (2003):

(Trust is) a deep seated human need to understand the social surroundings... that people are by their nature free agents and as such their behavior is not necessarily rational or predictable… When a social environment cannot be regulated through rules and customs, people adopt trust as a central social complexity reduction strategy… By trusting, people reduce their perceived social complexity through a belief that may be irrational, but rules out needing to analyze future behaviors. (p. 55)

If trust is used to reduce uncertainty in action, the degree people try to reduce uncertainty is different from culture to culture.

Cultural Differences

There are cultural differences in how people interact with one another. Hofstede (1980; 1991;

Table 3. Cultural dimensions with selected countries

Country	UAI	PDI	IDV	MAS	LTO
U.S.	46	40	91	62	29
UK	35	35	89	66	25
Australia	51	36	90	61	31
China	40	80	15	55	118
Hong Kong	29	68	25	57	96
Japan	92	54	46	95	80

Note: UAI: uncertainty-avoidance index; PDI: power-distance index; IDV: individualism; MAS: masculinity; LTO: long-term orientation (source: based on information from Hofstede (1991))

1994) suggested that five dimensions of culture were useful to measure differences between cultures: power distance, uncertainty avoidance, individualism (vs. collectivism), masculinity (vs. femininity), and long-term (vs. short-term) orientation.

According to Hofstede (1994), the effect of uncertainty avoidance, a desire for predictability, can affect trust, and suggests the possibility of research in how information is shared online between cultures. This has direct bearing on the nature of global communications and systems. With the growth of new technologies such as social networking or collaboration tools, the importance of global cultural differences may become more prominent. The following example illustrates the effect of difference in "uncertainty avoidance" on the design of SNSs.

Japan is rated as a country with a very high uncertainty-avoidance score (see Table 3) compared to the U.S. and other Anglo-nations (Hofstede, 1991). *Mixi*, the most popular SNS in Japan with over 10 million user accounts (as of August 5, 2007), is such an example to show the difference in culture between Japan and the U.S.

Case Study of Mixi

Mixi was launched in February 2004 (Cashmore, 2006). *Mixi* (the company name was e-Mercury then) was publishing Internet content on *Find-Job*, which provided recruiting information. One day, an international student-worker suggested Mr. Kasahara, then president of *e-Mercury,* use a SNS. He was using U.S.-based *Friendster* to contact other international students and exchange information. Mr. Kasahara tried *Friendster* and thought that it had the potential to be introduced in Japan. On the other hand, he also thought the *Friendster's* concept of "connecting unknown people for a career advantage," which is probably more typical in the U.S., might not be accepted well in the Japanese culture. He studied many existing SNSs and tried to evolve a new form of SNS in Japan (Sasaki, 2007).

At that time, there were already some SNSs in Japan, such as *Orcut* (Google) and *Gree* (Rakuten). While these SNSs were more business-oriented and geared toward extending business acquaintances, *Mixi* set its strategic position in the opposite direction. As there was a cultural background in which teenagers in Japan valued being connected with "known" friends through mails on portable phones (it is actually text messaging in the U.S., but that is what it is called there), *Mixi* tried to be an infrastructure by which they can connect with those friends easily. As a result, *Mixi* did not aim at "openness" in which users will develop new acquaintances, but its main focus is on a service by which a user will write a diary and his or her friends will put in a comment (Sasaki, 2007). To assure this "closed" characteristic, *Mixi* offers some distinct features when compared to most of the SNSs found in the U.S., like MySpace.

For example, the contents of the sites constructed by users, including the personal information posted by users, are visible only to members of *Mixi*. In a sense, the broadcasted information on *Mixi* is limited to the closed community. Also, the membership to *Mixi* is limited by invitation from the members. This limits the possibility of malicious users from participating in the community. Another distinctive feature is the fact that users can see who visited their pages. Even if you are searching for some information and stumble upon somebody's diary, you leave a footprint in his/her log. The owner of the diary will see who visited the site and find your name on it, and will trace it back to your pages and check to see if you are somebody he/she knows, or are just a visitor. If he/she thinks you are a malicious user, he/she can block your access to their diaries and other pages (Cashmore, 2006; Schellong, 2006). All these features give users a greater sense of security, and therefore, less "uncertainty." There are some SNSs, such as *Oskut*, which are in the U.S. and also "invite-only;" but by far, there are more SNSs for open access in the U.S. Cahsmore (2006) thinks that the *Mixi* format will not succeed in the U.S.

It is not certain, however, if this is only related to Hofstede's "uncertainty-avoidance" dimension, or if it has something to do with the "individualism-collectivism" dimension. Japan is a collectivistic culture, as opposed to an individualistic culture like the U.S. (see Table 3). In a collectivistic culture, "we," as meaning the insiders of a group the person belongs to, means that they are all trustworthy, and "they," the outsiders, are not. In an individualistic culture, "I," including close family members and a few best friends, are the only ones you trust (Hofstede, 1991). People may be friendly to others, but they are not trusted. Therefore, for those from individualistic cultures, the disclosure of information on MySpace is surprisingly open. On the other hand, for a collectivistic culture, even though the level of personal information on *Mixi* could be more open than MySpace, *Mixi* user's openness of the information does not get as much attention because it is open to "us."

One example that shows *Mixi*'s success because of its cultural orientation is the fact that younger people started using *Mixi* more than *2-Channel,* the once top young online community. A study by Web Advertising Bureau of Japan, Advertising Association Inc., revealed that the users of *2-Channel* were getting older, with about 53% of users over 30 years old. On the other hand, 62% of *Mixi*'s users are in their 20s (Sasaki, 2007). *2-Channel* is a bulletin-board type site where people talk anonymously. The anonymity gives the users freedom of speech; therefore, the discussion often becomes harsh, sometimes to the extent of a flame war. On the other hand, *Mixi* is more closed and you know who made the comments. Naturally, the comments become warm and cozy. Also, if the user limits the level of accessibility only to direct friends (*My Mixi*, or *Maimiku* in Japanese), he/she can write on very sensitive matters and get some advice from friends. This comfortableness of being there is one of the reasons *Mixi* became the fastest growing SNS in Japan.

As stated in the review of literature, at the root of social networking is a type of general trust toward the group as a whole, and people use trust to reduce complexity and uncertainty and to enable collaboration and communication. This is belief in the nature of the culture, and is reflected in the views that a person has of the society at large. This should vary from culture to culture, and according to Hofstede (1994), is reflected in the culture's dimensions of uncertainty avoidance and possibly individualism-collectivism. Consequently, what people are willing to post online may vary from culture to culture. The *Mixi* example has illustrated the difference between Japanese culture, in which SNSs such as *Mixi* try to accommodate the desire to connect to "known" people, and U.S. culture, in which SNSs are geared toward connecting unknown people for a career advantage. The issues arise in the U.S. as individual information is open to the "not trusted" public, whereas in Japan, the information is provided only in a "closed" community. In either case, the definition of trust discussed in this chapter applies to the SNSs. Knowing the success of the Japanese SNSs will lead to future development, especially with the issues raised in the U.S.

FUTURE TRENDS

There are some problems current with the rise of social networking. For users, there is the problem of not being aware of all the information they may be giving away. This problem is more typical in the U.S. compared to Japan. Because the community is "closed" to known friends in Japanese SNSs, such as *Mixi*, users do not need to reveal their real names. *Mixi* encouraged users to use their real names at first. However, it has toned down its policy since an incident when it was found that an actress who admitted past illegal activities was using *Mixi* with her real name, and her pages were flooded with harsh comments from other users (Harada, 2007). Still, some users are posting individual information without caution. Some ways to educate users to be aware of the dangers of revealing such information should be sought. In the case of U.S. SNSs, such as MySpace, the problem is more complex. As the main objectives of using SNSs are to make new friends, expand business contacts, and so forth, it is inevitable that some individual information to gain trust from other people is revealed. Some features used in Japanese SNSs may be applicable to the U.S. despite some previous thought that it might not be popular in the U.S. due to the cultural differences. For example, the "footprint" function by which the users are notified who visited their sites and in case of a malicious visitor, they are given an option of blocking the user from visiting and/or reading their blogs or diaries. An "invitation-only" function could be another possibility to limit the opportunity for malicious users to get into the community. Although it is not perfect, if combined with other methods, these features could enhance the security (Harada, 2007).

As for future research, opportunities in social networking and people's perception of trust will emerge. Such issues include:

- How much information is actually and accurately being given away/collected?
- To what extent do people trust the public and/or a specific party that requires them to give data?
- What benefits do people perceive to gain from giving away individual information?
- How aware are users of data being collected; what factors (e.g., ignorance/knowledge in cyber crimes) affect the behaviors of the users?
- What cultural differences exist in the act/behavior/attitude/perception of users?
- What effect do the reassurances from the service providers (i.e., it is not really open, you are among friends only, etc.) have on what people post?
- What role does the advance in technology play in all this?

CONCLUSION

This chapter examined the trust in SNSs where users post personal information to everyone with or without specific relationships. Many definitions of trust were reviewed and it was found that most of them were based on a specific relationship such as a buyer-seller relationship. One concept of trust, generalized or dispositional trust, may be the best to fit the online situation. Also, from a global, cultural viewpoint, Hofstede's (1980; 1991; 1994) uncertainty-avoidance and individualism dimensions were illustrated as related to the behavior and trust given to the public at large by the users of the SNSs.

Social networking is growing at a phenomenal rate, adding new features and users along the way. This phenomenon gives tremendous new opportunities for academicians and practitioners. For example, marketers will seek new ways to mine this enormous pile of data for their own use. Yet, with people growing aware of these activities, less information may be available as they try to hide their activities. Techniques to preserve privacy and gain information will increase as both parties seek to achieve their purpose. In the end, the general global perception of what should be revealed and available online may be standardized. For example, witness the effect of spam on handing out e-mail addresses online.

Chapter 5.19
Individual Differences in Social Networking Site Adoption

Harsha Gangadharbatla
University of Oregon, USA

ABSTRACT

This chapter focuses on detailing the role of five individual level factors—Internet self-efficacy, self-esteem, need to belong, need for information, and gender—in influencing the attitudes toward social networking sites (SNS) and the adoption of such sites. First, the growing importance of social networking sites in business is discussed, and their usage as advertising vehicles is outlined. Individual differences in SNS adoption are presented from a technology acceptance model framework. A paper-pencil-based survey is conducted and data obtained is used to test a structural model that explains the role of individual-level factors in influencing individuals' attitudes toward SNS, their willingness to join SNS, and their actual membership on SNS. Results are presented and managerial implications are drawn.

INTRODUCTION

The Internet has radically changed the way people shop, transact, bank, and communicate with others in the recent years. With an estimated 73% of all American adults now online (Madden, 2006), the impact of the Internet on communication, commerce, and society in general continues to grow. One such impact is the proliferation of social networking sites (SNS) that are particularly popular with teens and young adults. It is estimated that over 55% of online teens use social networks and at least 48% of them visit social networking Web sites daily or more often (Lenhart & Madden, 2007). However, very little research has been done to understand the process of social networking site (SNS) adoption.

The success of social networking sites and communication on such sites depends a lot on the innovation and adoption of such sites (Ridings & Gefen, 2004). With more and more businesses implementing these social networking sites, it becomes important to understand how and why people are deciding to use sites such as MySpace and Facebook (Wellman & Gulia, 1999). As with the successful adoption of any new consumer technology, the success of social networking sites also depends on numerous factors of which individual-level factors are often ignored in this area of research. Agarwal and Prasad (1999) suggest that individual differences are important in information technology acceptance and are often not included in technology acceptance

DOI:

models. Therefore, the current chapter fills the gap in literature by examining individual differences in SNS adoption from a technology acceptance model perspective.

The following section explains the concept and types of social networking sites before discussing the role of such sites in creating and adding value to businesses and their usage as advertising vehicles.

Social Networking Sites (SNS)

Social networking sites (SNS) have existed in some form or another since the advent of the Internet. Bulletin boards, user and discussion groups, multi user dungeons (MUDs), and other forms of online communities are predecessors to the present generation of networking sites like Facebook, Friendster, and MySpace. Advances in Internet technology have made it much easier for individuals to connect and communicate online through a new wave of technology often collectively referred to as Web 2.0 tools. Social networking sites are a type of online or virtual communities (such as Yahoogroups or Google Groups) with a few differences. The emphasis in social networking sites is on (1) the individual and his or her profile information, (2) the people that the individual is connected to, (3) the groups that he or she is part of, and (4) the explicit representation of relationships. These factors determine the individual's role, involvement, and usage of SNS in contrast to traditional virtual communities where the emphasis is on public discussions and the commonality that underlies the very existence of such communities. In other words, the emphasis in the case of social networking sites is on the user and his or her network of friends whereas in virtual communities and online discussion groups the emphasis is on the content generated by members. Social networking sites are about people and their network of relationships.

Networking sites can be classified into many types. For an excellent review of classifications, readers are advised to refer to Murchu, Breslin, and Decker (2004). Depending on the type of user profiles, networking sites can be either classified as business-oriented (Ecademy, LinkedIn, or Spoke) or as social networks (Friendster, MySpace, Friendzy, Meetup, Orkut, Tickle, or Tribe). However, some networks have transcended their original purposes to extend into the other category over the years. For example, Ryze was originally intended to serve online business networking purposes but members have ever since used it for dating and other social networking purposes. Members can join social networking sites in one of the two ways—via registration or via connection. In the registration-based model, individuals sign in with a valid e-mail address and the site is open to everyone without any sort of approval or moderation, whereas in the connection-based model, individuals can only become members if they know someone who is already a member of that social networking site (Murchu, Brestlin, & Decker 2004).

The usage of social networking sites has grown from 5% of American households in 2005 to over 10% in just one year. According to a recent survey by iProspect, over 25% of all Internet users visit social networking sites at least once a month (Lewis, 2007). MySpace, for example, has over 22 million members and is growing at a rate of 2 million users a month (Rosenbush, 2005). Social networking sites are not only becoming the hottest destination spots on the World Wide Web, but are also building huge databases of user information in the process. When registering with such sites, users voluntarily provide information about their choice of movies, books, television shows, radio stations, hobbies, political leanings, and music. Most sites also display users' demographics in terms of income level, location, education, and work information. Other kinds of information usually captured (and often displayed on users' profiles) include contact information such as phone numbers, e-mail addresses, and instant message ids, and personal information such as relationship status, sexuality, favorite activities, quotes, photos, conversations with friends, groups users belong to, and discussions users are taking part in. Different sites have different ways in which members can display their networks and connections with other members. Some allow members to rank their friends (Friendster and Facebook) while others allow for categorizing their friends (Orkut).

Social Networking Sites and Revenue

The business of social networking has grown into a multi-billion dollar sector even though it is still somewhat unclear as to what a viable business model should be for these sites to generate revenue. Broadly speaking, there are two operating business models for social networking sites: subscription-based and advertising revenue. Some sites, especially e-dating sites, have turned to a subscription-based business model while many social networking sites are still looking for a viable business model. Murchu, Breslin, and Decker (2004) suggest that social networking sites may be perfect vehicles for targeted advertising given the large amounts of valuable data these sites contain in terms of profile information. The success of both models requires that users register and sign up with these sites in large numbers. Therefore, it becomes crucial and important to understand usage and adoption of SNS.

Social networking sites are being increasingly used in advertising and marketing campaigns given the clutter problems associated with other advertising media, audience fragmentation and increased usage of newer media, and the threat of new technologies such as DVRs. The amount of money spent on social networking site for advertising in 2006 was $350 million, which increased to over twice that amount ($865 million) in just one year. Overall, advertising spending is expected to increase to $1.8 billion by 2010 and $2.1 billion by 2011 (eMarketer, 2006a). It is no surprise that a major share of the advertising dollars has gone to MySpace (roughly $525 million out of the total $865 in the year 2007) given that this SNS drew over 55 million unique visitors in September 2006 which is an increase from 21 million just a year before (Advertising Age, 2007).

There are also examples of how advertisers and media firms have begun to leverage the potential of social networking sites. For instance, Starcom Media Group (SMG) ran a MySpace campaign for one of its clients, Fanta®. SMG created a profile page "*The Fantanas*" that several of MySpace members added to their buddy list. Facebook features several classified and highly targeted advertisements that show up on users' home pages when they sign in. Social networking sites like MySpace make over $25 million per month in advertising (Cashmore, 2007), and it is for the same reason that MySpace was recently bought by Rupert Murdoch's New Corp.

The trend to use social networking sites for advertising and adding value to businesses is only expected to escalate given that almost half the people recently surveyed by eMarketer (2006b) claim that they would seek out shopping information including coupons and discounts on social networking sites if they were made available. Social networking sites can also let members link to other sites such as Amazon.com and attach an image of a CD they are listening to or a book they are reading or a videogame they are playing (Rapacki, 2007). This presents great opportunities for marketers to link with social networking sites and tap into the power of key influencers or opinion leaders. There are also instances where advertisers have created viral content to be transmitted by key influencers—identified by their network size and their activity on social networking sites—or created brand-related communities that members could be a part of and participate in discussions in a more advertiser-content environment (Smith, 2006).

With revenue of social networking sites tied to the number of users registered, it becomes imperative to study and understand the factors that influence adoption of SNS. Therefore, the current study focuses on individual differences in SNS usage and adoption. The following section examines literature on SNS adoption and usage from a technology acceptance model perspective.

THEORETICAL FRAMEWORK

Research Exploring SNS Adoption and Usage

The success or failure of any innovation is often linked to its ultimate adoption (DeLone & McLean, 1990; Agarwal & Prasad, 1999). This is true for social networking sites as well given that the success of both the revenue models discussed in the previous section depends largely on the number of users registered. However, understanding why users accept or reject technological innovations (such as social networking sites) is a difficult and challenging research problem (Swanson, 1988; Davis, Bagozzi, & Warshaw, 1989)

In order to better understand SNS adoption and usage, one needs to examine literature on the technology acceptance model and draw from attitude-intention-behavior models from social psychology. Technology acceptance model (TAM) suggests that the ultimate adoption of any innovation depends on two key factors: perceived usefulness and perceived ease of use (Davis et al., 1989; Venkatesh et al., 2003). Social networking sites fulfill various needs such as an individuals' need to stay in touch and keep tabs on friends, make plans with friends, make new friends and to even flirt with someone (Lenhart & Madden, 2007). Other factors motivating SNS adoption mentioned in the literature include feelings of affiliation and belonging, need for information, goal achievement, self-identity, values, and notions of accepted behavior (Ridings & Gefen, 2004). All of these factors relate to the perceived usefulness of social networking sites. The perceived ease of use is often conceptualized in SNS literature as Internet self-efficacy. Internet self-efficacy is defined as the personal confidence in one's ability to successfully understand, navigate, and evaluate content should alleviate doubts and suspicions when dealing with social networking sites (Daugherty, Eastin, & Gangadharbatla, 2005).

The technology acceptance model (TAM) draws extensively from attitude-intention-behavior models in social psychology. For instance, Fishbein and Ajzen's (1975) theory of reasoned action (TRA) suggests that attitudes are good predictors of behavioral intentions, which in turn successfully predict behavior across a wide variety of fields. This attitude-intention-behavior model is "designed to explain virtually any human behavior" (Ajzen & Fishbein, 1980, p.4) and could therefore be used to explain SNS adoption and usage as well. Individuals' attitudes toward social networking sites influence their intentions to join such sites, which in turn predict their actual adoption and usage. This basic TRA model when combined with technology acceptance model (TAM) explains the adoption process of almost all innovations and technological services (Gefen & Straub, 1997). However, a number of individual-level factors (e.g., gender) have not been included in this technology adoption model (Gefen & Straub, 1997; Agarwal & Prasad, 1999; Venkatesh & Morris, 2000). The following section examines individual differences frequently mentioned in technology adoption literature that can potentially influence SNS adoption and usage.

Individual-Level Differences in SNS Adoption

Researchers have frequently lamented that a "set of constructs not specifically included in TAM are variables related to individual differences" (Agarwal & Prasad, 1999, p. 362). These individual factors range from cognitive and personality traits to demographic and situational variables such as training and expertise (Zmud, 1979; Agarwal &

Prasad, 1999). Many researchers acknowledge the importance of individual differences in technology adoption (Agarwal & Prasad, 1999). Although a wide spectrum of individual-level variables are frequently mentioned in the technology adoption literature, only a few that are relevant to social networking site adoption and usage will be considered here.

Need to Belong

A commonly expressed motivation to join virtual communities is an individual's need to belong (Watson & Johnson, 1972; Ridings & Gefen, 2004). Need to belong is a personality variable that is considered a fundamental human motivation that all human beings posses (Baumeister & Leary, 1995). Over 90% of teens that visit social networking sites do so to stay in touch with friends, something that suggests the importance of need to belong. Other related reasons often mentioned in the literature include social support, friendship, and common interests (Ridings & Gefen, 2004). Furlong (1989) suggests that virtual communities are places where individuals go for emotional support, sense of belongingness, and encouragement in times of need. One of the main reasons for individuals joining virtual networks is finding social support on such sites (Herring, 1996) and making friends (Horrigan et al., 2001). Connections made online go beyond receiving support, as Ridings and Gefen (2004) suggest "the feeling of being together and being a member of a group of friends comes with the notions of being part of a group, spending time together, companionship, socializing, and networking" (p. 5). Online friendships go beyond just social support exchange. Internet makes it easy for individuals to connect to others in today's busy world. Social networking sites allow for individuals to reconnect with high school and college friends, ex-lovers, past and current colleagues, and sometimes even random strangers. This need to belong motivation is also related to individual usage of virtual communities. Leung (2001) found in a survey of 576 college students that students who were motivated by affection and sociability were the heaviest users of ICQ whereas light users were motivated by fashion.

Individuals have a strong motivation to "form and maintain at least a minimum quantity of lasting, positive, and significant interpersonal relationships" (Baumeister & Leary, 1995, p. 497). Due to this natural pursuit of maintaining belongingness, they propose that the strength and intensity would vary among individuals but that it would be "difficult or impossible for culture to eradicate the need to belong" (Baumeister & Leary, 1995, p. 499). Given that individuals vary in their levels of belongingness, it is only logical to except the effect of this "need to belong" on their SNS adoption and usage to also vary accordingly.

Internet Self-Efficacy

One of the chief determining factors of technology acceptance in TAM is individual's perceived ease of use of the technology. Perceived use of ease translates to Internet self-efficacy when dealing with social networking sites, which is represented in reasons such as "interface being ease to use" and "the search functionality being really cool" (Ridings & Gefen, 2004). Self-efficacy has been shown to have a significant impact on individuals' adoption of technology (Eastin & LaRose, 2000; Eastin, 2002). Self-efficacy is a person's ability to perform a task, a person's judgment about a future event, or even one's belief in their own ability (i.e., self-confidence) (Barbalet, 1998). This belief is a known predictor of involvement, intrinsic motivation, and task completion in a variety of domains (Ellen, Bearden, & Sharma, 1991). The effect of self-efficacy on consumer decision-making and behavior has been well documented in marketing literature (see Fleming & Courtney, 1984; Bettman, Johnson, & Payne, 1991; Bearden, Hardesty, & Rose, 2001) and information technology (Compeau & Higgins, 1995). However, none have directly examined the role of Internet self-efficacy on attitudes toward social networking sites and individuals' likelihood of adopting such Web sites.

Internet self-efficacy can be defined as the personal confidence in one's ability to successfully understand, navigate, and evaluate content, which should alleviate doubts and suspicions when dealing with social networking sites. Ajzen and Sexton (1999) suggest that as self-efficacy (i.e., beliefs) increases, attitudes toward the object of those beliefs will also increase. In other words, as individuals' levels of Internet self-efficacy increase their attitudes toward joining social networking sites should also increase.

Self-Esteem

A variable similar to self-efficacy is the individual's level of self-esteem. Rapacki (2007) argues that teens need places like MySpace as they help them express their ever-changing liquid self-concept in a non-permanent way as opposed to "permanent reminders like scares, bad credit, and tattoos" (p. 28). And self-esteem is an evaluative dimension of self-concept. The impact of self-esteem on technology adoption—in this case, adoption of social networking sites—has never been examined before. Given the expected positive relationship between self-efficacy and attitude toward SNS, one could also assume a positive influence of individual's self-esteem level on SNS adoption.

Need for Cognition

According to TAM, perceived usefulness of an innovation plays an important role in its ultimate adoption. Both need to belong and need for cognition in an individual can be linked to the perceived usefulness of social networking sites. Need to exchange information and goal achievement are often cited as reasons why individuals join virtual communities (Ridings & Gefen (2004). Need to exchange information relates to need for cognition or the desire to obtain information about a topic, educate oneself or learn new things. The successful adoption of virtual communities often depends on two key factors: individuals' need to access information and member-generated content (Furlong, 1989; Hagel & Armstrong, 1997; Ridings & Gefen, 2004). Many individuals join virtual groups mainly to obtain information and this is particularly true in the case of groups that are formed around special topics (Rheingold, 1993; Herring, 1996).

With social networking sites that allow for friends to keep tabs on each other, learn about each other's interests and groups, discuss and gather information on a wide variety of topics, the need for cognition should influence the usage and adoption. If an individual exhibits a high desire to gather this information, the likelihood of his or her adoption of SNS to serve such needs should also be high.

Gender

A number of demographic variables have been shown to influence technology adoption including age, income, education, occupation, and sex. The current study is limited to examining the effect of only one demographic variable—gender. Several studies examined the role of gender in technology adoption and usage (Gefen & Straub, 1997; Agarwal & Prasad, 1999; Venkatesh & Morris, 2000). Hawkins (1987) categorized various factors that are possible reasons for existing inequalities in computer usage between males and females. The first is the presence of a biological disadvantage in that girls find spatial and manipulative tasks required for interacting with a computer difficult and unappealing. The second reason suggests that usage of computers is incompatible with females' learning styles. Hawkins explains this further by saying that boys are more likely to attribute failure to external factors whereas girls tend to attribute failure to their own inability to succeed. The third reason is boarder and cultural in context in that most societies reinforce sexual stereotypes and prescribe gender-appropriate interests. Gender differences in computer skills and usage were found to transcend cultures as shown by Lowe and Krahn (1989) in their study of computer usage in Canada.

Gefen and Straub (1997) cite socio-linguistic literature to suggest that men tend to focus on hierarchy and independence, while females focus on intimacy and solidarity. This suggests gender differences in how individuals approach social networking sites. Self-efficacy and need for cognition might have a stronger say in SNS adoption for men whereas the need to belong might play a bigger role in SNS adoption for women. Lewis (2007) suggests the same in that social networking sites are primarily places to reconnect with friends from past for girls whereas for boys, the attraction to SNS is more geared toward making new friends (Lewis, 2007). In another study, it was found that female ICQ users spend more time on ICQ and chat longer for reasons of sociability and need to belong than males who tend to spend time chatting for recreation (Leung, 2001).

To summarize, the role of five individual-level factors in influencing an individuals' SNS adoption is examined. More precisely, the role of need to belong, need for cognition, Internet self-efficacy, self-esteem, and gender in influencing individuals' attitudes toward social networking sites and their willingness to join such sites is examined.

PRIMARY RESEARCH

Research Proposition

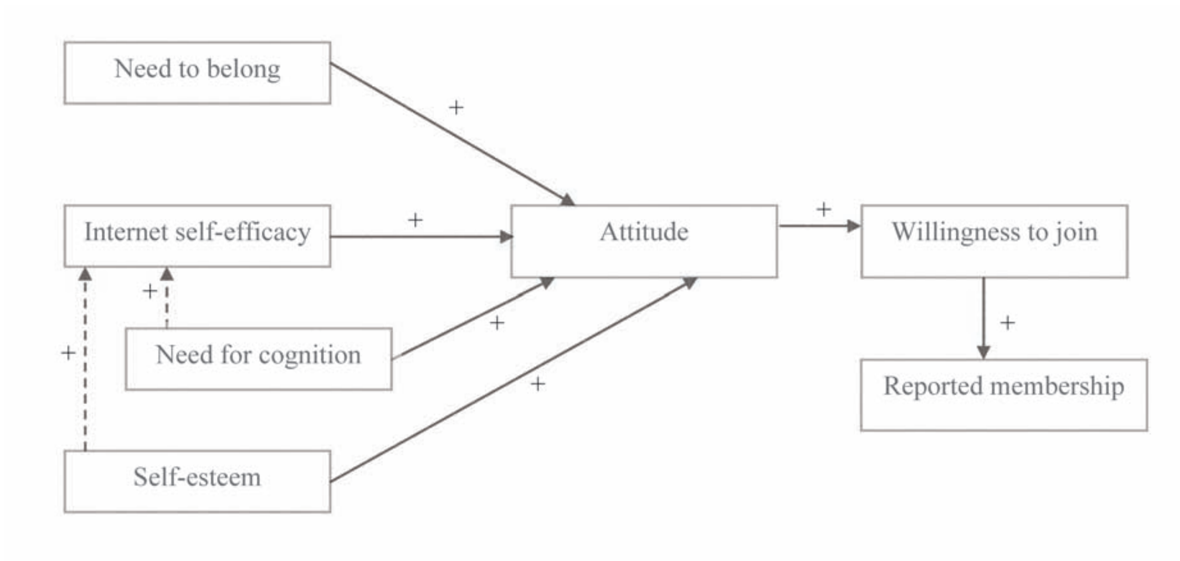
In order to better understand the role of Internet self-efficacy, need to belong, need for cognition, self-esteem, and gender in social networking site adoption, the following theoretical model is proposed based on the discussion in the earlier section. Although the model is the same for both genders, the magnitude of co-efficient estimates is expected to be different for males and females. Therefore, the grouping variable for the proposed model in Figure 1 is gender.

The principle research proposition is that individuals' need to belong, level of Internet self-efficacy, need for cognition, and self-esteem all positively affect their attitude toward social networking sites, which in turn positively affects their willingness to join such sites. Furthermore, this reported level of willingness to join SNS is positively related to their actual membership. This is reflected with solid line with + signs on top of them in the proposed model. Intuitively, Internet self-efficacy is expected to be dependent on individuals' need for cognition and their level of self-esteem. However, there were no direct studies found to support the directionality of this link, hence these relationships are represented by dotted lines with + signs on them.

Sample and Procedure

To test the proposed model, data was collected using a paper-pencil-based survey. An online version was not used to include both social networking site users and non-users. Furthermore, a paper-pencil-based survey would also ensure that non-users of the Internet are captured in the sample. A total of 237 undergraduate students (N=237) were recruited from a large southwestern university to participate in the study. Students were recruited to participate for extra credit during class time via an oral presentation given by the principal investigator. A student sample is justified given that social networking site users fit the demographics of college students between the ages 18 to 30 and that is the demographic of interest for the current study. Respondents took approximately 20 minutes to complete the entire survey. To maintain anonymity, no names were collected on the questionnaire.

Figure 1. Proposed model with gender as grouping variable



Questionnaire

A 65-item questionnaire was developed and pre-tested on a small sample of academic professionals and graduate students to insure clarity (additional data was collected but not analyzed for this study). Attitude was measured using an established six-item semantic differential scale (bad/good, foolish/clever, unpleasant/pleasant, useful/useless, boring/interesting, and negative/positive) (Bruner, James, & Hensel, 2001, p. 84). Willingness to join social networking sites was measured using four established semantic differential items (unlikely/likely, probably/probably not, impossible/possible, and definitely would/definitely would not) (MacKenzie & Spreng, 1992). Need to belong was measured using a seven-item Likert scale. Scale items included statements such as "I want other people to accept me," "I do not like being alone," and "I try hard to stay in touch with my friends" (Leary, 1957; Leary, Kelly, & Schreindorfer, 2001). Need for cognition was measured using Likert scale items such as "I prefer complex to simple problems" and "Thinking is not my idea of fun" (Cacioppo & Petty, 1982; Cacioppo, Petty, & Kao, 1984). Self-esteem was measured using six Likert scale items such as "On the whole, I am satisfied with myself," "I feel that I have a number of good qualities," and "I take a positive attitude toward myself" (Rosenberg, 1965). Finally, the Internet self-efficacy scale consisted of 10 items such as "I often surf the web for information," "I feel confident troubleshooting Internet problems," and "I am familiar with computers" (Eastin & LaRose, 2000). The questionnaire also asked about the number of hours subjects spent surfing the Web, the number of social networking sites they belonged to, the average number of times they signed on to their account on a social networking site, and the number of hours per week they spent on these sites. The survey concluded with demographic questions.

Results

The sample (N=237) consisted of 56% females (133) and 44%t males (104) with majority of subjects being Anglo (75%), followed by Hispanic American (8.4%). The mean age of the sample

Table 1. Mean, variance, and Cronbach's alpha coefficients for scales

Scale	Mean	Variance	α
Attitude toward social networking sites (6 items)	4.90	0.12	0.84
Willingness to join SNS (4 items)	5.19	0.07	0.89
Need for cognition (7 items)	4.00	0.21	0.75
Need to belong (7 items)	4.68	0.71	0.63
Self-esteem (6 items)	5.50	0.29	0.77
Internet self-efficacy (10 items)	4.74	0.42	0.91

was 22.6 with ages ranging from 18 to 46. Reliability analysis was conducted using Cronbach's Alpha. Table 1 lists the average scores, variances, and reliability indices for each scale used in the model. All scales had a Cronbach's Alpha of over 0.70 (Hair, Anderson, Tatham, & Black, 1998, p. 118) except for one (need to belong). However, need to belong was still used in the model given that it was over 0.60 and somewhat close to the prescribed limit.

The proposed model was estimated using AMOS software. Gender was used as a grouping variable in the model. In other words, the model was estimated twice, once for males in the sample and once for females. Table 2 depicts the correlation matrix of variables used in the model. The fit statistics for both models suggest that data fits the model very well. Both CFI (Comparative Fit Index= 0.984) and GFI (Goodness of Fit Index=0.967) are well above the prescribed limit of 0.90 (Tanaka & Huba, 1985; McDonald & Marsh, 1990), chi-square is not significant, and RMSEA (0.021) is below the limit of 0.80.

The various factors that influence individuals' attitude toward social networking sites are different for both genders as suggested by Figures 2 (a) and (b). For females in the sample, need to belong and self-esteem seem to play a part in influencing their attitudes toward social networking sites, whereas for males, only Internet self-efficacy seems to influence the attitudes. For both genders, attitude toward social networking site positively affects their willingness to join such sites, which in turn positively affects their actual membership. However, the magnitude of these effects is different for males and females.

Tables 3 (a) and (b) list the unstandardized and standardized co-efficients for females and Tables 4 (a) and (b) list the same for males.

For females, attitude toward social networking sites is dependent on their need to belong and self-esteem levels, whereas for males, attitude

Table 2. Correlation matrix

	Attitude	Willingness	Internet self-efficacy	Need for cognition	Need to belong	Self-esteem
Attitude	1.00

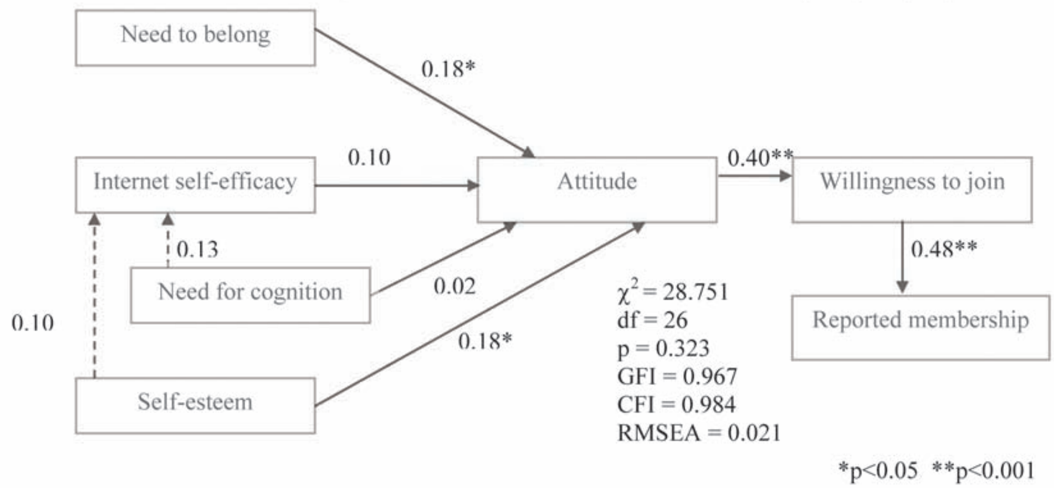

Figure 2.b Structural model with fit statistics and standardized estimates for group 2-males

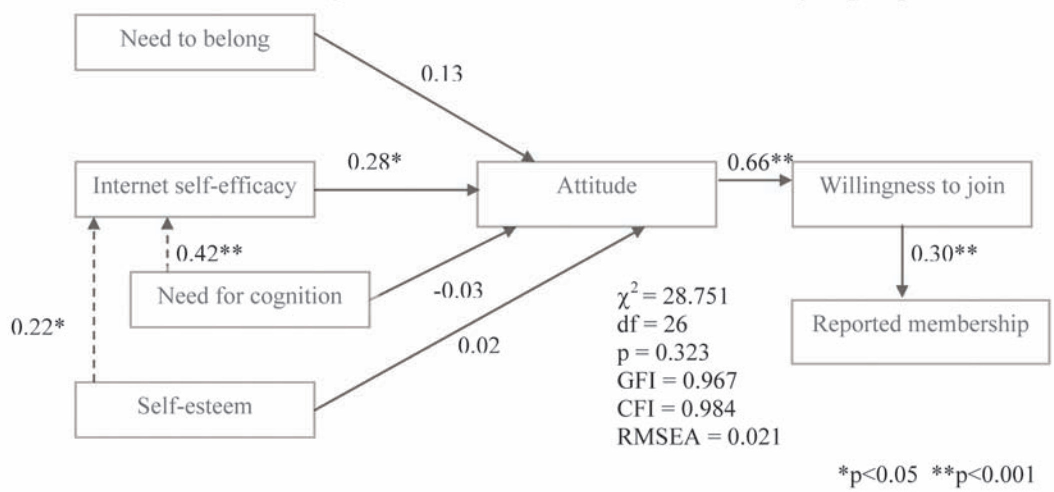

toward SNS is only dependent on their Internet self-efficacy level. To interpret the standardized co-efficient estimates, each value represents the amount of change in "attitude toward SNS" given a standard deviation unit change in X (X being Internet self-efficacy or need to belong or self-esteem). More precisely, attitude toward SNS changes by 0.28 given a standard deviation unit change in Internet self-efficacy level for men. Similarly, attitude toward SNS changes by 0.18 and 0.18 for each standard deviation unit changes in need to belong and self-esteem, respectively for females. The parameters can also be interpreted using the unstandardized co-efficient estimates. In this case, each unstandardized value represents the amount of change in "attitude toward SNS" given a single raw score unit change in X (again, X being Internet self-efficacy or need to belong

Table 3(a). Unstandardized regression weights (maximum likelihood estimation)-females

Attitude	<---	Need for cognition	-0.034
Attitude	<---	Need to belong	0.132
Attitude	<---	Internet self-efficacy	0.280*
Attitude	<---	Self-esteem	0.024
Willingness	<---	Attitude	0.661**
Reported membership	<---	Willingness	0.303**
*p<0.05 **p<0.001			

or self-esteem). Attitude toward SNS (on a scale of 1 to 7) increases by 0.253 for a unit increase in the value of Internet self-efficacy for men and by 0.251 and 0.226 for a unit increase in the values of need to belong and self-esteem, respectively for women.

Next, it is interesting to note the differences in attitude-intention-behavior relationship by gender. From the standardized co-efficient estimates, the link between attitude-intention is stronger for males than females, and the link between intention-behavior is stronger for females than males. In other words, men are more likely to report a willingness to join SNS if they have a favorable predisposition toward SNS but women are more likely to actually join SNS if they report a willingness to join SNS.

DISCUSSION

Social networking sites (SNS) are growing in importance not just as places for individuals to communicate, network, and express themselves but also as advertising/marketing vehicles. Of all the existing revenue models for SNS, the most viable so far seems to rely on advertising and use of SNS as vehicles for branding. And with expected advertising spending on such sites to be around $2 billion by 2010 (eMarketer, 2006a) it is imperative that researchers focus on SNS and SNS adoption. The present chapter presents a framework for understanding SNS adoption based on five individual-level factors: need to belong, need for cognition, Internet self-efficacy, self-esteem, and gender.

Researchers in the past have registered gender differences in technology acceptance. For instance, Gefen and Straub (1997) found that females view e-mail as being higher in social presence than men. Consistent with gender differences in TAM literature, the current study also found differences in the way males and females adopt social networking sites. For females, the need to belong and self-esteem level were significant predictors of SNS adoption whereas for males, only Internet self-efficacy was significant in predicting SNS adoption. Surprisingly, the need for cognition did not predict SNS adoption for both genders. This may be due to the fact that social networking sites are geared more toward building networks and appealing to other social needs more so than virtual communities and discussion groups such as Yahoogroups where the focus is on information access and the member-generated content.

Consistent with TRA literature, the current study provides more evidence for attitudes-intention-behavior model. For both genders, attitudes significantly predicted their willingness and intention to join social networking sites, which in turn positively predicted their actual usage. In other words, if individuals report a favorable attitude toward social networking sites they are more likely to express a willingness to join such sites, which in turn is significantly related to their actual usage and adoption of SNS. However, the magnitude of attitude-intention-behavior relationship seems to differ by gender for SNS. This is surprising and suggestive of individual differences in the TRA model itself based on gender. Attitudes-intention-behavior relationships in TAM have been tested and supported extensively, but the influence of individual-level factors on attitudes is yet to be detailed (Agarwal & Prasad, 1999). Future research should address this.

LIMITATIONS

The current study presents numerous limitations. First, the sample drawn is a convenience sample of college students. Although majority users of social networking sites are between the age groups 18 to 30, a convenience sample does limit the validity of findings. Second, a number of individual factors (age, income, education, and occupation) that potentially influence SNS adoption were not included in the current study. This is again due to the convenience sample that was used where variation in terms of age, education, income, and occupation was not much. Third, the low score in Cronbach's Alpha for need to belong also limits the overall reliability of the study. That said, individual differences in social networking site (SNS) adoption has never been investigated before and the author feels that the present study is a right step in the direction of furthering our initial understanding of social networking site adoption even with its limitations.

MANAGERIAL IMPLICATIONS

The focus on only individual factors might lead one to question the practical significance of the current study. One could argue that individual-level factors are beyond the control of brand managers, and therefore the current findings hold no managerial implications. Nonetheless, the author strongly believes that our understanding of the role of individual-level factors does help in devising effective strategies to increase membership of SNS as well as target individuals on such sites with relevant and effective promotional messages. Furthermore, the establishment of a relationship between individual level factors, brand attitude and behavior for social networking sites is of importance to academic scholars interested in theoretical research. The study's findings present many implications for social networking site (SNS) owners and advertisers looking to use these sites as advertising vehicles. For both parties, the common objective is to increase usage and membership and enable brand managers to develop new markets and improve their competitive positions. The following are some such strategies.

The success of a social networking site is directly related to the number of individuals registered with a particular SNS as higher membership translates to an increased number of eyeballs that could be potentially reached with a promotional message. The current study suggests that SNS adoption is significantly influenced by gender. The underlying factors that drive female membership—and this becomes relevant when dealing with social networking sites devoted to women or e-dating sites that typically have fewer women registered than men—are their levels of self-esteem and need to belong. Designing advertising campaigns around these two factors can significantly increase female membership. For instance, designing a TV commercial for an e-dating site that taps into a single woman's need to belong while at the same time emphasizing and applauding her individuality and independence (self-esteem factor) should evoke positive feelings toward that particular e-dating site, which in turns translates to a willingness to join such a network resulting in an actual registration, ultimately.

When the objective is to increase male membership, which is dependent on Internet self-efficacy, social networking site owners can design sites that are easier to navigate, and thereby influence the perceived level of confidence. Social networking sites that enhance members' sense of control by providing highly interactive environments and allow users to upload multimedia files, link to their blogs on others sites, link to videos on YouTube®, and provide Web 2.0 tools extensively are more likely to appeal to men. An increased sense of control translates to an increase in perceived level of self-efficacy, which leads to a favorable predisposition toward a SNS leading ultimately to its adoption.

Gender differences also exist in the strength of relationship of the attitude-intention-behavior in the proposed structural model. Based on the coefficients in the model, females are more likely to do something if they say they would as opposed to men who might be more willing to do something if they had a favorable predisposition toward it. A plausible strategy that exploits this finding is to attempt to increase men's attitudes toward SNS and for women, stress more on their willingness to join SNS. For example, promotional messages devoted to increasing the membership of an e-dating site should concentrate on changing the attitudes of men (by advertising) and in providing incentives to join for women (by offering discounts).

For brand managers and marketers looking to use social networking sites as advertising vehicles, it pays to note that men and women choose to register and be a part of a SNS for different reasons. This difference in motivations can become the basis for designing campaigns on social networking sites that appeal to different genders. If indeed women increasingly choose to become members of SNS owing to high levels of need to belong then ads placed on SNS should carry emotional appeals that tap into this need. Along the same lines, ads targeting women on SNS should also consider appealing to the self-esteem of members. Moreover, social networking sites may be best suited for products that can easily appeal to individual's need to belong and self-esteem (such as beauty-related products). As an example, when targeting women on an e-dating site with an ad for a beauty product, the emphasis of the creative could be on how the product enhances the individuals' personality and looks (and indirectly her self-esteem), which in turn makes her more desirable to others (need to belong).

Despite the model investigated in the current study being overly simplistic, it does present some theoretical implications for researchers interested in understanding SNS adoption. A number of other factors could potentially impact SNS adoption (factors such as type and genre of SNS, relevance, socio-economic factors of members, context, mood, influence of peers and relationships with members on one's network, perceived risk and privacy issues, parental influence and success) and future research should include these factors and test a modified version of the model presented in this chapter.

Chapter 5.20
The Impact of Individual Differences on Social Communication Pattern in Online Learning

ABSTRACT

This chapter describes the college students' online social communication patterns and behavior with a focus on the impact of individual differences on learners' online communication. The study consisted of 27 college students who engaged in an online discussion over a period of fourteen weeks as part of requirements in an undergraduate educational technology course. The findings indicated that cognitive styles such as field dependence and field independence played a critical role in forming learners' online social communication. Based on social compensation theory and Witkin et al.'s theory of individual differences, the authors claimed that effective individual communication in an online community can be fostered through creating learning support, taking into considerations factors like cognitive styles, complementary personality, interest and motivation in the process of design. Suggestions for future online learning are made with an emphasis on creating an effective online community for learning.

INTRODUCTION

As an important aspect in online learning, online social communication has drawn attention of educators and researchers (Willing, 2007; Zheng & Ferris, 2007). With the increasing use of Web course tools (e.g., WebCT, Blackboard, Moodle, etc.), particularly the availability of social communication function in such tools as asynchronous and synchronous communication, educators and researchers have become interested in investigating variables and factors that influence learners' socially engaged activities in online learning (Cook & Smith, 2004; Weller, 2007). Following this line of research, researchers have identified social factors (see Dietz-Uhler & Bishop-Clark, 2005; McKenna, Green, & Gleason, 2002; Peter, Valkenburg, & Schouten, 2006; Sheeks & Birchmeier, 2007; Valkenburg & Peter, 2007) and individual factors (Anolli, Villani & Riva, 2005; Chak & Leung, 2004; Johnson & Johnson, 2006; Madell & Muncer, 2007) that have pronounced impact on learners' social communication and behavior in online learning. While there is a plethora of literature pertinent to the social and individual factors that influence online learning, little research has been done to explore learners' social communication patterns in online learning environment, particularly how individual factors such as cognitive styles affect the way learners communicate in web-based learning.

Research indicates that understanding learners' online social communication and behavior is crucial in successfully implementing effective online instructional strategies such as collaboration, group work, etc. (Johnson & Johnson, 2006; Weller, 2007). Online learning is substantiated through the activities of a virtual learning community. Since individual learners constitute the body of online learning communities, individual factors such as cognitive styles can play an important role in formulating the communication pattern and behavior of that community (Johnson & Johnson, 2006). This chapter offers a discussion on online learners' social communication patterns and behavior by (a) studying the differences between field dependent and field independent learners in online social communication; (b) identifying the correlation between cognitive styles and related factors in online learning including self-confidence, support, interest, motivation and so forth; and (c) analyzing learners' performance in online discussion. Discussion on research in online social communication and behavior will be made with guidelines for future studies.

COGNITIVE STYLES AND LEARNING

In the last half century learners' cognitive styles have been heavily studied; these studies encompass a wide range of topics: from brain hemisphere function (Samples, 1975; Springer & Deutch, 1985), to temperament (Gregorc, 1982), to impulsive/reflective cognitive tempo (Kagan, 1966), to field dependent and field independent theory (Witkin & Goodenough,1977), just to name a few. In an early study Kirby (1979) provided a comprehensive summary of 19 cognitive styles and concluded that all learners learn differently. According to Chinien and Boutin (1992), cognitive styles refer to "the information processing habits representing the learners' typical mode of perceiving, thinking, problem solving, and remembering" (p. 303). They claimed that cognitive styles constitute important dimensions of individual differences among learners and have important implications for teaching and learning.

Differing from learning styles which describe the conditions (i.e., auditory, visual, haptic, etc.) under which we best learn, cognitive styles are about how we perceive and think (Lever-Duffy, McDonald, & Mizell, 2003). The construct of cognitive style has been considered as a consistent, stable variable in learning. Keefe (1982) stated that cognitive styles are "the cognitive, affective, and physiological traits that serve as relatively stable indicators of how learners perceive, interact with, and respond to the learning environment" (p. 1). This view is shared by Smith and Ragan (2005) who propose a framework of learners' characteristics in which cognitive styles are subsumed under the category of stable-differences. Unlike psychosocial factors and prior knowledge which change during learning, cognitive styles are comparatively stable with little change over time. Whereas sensory capacities bear similarities among humans, cognitive styles are marked by a wide spectrum of differences with respect to how people perceive and respond to their learning environment. Because of their dual nature of stability and difference, cognitive styles are considered to have "the most potential utility to instructional design" (Smith & Ragan, 2005, p. 62). Smith and Ragan point out that understanding cognitive styles is important because it not only provides insight into how individual learners learn but also sheds light on why differing learning occurs.

Riding and Read (1996) investigated the relationship between learners' cognitive styles and learning performance and found that learners' cognitive profiles were consistent with their preferences in learning. For example, wholist-imagers like to use pictures whereas verbalizers were more prone to writing. In social learning context, wholist-imagers displayed a tendency for group work whereas analytics, such as verbalizers, preferred individual work. Russell (1997) conducted a similar study and reported that learners' cognitive styles, along with other variables like age and attitude could significantly influence their performance. Ates and Cataloglu (2007) studied first year undergraduates majoring in mechanics and tried to determine if cognitive styles have an influence on learners' achievements and problem-solving skills. Interestingly, they found no significant correlation between cognitive styles and pre/post achievement scores. However, they noted that learners' problem-solving skills were statistically related to their style. With the increasing presence of computers in teaching and learning, research on cognitive styles and learning has been extended to areas of computer assisted learning (CAL), hypermedia, and distance learning. Ford (2000) examined learners' information processing and strategies and their deep (transformational) and surface (reproductive) Riding and Read (1996) investigated the relationship between learners' cognitive styles and learning performance and found that learners' cognitive profiles were consistent with their preferences in learning. For example, wholist-imagers like to use pictures whereas verbalizers were more prone to writing. In social learning context, wholist-imagers displayed a tendency for group work whereas analytics, such as verbalizers, preferred individual work. Russell (1997) conducted a similar study and reported that learners' cognitive styles, along with other variables like age and attitude could significantly influence their performance. Ates and Cataloglu (2007) studied first year undergraduates majoring in mechanics and tried to determine if cognitive styles have an influence on learners' achievements and problem-solving skills. Interestingly, they found no significant correlation between cognitive styles and pre/post achievement scores. However, they noted that learners' problem-solving skills were statistically related to their cognitive style. With the increasing presence of computers in teaching and learning, research on cognitive styles and learning has been extended to areas of computer assisted learning (CAL), hypermedia, and distance learning. Ford (2000) examined learners' information processing styles and strategies and their deep (transformational) and surface (reproductive) learning in an online environment. He found that the unique features of online learning such as anonymity, synchronous and asynchronous communication enable learners of various cognitive styles to process information differently, which consequently impact their ability to learn both at deep and surface levels. Chen (2002) evaluated the effects of cognitive styles on student-centered learning in a hypermedia program. The author noticed that differences in cognitive style can affect different learners' learning in hypermedia. For example, the flexibility of hypermedia learning environment, e.g., non-linear learning, facilitates positive learning for field-independent learners and impedes the performance of field-dependent learners who often take a passive approach in learning. Taken together, the above research demonstrates that individuals learn differently and their various cognitive styles may affect the way they learn. In addition, educational technology such as hypermedia and the Internet may mediate learners' cognitive styles which could result in differences among learners in terms of their approaches to learning.

As was discussed elsewhere in the chapter, cognitive styles refer to an individual's preferred and habitual approach to organizing and representing information. Within the area of cognitive styles, field dependence (FD) and field independence (FI) have emerged as one of the most widely studied dimensions with the broadest application to problems in education (Meng & Patty, 1991; Witkin & Goodenough, 1977). The following section will focus on the characteristics and function of FD and FI, followed by a discussion on instructional conditions related to FD and FI learning. Field Dependence (FD) and Field Independence (FI)

Witkin and Goodenough (1977) defined field dependence and field independence as individuals' "tendencies to rely on self or field as primary referents" (p. 661). The word "field" can be a set of thoughts, ideas, or feelings. According to Witkin and Goodenough, people with field-dependent (FD) or field-independent (FI) cognitive styles are different in their interpersonal behavior, social skills, and information processing. FD people tend to make use of external social referents whereas FI people function with greater autonomy under such conditions. FD people are more attentive to social cues than are FI people. As a result, FD people show more interest in others, prefer to be physically close to people, and are emotionally more open, and gravitate toward social situations. In contrast, FI people are characterized by an impersonal orientation, less interested in others, show physical and psychological distancing from people, and prefer non-social situations (Ikegulu & Ikegulu, 1999; Liu & Reed, 1994; Witkin, Moore, Goodenough, & Cox, 1977). The practical implications of FD and FI research have indicated that different learning styles among individuals bear direct impact upon their achievement performance (Zheng, Yang, Garcia, & McCadden, 2008). Many studies have shown that FI people tend to outperform FD people in various settings. In a study by Griffin and Franklin (1996), one hundred and forty-three subjects were identified as FI or FD based on their performance on the Group Embedded Figures Test (GEFT). The results of their study indicated FI students performed significantly better on course tests. The study also suggested that FI students had higher academic potential than their FD counterparts. This finding was echoed by Richards, Fajen, Sullivan, and Gillespie (1997) who conducted two experiments, one in listening and one in reading, in connection to FD/FI cognitive styles. They examined the relationships among signaling (structural cues), notetaking, and FD/FI styles in college students. The results of both studies indicated that FI subjects seemed to use a tacit structure strategy, whereas FD subjects displayed structuring skills when notetaking. Along the same line, Danili and Reid (2004) studied 105 Greek pupils aged 15 to 16 and found that FI pupils were more organized and self-initiated than FD pupils in learning.

Instructional Conditions Related to FD and FI Learning

There is a concerted view among researchers and educators that instructional conditions should be identified to match the learning for FD and FI learners (Jonassen & Grabowski, 1993; Schmeck, 1988; Smith & Easterday, 1994). Witkin et al. (1977) point out that field dependence and field independence appear to affect many aspects of daily life including the ability to learn, particularly with regard to types of educational reinforcement needed to enhance learning, amount of structure required in an educational environment, cue salience, interaction between teachers and students, and so forth. One of the questions raised by Witkin et al. was whether teachers can adapt their teaching techniques to accommodate students with different cognitive styles. Related to this question is,

Table 1. Instructional conditions that capitalize on the preferences of and challenges to FD-I learners

Instructional Conditions Capitalized on the Preferences of FD Learners and Challenges to FI Learners	*Instructional Conditions Capitalized on the Preferences of FI Learners and Challenges to FD Learners*
•Providing structural support with salient cues •Including an advance organizer •Including an outline or graphic organizer of the content •Giving clear directions and guidance in instruction •Giving prototype examples •Facilitating a synergetic, social learning environment •Providing timely and detailed feedback •Embedding questions throughout learning •Providing multiple cues including visual, oral, and auditory, etc. •Providing detailed steps for deductive or inductive instruction	•Providing abundant content resources and reference material to sort through •Employing inquiry and discovery methods •Including minimal guidance and direction •Providing independent, contract-based self-instruction •Facilitating an independent learning environment •Encouraging learners to self-initiate questions •Employing inductive methods for instruction and learning •Employing outlines, pattern notes, concept maps as instructional strategies for teaching and learning •Using theoretical elaboration sequences

what are the instructional conditions needed to support FD and FI learners to learn effectively and efficiently? Jonassen and Grabowski (1993) summarized the research on the implications of the style characteristics and came to the conclusion that the instructional conditions differ between FD learners and FI learners. While some instructional conditions support FD learners, they can become, at the same time, challenges to FI learners.Table 1is a summary of the conditions that capitalize on the preferences of FD and FI learners and challenges to their respective counterparts.

To effectively utilize the instructional conditions so that FD and FI learners can maximally benefit from such learning, it is important to raise the awareness of cognitive style among learners. Perry (1994) pointed out that if there was an understanding of cognitive/learning styles, cooperative arrangements could be made between individuals of different styles to possibly compensate for the deficiencies of one style. He also suggested that an appreciation of the diversities (i.e., different cognitive styles) was important in any educational environment. According to Perry, when we allow learners to understand how they learn, there is greater possibility for efficient and effective learning and teaching. To elaborate on the compensatory role between different cognitive styles, our discussion in the next section will introduce social compensation theory to illuminate how learners with different cognitive styles may interact within a social learning environment and how external conditions may facilitate socially compensatory behavior.

SOCIAL COMPENSATION THEORY

Social compensation theory can be traced back to early works done by Otto Kohler (1926, 1927 cited from Williams & Karau, 1991) who demonstrated with dyads or triads working on a conjunctive work, that group performance depended on the relative individual performance of the group members. Kohler explored the group performance of members who showed moderate discrepancies in ability level and found that weaker members worked harder in groups than individually. Kohler explained that the most probable cause being that the weaker members tried to avoid the embarrassment of lowering the group product. Following Kohler's studies conducted some sixty years ago, Williams and Karau (1991) did several experiments to test the hypotheses that a group member will work harder in a group setting than individually if (a) the production of the public good is very important, (b) the task is addictive, (c) the individual perceives control over the production of the public good, and (d) the other group members are unable or unwilling to contribute to the production of the good. Their studies led to several important conclusions.

First, when subjects were led to believe that their coworkers were unable or unwilling to contribute to the group product, subjects produced substantially more ideas when working in a group rather than individually. Second, social compensation was only likely to occur under conditions where a capable group member was able and willing to compensate for the weaker member(s) of the team. Similar findings were obtained by Stroebe, Diehl, & Abakoumkin (1996) who identified a social compensatory relationship between high and low ability members in the group. They argued that discrepancy among individual abilities created optimal conditions for mutual influence and resonance. On the one hand, the stronger member somehow motivated the weaker member to work harder while at the same time increasing his own performance. On the other, the weaker member was galvanized by the member responsibility and the urge to avoid the embarrassment of lowering the group product.

The early work on social compensation (Kohler, 1926, 1927 cited from Stroebe et al., 1996; Williams & Karau, 1991) focuses primarily on the relationship between individual abilities and group performance. For example, Kohler's studies (1926, 1927) explored the group social compensation behavior based on the differences between physical strength of weight lifters. That is, the stronger weight lifter appeared to be more willing to contribute to the group performance as he took upon himself as a social obligation to help improve the scores of his group. The similar pattern was found for the group brainstorm activity where the more able learners became actively involved in brainstorming when they realized that it was they, rather than the less able learners, who could make difference in group brainstorming (Williams & Karau, 1991). However, the early work did not explore the social compensation phenomenon from the perspective of learners' cognitive styles, which are considered by many to be crucial in understanding the dynamics of social compensatory behavior (Peter, Valkenburg, & Schouten, 2005; Valkenburg & Peter, 2007). With the increasing presence of the Internet, this line of research seems to be more important as social compensation and cognitive styles are related and intertwined to form the ground for the study of social online communication and behavior.

Social Compensation, Cognitive Styles and Online Communication

A significant body of work has attempted to describe the relationships between individual differences and adolescent online communication (Anolli et al., 2005; Chak & Leung, 2004; Madell & Muncer, 2007; Sheeks & Birchmeier, 2007). Researchers are particularly interested in finding out how personality traits such as introversion/extroversion, neuroticism, and psychoticism would affect adolescents' behaviors in online communication (Anolli et al., 2005; Chak & Leung, 2004; Madell & Muncer, 2007). Research on introversion and extroversion is polarized in terms of the impact of each of the above personality traits on adolescent online communication. Some researchers argue that since extroverted people are "social, needing to have people to talk to, and disliking reading or studying by him or herself" (Bianchi & Phillips, 2005, p. 41), the Internet which has no time and geographic limitation thus becomes an ideal place for them to establish their social network. Researchers in this school (e.g., Amichai-Hamburger, 2002; Bianchi and Phillip, 2005; Valkenburg & Peter, 2007) support the rich-get-richer hypothesis that extroverted people may be compensated by online social environments that make them become more socially involved in online communication. They also note that extroverted people could become addicted to online communication due to the flexibility, ease of control, and multiple synchronous connections among participants (Madell & Muncer, 2007).

Contrary to the assumptions that the extroversion causes people to become addicted to the Internet communication, researchers (e.g., Chak

& Leung, 2004; Widyanto & McMurran, 2004) who studied the relationship between introversion and online behaviors found that the Internet communication appeals to introverted people and the introversion may be the reason to cause people to become addicted to online chat. They argue that introverted people are usually socially shy and often have difficulty in developing relationships with others in a face-to-face setting, particularly when such relationship development is affected by the "gating features" when the individual perceives a self-defeating social inhibitor such as stuttering. Chak and Leung (2004) contend that because of the perceived control of online communication, introverted people are more likely to go to the Internet to meet their social and intimacy needs. With all the affordances of the Internet, that is, anonymity, flexibility, multiple interaction, and so forth, socially anxious or lonely people can be socially compensated by communicating online with others without being overly conscious about who they are or what they say, and at the same time feel that their self-image is safeguarded. This group supports the stimulation hypothesis, arguing that reduced visual and auditory cues in the Internet can alleviate the social anxiety that introverted people experience and *stimulate* them to develop positive relationships with others (Subrahmanyan, Smahel, & Greenfield, 2006; Tajfel, 1978).

As with the research of introvert and extrovert in online communication, studies on personality traits including psychoticism, neuroticism, and etc. have also drawn the attention of researchers. Psychoticism, according to Eysenck and Eysenck (1964), refers to people who are impulsive, hostile, and creative whereas neuroticism includes those who are shy, anxious, and depressed. Anolli et al. (2005) studied the impacts of neuroticism on individuals' online behavior and found a significant correlation between neuroticism and age in terms of online chatting, with similar findings for psychoticism. Conversely, studies by Bianchi and Phillips (2005) and Madell and Muncer (2007) found that neuroticism was negatively related to web usage such as online chat since neurotic people are often overly sensitive and would resist to sensitive talk posted anonymously (also see McKenna & Bargh, 2000). Both studies excluded neuroticism as a factor for influencing individuals' behaviors in online communication. Obviously, research on online communication pertaining to cognitive styles is inconclusive. Evidence from recent research indicates that further study is needed to better understand the relationship between learners' online communication behavior and their cognitive styles (Peter et al., 2005).

Peter et al. (2005) studied online social communication and behavior. Drawing from a sample of 412 Dutch adolescents, the authors found that the motives of social compensation, along with entertainment and meeting with people, increased adolescents' online communication with strangers. Interestingly, they found no correlation between introversion and adolescents' tendency to talk, a finding that ran counter to the results obtained by Chak and Leung (2004) and Widyanto and McMurran (2004). So far, research on social compensation and cognitive styles in online communication has been limited to Eysenck and Eysenck's framework that focuses on psychoticism, neuroticism, introversion, and extroversion. Few studies have been conducted to explore the relationship between social compensation and FD/FI cognitive styles in online learning. Since FD/FI represent robust cognitive styles related to learning (Witkin et al., 1977), studies on how FD online learners are socially compensated by their counterparts and vice versa would provide important information about as well as new perspectives on learners' online social communication patterns and behavior, thus enabling instructional designers and educators to design and develop strategies and methods that are effective for online learning.

THE STUDY

To understand how FD/FI cognitive styles and other related variables influence learners' online social communication and behavior, and how FD/FI learners differ in their social communication, a study was conducted with the research questions formulated based on the above literature. The specific research questions pertaining to this study are:

1. Is there a difference in performance between FD and FI learners in online discussion?
2. Is there a correlation between cognitive style and related factors such as self-confidence, support, interest, and motivation?
3. Is there a difference between FD and FI learners in terms of postings?
4. Is there a difference between FD and FI learners in terms of computer skills and online chat experience?

Description of the Study

Twenty seven undergraduate students were recruited from a teaching education program in a research I university in the western part of the United States. Participants registered for non-online courses with an on-online component (WebCT) where the online discussion was part of regular course requirements. Participants were asked to (a) complete a demographic questionnaire that collects information about gender, age, etc. and (b) take the Group Embedded Figures Test (GEFT) which measures field dependent (FD) and field independent (FI) learners (Oltman, Raskin, & Witkin, 2003). They then joined in an online discussion forum and were assigned to seven discussion topics over a period of 14 weeks during which time period they (1) self-posted their own comments and (2) critiqued other participants' comments. At the end of the study participants were asked to take a survey of online discussion.

About 15 percent of the participants (n = 4) were males and 85 percent were females. A majority of them (n = 20) were under age 25 with two between the age of 26-35, two between 36-45, and one over 45. About 26 percent (n = 7) reported having excellent computer skills, 63 percent (n = 17) having good computer skills, and 11 percent (n = 3) having poor computer skills. With regard to online chat experience, 85 percent (n = 23) reported having been involved in online discussion, and 15 percent (n = 4) reported having no experience at all. Of 27 participants, 17 reported having home access, 2 having work access, and 8 having campus access.

Instrumentation

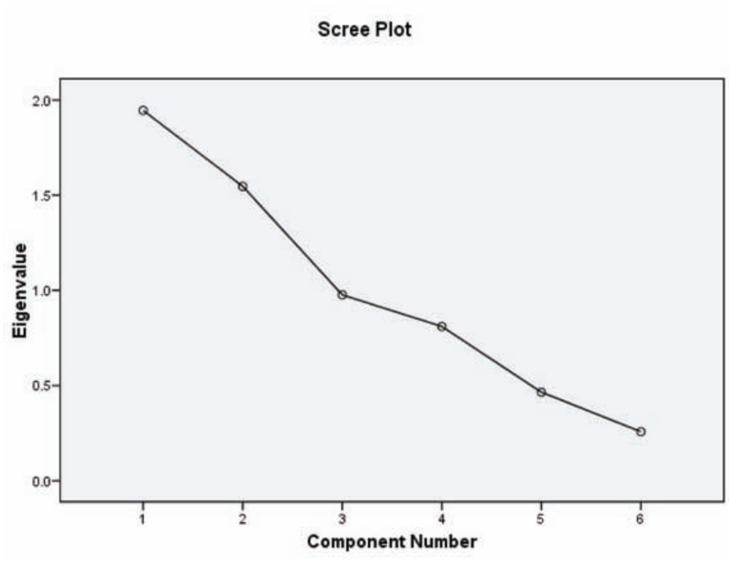
Group Embedded Figure Test (GEFT)

The GEFT was developed by Oltman et al. (2003). The test is designed to measure learners' perceptual ability. It consists of three sections with second and third sections being counted as valid GEFT test scores. The first section is not scored but can be used as reference for the final GEFT scores. Participants were provided with a sample form sheet that has eight sample figures. They were required to identify the embedded figure in the test item that matches one of the figures in the sample form. It took about 12 minutes to complete the entire test. The total possible score for the test is 18 points. A moderate-to-high reliability was reported for college students with a Cronbach alpha of .85 and .79 for males and females respectively.

Online Discussion Study Survey (ODSS)

The survey was developed by the first author based on social cognitive theories (Bandura, 1993); motivation (Keller, 1987); and social compensation (Peter et al., 2005; Valkenburg & Peter, 2007). The instrument contain ten items with items 1 and 10 probing into students' motivation, 3 and 9 for values, 5 and 6 for social compensation, 2

Figure 1. Scree plot for factors related to ODSS



for self-confidence, and 4 for social support. The instrument was reviewed by a panel of experts who have used online social communication tools in their instruction. Feedback from the panel members was carefully considered to further revise the survey. The survey uses a 5-point Likert scale with *Strongly disagree/Very low* = 1 and *Strongly agree/Very high* = 5 (Appendix I). The factor analysis was conducted to identify the factors related to ODSS. Figure 1 shows the scree plot of six factors. Three valid factors were extracted based on the criteria of (1) factor loading greater .40 (Hair, Anderson, Tatham, & Black, 1998) and (2) eigenvalue greater than 1. The factors and variances are presented in Figure 2. The instrument reports a medium inter-item reliability with Cronbach Alpha = .79.

Methodology

Several methods were employed pertaining to the research questions previously proposed. They

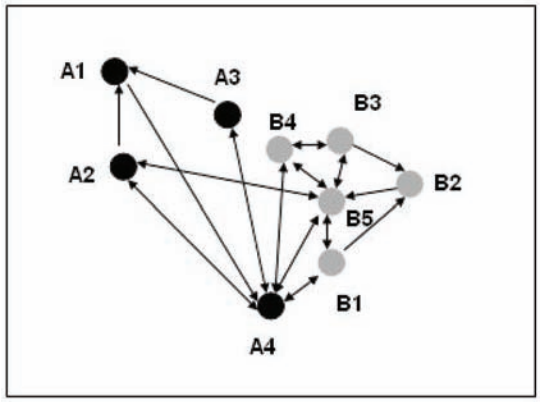
Figure 3. Sample of sociogram representing nodes and arcs



include social network analysis (SNA), correlation and t-test analyses.

Social Network Analysis

According to Willging (2007), SNA is widely used to analyze participation, interaction, and learning in asynchronous online discussions. It provided important applications for organizational behavior, inter-organizational relations, social support, and so forth. Although traditional statistical approach has been predominately used to analyze the behavior of online performance and learning, such an approach often emphasizes linear causal relationship while overlooking the structural characteristics of the interactions. SNA has been applied to a variety of problems, and they have been successful in uncovering relationships not seen with any other traditional methods.

As was mentioned above, SNA tried to unveil the patterns of people's behavioral interaction. SNA measures many structural characteristics of the network such as the existence of subgroups, the relative importance of individuals which are called actors or nodes, and the strength of the links between actors or nodes (Wasserman & Faust, 1994; Willging, 2007). While providing a complete treatment of the SNA methodology is out of the reach of this chapter, some basic definitions are needed to conceptualize the SNA. The following discussion focuses on key concepts pertinent to SNA (See Appendix II for a SNA vocabulary list).

Components of SNA. The component of SNA consists of a set of nodes and arcs, a sociogram, and a sociomatrix. The nodes which are otherwise called actors can be persons, organizations, or groups. The arcs are the relationships between the nodes. Their strength is measured by the distance between the nodes. The shorter the distance is between the nodes, the stronger the relationship will be. The sociogram is actually a graphic that visually represents the relationships among the nodes. It provides a diagram where researchers can analyze the patterns of group behavior. Finally, the sociomatrix or adjacency matrix delineates the relationship between nodes through a mathematical representation in the form of a matrix (Hanneman & Riddle, 2005). Figure 3 provides an example of SNA in which the relationships between nodes and arcs are presented in a sociogram.

Figure 3 shows two subgroups with dark nodes representing group A and light nodes representing group B. The relationships among the nodes are defined by the arcs (i.e., links). Group B shows a close relationship among the individuals due to the immediate distance among the nodes. In contrast, individuals in group A are less closely connected due to the remote distance among the nodes. Individual A4 plays a mediating role that connects group A and group B.

Density, centrality, and cohesion. In analyzing group social interaction the concepts of density, centrality, and cohesion are critical in explaining how individuals respond and react to people around them. The density of interaction in a social network means the proportion of all possible ties that are actually present. It is calculated as the sum of ties divided by the number of possible ties. Hanneman and Riddle (2005) noted that density is closely related to the power in a network system. According to Hanneman and Riddle (2005), the power is defined as the number of incoming and outgoing ties of the nodes, which is also known as the communication power among nodes. In a system that has low density, usually not much power can be exerted. Conversely, in high density systems there is a potential for greater power.

The concept of centrality describes how a particular focal node is related to other nodes. This is defined in terms of in- and out-degree of a node. That is, a node that has many ties may have access to (out-degree), and be accessed by other nodes (in-degree) in the network. For example, both A4 and B5 in Figure 1 have high in- and out-degree and are thus considered influential nodes. So, a very simple, but often very effective measure of a node's centrality and power potential is its in- and out-degree (Willging, 2007). Of particular interest to researchers is the betweenness of a node. That is, the intermediatory role that a node plays between groups of points. For example, A4 has a high level of betweenness. If B1 wants to access A2 or A3, it has to go through A4.

The concept of cohesion refers to the homogeneity of the subgroups or network. It is measured by the density, reciprocity, and Geodesic distances among the nodes (Hanneman & Riddle, 2005). The reciprocity ranges from 0 to 1, with 0 indicating minimum reciprocity and 1 maximum reciprocity. In a social network high symmetric reciprocity among the nodes indicates high degree of cohesiveness among the participants. Finally, the Geodesic distance is indexed by a distance-based cohesion ("compactness") which ranges between 0 and 1 with larger values showing greater cohesiveness.

Data Scoring and Encoding

For the purpose of t-test analyses behavioral data were obtained which included learners' performance in both online postings: self-posting and critiquing. They were scored by two researchers using a rubric with numeric values ranging from 1 = *poor performance* to 5 = *excellent performance*. The data were used to analyze participants' performance in online discussion.

Next, the SNA data encoding was performed. The encoding process focused on the presence of critiquing postings. For example, if participant A critiques participants B and C's viewpoints, he/she gets one point for each. If participant B critiques participant C but not A, he/she gets only one point. Then each participant was matched with his/her cognitive profile based on the results of GEFT test. The data were entered in the UCINET software (Borgatti, Everett, & Freeman, 2002) to create a matrix for social network analysis.

Results and Analysis

Records of online asynchronous discussions which were kept and archived in an online learning system (WebCT) were retrieved by the researchers for data analysis. A total of 541 online discussion messages were retrieved which were generated over a period of 14 weeks. The data were coded with a combination of letters and numbers to protect the anonymity of participants.

Specifically, the researchers were interested in finding out how FD and FI participants differed in online communication. To answer the above question, the SNA was employed to analyze the participants' behavior in online communication.

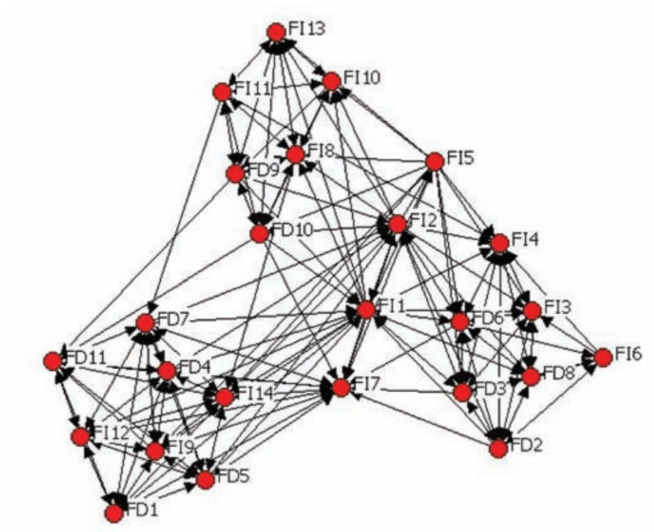
Results of SNA

The SNA analysis was performed with the UCINET software (Borgatti, Everett, & Freeman, 2002). A sociomatrix is presented in Figure 4 which delineates the social communication relationships between FD and FI learners in an asynchronous online forum. Based on the above results, a sociogram was created to display the relationship among members in online social community. Three social groups were formed as the result of the SNA analysis. Figure 3 indicates that FD and FI learners were distinctly separated into three groups generated by the UCINET software based on the input data. The sociogram identified focal actors (e.g., FI14, FI9, FI8, FI1, FI2, FI3, FI4, FD4, and FD6) who played a prominent role in organizing the group and implementing the online discussion, which was evidenced by the number of incoming and outgoing ties in the social groups.

Next, analyses on density, centrality, and cohesion of participants' online social communication were performed. Results showed a high degree of density (=.72), which means 72% of all possible ties are present. The analysis of geodesic distance revealed a moderate distance-based cohesion (= .609) which showed moderate-high cohesiveness among the members in the social

Figure 5. Sociogram for FD and FI online participants



network. The results showed that FI participants in general played a leading role in online social communication when online discussion involved critiquing and challenging others. In contrast, FD participants seemed to rely on the initiation of FI participants while engaging in online discussion (see Figure 5).

The tests of centrality, reciprocity, closeness (in- and out-closeness) and betweenness were conducted to explore the strength of social communication among the members. The Freeman's degree centrality analysis reported a mean degree of 10.4 (SD = 3.262). Results showed that focal actors (e.g., FI14, FI9, FI8, FI1, FI2, FI3, FI4, FD4, and FD6) played a central role in organizing and keeping the members together in online discussion (see Figure 6). They were prominent actors to whom many other actors sought to direct ties. The finding is further supported by the high reciprocity between the focal actors and their constituent members. As indicated, high reciprocity means high degree of cohesiveness among the participants.

To find out how participants responded to each other in online communication, the test of closeness was run which identified the incoming and outgoing ties of the participants. There was a consistency across the centrality, reciprocity, closeness (in-closeness and out-closeness) for the FI participants. That is, FI participants (e.g., FI14, FI9, FI8, FI1, FI2, and FI3) who scored high on centrality and reciprocity also scored high on closeness. They received more incoming and outgoing ties in social communication than did FD participants (see Table 4). However, FD participants (e.g., FD4 and FD6) who scored high on in-closeness did not score as high on out-closeness. This suggests that FD participants who did well on receiving incoming ties failed to reach out successfully to others. In this study both FD and FI participants received the same support in online discussion. However, due to their heavy reliance on external conditions/support, FD students needed more support than did their counterparts. Thus, it is possible that inadequate support led FD participants to fail to reach out to other participants in online communication. Finally, the results of betweenness indicated that FI participants played a critical role in mediating the group discussions. This is shown in Figure 3 in which FI1, FI2, FI5, and FI7 mediated between the participants from three discussion groups.

Figure 6. Centrality, reciprocity, closeness, and betweenness of social communication among online participants

FD2	6.000	0.434	50.000	46.290	17.241

Correlation Analysis

To answer research question two, a correlation analysis was performed with SPSS version 14.0. The following variables were entered for the correlation analysis. They are self-confidence, personal support, motivation, interest, complementary personality, and FDFI type. The results showed that motivation was significantly correlated with personal support ($r = .584$, $p < .01$), interest was significantly correlated with personal support ($r = .440$, $p < .05$) and motivation ($r = .530$, $p < .01$), complementary personality was significantly correlated with interest ($r = .445$, $p < .05$) and motivation ($r = .592$, $p < .01$), and value was significantly correlated with personal support ($r = .564$, $p < .01$), motivation ($r = .793$, $p < .01$), interest ($r = .487$, $p < .05$) and complementary personality ($r = .432$, $p < .05$). The correlations of FDFI with other variables were not significant. However, a marginal significant correlation was observed between FDFI and complementary personality (r = .361, p = .058) (Figure 7). This suggests that FD and FI learners perceived complementary personality as a contributing factor to the formation of online social community, which is consistent with the social compensation theory that posits people with different personalities and interests tend to draw toward each other as a gesture of social compensation. The finding is supported by the social communication pattern generated by the above SNA analyses where people with opposite cognitive styles worked closely together in online learning environment (see Figure 3).

t-Test Analyses

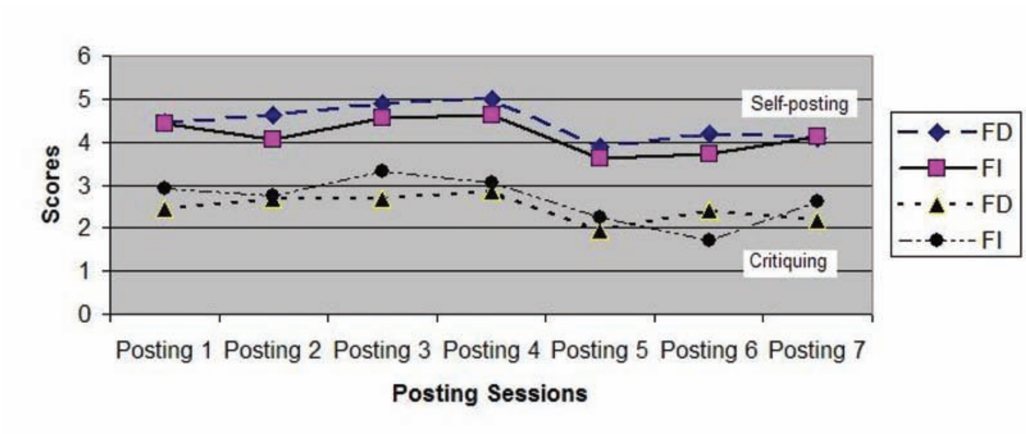
Research question three asked whether there was a difference in performance between FD and FI learners with regard to online postings. The independent variable which consists of two levels, that is, FD and FI learners was created based on the results of the GEFT test. The dependent variables which included self-posting and critiquing were obtained based on participants' performance scores. A *t* test was conducted. The means and standard deviations for online postings are reported as follows (see Figure 8).

Given the small sample size, the results of *t* test showed no significant difference between FD and FI learners in self-posting (t (25) = .875, p = .441) and critiquing (t (25) = -.438, p = .666). However, there was an interesting trend that differentiated FD learners from FI learners in terms of self-posting and critiquing others' messages. Figure 9 demonstrates that FD learners in general outperformed FI learners in self-posting, but didn't perform as well in critiquing. This finding is aligned with the literature that FD learners usually do well in a learning that provides structural support with salient cues. In self-posting, learning is structured around the topics. Therefore, FD learners were able to pick up the cues more easily in their learning. However, in critiquing, learning is dependent on learners' abilities to discern differences in viewpoints, organize relevant resources and develop abstract critical thinking

Figure 8. Descriptive Statistics for FD and FI Learners in self-posting and critiquing messages

		Postings						
	Field Type	1	2	3	4	5	6	7
Self Posting	FD	4.45 (1.50)	4.63 (0.67)	4.91 (0.30)	5.00 (0.94)	3.90 (1.04)	4.18 (1.40)	4.09 (1.57)
	FI	4.44 (0.36)	4.06 (0.34)	4.56 (0.26)	4.62 (0.25)	3.62 (0.70)	3.73 (1.83)	4.13 (1.72)
Critiquing	FD	2.45 (1.25)	2.68 (1.47)	2.68 (0.78)	2.86 (1.45)	1.95 (1.21)	2.40 (1.60)	2.18 (1.48)
	FI	2.93 (0.26)	2.75 (0.50)	3.31 (0.11)	3.06 (0.27)	2.25 (0.65)	1.70 (1.42)	2.63 (1.67)

Figure 9. FD and FI learners' performance chart



skills. Simply providing a structure with topics will not suffice as FD learners need

Research question 4 probes into the differences between FD and FI participants in terms of their computer skills and online chat experience. The t-test results revealed a significant difference between FD and FI participants for computer skills (t (25) = 2.714, p = .012) and a marginal significance for online chat experience (t (25) = -2.010, p = .055).

DISCUSSIONS AND CONCLUSION

Different from traditional learning environment, online learning can become quite challenging to both instructors and learners, partly because the learning cues that are observable in traditional classroom become non-existent in online learning, and partly because people often take with them the same traditional teaching and learning paradigms or even the same mentality as they move onto online environment (Zheng, 2006; Zheng & Ferris, 2007). The results of this study indicate that online learning should be designed differently from traditional learning. The following discussion will therefore focus on the important aspects of online instructional design with regard to cognitive styles, learning support, and critical factors related to the success of online learning.

Role of Cognitive Styles in Online Learning

The findings of the study show that cognitive styles can significantly impact learners' social communication and behavior in learning. The SNA revealed a consistent pattern across three online discussion groups where FD and FI learners collaborated in online learning (see Figure 3). According to social compensation theory, discrepancy among individual abilities created optimal conditions for mutual influence and resonance (Stroebe et al., 1996). Research in online communication supports the above conclusion, showing a strong correlation between individual differences and patterns of communication in an online environment (Chak & Leung, 2004; Widyanto & McMurran, 2004).

There is a difference between FD and FI learners with respect to their roles in online community. It appears that FI learners were more active in initiating discussions and had more in- and out-connections among group members. This is especially true when learning involved critiquing others' viewpoints, in which critical thinking skills were demanded. Based on the findings of the study, it is suggested that the design of online instruction should put cognitive styles in perspective, particularly when the design involves developing and promoting high level thinking skills.

Learning Support for FD and FI Learners

When designing instruction to develop learners' critical thinking skills, it is essential that such instruction include adequate support for FD and FI learners. Results from the study showed that FD learners need clear instructional directions and salient cues in learning. This is consistent with the literature pertinent to the instructional conditions for FD learners. The study found that the FD learners performed less well when they engaged in learning activities that required them to critique others' messages than when they self-posted the messages (see Table 6 and Figure 4). The difference in FD learners' performances for two learning tasks was most likely due to (1) a change in the task demand, i.e., moving from posting messages to critiquing others' messages, and (2) a lack of support to match the task demand. For FD learners, providing support such as giving detailed steps, multiple cues, embedding questions, including an advance organizer, etc. would help them succeed in learning. Likewise, providing abundant content resources, employing inquiry and discovery methods, encouraging self-initiated questions, etc. would give FI learners the kind of support they need to be successful in online learning.

Factors for Successful Online Learning

As discussed above, cognitive styles and learning support are important in online learning. However, based on the findings of the study, other factors like complementary personality, interest, motivation, support and value have shown to be significantly correlated in online learning (see Table 6). Factors like complementary personality, support and value are significantly correlated with interest and motivation – the two most important factors in learning. Additionally, computer skills and online chat experience were seen to influence learners with different cognitive styles. Effective utilization of these factors to leverage online social learning is important for teachers and online trainers.

One of the messages that online instructional designers can probably carry home from this finding is that designers should examine the roles and function of complementary personality, support and value as they design and develop instruction to get learners interested and motivated in online learning. It is thus suggested that online research should encompass a larger context in which cognitive styles, motivation, interest, learning support, value, and so forth are examined to better understand the factors contributing to the success of online learning.

Limitations of the Study

There are several limitations to the study. Firstly, the small sample size affected the statistical power in t-test analysis which explained the reason why no significance was found for self-posted and critiquing postings. Secondly, the population was limited to one university with primarily educational major students. This could affect the generalizablity of the findings. However, this was a pilot study that would hopefully lead toward a series of more in-depth studies in this area. In fact, the initial findings have already pointed to the need of developing effective instructional intervention to mitigate the difference between FD and FI learners' abilities in critiquing and challenging other people's viewpoints.

In conclusion, this study has provided initial evidence that social compensation is shown to be one of the factors that accounts for the social communication pattern among learners with different cognitive styles. It also shows that other factors such as interest, motivation, support, value as well as learners' computer skills and online chat experience may play important roles in influencing FD and FI learners in online social communication. Results indicate that adequate support is essential for FD learners to obtain positive experience in online learning. It is suggested that future studies should investigate the role of support and its design mechanism so that both FD and FI learners can benefit from this unique form of learning.

ACKNOWLEDGMENT

APPENDIX A

Online Discussion Study Survey

Please circle one of the following that mostly reflects your experience of web-based learning. (Table 2)

Table 2.

Items	1	2	3	4	5
1. The online discussion mode can motivate learners to engage in meaningful learning.	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
2. When I was discussing online with other people, my level of self-confidence was	Very low	Low	Don't know	High	Very high
3. The online discussion is an effective tool for social communication	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
4. The online discussion builds up positive support among students	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
5. The rule of complementary personality applies to online discussion as people like to hang around with those of opposite personality	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
6. The rule of congeniality works in online discussion because people like to hang around with those of similar personality	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
7. The rule of complementary personality applies to online discussion as people hang around with those of different interest	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
8. The rule of congeniality works in online discussion as people like to hang around with those of similar interest	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
9. Individuals would be likely to retain in online discussion if they value what they have learned in online	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree
10. Individuals would be likely to retain in online discussion if they are motivated by what have learned in online	Strongly Disagree	Disagree	Don't Know	Agree	Strongly Agree

Appendix B

Vocabulary list for SNA Analysis

Arcs: Arcs are the relationships between the nodes. Their strength is measured by the distance between the nodes. The shorter the distance is between the nodes, the stronger the relationship will be.

Betweenness: Betweenness of a node refers to the intermediatory role that a node plays between groups of points.

Centrality: Centrality describes how a particular focal node is related to other nodes. This is defined in terms of in- and out-degree of a node. That is, a node that has many ties may have access to (out-degree), and be accessed by other nodes (in-degree) in the network. A very simple, but often very effective measure of a node's centrality and power potential is its in- and out-degree.

Cohesion: Cohesion refers to the homogeneity of the subgroups or network. It is measured by the density, reciprocity, and Geodesic distances among the nodes. Reciprocity ranges from 0 to 1, with 0 indicating minimum reciprocity and 1 maximum reciprocity. In a social network high symmetric reciprocity among the nodes indicates high degree of cohesiveness among the participants. Finally, the Geodesic distance is indexed by a distance-based cohesion ("compactness") which ranges between 0 and 1 with larger values showing greater cohesiveness.

Density: Density of interaction in a social network means the proportion of all possible ties that are actually present. It is calculated as the sum of ties divided by the number of possible ties. Density is closely related to the power in a network system which is defined as the number of incoming and outgoing ties of the nodes, which is also known as the communication power among nodes. In a system that has low density, usually not much power can be exerted. Conversely, in high density systems there is a potential for greater power.

Nodes: Nodes which are otherwise called actors can be persons, organizations, or groups.

Sociogram: Sociogram is actually a graphic that visually represents the relationships among the nodes. It provides a diagram where researchers can analyze the patterns of group behavior.

Sociomatrix: Sociomatrix or adjacency matrix delineates the relationship between nodes through a mathematical representation in the form of a matrix.

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of social computing. Particular contributions address the importance of guarding corporate data from social engineering attacks and explore a professional social network system. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how social computing can impact and inform practices and behavior.

Chapter 6.1

Exploring a Professional Social Network System to Support Learning in the Workplace

Anthony "Skip" Basiel
Middlesex University – IWBL, UK

Paul Coyne
Emerald Group Publishing Ltd, UK

ABSTRACT

This chapter sets out to explore how professionals can network, collaborate and capture informal learning in an online work-based environment. It addresses the pedagogical approaches that underpin emerging Web 2.0 technological trends and provide recommendations for future use of such online environments. Existing Virtual Learning Environments (VLEs) are primarily content driven with little provision for social engagement and stakeholder-generated material. Similarly, many organisations have little or no structure for facilitating online interaction in a work based learning context. Since 2006 Emerald Group Publishing and the Middlesex Centre for Excellence in Work Based Learning have been partnering to develop, test and implement an online platform that will support collaborative, interactive learning. This link between Industry and Higher Education is critically reviewed. The InTouch (2008) platform was incorporated into the syllabus for MCEWBL's work-based Professional Practice BA Honours programme in 2007 to support newly trained professionals as they worked through a professional development work based learning programme. The pedagogical underpinning of the course was reflective, self-directed learning and the blog, Wiki and profiling tools provided had the potential to either contribute to this aim or become a major part of how students construct their understanding of themselves in their professional practice. Emerald and MCEWBL have been monitoring the adoption, use and challenges associated with using Web 2.0 technology to support work based learning in order make recommendations about future pedagogical frameworks and approaches. This platform and related online pedagogic principles fills the gap between informal, free tools that provide little security or structure and heavyweight VLEs that offer tutor-made content, but do not naturally support social interaction for learning. The chapter provides some ideas and strategic options about implementing

DOI: 10.4018/978-1-60566-272-5.ch001

similar tools in other organisational settings and provides frameworks to evaluate these options in line with existing resources and capabilities. It concludes with an in-progress web-based learning design or ePedagogy that unifies the threads of the online learning experience.

INTRODUCTION

Middlesex University work based learning (WBL) has been operating for over ten years at the time of this writing. Its original distance learning design was a paper-based correspondence model which relied heavily on the content in the handbooks and one-to-one (1-2-1) tutorial support from WBL Learning Development Tutors predominantly through email and phone feedback. Over the past few years there has been a steady transition into the use of a commercial virtual learning environment (VLE) in the form of Blackboard/WebCT.

At first this system matched the WBL teaching and learning design since there was a strong reliance on the course handbook for information and guidance. However, as student numbers increased the student-teacher ratio meant this model was not sustainable for the future. The 1-2-1 pedagogic model would need to expand into a triad that would promote and support peer involvement. Students were growing in their ICT confidence and capability with the increased use of Web 2.0 social network systems such as Facebook and YouTube. This was evidenced by student representatives at the WBL Board of Studies sighting the need to continue to improve the VLE for the future (BOS, 2007).

Cohorts of WBL candidates identified the need for a shift from a content-driven eLearning system to one which could support the type of peer review that WBL was growing into. The WBL programme structure has three main stages. First, students construct a portfolio of their prior professional knowledge. This Recognition of Accredited learning (RAL or a.k.a. Accreditation of Prior Experiential Learning (APEL)) stage benefited by candidates sharing professional experiences in constructing their areas of learning claims (Armsby, 2006). Next, WBL students would formulate an individual learning agreement that would guide the construction of the degree programme based on how much Higher Education (HE) credit was attained in the RAL stage. In conjunction with this activity they would learn about methods of conducting research in the workplace which would prepare them for the final stage of the degree. Lastly, research systems would be carried out in the workplace to amass enough credit to complete the programme. The nature of this learner-managed-learning approach to WBL meant that as the candidate progressed through the programme peer-support became increasingly beneficial (Stephenson, 2007).

In a work based learning context, then, there can be both a *formal* and *informal learning* scenarios. The traditional formal learning setting might be one of the blended learning tutorial sessions for WBL candidate getting an induction on how to compose a prior learning accreditation portfolio. Here the training pedagogy would be teacher-led and supported by on/offline discussions. But it could be argued that the ‘real learning’ transpired informally after the ‘taught session’. Informally the students may meet to debrief with each other at the café over coffee. There they would compare their interpretation of the learning event which would lead to the formation of learning partnerships. This learning support network would communicate to provide peer-review of draft work for the portfolio. An online system was needed to facilitate this evolving professional social network for practitioner researchers.

It was at a conference at University College London (2006) that a dialogue opened between the MU-WBL group and the Emerald Publishing InTouch contingent. The open source Elgg Social Network platform being developed by Emerald would be the new approach to address these needs.

A university / industry partnership association was also a positive deliverable of this network collaboration. Emerald Publishing had a good test bed and source of evaluation data in the WBL pilot case study group. This is discussed in detail later in the chapter. The Institute for Work Based Learning benefited by having a professional social network to support its learners. Additionally, both groups collaborated in scholarly activity. Co-authored research system proposals were written for JISC (2008) in the UK and the FP7 European Commission (2008).

Another joint effort was seen in international conference publications and poster-demo presentations. The 7th European Conference on e-Learning (2008) held in Cyprus gave both organisations the opportunity to get feedback from the eLearning community and share the services they provide to potential clients. Future collaborations are currently being investigated.

A PROFESSIONAL SOCIAL NETWORK (PSN) APPROACH

A variation of social networking focuses on a professional context which demonstrates how an innovative combination of existing technologies and interoperability standards can be harnessed to support the learning paradigm shift taking place from learning by knowledge transfer to learning by knowledge construction. This next section of the chapter discusses a European Commission (FP7, 2008) project proposal.

The PSN group brings together a range of extant and emerging standards and technologies to provide a next generation platform for Technology Enhanced Learning that will have a significant impact on learning outcomes.

The PSN enables:

- Faster and more effective learning, acquisition of knowledge, competences and skills.
- Unlocking people's and organisations' ability to master knowledge and apply it.
- Increased knowledge worker productivity.
- More efficient organisational learning processes.

System Outcomes

The motivating factor for the technology objectives is not the technology itself but the comprehension and application of specific technology in the service of learning and development.

Our semantically rich PSN platform promotes networked learning by connecting stakeholders in real-time through an agent or 'mentor-help' system. This can be achieved through a combination of technologies and standards, including the Elgg server, RDF (Resource Description Framework), SKOS (Simple Knowledge Organisation System) and FOAF (Friend of a Friend). Interoperability with existing services and standards ensures the long term sustainability of the system. Therefore the PSN, where possible, offers users the ability to search across currently popular network sites using a web services approach – e.g. OpenSocial, OpenID, FaceBook, and Explode.us.

Social and Organisational Learning Objectives

Our initial proposition is that effective learning in a networked society includes the natural discovery of learning resources, contextualised support services (i.e. Mentor-Help) and the mining of personal profiles, opinions and social networks, wherever they are located. Specifically, the system aims to develop a deep understanding of the pedagogies and technologies required to exploit the strategic learning opportunities that a richly connected society offers European businesses, government agencies and academic organisations.

The system also aims to advance the collective understanding of the issues involved in deploying and integrating PSNs in organisational learning infrastructures. This work uncovers reasons for success or failure and asks if these outcomes are related to culture, technology or something else entirely. The findings help inform non-technological strategies for organisations attempting to exploit these new tools to achieve and sustain EU competitive advantages regardless of industry or sector. As such, the system models are scalable and flexible for re-use.

System design should allow for scalability in the provision of adding languages to the system database:

- This would allow real-time text communication in a trans-national fashion.
- Support system can be accessed via mobile interfaces via text and/or voice.
- Feedback from the support system will factor in psychological considerations to match appropriate levels of help to the user making the query.

An intelligent and adaptive support system provides end-users with the resources to engage confidently with the network members and maintain motivation within the online community.

Technology Objectives

The PSN group are developing a next-generation multi-modal, multi-lingual professional social networking platform with the following characteristics:

- **Organisational Design:** Structurally neutral to allow a generic PSN to be deployed to academic, corporate or government organisations.
- **Simple System Design:** Scaleable and portable and easy to deploy technology that requires little or no overhead to existing IT investments.
- **Plug-in Technology Architecture:** Can be flexed in a number of directions to support content and services supporting many subjects/disciplines and industry sectors through the addition or removal of plug-in software modules.
- **Open Standards Compliant:** SKOS, SIOC, FOAF, OpenID, OpenSocial.

Progress Beyond the State-of-the-Art

We can form a common ground of understanding that the '**state of the art'** is *the current stage of development of a practical or technological subject; freq. (esp. in attrib. use) implying the use of the latest techniques in a product or activity* (OED Definition 2008).

In this section we broadly define the 'State of the art' for the key technical and infrastructural and pedagogical components of the system. We refer to both the theory and practice surrounding:

- Social networks
- Semantic web
- Organisational learning models of European SMEs
- Mobile and Multimodal interfaces for social and professional activities via web platforms

Once the state of the art has been defined we proceed to describe how the PSN system moves beyond what is currently the state of the art in order to achieve the goals of the system.

In an attempt to understand the current state of the art, as it relates to the strands of development of the PSN we have carried out an extensive literature and patent review.

Social Networking and the Semantic Web

Social networking web sites fostering the development of explicit ties between individuals as "friends" began to appear in 2002. Sites such as Friendster, Tribe, Flickr the Facebook and

LinkedIn were early examples. Less explicitly based on fostering relationships than, say, online dating sites, these sites nonetheless sought to develop networks or "social circles" of individuals of mutual interest. LinkedIn, for example, seeks to connect potential business partners or prospective employers with potential employers. Flickr connects people according to their mutual interest in photography. And numerous sites offer dating or matchmaking services. Emerald InTouch connects researchers, academics and practitioners concerned with, amongst other things, management theory and practice, publishing, learning and research.

The semantic web, as originally conceived by Tim Berners-Lee, "provides a common framework that allows data to be shared and reused across application, enterprise, and community boundaries" (W3C, 2001). Developed using the resource description framework (RDF), it consists of an interlocking set of statements (known as "triples"). "Information is given well-defined meaning, better enabling computers and people to work in cooperation" (Berners-Lee et al., 2001). The semantic web is therefore, a network of statements about resources.

Outside professional and academic circles, arguably the most widespread adoption of the semantic web has been in the use of RSS. RSS, known variously as rich site summary, RDF site summary or really simple syndication, was devised by Netscape in order to allow content publishers to syndicate their content, in the form of headlines and short introductory descriptions, on its My Netscape web site (Downes, 2000). The use of RSS has increased exponentially, and now RSS descriptions (or its closely related cousin, Atom) are used to summarise the contents of hundreds of newspapers and journals, weblogs (including the roughly eight million weblogs hosted collectively by Emerald InTouch, Blogger, Typepad, LiveJournal and Userland), Wikis and more.

Initiatives to represent information about people in RDF or XML have been fewer and demonstrably much less widely used. The HR-XML (Human Resources XML) Consortium has developed a library of schemas "define the data elements for particular HR transactions, as well as options and constraints governing the use of those elements" (HR-XML Consortium, 2005). Customer Information Quality TC, an OASIS specification, remains in formative stages (OASIS, 2005). And the IMS learner information package specification restricts itself to educational use (IMS, 2005). It is probably safe to say that there is no commonly accepted and widely used specification for the description of people and personal information. As suggested above, developments in the semantic web have addressed themselves almost entirely to the description of resources, and in particular, documents.

Outside the professional and academic circles, there have been efforts to represent the relations between persons found in social networks explicitly in XML and RDF. Probably the best known of these is the Friend of a Friend (FOAF) specification (Dumbill, 2002). Explicitly RDF, a FOAF description will include data elements for personal information, such as one's name, e-mail address, web site, and even one's nearest airport. FOAF also allows a person to list in the same document a set of "friends" to whom the individual feels connected. A similar initiative is the XHTML Friends Network (XFN) (GPMG, 2003). XFM involves the use of "rel" attributes within links contained in a blogroll (a "blogroll" is a list of web sites the owner of a Blog will post to indicate readership).

Currently there is little in the way of personal description in the semantic web. The vast majority of XML and RDF specifications identify persons (authors, editors, and the like) with a string rather than with a reference to a resource. And such strings are ambiguous; such strings do not uniquely identify a person (after all, how many people named John Smith are there?) and they do not identify a location where more information may be found (with the result that many specifications require that additional information be contained in the resource description, resulting in, for example, the embedding of VCard information in LOM files).

The Learning Organisation and Networks

A recent benchmark study from Nemertes Research (2007) showed that 83 percent of organisations now consider themselves to be "virtual" with workgroups spread across multiple locations and geographies. The workforce is increasingly mobile. According to Nemertes, fully 91% of company employees do at least some work outside of traditional headquarter locations, and 96 percent use some form of real-time collaboration tools (e.g. IM, Web or audio/video conferencing).

But Nemertes also found that only 43% of global organisations had a mobility strategy (with another 26% currently developing one). Among US and EU based companies, only 35% had a strategy, with another 16% having one in development; thus, almost half of US and EU enterprises have no organisation-wide strategy for supporting the needs of the mobile workforce. Even more noteworthy, only 15% of all organisations interviewed had a specific mobility budget.

Although collaboration is an increasingly vital feature of business life, companies often promote collaboration indiscriminately. Directive mandates to "just collaborate" create confusion and bottlenecks, diminishing organisational effectiveness (Cross et al., 2004). Creating a business case for exploring and creating cooperative workplaces seems to be more fitting. The word cooperative is defined as the engagement in joint economic activity. It also suggests an enterprise may be operated jointly by those who use its facilities or services.

It is also clear however from the following research, and from Nemertes, that the competitive advantages that can be created through the networked relationships formed in the pursuit of learning and training is uneven.

However, co-operation between organisations within markets has long been identified as a factor in economic success and networking between organisations can contribute to stability and reduce uncertainty (Porter, 1990). These networks can evolve over time as 'natural' clustering's of enterprises, or can be 'induced' artificially as a result of interventions like the development of business or science parks.

Mobile and MultiModal/ MultiLingual Social Networks for Organisational Learning

A key design requirement of a Professional Social Network is that is should be able to support multiple languages and modalities.

A brief survey of Social Professional networking sites that exhibit mobile characteristics produced list shown in Table 1.

Many of these sites and services offer a simplified location-based service for connecting with friends and groups to coordinate activities and stay in touch and have little impact or relevance to issues of work based or organisational learning.

However new developments centred on the convergence of location based services, social networking and semantic web are underway. Artilium (2008), a US based provider of enhanced mobile communications is leading the way on next

generation context-aware services, presence and personalisation in the mobile networking arena and their expertise in this area is acknowledge. The PSN team however believe that many of the characteristics of the Artilium offer can be provided through the applied combination and improved interoperability of the component parts the PSN team bring to the system.

Additional searches through the patent registers of the EU, Europe and the US highlighted some basic work in this area from the private sector.

Standards and Interoperability

The Social Networking phenomenon, as described in the previous section began to appear in 2002. Sites such as Friendster, Tribe, Flickr the Facebook and LinkedIn were early examples. Recently there has emerged a move towards the standardisation of Social Network Profiles in an attempt to manage Access and Identity Management (AIM) and provide more opportunities to connect across networks from LinkedIn, Google, FaceBook and so on. Such a development is often referred to as OpenAPI.

Open API (often referred to as OpenAPI) is a word used to describe sets of technologies that enable websites to interact with each other by using SOAP, JavaScript any other web technology. While its possibilities aren't limited to web-based applications, it's becoming an increasing trend in so-called Web 2.0 applications including social and professional networks. The term API stands for Application programming interface. With the advent of the Facebook Platform, launched June 1st 2007, Facebook incorporated an OpenAPI into its business model.

OpenSocial is currently being developed by Google in conjunction with MySpace and other social networks including Bebo.com Engage.

com, Friendster, hi5, Hyves, imeem, LinkedIn, MySpace, Ning, Oracle, orkut, Plaxo, Salesforce.com, Six Apart, Tianji, Viadeo, and XING. The ultimate goal is for any social website to be able to implement the APIs and host 3rd party social applications. Explode.US is the OpenAPI of the Emerald InTouch platform.

Beyond State of the Art?

The previous section reviewed developments and current capabilities in:

- Social & professional networks
- Semantic web
- Organisational learning
- Mobile and Multimodal Interfaces to social networks
- Standards and interoperability

We identified the key technologies, trends and theories that one should be aware of in any discussion of professional networks, interoperability and organisational learning as seen in Table 3.

Development of a Semantic Web Capability within a Mainstreamed and Practical Platform for Organisational Learning

The links found in the web pages of social networks are instances of what are known as "weak ties". Weak ties are acquaintances that are not part of your closest social circle, and as such have the power to act as a bridge between your social cluster and someone else's (Cervini, 2005).

As matters currently stand, if I conducted a search for "social networking" then probability dictates that I would most likely land on the pages of Tony Karrer, since he is cited in most places I am likely to find through a random search. But Karrer's organisational affiliation and location may be very different from mine; it may also be preferable to find a resource authored by someone who shares my own perspective more closely or is, geographically more convenient. Therefore, it is reasonable to suppose that if I were to search for a resource based on both the properties of the resource and the properties of the author, I would be more likely to find a resource than were I to search for a random author.

Such a search, however, is impossible unless the properties of the author are available in some form (something like a FOAF RDF file), and also importantly, that the properties of the author are connected in an unambiguous way to the resources being sought.

The explicit conjunction of personal information and resource information within the context of a single distributed search system will facilitate much more fine-grained searches and levels of rich interactivity than either system considered separately.

A convergence of these disparate technolo-

gies brought together in a unified and applied format represents a true step beyond the current state of the art in Professional Social Networks for learning.

Figure 2 presents a simplified schematic of the PSN. With reference to Figure 1, it is now possible to perceive the step forward in interoperability and the concomitant benefits for personal and organisational learning that the PSN offers.

Mobile and MultiModal Interfaces to Social Networks: The PSN Agent

The PSN agent provides a natural language style interface to the people and resources of the site. By employing 'Call-Centre-like technology' any user will be able to call the PSN and submit a request to the agent facilitating a natural, although remote, interaction with the PSN to discover network human resources and content.

The agent and the PSN platform interact with each other as a direct benefit from the newly developed semantic profiling work provided through the FOAF module and the inclusion of a SKOS conformant ontology. Such interactions allow for complex queries to be made in a natural and language neutral fashion. We believe this represents a step forward in multilingual and Multimodal access to professional social networks.

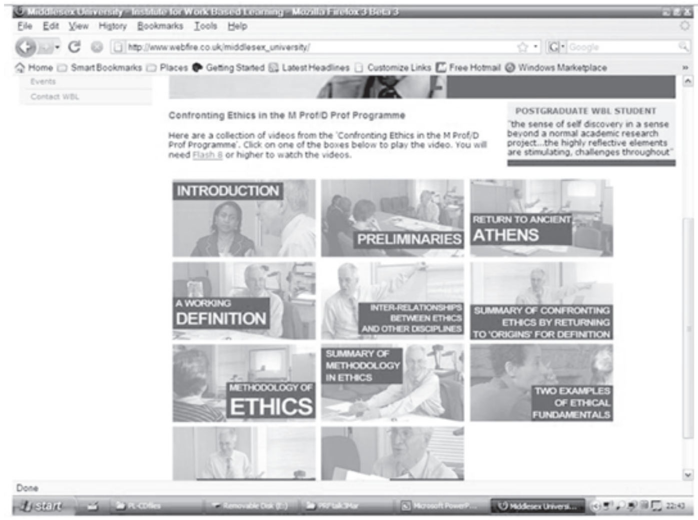
Adoption and Support

The biggest threat to the system is that we have a well designed online Professional Social Network that no one uses. Our answer to this challenge is addressed by our New Media Induction design. First, state of the art of induction and training applies a marketing approach. The pedagogic design of the induction is closer to a movie trailer or television advertisement than the traditional instructional design. Information is provided in smaller chunks with an emphasis on building personal connections as much as learning how to use the system. Next, our blended approach to dissemination is taken to this induction process. A face-to-face session is sandwiched between online sessions to strengthen motivation. Figure 3 shows a collection of short 10 minute digital videos that are used to reinforce the issues addressed in the induction process.

The innovative PSN induction pedagogic design builds on the members' prior knowledge of ICT systems and human networks to apply to our new eLearning environment. Just-in-time/

Figure 3. New Media captioned web video



case pedagogic design appeals to the full-time workplace based learner in our busy knowledge economy.

Standards and Interoperability: The PSN API

The current methods of accessing disparate social and professional networks are limited. However, as mentioned in the previous section, there is much work underway to develop an OpenAPI approach to network connectedness. Mobile and Multimodal access is developing at a variable rate but is limited to leisure and social networks.

The work of the PSN team seeks to build upon the work of the SIOC, SKOS and FOAF working groups and in addition seek to incorporate the work of the OpenSocial and OpenID movements to ensure the long term sustainability and interoperability of the PSN.

The PSN API and in particular the documentation supporting the architectural development work will we believe provide other groups with a solid basis for extending and creating professional and social sites which will be quite different from the PSN but backwards and forwards compatible dues to the adoption and integration of multiple and non-proprietary standards.

CASE STUDY

The following case study explores the use of Emerald InTouch (2008) social network environment where the programme tutor, Alan Durrant, shared his experience:

… I thought about how to use Web 2.0 technology as part of my teaching (and) considered the requirements of learners coming onto the Professional Practice BA Hons. programme. The course is for professional performing arts students (i.e. dancers, musicians or actors) where training has been very hands-on and directed. I wanted to give these students a higher education experience counter to this approach, where they would have to take much more autonomous control over their programme of study. The pedagogical underpinning of this method is reflective, self-directed learning. I wanted to help students develop their career management, critical and reflective skills in order to pursue their career more effectively.

The biggest challenge for the pilot study was that of adoption. Although it was one of the course requirements to use Emerald InTouch, there were mixed levels of usage. Some students regularly posted blogs and updated their profiles, whereas others did not log-on since the induction sessions. Durrant said he "*adopted an approach of strong encouragement"*. As he points out:

there are always going to be questions about how a system like InTouch fits into an academic programme. My feeling is that students are often busy people who may not take time to reflect and will simply do what they need to do to complete the course. So if we want to develop them as reflective practitioners then we have to create situations where they are forced to reflect.

One of the ways to do this would be by replacing assignments with assessment of the effectiveness of a students' contribution to the collective discussions on the blog or the wiki:

This approach may be something we consider at Middlesex, but at present we are starting by creating situations where students must record reflections via InTouch without the assessment imperative. At the start of the course this was very tutor-driven but we are now seeing more peer-to-peer interaction as compared with a lot of e-learning systems. InTouch is very intuitive. However, like any system, you need to use it often enough to feel confident on it. We have found that the students that did not attend the induction session took a long time to understand the system. Next year it will be essential for students to attend the (face-to-face or online) induction where we will carry out a more in-depth introduction to this platform.

Alan's conclusions highlight the importance of a well designed new media induction resource. If you want to use this type of social network system, it is important to identify the value of the new media system induction that can be designed to engage the stakeholders of the Professional Social Network (PSN) System.

As well as student usage, it has also been important to ensure that there are protocols in place for the tutors. Durrant acknowledges that he also had to do some work to ensure complete familiarity with the platform and also to regularly check InTouch for comments and new blog posts as, he asserted, "*There was nothing more demoralising than posting a comment and your tutor does not respond to because they have long since stopped checking the site*." In response the Emerald technical team have added an 'alert tool' to email when changes are made to the system.

Basiel (1999) refers to this accessibility issue as a 'push-pull learning preference'. Some online learners like to go to a website or learning system to engage with the learning resources or communication / collaboration tools. They 'pull' their learning from the system. Others prefer to have prompts sent to them. This may take the form of an email alert or a text SMS message to their phone. This preference may differ for the various functionalities of the VLE. For example, the learner may want to have a text message sent when a new meeting is posted in the online diary, but not get an alert every time someone enters a message on the text discussion board.

This 'media literacy spectrum', as coined by Basiel et. al. (2008) can be observed when developing the learners' profile. Some attributes are summarised in Table 4.

A functionality of the platform was the profiling tool which connected students through shared interests, research areas, courses or via a simple keyword search. According to Durrant, "(this) tool was extremely helpful because students would be coming onto the programme largely, if not completely working at a distance. Keyword linking made instant connections between people with the same interests, a great icebreaker." Campus based induction focused on the profiling tool to allow students to become familiar with the

Push-pull preference	*Tend to go to sources of knowledge*	Tend to have up-to-the-minute information sent

system. Many of the students were already using social software such as Facebook and were more comfortable about uploading information about themselves rather than starting off with some sort of course-related or professional blog.

An instantiation of the success behind the pedagogic design of the system to develop an online community was demonstrated by one of the distant (off-campus) German students inviting a UK colleague to visit over the Christmas holiday. This comradery was fostered through the InTouch online social system design.

SUMMARY DISCUSSION

This chapter has addressed some interesting issues about the evolution of learning from an individual face-to-face context to one of an online professional social network model. We have stressed the importance of examining the underpinning pedagogic designs of the learning systems to guide the appropriate choice of online support tools.

In summary now we provide a critical discourse in the current 'gap in state of the art'. The main issues concerning social networks that are flourishing on the web now focus on the Web 2.0 semantic web design. Present tagging conventions are not adequate to progress the value of the systems forward. Accessibility to multimodal interfaces is improving with mobile systems, but there is a need to adapt and apply pedagogic design principles from this chapter to improve mobile performance. Standards and interoperability is in its early stages with web 1.0 content. More work is needed to synthesise these guidelines to professional social network system.

The case study offered in this chapter provided us with a grounded experience of using a professional social network. Both barriers and lessons learnt are now highlighted.

Barriers to professional social networks:

- **Adoption:** How can we get full-time working professionals to use a PSN? No evidence has emerged in this chapter to suggest that a 'silent member' of the PSN is not learning. Further studies are needed to challenge this possible misconception.
- **Induction design:** To address the concern about active participation through to the completion of the eLearning event the value of new media design was emphasised.

Traditional instructional design training strategies should be challenged in this new PSN context.

Lessons learnt from the case study:

- **Protocols:** Communication and collaboration guidelines are needed to be made explicit in a PSN system. A mix of top-down (managers) and bottom-up (learners) approaches should be taken to get feedback from PSN stakeholders. These protocols are negotiable over time and will continue to adapt with the flexibility of the system.
- **Evaluation:** The PSN must have in place an evaluation strategy and associated technical system. Through the constant collection and analysis of data from PSN stakeholders the natural evolution of the system can continue.

The closing thoughts for our chapter on professional social networks offer some recommendations to those readers that may want to venture into this area of organisational eLearning:

- **Establish learner's profiles:** Profiles of the PSN members should be done at several levels. First, a feasibility study will show the needs identified by the stakeholders. Next, personal Web 2.0 profiles identify learning styles and preferences.
- **Define the type of VLE (online pedagogy):** Will the eLearning model be content driven with a strong set of digital resources? Or, will the focus be on the communication and support needed to network and collaborate?
- **Define the tools to use (eg: blogs, Wikis, etc.) and the deployment strategy (eg: how many and at what stage):** Appropriate eLearning toolsets should be mapped over from the PSN member profiles.
- **Design induction pedagogy and new media presentation:** Get good initial motivation to promote a culture of change to adopt regular use of the PSN. By getting its use to be part of the daily routine you can address drop out prevention.
- **Explore organisational learning for your context:** Can you progress individual learning to a networked context? What system changes will be needed to adjust for this scalability?
- **Plan a shift to a professional network context:** How can you adapt existing eLearning protocols and systems to a PSN context? Or, will it be easier to start over fresh with a new system?
- **Decide on the appropriate online support model for your PSN:** The range of support may range from a static FAQ to mobile web bot agent model. From your feasibility study data pick an appropriate set of tools to provide academic, technical and administrative help in the media and mobile platform that the learner's need.
- **Formative feedback:** In the annual review strategy be sure to have systems in place to act on the changes needed to keep the PSN current to the learner's needs.

If you are a member of a professional organisation then this chapter has critically discussed some issues to take you forward into the 21st century learning society. The Web 2.0 pedagogic models, tool sets and protocols have been offered to provide a framework by which you will be able to open and establish the communication needed to help your organisation progress.

Chapter 6.2
Managing Relationships in Virtual Team Socialization

INTRODUCTION

The traditional organizational workplace is dramatically changing. An increasing number of organizations are employing workers who are physically and geographically dispersed and electronically dependent on each other to accomplish work (Gibson & Cohen, 2003; Griffith, Sawyer, & Neale, 2003). Recent technological advances, combined with more flexible job design, have helped increase the number of people working in distributed environments. Hence, more employees are working individually and on teams that seldom, if ever, meet face to face. These virtual employees have the same work responsibilities as traditional employees in addition to the challenge of operating within the dynamics of these newly designed mediated workplaces.

Rapid developments in communication technology and the increasing influence of globalization and efficiency on organizations have significantly accelerated the growth and importance of virtual teams in contemporary workplaces. Virtual teams are becoming more commonplace because of the possibilities of a more efficient, less expensive, and more productive workplace. Additionally, distributed teams are less difficult to organize temporal organizational members than traditional co-located teams (Larsen & McInerney, 2002; Lurey & Raisinghani, 2001; Piccoli & Ives, 2003).

Although there are apparent advantages of organizing work virtually, the challenge for new member integration lies in the fact that team members must communicate primarily through communication technology such as electronic mail, telephone, and videoconferencing or computer conferencing. This increased dependence on technology as a medium of communication significantly alters the way new members are socialized to work teams. Additionally, team members' ability to use complex communication technologies varies across individuals. This variation potentially may lead to inter- and intra-group conflict, as well as creating organizational work ambiguity, which refers to the existence of conflicting and multiple interpretations of a work issue (Miller, 2006). This article addresses the challenges of virtual team socialization with regard to newcomer assimilation and how newcomer encounter is an embedded process of virtual team assimilation.

BACKGROUND

Effective communication is central to organizational and team socialization. The way individuals are socialized in a team may determine his or her success within the team and the successful achievement of organizational and team goals. Team socialization and the communication practices associated with newcomer integration have been researched extensively (e.g., Brockmann, & Anthony, 2002; Lagerstrom & Anderson, 2003) since Jablin (1982) first explored this multilayered process. Socialization occurs when a newcomer of a team acquires the knowledge, behavior, and attitudes needed to participate fully as a member of that team. Jablin (1987) framed the stages of socialization as anticipatory socialization, organizational assimilation (encounter and metamorphosis), and organizational exit. Although there is an abundance of literature on traditional organizational socialization, research on virtual team socialization is beginning to emerge (Ahuja & Galvin, 2003; Picherit-Duthler, Long, & Kohut, 2004; Long, Kohut, & Picherit-Duthler, 2004).

NEWCOMER ASSIMILATION IN VIRTUAL TEAMS

Organizational assimilation is perhaps the most important, yet complicated, stage of virtual team socialization. Assimilation concerns the ongoing behavioral and cognitive processes of integrating individuals into the culture of an organization (Jablin, 1982). Assimilation is a dual-action process that consists of planned and unintentional efforts by the organization to "socialize" employees, while at the same time the organizational members attempt to modify their work roles and environment to coincide with their own individual values, attitudes, and needs. Jablin (1987) suggests that organizational roles are negotiated and socially constructed by actively and reactively communicating role expectations by both the organization and its members. Newcomers typically enact this negotiation through information-seeking tactics.

Organizational culture also informs how newcomers are assimilated in virtual teams. Socialization is one of the most important processes by which organizations communicate their culture (Cheney, Christensen, Zorn, & Ganesh, 2004). While each member entering the organization learns the values, beliefs, and practices of the organization, they simultaneously shape the organization through their "reading" of those values. Because the spirit of virtual teams focuses on innovation, change, dynamic structure, and participant diversity, we should expect newcomers to be able to do more to shape the culture of their virtual team with their own values, beliefs, and practices than in the traditional team structure.

Organizational encounter as a phase of socialization is a time for newcomers to learn behaviors, values, and beliefs associated with their jobs and organizations (Schein, 1988). By entering a new situation, newcomers want to clarify their situational identity through their work roles (Berlew & Hall, 1966; Feldman, 1976), or through securing approval of others (Graen & Ginsburgh, 1977; Katz, 1978; Wanous, 1980). To reduce uncertainty, newcomers often search for information that allows them to adjust by defining the expectations of others and orienting their behavior to the behavior of others.

The speed that virtual teams form demands that workers deal with change rapidly. Although research on teamwork suggests that teams function optimally after they have worked together for a period of time, virtual teams may not have the luxury of establishing working relationships over an extended period of time (e.g., Furst, Blackburn, & Rosen, 1999; Mark, 2001). Hence, it is vital for newcomers to quickly establish and develop relationships with others in the work setting, especially with peers and supervisors (Jablin, 2001).

Among other things, organizational relationships provide newcomers with support that facilitates the learning process and reduces stress and uncertainty associated with adjusting to a new work environment (Jablin, 2001). Much of the research on relationship development in the organizational encounter stage focuses on information seeking and information giving (e.g., Boyd & Taylor, 1998), learning behaviors and attitudes through exchange activities (e.g., Comer, 1991), technical or social information (Comer, 1991; Morrison, 1995), and regulative and normative information (e.g., Galvin & Ahuja, 2001). Evidence suggests that formal and informal socialization practices may affect the level of organizational commitment (Berlew & Hall, 1966; Buchanan, 1974), longevity in the organization (Katz, 1978; Wanous, 1980), and satisfaction and feelings of personal worth (Feldman, 1976). In fact, Gibson and Gibbs (2005) propose that a supportive communication climate, defined as an atmosphere that encourages open, constructive, and honest and effective interaction (p .4), often enables innovation.

The next section examines the three central areas of relationship building in virtual teams: peer relationships, supervisory relationships, and mentoring relationships.

Peer Relationships

Working with others on a team may be problematic. Several questions arise when working with others in this context. Do individuals meet the expectations the team has of them? Are they easy to get along with? Are they competent? Peers help newcomers integrate disjointed pieces of information (Van Maanen, 1984) and communicate subtle values and norms that may not be explicitly expressed by their supervisors. Newcomers have more contact with coworkers, and as a consequence, more opportunities to share information with them and develop relationships (Jablin, 2001; Comer, 1991; Teboul, 1994). Sias and Cahill (1998) proposed a variety of contextual factors, including shared tasks and group cohesion (e.g., Fine, 1986), physical proximity (e.g., Griffin & Sparks, 1990), lack of supervisor consideration (Odden & Sias, 1997), and life events outside the workplace, as well as individual factors, such as perceived similarity in attitudes and beliefs as well as demographic similarity (Adkins, Ravlin, & Meglino, 1996; Duck, 1994; Glaman, Jones, & Rozelle, 1996; Kirchmeyer, 1995), that may affect the development of relationships with peers.

Trust is a key factor in developing close relationships. However, due to the lack of physical proximity and the reliance on communication technologies, our understanding of trust in virtual teams is different from the trust in traditional teams. Piccoli and Ives (2003) define team trust as the belief that an individual or group makes good-faith efforts to behave in accordance with any commitments both explicit and implicit. Cummings and Bromley (1996) further define trust as honesty in whatever negotiations preceded the commitment as well as not taking excessive advantage of another even when the opportunity is available (Cummings and Bromley, 1996). Meyerson, Weick, and Kramer (1996) coined the term “swift trust” to describe how virtual teams develop a different type of trust than in traditional teams. Due to the highly interdependent nature of task orientation of the team, newcomers develop trust more quickly. Team members are able to develop trust in the relationships on the basis of shared tasks rather than on the basis of similar demographics and/or physical proximity found in traditional teams (Jarvenpaa & Leidner, 1999).

However, swift trust is not enough to develop close peer relationships. Team members face a number of challenges including: technological mistrust by both newcomers and established members, intuitive fear of the misuse of archived communication (e.g., e-mail trails), and the difficulty of sharing personal or non-work-related issues. Thus, virtual newcomers may be unable or unwilling to take advantage of the informal organizational development that appears central to organizational socialization in traditional teams. This clearly inhibits the development of close peer relationships in virtual teams, which in turn may inhibit constructive team cohesion. Similarly, opportunities to understand organizational politics are greatly reduced by the inherent dispersed nature of virtual teams. Unless the communication among team members is open, power alliances may form that foster certain behaviors such as social loafing, domination, and the formation of cliques to occur. Groups or individuals are alienated by these behaviors and may differ in their responses based on location or functional role. The outcome is the same — limited effectiveness of the team, low commitment, low loyalty, and mistrust. Other sources of information such as supervisors and mentors may prove more helpful in recognizing and adapting to political nuances.

Supervisor Relationships

Supervisors are important for assimilating newcomers to organizations by helping build a shared interpretive system that is reflective of assimilation (Berlew & Hall, 1966; Feldman, 1976; Graen, 1976; Kozlowski & Doherty, 1989; Ostroff & Kozlowski, 1992; Schein, 1988). Supervisors who frequently communicate with newcomers serve as a role model. These supervisors filter and interpret formal downward-directed management messages, have positional power to administer rewards and punishments, are a central source of information related to job and organizational expectations as well as feedback on task performance, and are pivotal in the newcomer's ability to negotiate his or her role (Ben-Yoav & Hartman, 1988; Jablin, 2001). According to Staples, Hulland, and Higgins (1998), workers who learn their communication practices by modeling their managers' behaviors have greater self-efficacy, better performance, and more positive job attitudes.

The supervisor-subordinate relationship is more important in virtual teams than in traditional teams due to the dislocated nature of the virtual structure (Long et al., 2005). The supervisor-subordinate relationship is complicated by the absence of a physical communication context that characterizes most traditional teams. The supervisor's coordination of virtual team activities is more difficult because of the distinct nature of technological feedback (synchronous vs. asynchronous), the lack of robust spontaneous information exchange between supervisor-subordinate, and the obvious reduction of face-to-face verbal and nonverbal communication cues. On the other hand, some findings suggest that assessment of team member contributions may be more accurate in virtual rather than face-to-face environments. For example, Weisband and Atwater (1999) found that ratings of liking contributed less bias to evaluations of contribution for virtual groups than face-to-face groups. Similarly, Hedlund, Ilgen, and Hollenbeck (1998) found that leaders of computer-mediated teams were better able to differentiate quality of decisions compared to leaders in face-to-face teams.

Regardless of whether the supervisor is part of the team or not, the effective supervisor-subordinate relationship depends in large part on whether the organization uses a traditional approach to managing the virtual team. In traditional teams, often supervisor-subordinate relationships are characterized by hierarchical embedded roles in responsibilities, more formalized rules, procedures, and structures (McPhee & Poole, 2001). However, in virtual teams there is a loosening of the rules and responsibilities in the supervisor-subordinate relationship. The virtual setting reduces tangible cues that distinguish the status and/or hierarchy of the team members. Thus, the supervisor-subordinate relationships in a virtual team rely more on co-orientation, which facilitates the socialization process more effectively. Mentoring relationships is also important to newcomers' adjustment to socialization efforts.

Mentoring Relationships

When discussing relationship building as part of the assimilation process, mentoring relationships is an important aspect. Mentors facilitate newcomer organizational adjustment by offering advice, support, and if appropriate, coaching behaviors to accomplish goals. Wigand and Boster (1991) suggest that "mentoring speeds up socialization into the work role, encourages social interaction, provides an opportunity for high-quality interpersonal interactions, and enhances identification with and commitment to the organization" (p. 16).

Mentoring relationships are formal and informal. Formal mentoring is a "deliberative pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed upon goal of having the lesser skilled or experienced person grow and develop specific competencies" (Murray & Owen, 1991, p. xiv). Several scholars (e.g., Allen, McManus, & Russell, 1999; Heimann & Pittenger, 1996; Seibert, 1999) acknowledge that newcomers who participate in formal mentoring relationships in traditional organizations realize greater benefits than those who do not have formal mentoring. Specifically, participation in formal mentoring increases the newcomers' understanding of various organizational issues and increases their level of organizational and job satisfaction.

Informal mentoring relationships develop naturally at the discretion of the mentor and protégé, and exist as long as the parties involved experience sufficient positive outcomes (Jablin, 2001). Newcomers who are informally mentored are privileged to information not directly associated with the job role or organizational tasks. This indirect communication includes organizational power and politics, involved career-related support, "inside" information about various organizational issues, and increased social interaction outside of the workplace. As trust, commitment, and identification in the virtual team develops for both the newcomer and more experienced workers, informal mentoring will naturally occur. Virtual teams are more effective when communication barriers such as role uncertainty, task ambiguity, and tacit norms of the team are dismantled.

Organizations benefit when they recognize the value of both formal and informal mentoring relationships. Acknowledging the positive impact mentoring has on newcomer assimilation in a traditional team arrangement leads us to assume that mentoring will have similar impact on virtual team assimilation. However, due to the structural challenges of virtual teams, organizations should consider both formal and informal mentoring programs as tools to socialize newcomers to virtual teams.

In summary, virtual teams face an uncertain, but promising future. The socialization process of team members can become an enigma when building virtual teams. The next section outlines future trends in newcomer assimilation in virtual team socialization.

FUTURE TRENDS

Three interrelated relational aspects of virtual team assimilation are important to note when attempting to predict future trends in this emerging field of study. First, growing interest in virtual team socialization will lead to an accelerated interest in how trust is developed and maintained in virtual team relationships. Trust is a major factor influencing the cohesiveness among virtual team members (Sarker, Valacich, & Sarker, 2003). Instrument development and validation is of central concern as virtual teams become a ubiquitous aspect of organizational life. Scholars and practitioners both have a vested interest in fully developing this aspect of virtual team scholarship, as more individuals will work in this new organizational configuration and become more dependent upon the work of others in their virtual team. Working remotely clearly has its benefits, but opportunities will only be maximized when trust is fully realized among all organizational citizens, especially virtual team members.

Second, focused attention should be given to the amount of social contact individuals experience via mediated communication with their peers and supervisors. As workers become increasingly more isolated because of the flexibility technology affords them (e.g., telecommuting, flex hours), managers should be proactive in ensuring that many of the social components characteristic of working in traditional "brick-and-mortar" workplaces—the characteristics that keep individuals socially satisfied and committed to the organization—are transferred to the new dislocated work environment. Several scholars have suggested that the informal organization is equally, if not more powerful than the formal organization (e.g., Rogers & Kincaid, 1981; Monge & Contractor, 2001; Monge & Eisenberg, 1987). In order to maintain a consistently committed and talented workforce, deliberate attention should be earmarked to foster the intangible social relational aspect of virtual team functioning.

Finally, managers and scholars should work in tandem to fully realize the opportunities and potential for virtual mentoring. Networking and building informal coalitions and communities with others within and outside of their employing organization is a key strategy for upward mobility for individuals, especially minority organizational members (Bell & Nkomo, 2001; Parker, 2003). As more individuals are hired and socialized to work in more virtual team-based structures, it is critical that organizational leaders leverage the power of mentoring as a means to create a more committed workforce and reduce job transfers and turnover. Establishing a protégé and mentor relationship is critical, as technological uncertainty and task ambiguity increase due to the erosion of traditionally rich media forms such as face-to-face communication. Implementing formal and informal mentoring programs is certainly a future trend in virtual team socialization.

CONCLUSION

Organizations are turning to virtual teams as a way to remain competitive in an environment characterized by globalization, mergers, acquisitions, and dependence on information technologies. A great deal of attention is paid to how to provide adequate virtual team infrastructure such as hardware and software components. However, little attention has been devoted to the "human-structure" of virtual team organizing. Future research and organizational attention should focus on the methods of assimilating newcomers in virtual teams. This communication process is as important as the technology selected to accomplish work.

Some aspects of virtual team assimilation are similar to traditional team assimilation, but many are not congruent. Staples and Webster (2007) posit that the distinction between traditional and virtual teams is no longer needed, as all types of teams are characterized by varying degrees of virtuality. The primary difference is that virtual team members are typically more reliant on information technology as the medium for communicating, and virtual team members are more likely to be isolated from the rest of their team — hence, the importance of examining how virtual team members build relationships in this new organizational structure. Communication in peer, supervisor, and mentoring relationships is vital in optimizing organizational functioning, yet little attention is focused on these important relationships in the virtual team environment. In addition to the traditionally studied outcome variables such as costs, productivity, and effectiveness, organizations should also be mindful of the importance of issues related to the internal team and interpersonal communication processes that embody and constitute organizations.

Effective virtual team assimilation, just like traditional team assimilation, fosters loyalty, commitment, trust, and potentially greater cohesiveness with the team. Virtual team socialization is a shared relational responsibility for the newcomer, the supervisor, and the organization. If little concern is given to building the relationships, then the long-term stability of the virtual team may be threatened.

KEY TERMS

Co-Located Team: A traditional team that shares a common goal and works toward that goal in a face-to-face, same-office environment.

Formal Mentoring: A deliberate pairing of a more skilled or experienced person with a lesser skilled or experienced one, with the agreed-upon goal of having the lesser skilled or experienced person grow and develop specific competencies.

Informal Mentoring: The non-assigned pairing of an experienced person who respects, guides, protects, sponsors, promotes, and teaches a younger, less experienced personnel member who develops naturally at the discretion of the mentor and protégé, and persists as long as the parties involved experience sufficient positive outcomes.

Organizational Assimilation: The processes by with individuals become integrated into the culture of an organization.

Newcomer Encounter: A time for newcomers to learn behaviors, values, and beliefs associated with their jobs and organizations.

Socialization: The process in which that member of a team acquires the knowledge, behavior, and attitude needed to participate fully as a member of the team.

Swift Trust: A type of trust that develops quickly on the basis of shared tasks rather than on the basis of similar demographics or physical proximity.

Virtual Team: A group of geographically and organizationally dispersed workers brought together across time and space through information and communication technologies.

Chapter 6.3
Guarding Corporate Data from Social Engineering Attacks

Christopher M. Botelho
Baylor Health, USA

Joseph A. Cazier
Appalachian State University, USA

ABSTRACT

The threat of social engineering attacks is prevalent in today's society. Even with the pervasiveness of mass media's coverage of hackers and security intrusions, the general population is not aware of the possible damage that could occur should they be subjected to a social engineering attack. In order to show the damage caused by these attacks, we will discuss the results of a social engineering attack based on a survey conducted in the downtown area of a large financial center in the United States. The authors make suggestions companies can incorporate into their policies in order to protect their employees, as well as systems from intrusions based on social engineering attacks.

INTRODUCTION

As more and more organizations invest in technology to ease the delivery and dissemination of information, more opportunities are created for security incidents. Before the Internet was a part of everyday life, intruders usually gained access to sensitive data by physically setting foot on a company's premises and breaking into a safe or file cabinet. As a result, companies installed security cameras, door locks, and alarm systems.

Today, corporations still have these devices but must also protect their digital data. Investments in devices, such as intrusion detection/prevention systems to alert them of a security incident; firewalls to protect their internal network; and virtual private networks to ensure individuals connecting from the outside are authorized and have a secure connection are necessary expenses.

Another tool corporations use are organizational controls. These are processes and procedures put in place to control and protect assets, which include physical goods, buildings, money, and even a firm's reputation and image. Of the many types of controls, one of the most fundamental is access control. Access controls restrict access to your business systems to authorized personnel. These controls are key to information security and are one of the ten required

DOI: 10.4018/978-1-59904-855-0.ch037

domains of study for the certified information systems security professional (CISSP) certification exam (Krutz & Vines, 2001).

One of the most critical types of access control in today's internet-connected world is the use of passwords. We use passwords to access many of our online and company accounts (Zivran & Haga, 1999). Usernames and passwords are the most common form of authentication, but are also the weakest due to human error (Ciampa, 2005). One weakness of passwords is they are difficult to remember, leading people to choose weak passwords they can remember (Cazier & Medlin, 2006) and the tendency of people to reuse their passwords for multiple accounts, making the danger of a weak password greater as it can compromise multiple systems (Ives, Walsh, & Schneider, 2004).

Today, most network and system security devices rely on the username and password to grant access. As such, obtaining this information is the equivalent of hitting the jackpot for a hacker. When a hacker is attempting to break into a system, they want to find the quickest and easiest point of entry. The longer it takes to break into a system, the more information the hacker leaves to get caught in the end. Better security technologies are continually being invented to make it more difficult for an attacker to gain access. As a result, many hackers will rely on social engineering methods, that is, using social skills to obtain information, such as a user's password (Krutz & Vines, 2001), to gain access to a target since in many cases it is a lot easier to exploit a human than a system (Mitnick, 2002). The social engineer utilizes an arsenal of methods, allowing him or her to leverage the emotions of a victim, aiding in an attack. The social engineer can flirt with the victim in an attempt to gain information; make the victim feel guilty so they divulge information they would not have otherwise; or even convince the victim that their job could depend on giving the attacker the requested information (Mitnick, 2002).

With this research, empirical data is presented on the current susceptibility of social engineering attacks on companies. From this information, several suggestions are made for companies to ensure social engineers do not succeed. Recommendations are aimed at preventing potential attacks. Lastly, possible future research aimed at studying social engineering further in different areas is discussed.

BACKGROUND

Each day, numerous employees have access to sensitive data in order to do their job. Generally, they will use a password to access this data. Their password is one of the only things keeping a potential intruder out of their employer's network. In the event their password is compromised, the entire company's infrastructure is at risk. Social engineers use human weaknesses, such as trust and fear, to their advantage to exploit these people and get as much information as possible. With experienced social engineers, the employee will not even know what has happened and will continue their day without so much as a second thought. This creates even more risk, as not only does the social engineer have the employee's password, but he or she also avoids detection and possibly can have free roam of the company's network and systems.

Social engineering is the act of gaining either unauthorized access to a system or sensitive information, such as passwords, through the use of trust and relationship building with those who have access to such information (Damie, 2002). A social engineer uses human psychology to exploit people for his or her own use.

According to Kevin Mitnick, a prominent social engineer, "Savvy technologists have painstakingly developed information-security solutions to minimize the risks connected with the use of computers, yet left unaddressed the most significant vulnerability, the human factor"

(Mitnick, 2002, p. 8). In 2005, the FBI conducted a computer crime survey with a sample of 2066 organizations in the U.S. They found that the average cost for the companies that had an incident was $24,000, with a total cost of $31,732,500 for all respondents (FBI, 2006). Based on this information, they estimated a total cost of $67.2 billion per year for security incidents.

Social engineering attacks can take on many methods. Each method uses the same basic four-step cycle in order for the social engineer to be successful. The first step is to gather information about the target and potential weak points (Allen, 2006). The attacker can gather names of people through a company's site, co-workers, or even a phone directory. Since most employees have their name, job title, and whether they will be in the office on their voicemail, an attacker can simply find a day when a specific person is not in the office and imitate them to an unsuspecting employee (Mitnick, 2002). Additionally, most employees who have security badges wear them in public places. This could be during a lunch break, going out after work, or even going out with friends at night and simply forgetting to remove their badge. The attacker could find an area where many employees from the target company congregate and use the information on the badge or from the employee to their advantage. Other methods for the social engineer to gain information are:

- **Call specific personnel.** This generally involves convincing people over the phone into giving them information through persuasion with tools such as fear, imitation, and compassion (Granger, 2001).
- **Dumpster diving.** The social engineer physically goes through a company's garbage to find useful information (Mitnick, 2002). This could lead to a sticky-note with a password on it, or even other sensitive internal documents that a careless employee forgot to shred (Castelluccio, 2002). An example of another useful find is organization charts with names that can enable the social engineer to proceed with another method, such as using the phone, in order to impersonate personnel based on their standing in the company.
- **The Internet.** Not only does it provides anonymity but also allows them to maximize their impact. This method is being used primarily by phishers in an attempt to defraud unsuspecting individuals by getting them to divulge personal financial data. In 2006, the total cost of identity fraud in the US was $56.6 billion. Of this amount, 3 percent was obtained through phishing attacks on home users (Javelin Strategy & Research, 2006).
- **Site visitation.** This method involves the attacker physically going to the target site to carry out their attack. However, the attacker may decide the easiest way to get access to the network is to simply go to the target's site and log in (Mitnick, 2002).

The second step is to develop a relationship with the target individual(s) (Allen, 2006). This is needed in order to build trust with the individual in order to exploit them and continue to use them in the future (Mitnick, 2002). General human nature is to trust others and to receive a sense of satisfaction out of helping others (Dolan, 2004). The social engineer builds this trust in order to exploit it. This can involve simply talking on the phone with the target for a few minutes (Dolan, 2004), or striking up a conversation and exchanging business cards at a bar the target frequently attends (Mitnick, 2002).

The third step is to exploit the trust that has been built with the target by manipulating the target into doing something they would not normally have done (Allen, 2006). The key to this step is to ensure the target does not at any point catch on to what is happening and leaves with a sense of satisfaction. This allows the attacker to continue the trust that has been built up with the target in order to exploit them again in the future (Mitnick, 2002).

The fourth and final step is the execution. Once reached, the target has completed the task requested by the social engineer (Allen, 2006). The goal with this final step is to not only have the desired task completed, but to ensure a continual relationship with the target (Mitnick, 2002).

METHODOLOGY

A survey was created and administered with multiple purposes and multiple sections. Data was gathered to not only establish how many people would disclose their passwords, but also to simulate the type of information a social engineer would attempt to gather, other than a password. The survey was divided into three sections: (Table 1)

The first section of the survey was designed to gather personal non-identifying information, such as a favorite movie, television show, place of birth, or pet. These categories were chosen based on research performed by Medlin, Cazier, and Dave (2006). In their research, they found 19.3 percent of passwords gathered were based on family, 2.1 percent were based on being a fan, 5.7 percent were based on faith, and 1.3 percent were based on places. The survey incorporated as many of these as possible into this section without being overwhelming in order to simulate guessing a password in the event a password was not disclosed.

The second section of the survey was designed to gather information on their employer's information security climate. Through this the researchers are able to show how training and individual awareness relate to success in receiving the individual's password. Since training is considered to be the greatest way of preventing attacks, the researchers felt it was important to include this information to assess if training, and how much, helps prevent these attacks.

The final section was designed primarily to convince the individual that the researchers were doing password research and needed their help. Questions were created based on best password principles, and were designed to show if there was a significant correlation between those who divulged their password and other factors such as password length and composition. Additionally, the section was designed so that in the event a password was not given, the information from the first section and last could be combined to guess the individual's password.

Some personal demographics were also gathered for informative purposes in order to support the research. This was gathered under the context of a drawing for a gift certificate to a local restaurant, and respondents were given a separate sheet of paper with personally identifying information, such as name, address, and phone number, as well as place of employment and email address. The last two pieces of information were especially important in the event of a true social engineering attack. This would give an attacker the company's name, possible login information

Table 1.

Item	Survey Question	Percent
A	Gave Their Password	52%
B	Password Security Training Offered	56%
C	General Security Training Offered	63%
D	Choose Own Password	89%
E	Password is Alpha-Numeric	91%
F	Password Contains Special Passwords	51%

from the email address, and the password in the event it was filled out.

The survey and demographics were kept separate for two reasons. The first was to protect the respondents as well as the researchers from possible privacy breaches. The second reason was to put them at ease with filling out the survey and to facilitate a greater percentage of respondents disclosing their password by giving the impression the survey was truly anonymous. For ethical reasons, the researchers chose to keep everyone anonymous exactly as promised, however it would have been a simple matter for a social engineer to combine the data.

Sample

In order to assess the current awareness of information security in today's climate, a survey was aimed at corporate employees. However, in order to better represent what a social engineer might be able to do, a survey booth was set up outside the corporate headquarters of several major businesses, rather than have the companies ask their employees to participate. The corporate employees were targeted due to the sensitive information about individuals they are entitled to. Members of this group often have access to social security numbers, account information, healthcare records, or credit information on a daily basis. Additionally, they may have access to the intellectual property of their employer.

The term "corporate employees" is being used as a general category for the random sample of people from the downtown area of a large financial center in the United States. In order to take this sample, the researchers took every step possible to ensure there were no ethics violations and were completely honest with those surveyed. The researchers identified that they were from a university and wore name tags to identify themselves and did exactly what they told people they were doing. A real social engineer would not have this handicap.

A table was set up in the downtown area in front of one of the top five banks in the U.S., with another of the top five only a block away, and an energy company two blocks away. This location was selected due to its centralized nature, as well as the employers it was around. This area has a high concentration of financial institutions, making it a target for not only domestic hackers but terrorists as well. We chose this location to test our attack in an area likely to be more secure than areas with less to protect. This study likely *underestimates* the amount of information the average person is likely to share.

People walking by our table were randomly asked to fill out a survey in exchange for candy and the opportunity to win a free gift card to a restaurant from a drawing. All personal information for the drawing was filled out on a separate piece of paper in order to protect all persons involved, including the researchers.

RESULTS

In all, 53 surveys were completely filled out, with three not being fully filled out (only one side was completed) for a total of 56 surveys. Seventy-four percent of respondents were male. There was no significant difference between males and females in terms of willingness to share their password.

This sample included employees of energy companies, banks, and technology companies. While no identifying information was gathered at any point of filling out the survey, the researchers had the opportunity to mark each survey as well as the demographics slips. Many of the respondents had ID badges, identifying their name, company, and position. It would have been a simple matter to write this info down, or capture it with hidden cameras.

In our sample, 52 percent of respondents shared their password. This was accomplished with very little to no pressure in order to ascertain the true level of ease with which people would give up their passwords. Fifty-six percent work for a company that offers password security training, 63 percent offer general security training. Most people were allowed to choose their own password (89 percent) with 91 percent having both letters and numbers. However, only 51 percent of respondents reported using special characters in their password.

In addition, the average person in our sample accessed a system using a password in the very often range, occasionally changed their password and occasionally too often used the same password on multiple systems. We also measured the last time the users participated in a security training program, with the average person indicating they had participated within the last year. In fact, 63 percent had participated within the last year, with many of those participating more recently.

A test was run to compare whether a password was given to us based on factors found in the survey. We found people who use the same password on more than one system were more likely to share it with us, however security training was found to *not* be a significant factor in whether the password was shared.

Lastly, we ran a test for differences between groups that had training in password security and those that had not. Fortunately those that used passwords the most were also more likely to have received training. Those that had training were more likely to change their passwords frequently and have special characters. However they were not significantly more likely to *not* reuse their passwords, have longer passwords, or to incorporate numbers into their passwords. Most importantly, password security training had *no* measurable impact on their willingness to share, or not to share their password with us!

DISCUSSION

This study found that those users who used the same password across multiple systems were more likely to disclose their password. Using a scale of one to five, with one being very often and five being never, the study found that those users who disclosed their password stated they used the same password across multiple systems "often," or an average of a 2.00. On the converse, those who did not disclose their password had an average of 2.60, falling in between "often" and "occasionally." Altogether, 38.5 percent stated they used the same password across multiple systems "very often," and a mere 6.9 percent stated they "never" reused passwords. That those that used the same password on multiple accounts were also the same ones that were more willing to share their password is especially ironic as these people have the most to lose from sharing their password because they can be attacked from multiple angles.

It is also interesting to note that security training was not found to be significant in the sharing of people's passwords. While many would expect this to be the biggest prevention of a social engineering attack, there was no correlation between those who had training and those who did not. Even though a significant correlation was not found, it is important to note that without training, there is no possible way for employees to understand social engineering attacks or even begin to know how to prevent them.

However, even though training did not prevent people from sharing their passwords, those with training did have more secure ones. While this is important, giving your password to a stranger defeats the purpose of having a stronger password. This suggests that security training, while important, perhaps needs to be refocused or expanded to include more on social engineering attacks.

RECOMMENDATIONS

This study finds that employees are way too vulnerable to a social engineering attack. Even though training did not affect the willingness to share the password, it did have some impact on the strength of the password. This shows that if the training program were designed better, it might have a better chance of effecting change. Unfortunately, our other options for improving security are limited. Password strength may be improved through technical means and system requirements. However, people are often the weakest link in the security process. This is a weakness that needs to be addressed.

According to Pramod Damie (2002), "a three-phased approach is helpful in combating social engineering." This three phased approach covers training, policy creation, and testing to ensure the training was understood and policies are being adhered to. Through these processes, an organization can work towards preventing social engineering attacks, and ensuring their infrastructure, employees, and customers are protected.

The first phase of this approach is an elaborate and comprehensive training program. These training programs must cover a wide array of potential vulnerabilities within an organization. In particular, the program must cover the risk of social engineering attacks to the organization, how to spot these attacks, and how to protect against them.

Users must be trained on social engineering attacks and given the knowledge needed to protect the organization as a whole (Dolan, 2004). In a study of user's knowledge of security issues within an organization, it was found that users were "not sufficiently informed about security issues" (Adams & Sasse, 1999, p. 43). The point of the training program must be to eliminate this issue, and ensure all users are informed and well trained.

The second phase is creating policies and procedures in order to protect the organization. These policies must be created with the user, as well as the organization, in mind. The policy outlines the expectations and responsibilities of the employees, as well as the procedures to follow in the event of a breach or attempted attack (Dolan, 2004).

The following outlines areas training programs and policies should include protecting against a social engineering attack:

Password security. At no time should a password ever be shared with anyone. Social engineers will sometimes pose as technical support personnel in order to get the user to disclose information such as username and password (Allen, 2006). The company's help desk and IS/IT department should never need to ask a user for their password. This allows the employee to be told point blank that no one will ever ask them for their password, and in the event they are asked, they should not give it out. In this study, the perception of anonymity was used as well as the request of college students doing research to exploit individual's human emotions.

Ensure users adhere to a password criteria policy. This policy needs to include factors such as special characters, numbers, letter case, and reuse within the company. The user must know not to reuse passwords, and a system needs to be in place to verify that the user is at least not reusing his or her password on their system. Lastly, dictionary words should not be allowed and again, a system needs to be put in place to ensure the user is not using dictionary words.

Users must understand not to write down their password in any location. In the event a social engineer decides to physically access the company's site, any passwords written down can become a valuable resource. The social engineer needs to only walk past an employee's workspace to gather the information they need to attack the company's infrastructure (Dolan, 2004).

Additionally, two-factor authentication in the form of a token can be used to prevent unauthorized access to the company's system. An asynchronous dynamic password token with a number changing at fixed intervals would significantly decrease the likelihood of an intruder getting into a system, since even if a social engineer gets access to a user's PIN, the password would change each time the specified interval lapses (Krutz & Vines, 2001).

Employee verification. The company must establish policies and procedures for allowing employees to verify people who call them are who they say they are.

For companies with internal caller-ID phones, the system must display their name as well as extension number. The employee must know to verify who they are speaking with and compare it to the display of their phone system. In the event of a discrepancy between the two, the employee should instead rely on an internal directory and inform the caller they need to verify their identity before speaking with them. For companies without an internal caller-id phone system, the end user must know to verify who they are speaking with before disclosing any information. The simplest method is to use an internal directory and the end users tell the caller they will be called back at their extension (Mitnick, 2002). This gives a two-fold protection, since not only does the user call the extension back, establishing the caller was really at that extension, but also by using the directory, the user is guaranteeing they are calling the correct person back (Gragg, 2002).

Physical access. Ensure all employees have an ID badge with a large print of their photo on it. The large photo prevents a social engineer from obtaining a legitimate badge from an employee and relying on having a badge with a smaller picture that cannot be seen.

A determined social engineer may photograph an employee's badge and create their own based off the photograph (Gragg, 2002). With the power of photo editing software, this is a simple task. To combat this, the badge needs to incorporate a form of protection against being counterfeited or have a policy that employees cannot wear their badge off company property. A simple form of counterfeit protection would be a hologram specifically designed for the organization, or printing with ink that can only be seen under a blacklight.

Task all employees with protecting the organization, and inform them they have the right to question anyone, at any time, anywhere. Social engineers sometimes rely on having the appearance of being a person of authority in order to intimidate employees so they will not be questioned (Gragg, 2002). If an employee does not see a badge on an individual in the building, they must stop and ask them to see the badge; otherwise they have to escort them to the front desk.

Sensitive locations, such as the mail room and networking closets, must be secured. The mail room provides a means for an attacker to deliver a forged memo that seems to be internal (Granger, 2002).

Visitor badges must be given to every person who is not an employee, and must be clearly marked as a visitor. Employees should be trained on areas where visitors have to be escorted, as well as areas where a visitor may be without an escort. The employees must have the authority to challenge visitors, and be allowed to report any suspicious behavior to a specific individual (Arthurs, 2001).

Document and media disposal. Employees must be educated on the importance of shredding any and all documents, and ensuring all media that is no longer needed is destroyed. What the employee may view as safe may actually be the only thing the social engineer needs to attack the organization. Items such as company directories, calendars, planners, and organizational charts can be prized finds for a social engineer (Granger, 2001). This is why all documents must be shredded, regardless of the user's perception of the safety of the contained information.

For documents and media, such as floppy disks and CDs, a licensed disposal company should be used which gives the organization a certificate of destruction and performs the destruction on-site rather than transporting to a separate facility. The company should provide locked trash bins, where all employees would be required to dispose of their documents. They need to be trained to never place documents in a trash can.

General training. Employees must be educated on spotting social engineering attacks, whether through the phone, physically, or spotting someone dumpster diving. They must have specific steps to follow and people to contact to report an incident (Granger, 2002), rather than keeping them private. Many times when an employee falls victim to an attack, they do not tell anyone about it out of fear of ridicule or punishment (Mitnick, 2002). In order to ensure incidents are reported, the employee must feel safe and free from punishment, otherwise they will be more inclined to not report the incident.

The program needs to inform the employee about the organization's policies, as well as the sensitivity of information they give out. This involves personalizing the training to each person and how it applies to them as well as their company (Arthurs, 2001).

Employees must be able to spot and understand emotional social engineering attempts. Frequently, this involves exploiting the employee's natural inclination to help a fellow employee in a time of need (Farber, 2001). Many times this will involve the attacker pretending to have a deadline or other immediate need, and attempts to appeal to the victim's emotions (Mitnick, 2002). The user must understand they have the right to say "no" at any time, and have absolutely no fear of reprimand should the request be legitimate.

The final phase is testing to see whether the training has been understood, and policies are being followed. The testing should be implemented *only* after all employees have been trained. Due to the sensitive nature of social engineering, employees can feel deceived and morale can be hurt from a test (Kabay, 2000).

Once the test has been performed, all employees should meet together to discuss the results of the test without any particular person or department being named (Kabay, 2000). The results of the test can be used to further mold the training program, as well as educating those who participated in the training and creating areas of focus (Coffin, 2003).

All policies and training should have the support of upper management. Employees must understand if they see the CEO of their organization walking down the hallway without his or her badge that they must be challenged without fear of reprimand. Without this, employees may not feel comfortable questioning someone who appears to have authority, and thus may let an intruder roam their premises without any problem. Rather, a reward system should be implemented in the event an employee challenges any member of management. This reinforces that they have the authority and obligation to challenge anyone they see without a badge, further protecting the organization as a whole.

FUTURE RESEARCH

With permission of companies, it would be interesting to put other social engineering methodologies to the test to assess the organizations themselves. Using methods described above, a thorough analysis of multiple organizations could be created and the results compared with other organizations.

An additional area of interest would be how different regions respond to the same type of attack. In 2004, an experiment similar to this one was conducted in the United Kingdom by Claire Sellick, event director for Infosecurity Europe. She found 37 percent of people immediately gave her their password (Kotadia, 2004). This is a much smaller number than the 73 percent, leading to the assumption that different regions can yield different results.

CONCLUSION

The fact that even a single password was gathered shows a distinct need for more training and awareness among users. Having gathered the passwords of 52 percent of those surveyed shows that there is a real threat of social engineering to the corporate environment. A social engineer may need only one username and password in order to gain access to the company's network. After this point, they essentially have free reign, potentially costing the company thousands of dollars per incident (FBI, 2006).

In addition, a stronger emphasis should also be placed on security while students are still in school. Since these are the future employees, they need to have a basic understanding before entering the workforce; otherwise they will become the target of social engineers. They should also feel free to challenge authority if they do not feel comfortable giving out sensitive information. This gives them the ability to enter into a corporate information security training program with a basis of challenging individuals who should not have physical access.

In spite of training, users still voluntarily gave their passwords. These users can end up being the weakest link in a corporate security program, showing a need for a different training strategy since 63 percent of users had participated in a training program within the past year, but 52 percent of those surveyed provided their passwords. The training programs need to have more emphasis on protecting the user's login information, and education on how simple it can be to obtain a password through various social engineering techniques.

Users must be educated in social engineering attacks and have the knowledge to spot and protect against these attacks. They must be given the authority to challenge people they do not believe should have physical access to the company's site. Without the support of management, training programs will fail, and policies will not be followed.

As more and more information becomes digitalized, there needs to be a greater increase in security awareness. This awareness can be the difference between an organization falling victim to a corporate espionage attack, or ensuring their future success.

KEY TERMS

Authentication: The process of verifying that a person or resource accessing your system is actually how they claim to be.

Access Controls: Controls that restrict access to your business systems to authorized personnel.

Corporate Espionage: The act of covertly obtaining sensitive information on a competing organization. Similar to governments spying on each other, corporations also spy on others.

Dumpster Diving: The act of sifting through discarded items looking for something of value. This can include trash, documents, computer hard drives, or information unintentionally left online.

Hacker: A person trying to break into an information system, either to cause damage, find information or to satisfy their curiosity.

Password: A secret word used to verify a person is authorized to access a system.

Phishing: The art of trying to gain sensitive information through impersonating a legitimate organization and individual interacts with.

Social Engineering: The act of gaining either unauthorized access to a system or sensitive information, such as passwords, through the use of trust and relationship building with those who have access to such information.

Username: The name of a person or object on a system used of identification. Often used with a password for authentication.

Chapter 6.4

Social Interaction Technologies:
A Case Study of Guanxi and Women Managers' Careers in Information Technology in China

Jiehua Huang
Guangzhou University, China and Lappeenranta University of Technology, Finland

Iiris Aaltio
University of Jyväskylä, Finland

ABSTRACT

This chapter explores a relationship between social interaction technologies (SIT) and guanxi, a major Chinese informal style of networking, in the context of the careers of women managers in the information technology (IT) field in China. Addressing women's under-representation in non-traditional occupations (such as IT), prior research has established that networking, especially informal, is an important career management tool for women. Recent advances in social capital theory and social network analysis provide a framework for understanding the role of social processes in achieving career success. Today, the growing Web-based social and professional networking in China weighs against the traditional forms of relationships, such as personal networks based on guanxi. The study indicates that SIT and guanxi should be viewed as complementary rather than mutually exclusive influences.

DOI: 10.4018/978-1-60566-368-5.ch023

INTRODUCTION

Careers are a window to a network of values of the institutions where they are actually made. Recent advances in social capital theory have helped analyze the ways in which the social networks of individuals affect their careers in organizations (Burt, 1997; Coleman, 1990; Ibarra, 1995; Kanter, 1977; Lin, 1999; Podolny & Baron, 1997). This theoretical background provides scholars with knowledge for understanding the role of social processes in career success. Information technology (IT) and information and communication technology (ICT) refer to an industry that broadly covers the technologies of information and communication. In China, as in other countries around the world, more and more women are today working in this field as managers—although only a few at the top level (Aaltio & Huang, 2007). Ahuja (2002) stated that the barriers to female positioning in the IT industry are due to an "old boys network"—a large pool of more qualified and experienced male professionals, the lack of female role models and mentors, and established discriminatory practices. Kaplan and Niederman (2006) argued that inadequate social networks, skill obsolescence and limited vertical/internal job mobility present challenges to the career success of women in IT. In contrast, women who have more demographically diverse networks generally experience greater levels of career success (Cox, 1994; Ely, 1994; Ibarra, 1995). A lack of social networks and role models has been related to women's under-representation in the field of IT.

Social relations and ties between actors characterize today's business culture. As expected, prosperity and social capital cumulate in the interplay between human partners and organizations (Bourdieu, 2005). There is a trend to understand business life more as a product of collective and shared interactions than separate individual efforts. This collectivity is not universal by nature but has country-specific and local features. Recently, *guanxi,* a major Chinese networking style, has been receiving a heightened research interest in the Western management field, with a major expansion in the literature on the growing importance of networks, networking, and network organizations (Puhakka, 2002; Steier & Greenwood, 2000; Tallberg, 2004; Wellman, Chen, & Dong, 2002). This is partly driven by the continuing and changing impact of ICT and the technological and social aspects of networking through them (Wellman, 2001). The very nature of ICT, incorporating both information and communication technologies, reflects how computers, communication, and social networks have become intertwined in people's everyday life. This is also in line with the argument according to which networks have a positive impact on entrepreneurial success (Puhakka, 2002; Steier & Greenwood, 2000). Leung (2000) points out that gender issues and Chinese cultural traditions, such as *guanxi*, are major factors influencing career development and managerial growth in China.

The development of Internet-based social networking sites have advanced social interaction, collaboration, and sharing of information (Boase & Wellman, 2006; Kavanaugh, Reese, Carroll, & Rosson, 2005), which weigh against the traditional forms of relationships—the social network and *guanxi*. According to Barry Wellman and collegues (2002), *guanxi* can be studied with a social network approach. According to social network analysis (SNA), Internet-based social networking enlarges people's weak ties, which are different from the strong ties in *guanxi* and are essential to the effective spread of information between people in separate clusters (Burt, 1992; Granovetter, 1973; Wellman, Chen & Dong, 2002). From this perspective, SIT should enhance women's networks and, therefore, benefit women IT managers' career development.

Based on a social network perspective and *guanxi*, this chapter explores the impact of SIT and *guanxi* on women managers' careers in the context of the IT field in China. The chapter starts with a literature review on *guanxi*, SIT, and women's careers in IT. The authors then analyze the results of a case study conducted in China and continue by covering future trends, a discussion, and a conclusion.

BACKGROUND

Guanxi and *Guanxi* ties

In the Chinese language, *guanxi* has different meanings. It could refer to one of three things: (1) the existence of a relationship between people who share a group status or are related to a common person, (2) the actual connections with people and frequent contact between them, or (3) a contact person with little direct interaction (Bian, 1994). Commonly, *guanxi* is defined as the special relationships that two individuals have with each other, referring to a relationship between a person who needs something and a person who has the ability to give something.

According to Fei (1992), the Chinese society is organized by concentric *guanxi* circles, extending outward from the family (the core) to relatives, friends, and business colleagues. The core of Chinese values is the differentiated attitudes toward parents, children, siblings, kinsmen, and friends, which Fei (1992) calls the "differentiated mode of association": "No tie, no obligation, and no rights" (Lee & Dawes, 2005, pp. 29). *Guanxi* is based implicitly on mutual interests and benefits (Yang, 1994): such as, respect towards seniors coupled with respect from juniors, or the soliciting and giving of favors explicitly or implicitly (Wong & Slater, 2002). Yang (1994) categorizes interpersonal relationships (*guanxi*) in China into three groups: (1) between family members; (2) between familiar people (such as neighbors, friends, classmates and colleagues); and (3) between strangers or mere acquaintances. This classification is consistent with that of Hwang (1987) who argues that the relationships with family members primarily consist of expressive ties, with strangers of instrumental ties, and with familiar people of mixed ties. Instrumental ties are unstable and temporary, impersonal and utilitarian, and based on the norm of equity (resource allocation based on contribution). Mixed ties are in between and somewhat permanent and stable, such as those between friends, within the hometown, the same area, and the same school.

The Impact of SIT on Social Networking and *Guanxi*

The development of web-based social networking sites weighs against the traditional forms of relationships—personal networks and *guanxi*—and has significant implications for the way people acquire information, interact with each other, learn, and entertain themselves.

Social networking proliferated before the coming of the Internet and the web. Since the 1990s, there has been a shift from place-to-place networking towards person-to-person networking, which Wellman (2001) calls *networked individualism*, meaning that people have flexible autonomy using social networks. This is enhanced by the application of the Internet and its progeny, following a myriad of SIT: instant messages, webcams connecting individuals; chat rooms connecting groups; and blogs, photoblogs and podcasts to broadcast thoughts, pictures and sounds. Meanwhile, there has been a global expansion of mobile phone use, carrying both voice and text. People's social interactions are mediated by modernity and technologies. The authors use social networking software to find, connect and capitalize on thousands of current, former, and potential network members. To note, one person achieved nearly 8,000 connections through LinkedIn (Mayaud, 2005).

Early literature on the Internet's role in society often made assertions that were either extremely optimistic or pessimistic (Boase & Wellman, 2006). Recently, research has begun to address this issue by providing evidence about the relationship between Internet use and contacts with friends and family, the extent to which the Internet is used to form new relationships, and the web's role in neighbor relations. Based on an investigation with 350 randomly selected English-speaking non-frail adult online Toronto residents, the results of Connected Lives Project (Wellman et al., 2006) supported the theory of networked individualism—the Internet does not turn people away from their supportive ties. Internet-based social interaction software help people get a variety of social support—major and minor goods and services as well as emotional support. The findings from these studies indicate that the web adds to the overall volume of communication, helping maintain various kinds of relationships. Networking through Internet-based SIT can reduce the perceived hierarchies because gender, social class, ethnicity, age, life-style, etc. are less visible.

Social capital is captured from embedded resources in social networks. The premise behind this notion is investment in social relations with expected returns (Lin, 1999). This is parallel with the nature of *guanxi*—reciprocity (Luo, 1997). For example, when one person offers a favor to another, the recipient must do an even bigger favor for him/her later: "The concept of social capital in a Chinese social context has been closely linked with the concept of *guanxi*" (Putnam, 2004). G*uanxi* also carries the meaning of power, social status, social capital, and resource transmission. It has been found that g*uanxi* is a source of sustainable competitive advantage (Tsang, 1998), and Chinese managers' career success depends on ties within and outside their firm (Dittmer & Lu, 1996). However, during the past two decades, China has experienced great economic and technological progress, which in turn affects people's social interaction. As people are more mobile, the types of ties that lead to strong *guanxi* are presumably harder to maintain. The increase of information flows through SIT also weighs against the traditional forms of relationships, as people have more direct sources of information and influence. From this perspective, the application of SIT can surpass the hierarchical organization structure and gendered *guanxi* (examined in more detail in the third section) to facilitate personal networks, especially women's networking.

SIT and Women's Careers in IT

The extensive application of IT has restructured the world economic system and exerted a great influence on women's role in the world economies. However, the IT industry is also one of the most competitive industries around the world. Most IT companies are in their infancy. Growth in business and changes in the business environment have happened continuously. This situation causes pressure on management. In IT companies, there exists a need to accordingly develop management and leadership methods. Rapid movements in business have decreased systematic development. The span of planning has become short-term and plans may be controlled yearly, quarterly or even monthly. Profitability is now more important than growth. The most important target of human resource management (HRM) is personnel motivation and satisfaction. The CEOs of small IT companies take care of personnel matters with other responsibilities in the firm. The most important HRM practices in small-medium enterprises of IT seem to be recruitment, familiarizing, development, and motivation. In contrast, HRM processes in bigger companies are more precisely defined and planned.

A study conducted by the Guanghua School of Management at Peking University shows that in a typical IT enterprise in China, females are concentrated in the departments of human resources and administration (73%) and marketing and financing (60%). From women employees, 12% are research employees and 16% of those in manufacturing (Shen & Ge, 2005). Women IT managers face both opportunities and challenges in their career. On one hand, they have passion and confidence. As among the female university graduates who can choose their career, the IT industry still takes precedence and becomes the most preferred occupation. Moreover, women's average salary in the IT industry is 5 to 15% higher than that in other sectors (Shen & Ge, 2005). On the other hand, there are still many constraining factors preventing women's career development in the IT industry.

The report of the Blue Ribbon Panel (ITAA, 2003) lists five reasons for possible barriers women face in their entry into IT careers. These include the lack of role models and networking opportunities, the information gap about the academic requirements expected of high school students to enter the field, the unattractiveness of IT as a work environment, the lack of strong corporate commitment, and gender-related stereotypes that may impede women's hiring and advancement opportunities. The lack of social networks and role models has been related to women's under-representation in the IT field (Ahuja, 2002; Kaplan & Niederman, 2006). Companies like hiring and promoting individuals with personal connections because those personal connections provide greater assurances that the individual will fit into the culture. Women in IT are still searching for appropriate expressions of behavior and values in organizations. Research has shown that women (in male dominated organizations) and minorities who have more demographically diverse networks generally experience greater levels of career success (Cox, 1994; Ely, 1994; Ibarra, 1995).

The application of SIT makes it possible to facilitate women's social networking. For example, WorldWIT (World Women. Insights. Technology) is the largest online networking group for women in business with free chapters in 24 countries. WorldWIT (2004) is the women's version of social networking: a true community offering career advice, job opportunities, and business planning tips. As in "I know a guy who knows a guy," it is the virtual solution to the old boys' network. Mimi Francis, WorldWIT's Chief Revenue Officer says: "Men tend to network on the golf course, which has historically left many professional women out in the cold. Today, women are networking on WorldWIT." As the founder of WorldWIT, Liz Ryan says: "In today's business climate, networking has become increasingly vital, especially for women. WorldWIT … is about making very real connections with other women who are hiring, mentoring, and building businesses."

Another study (Rutkowski et al., 2002) also indicates that Groupware, and particularly Group Support System (GSS) tools, support organizational co-ordination and interaction between various organizational structures. This implies that distance education, when employing group communication software, can produce educational results as good as face-to-face learning.

Case Study

To explore *guanxi* from gender and career perspectives, the authors conducted an empirical study focusing on the characteristics of *guanxi* bases of women managers in IT in Mainland China[1] (Huang & Aaltio, 2008). The study is based on a social network theory perspective, which focuses on the structure of social interactions and how these structures enhance or constrain access to valued resources (Burt, 1992, 1997; Granovetter, 1973). Concerned with the fact that only few women in China play a part in the management, the authors specifically explore the composition and structure of these women IT managers' *guanxi* bases and how they affect their careers and lives, partly using SNA.

With the snowball sampling method (Singleton & Straits, 1999), the data about 21 women IT managers in southern China (Aaltio & Huang, 2007) was collected based on a face-to-face in-depth interviews and a questionnaire. The participants were asked to provide information on their associates in five network contents. The name-generator approach (Marsden, 1987) can be employed to ascertain the composition of social networks. This approach focuses on a core discussion network. A simplified name-eliciting method that allowed the associates to remain anonymous was adopted. This works well to help dismiss the suspicion of the participants. Since previous results indicate that 95% of people report fewer than five individuals in their (core discussion) networks (Marsden, 1987), the participants were asked to identify up to five persons with whom they had discussions: (1) to seek advice on a decision you have to make, (2) to seek information on what is going on in the organization, (3) to seek help when you want to influence the outcome of an important decision at work, (4) to seek help in times of (personal)

Table 1. Demographic characteristics of the participants and their associates

		Participants (%) (n = 21)	Associates (%) (n = 190)	
Age		100	46.4	
	≤30	23.8	21.6	
	31-35	28.6	23.2	
	36-40	33.3	22.1	
	41-45	14.3	10.0	
	45+		23.2	
Married		52.4[^]	72.1	
College degree (Master's degree and above)		90.5 (33.4)	69.5 (24.2)	

[^] 29% of the participants were married and had one child.

crisis, and (5) to socialize with outside work. The five questions summarize the network contents of these IT women concerning their work and lives. For each associate identified, the participant was asked about her relationship with the associate and the associate's demographic characteristics, including age, gender, education and marital status. Table 1 shows the characteristics of the participants and their associates.

By exploring the composition and structure of the associates, the authors found that the *guanxi* bases of these IT women are limited. The findings show that the average network size of these women IT managers is about 9 individuals. Compared with 14 individuals in the study of Chow and Ng (2004) in which the majority of the participants were male, our participants' average network size is significantly smaller. The study also found the effect of female-to-male dyads, which are mainly within power-related and work-related *guanxi.* Women, who have a successful managerial career in IT, get wide *guanxi* networks and their career success network ties, especially power ties, are with men. For example, the majority of these women's supervisors are over 45 years old (50%) and male (78.6%). The main role of supervisors is that of influence. This indicates the masculine and hierarchical managerial model even in a new industry such as IT. Female-to-female dyads are mostly related to socialized *guanxi*.

The results demonstrate that the first three largest *guanxi* bases are coworkers, classmates, and family members. This indicates that women IT managers' networks are mainly work-related (or professional) networks, although personal life and family ties are also important for them. Coworkers, especially supervisors, are the most important *guanxi* base for these women managers concerning career and work. Classmates are also a very important *guanxi* base to the participants. As one participant reported: "Classmates are important for me because by interacting with my classmates, it's quite possible for me to get access to their networks." Obviously, the role of classmates is in personal life and career networks. The age of classmates shows that most of them are younger than the participants; this indicates the tendency of on the job training and lifelong learning in the IT industry; and, it supports the research finding that women are more likely than men to try to learn more and to want more education as career tactics (Granrose, 2007).

The results indicate that the majority of *guanxi* ties which have an impact on career (influence ties) are with older men, and these networks of ties are smaller than those of men's as shown by Chow and Ng (2004). This implies a relatively narrow scope for women's informal networking and weak ties. Researchers have argued that informal networks and weak ties are more important for women's career success (e.g., Burt, 1992; Travers & Pemberton, 2000). However, women in organizational settings are often reported to experience a limited or indeed no access to informal networks (Kanter, 1977; O'Leary & Ickovics, 1992). This means that women's access to the instrumental resources is limited, which are critical to one's job effectiveness and career advancement, and are allocated by these networks. Besides, informal networks also provide friendships and social support. The disadvantages of experiencing difficulty in getting access to the networks include restricted knowledge of what is going on within the organization (or information) and difficulty in forming alliances—these in turn may be linked to career advancement issues, such as limited mobility and the glass ceiling effect.

Obviously, networking with supervisors (most of them are older men, as shown by the results) concerning work and career issues is one of the strategies these women IT managers adopt. This to some degree limits women's weak ties. Besides, all formulations and applications of the concept of *guanxi* are based on the idea of reciprocity as a key mechanism by which relationships may be transformed into a variety of assets. Researchers differ with respect to assessing the effects of reciprocal obligations on action. Some see reciprocity as the primary basis of social identity, leading to strong social relations, conveying a sense of belonging, and creating a clear normative order within which individuals can optimize their performance (Podolny & Baron, 1997). Others view reciprocity as a potential source of "structural arthritis" (Burt, 1997) because cohesive social ties may lock individuals into a continued mutual exchange. For example, one participant said: "I have good *guanxi* with my supervisor. Because of this, I can always get positive support and valuable information from him for my work. You know this is very important for my career…Of course I work hard in return." There are two sides to a coin; thus reciprocity obligations, cemented by strong social ties, may make it difficult for individuals to extricate themselves from those obligations and to cultivate new relationships. Sometimes *guanxi* receivers feel a burden to "pay back." As one participant emphasized, "After I got support or help from my coworkers, especially from my supervisors, I always think of "paying back" somehow one day. Sometimes this is really a burden for me. Because of this, I gave up an opportunity to work for another company with higher salary last year… I don't know if I will regret, but this is what I should follow…" This implies that women are experiencing some emotional costs for maintaining the *guanxi* ties.

From the in-depth interviews, it was found that in the gendered IT industry, women managers are finding a way of coping with the limited network. They either try to cope at work by somehow negating their gender, by being an "it" in IT (Adam et al., 2006), by networking in accordance with the principles of *guanxi*, or by using SIT to widen their networks and keep contact with their networks. Some participants talked about how they have joined the web-based communities and share information among members. SIT provide people with alternative ways of acquiring information and interacting with each other regardless of time, space, and physical presence. This makes it possible for these women to surmount gendered *guanxi* and the perceived hierarchies in an organization because the gender, social class, age, etc. are less visible in SIT-based networking. Based partly on the social network analysis, SIT-based networking can enlarge women's weak ties and release the "paying back" burden for these women. For instance, one participant reported she got her recent position (vice president) through an Internet-based headhunter company. Another participant, who is the CEO of a cross regional IT company, talked about how she managed her company through an Internet-based platform. When talking about SIT and *guanxi*, one participant noted: "Networking through SIT looks easy and simple; however, there exists uncertainty because of less, even no commitment and obligation between networking individuals. From this perspective, networking by *guanxi* is more efficient because it is based on obligation and long-term trust." This indicates that the use of SIT as an efficient way of networking for women IT managers has just begun. This also implies the significant effect of the traditional culture on people's lives and communications. Overall, the study indicates that SIT and *guanxi* should be viewed as complementary rather than mutually exclusive or separate influences.

SIT and Women in China

Traditionally people in China, as in other emerging markets and developing nations, rely on their social networks as information sources, and public institutions tend to be fairly weak as citizen resources. With the development of the information technology, social software has shown itself to have significant potential for people's interactions.

According to *The 22nd Statistics Report of China's Networks Development* issued by the China National Net Information Center (CNNIC, 2008), the domestic IT industry and market in China have undergone rapid development, with the number of Internet users reaching 253 million and the number of mobile phone users nearing 592 million. Chinese female netizens totaled 46.4% of all Internet users, which has formed a subset of IT users with strong potential. Compared with men's use of the Internet, Chinese women mainly use the web for entertainment, sensibility needs, information, and networking with friends. It is interesting to note that more women (17%) than men (7%) in China use the Internet for developing friendships (Shen & Ge, 2005). This indicates that Chinese women emphasize the social networking function of the Internet more than men. Networking online affords people the ability to maintain larger networks of weak ties with a minimum effort, however, such networks can be viewed as physically distant, sparsely knit, transitory, socially diverse, and weak (Boase & Wellman, 2006; Wellman, 2001).

Since the face-to-face network is still a key component of people's daily life in China, it is not surprising that mobile phone usage is outpacing the rate of Internet adoption. The use of text messaging through mobile phone is an inexpensive way to maintain contacts with friends and family; it is also a mode of information exchange within a professional network. Social software applications used for networking (e.g., QQ, MSN Messenger, Yahoo Messenger, Skype, and Google Talk) have been widely adopted among certain demographics for a variety of purposes including career management. In China, a growing number of companies are applying SNS for employment recruitment (e.g., Zhaopin Ltd.[2]).

Weblogs (or blogs) are becoming a "new form of mainstream personal communication" (Rosenbloom, 2004, p. 31) for millions of people to publish and exchange knowledge and information as well as to establish networks or build relationships. In 2007, there were about 46.98 million bloggers in China, which is about 26.1% of the netizens (CNNIC, 2007). Recent releases of blogging tools provide enhanced features for between-blog interactivity, thus promoting the creation of social networks among bloggers. As innovative social interaction technologies, these advances enable web-based word-of-mouth (through blogging activities) and demonstrate that it is not accidental that just a few years ago blogs were identified as being among the top "10 tech trends to watch" by the Fortune magazine (Vogelstein et al., 2005, p. 43). Additionally, web-based SIT are being increasingly used by Chinese women as efficient tools for compensating their inadequate networking in the male-dominated industries.

FUTURE TRENDS

Since g*uanxi* networks include connotations that are gendered and culturally bound, the authors argue that the research of professional networking in China needs to address the nature of social ties that create networks. These networks can be based on local and country-specific traditions even when displaying similarity with Western prototypes at the surface level. The present case study indicates that the application of SIT to personal networking can weaken the negative impact of gendered *guanxi* and expand the women's network. The implementation of SIT can be a positive strategy for women's managerial careers. These findings have important implications for organizations' human resource management practices. Future research should focus more specifically on the impact of SIT on social networking in China, especially from the gender perspective: for example, showing how women can be trained to use SIT, comparing how women and men can equally benefit from using SIT, and drafting a legal framework to support the application of SIT. Furthermore, the application of SIT within cross-cultural contexts should be examined to understand how Chinese women's social networking differs from their Western counterparts, considering *guanxi* as a central concept in Chinese society.

CONCLUSION

The under-representation of women in the IT sector worldwide, especially in managerial positions, has been widely documented in the research literature. Most of the studies reported that inadequate networking and the lack of female role models and mentors are the main barriers for women entering the IT industry. The case study conducted in China and presented in this chapter also found evidence of the gendered *guanxi* and women's limited networking abilities (Huang & Aaltio, 2008).

In practice, women respond to male-dominated organizational cultures in a variety of ways, including the development of female associations or networks (Mills & Murgatroyd, 1991). Within the IT field, women have taken advantage of the emerging SIT to develop support networks to reach beyond organizational boundaries and create associations in cyberspace (see Lahey, 2002; WorldWIT, 2004). These female-centered formal and informal networks are aimed at encouraging and promoting IT as a professional field for women and developing effective networking and mentoring relationships for women across industries and IT interests (Ahuja, 2002). However, some scholars warn that organizations should be careful about the obvious matching of women with women in mentoring programs. Kaplan and Niederman (2006) argue that selecting women as mentors is perfectly suitable as long as the potential mentor has a diverse and powerful social network; otherwise, all else equal, a potential female protégé could arguably benefit more by being paired up with a male mentor, as this would address the important cross-gender networking concerns.

Based on the results of the above case study and social network perspective, the authors can explicate about the ways SIT may impact women managers' networking:

- **Advice and Information:** Both consultation (advice) and information (*guanxi*) have been successfully linked to the strength-of-weak-ties hypothesis (Granovetter, 1973). Therefore, SIT may allow for better networking, enlarge the possibility to seek advice and new information by using their effective communication abilities, and lessen the gender inequality based on "old boys" networks.
- **Influence:** By using SIT, women can overcome old normative barriers which are based on traditions and gender stereotypes.
- **Seeking Help:** SIT may help women contact their affective *guanxi* networks (family, relatives, friends, etc.) when they are distant.
- **Socializing:** SIT can help women build careers and use networking strategies based on technology applications.

Overall, although the impact of SIT is not revolutionary, new technologies enlarge possibilities for networking and create situations in which the impact of traditions, norms, and gendered values is lessened. Therefore, the influence of SIT is empowering for women who build careers in the IT industry.

For most of the women IT managers, a career epitomizes the advancement of individual abilities.

Successful functioning in professional networks requires efficient communicational skills. Because much of their work is based on collaboration, women need to adapt to this reality if they seek to be successful in their careers. At the same time, the increased use of the multidimensional networks of organizations as vehicles for economic and political decision-making requires a distinct set of organizational, communication, and managerial skills, in which women have traditionally been considered proficient (Fountain, 2000; Morrison, Randall, & Van Velsor, 1992).

Currently, the IT industry is in transition between the old sense of identity, which is based on masculine culture (the technical side), and the new one, based on inherently female values (the communication side) (Colwill & Townsend, 1999). Gender-biased cultural expectations still create a barrier to female managers' careers in IT. However, the changing nature of IT work and the implementation of SIT opens it to diverse expertise and values. Considering that China is in transition at both social and organizational levels, the authors suggest that IT organizations may develop mentoring programs, especially informal ones, to address inadequate representation of women in the field and to support women managers' careers in IT. Besides, women need to be more strategic when deciding how to develop relationships within and outside their organizations, which will benefit their career development in the field of IT.

KEY TERMS AND DEFINITIONS

Career: Consists of the sequential choices made by an individual, and is a development process of creating and managing a professional identity and personality.

Culture: A process of constructing shared meaning and is based on a unique human capacity for self-consciousness and awareness of others.

Gender: Refers to the cultural construction of femininity and masculinity.

Guanxi: a central concept in Chinese society, is defined as a personal network, a network of ties, or as a special relationship between two or more individuals, which has wide cultural implications

Guanxi Base: Defined as a shared common identification held by two or more persons.

Social Network: Refers to a social structure made of nodes (which are generally individuals or organizations) that are tied by one or more specific types of interdependency (such as values, visions, exchange, friends, kinship, dislike, trade, or sexual relations).

Social Network Analysis (SNA): Views the attributes of individuals as less important than their relationships and ties with other actors within the social network. SNA has turned out to be useful for explaining many real-world phenomena, but it leaves less room for individual agency. It provides both a visual and a mathematical analysis of human relationships.

ENDNOTES

1 This study was supported by the Social Sciences Fund of Guangdong Province, China (No. XLY0313).

2 Founded in 1997 and with branch offices in over 30 cities, Zhaopin Ltd. (www.zhaopin.com) is one of the leading recruitment and management agencies in China. Its services include: Internet-based and traditional media recruitment, campus recruiting, human resources outsourcing, corporate training, and staff assessment. Currently, there are hundreds of online-based recruitment companies in China.

ABSTRACT

The aim of this chapter is to investigate the potential role of social software inside business settings in integrating knowledge exploitation and knowledge exploration strategies. These strategies are approached through the lens of dynamic capabilities, organisational learning and knowledge lifecycle models. The authors argue that while current enterprise Information Technology (IT) systems focus more on knowledge lifecycle processes concerning the distribution and application of knowledge, enterprise social software can support knowledge exploration strategies and leverage knowledge creation and validation procedures. We present secondary data from the utilisation of enterprise social computing tools inside two companies for that matter. The first case illustrates how social computing tools were deployed in an international bank, and the other presents the employment of these technologies in an international broadcasting company. The authors suggest that free-form and pre-defined structures can co-exist in bounded organisational environments, in which knowledge

DOI: 10.4018/978-1-60566-208-4.ch020

exploitation and knowledge exploration strategies can harmonically interact. This chapter concludes with some managerial implications and future research avenues.

INTRODUCTION

During the last decade, industry and scholarly communities have equally highlighted the importance of managing organisational knowledge and posited that intangible assets form a critical enterprise resource asset (Metaxiotis et al., 2005; Davenport and Prusak, 1998). Knowledge management has been previously associated with the exploitation and growth of the organisational knowledge assets (Davenport and Prusak, 1998) aiming at increased operational efficiency and continuous time-to-market improvement. Yet, recent developments associate knowledge strategies with the ability of the organisation to explore and identify critical changes of the external operating environment, ultimately renewing its internal knowledge base and core competencies (Bhatt et al., 2005). Hence, the mere existence of strong organisational resources and capabilities appear to be inadequate for obtaining long-term sustainable competitive advantage.

The term "Enterprise 2.0" promptly followed the widespread of the so-called "Web 2.0" and dominated the discourse surrounding the utilisation of business concepts in relation not only to enterprise information applications, but also to associated managerial approaches related to our post-industrial age (Bughin, 2008; Hamel, 2007). The use of the decimal point in the term implies a proposed discontinuity from previous forms of organisational contextures, emphasising on a suggested transformative role of social computing inside companies (e.g. wikis, blogs, podcasts, RSS (Really Simple Syndication), Instant Messaging, social bookmarking, etc) (McAfee, 2006). Now, there is a heated debate between sceptics who argue that the term "Enterprise 2.0" has nothing to offer other than basic managerial selections regarding the utilisation of generic networked business applications (Stenmark, 2008), while supporters claim that the term conveys something new: a flexible and adaptable perspective to organisational knowledge strategies (Bibikas et al., 2008; Ip & Wagner, 2008; Kosonen & Kianto, 2008; Marfleet, 2008; Patrick & Dotsika, 2007; Coakes, 2006; McAfee, 2006) and a key driver towards the development of dynamic capabilities (Shuen, 2008). Has Enterprise 2.0 some actual meaning or the term should just be approached metaphorically? In this paper, we explore whether Enterprise 2.0 can provide strategic business value affecting key knowledge processes and adaptive capabilities of organizations.

The remaining of this chapter is structured in five parts: The first presents the research approach and study methodology. The next section explores knowledge exploitation and knowledge exploration strategies through the lens of dynamic capabilities theory. The third part presents some of the main characteristics of Enterprise 2.0 and investigates the potential of social software in the future of organisational information and knowledge management systems. We argue that these technologies can help towards the integration of exploitation and exploration knowledge strategies. The fourth session presents secondary data from the utilisation of enterprise social computing tools inside two multinational companies. Finally, suggestions and managerial implications are presented along with future research directions.

Research Approach

This article is an early exploratory study and employs a deductive qualitative research approach. It uses a combination of critical literature review on dynamic capabilities theory, knowledge lifecycle and organisational learning in order to conceptualise a model illustrating the potential role of enterprise social software in bridging knowledge exploitation and exploration strategies. Subsequently, this model is tested through secondary data from use cases of social computing inside two large organisations. Since empirical studies providing insights and concrete results on the use of social computing tools for knowledge management purposes are rare, a few anecdotal case studies present some early indications. This research was performed using a desk study method, exclusively using secondary sources. Desk research approaches are usually regarded as mere literature reviews in order for the researcher to be familiarised with background knowledge (Remenyi et al., 1998; Gill and Johnson, 1991). However, this chapter aims at having the desk study as the main method of research. The objective of this article is to adopt a deductive argument in order to conceptualise the role of enterprise social software in an integrated knowledge exploitation and knowledge exploration model. This model is later juxtaposed with secondary data of social software deployments inside organisations. Therefore, this chapter adopts a deductive desk research approach and involves the development of a theory that is subsequently subjected to a test (Collis and Hussey, 2003).

Through this preliminary exploratory investigation it is proposed that social software can be employed to support organisational knowledge exploration strategies. Yet, one cannot neglect the limitations of this particular approach and emphasise on the need to further investigate the suggested theoretical model to other companies and industry sectors, through primary data and field investigation methods.

EXPLOITATION AND EXPLORATION PERSPECTIVES OF KNOWLEDGE MANAGEMENT

Knowledge Exploitation and Exploration as Organisational Learning Strategies

Learning organisations are defined by Senge (1990) as places in which creative thinking is cultivated and continuous learning is fostered. Today's businesses face the challenge of continuous learning and usable knowledge generation in order to increase their responsive capabilities to market changes and advance their innovation outcomes. Therefore, current businesses – which in this chapter are approached as "learning organisations" – plan and implement various knowledge management strategies. Often these practices lay between two largely defined selections: knowledge exploitation and knowledge exploration (March, 1991; Liu, 2006). Knowledge exploitation strategies consist of organisational learning practices for the optimisation of existing processes and improvement of pre-existing knowledge assets. It mainly involves the deployment of resources the enterprise already holds on its possession (Sitkin et al., 1994). On the contrary, knowledge exploration strategies comprise organisational learning practices regarding the creation of new knowledge for the development of new products, services and processes. The latter often lead to the creation and addition of new resources and organisational knowledge assets (Sitkin et al., 1994). Knowledge exploitation reflects moderate yet definite and immediate returns on organisational performance by continuously adopting, synthesizing and applying current knowledge(Liu, 2006). On the contrary, the highly uncertain and unpredictable nature of knowledge exploration process reflects the capability of an organisation to create new core competences, by investing in flexibility, risk, experimentation and innovation (March, 1991; Liu, 2006).

There seems to be a tight link between organisational dynamic capabilities and the two abovementioned organisational knowledge management strategies (i.e. exploitation and exploration). Exploitation and exploration activities can be associated with key knowledge management processes that *create*, *validate*, *present*, *distribute* and *apply* knowledge-based resources of the firm through an iterative circle of change, renewal and exploitation (Bhatt, 2001; Nielsen, 2006). This dynamic interconnection between exploitation and exploration knowledge practices creates an iterative flow towards and from the firm's stock of knowledge-based resources. In particular, dynamic capabilities through knowledge exploration contribute to the organisational stock of knowledge – thus creating an "in-flow" stream to the firm's stock of knowledge. On the other hand, dynamic capabilities through knowledge exploitation practices utilise existing resources for the development of new products, services and procedures – thus creating an "out-flow" stream from the firm's stock of knowledge (Nielsen, 2006). Consequently, the knowledge lifecycle refers to the phases of knowledge process management that an organisation utilises in order to learn, reflect and act upon available resources (Bhatt, 2001): a) *knowledge creation* can lead to the generation of innovative ideas and uncover hidden solutions to existing problems; b) the *knowledge validation* phase provides revision and reflection upon available organisational resources in order to investigate whether these intangible assts are in line with the current state of the art or outdated by more recent developments; c) *knowledge presentation* depicts the means of knowledge illustration in organisational settings through a variety of procedures, media, departments and work practices; d) the *knowledge distribution* process allows knowledge to be shared across organisational boundaries by means of interaction between available communication technologies, management techniques and people; e) *knowledge application* usually refers to the embodiment of available knowledge resources in the organisational value creating system through its products or processes.

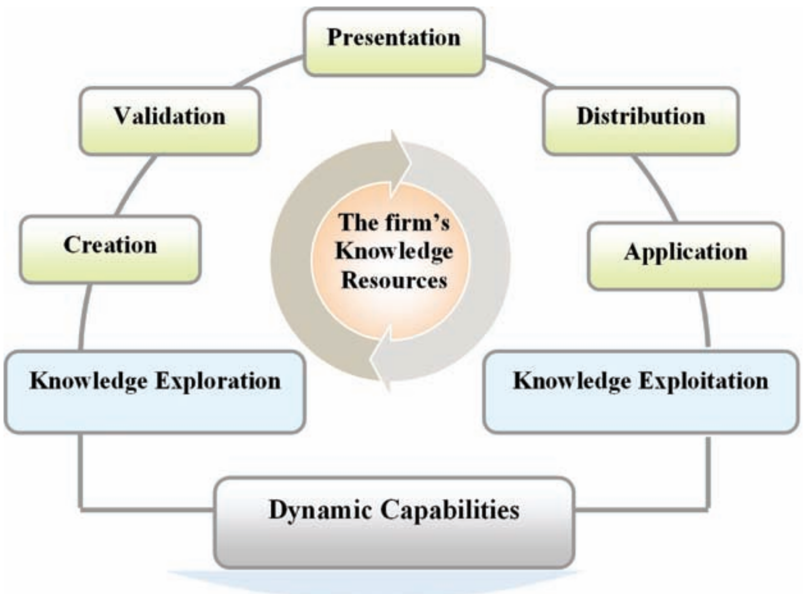
It is proposed that a vital aim of the knowledge lifecycle is to harmonise *knowledge exploration* and *knowledge exploitation*, where the five distinct stages of the knowledge process management appear to be an amalgamation of new knowledge formation (i.e. creation, validation and presentation procedures) with existing knowledge employment, iteration or removal (i.e. distribution and application) (Liu, 2006, Bhatt et al., 2005). The above figure (Figure 1) depicts the association of knowledge lifecycle with knowledge exploitation and exploration strategies in respect to organisational dynamic capabilities.

The Potential of Enterprise Social Software in Knowledge Exploration

It is argued that the use of a new breed of emerging collaborative environments in knowledge intensive organisations can facilitate knowledge work (Bibikas et al., 2008; Bughin, 2008; Ip & Wagner, 2008; McKelvie et al., 2007; Patrick & Dotsika, 2007; McAfee, 2006). These new digital environments for generating, sharing and refining knowledge are already popular on the Internet, where they are collectively labelled as "Web 2.0" technologies. Interestingly enough, these technologies are entering enterprise bounded environments for creating and sharing organisational knowledge (Bughin, 2008). Although "Web 2.0" technologies in organisational settings can be viewed from varying perspectives and can be referred to employing different names (i.e. social software, social computing, Enterprise 2.0, etc), their main general operations appear to be (McAfee, 2006):

- Search, to provide mechanisms for discovering information.

Figure 1. The role of knowledge lifecycle in forming the dynamic capabilities11311



- Links, to provide guidance to knowledge workers in order to discover the needed knowledge and ensure emergent structure to online content.
- Authoring, to enable knowledge workers to share their opinions with a broad audience.
- Tags, to present an alternative navigational experience exploiting un-hierarchical categorisation of intranet content.
- Extensions, to exploit collaborative intelligence and recommend to knowledge workers contextually relevant content.
- Signals, to automatically alert knowledge workers for newly created and relevant content.

From a technological point of view these technological features are hardly new (i.e. search, links, metadata and signalling technologies – such as electronic mail – existed from the very beginning of the Internet), yet they are becoming more and more easy to use. Perhaps more importantly, they convey a novel perspective regarding the process of utilising enterprise information and developing knowledge management systems in organisations. Unlike the design of current technologies, where particular tools usually predefine their employment (i.e. presenting certain business rules and specific procedural requirements), enterprise social software can be abstracted from its practical use, in a manner that the tools are not directly defining their utilisation. However, these applications cannot be considered "social" as such. Rather they provide functionality in order for the social constructs of organisations (i.e. individuals, teams, units, customers, partners, etc) to engage in social activities (Bouman et al., 2008). As an example, a wiki application can be utilised from formal business policy documents editing to brainstorming and realising meeting agendas. Similarly, a blog can be employed from business project activities reporting to posting personal work-related thoughts and reflections. Therefore, the deployment of enterprise social software can be eventually emergent according to adapting needs, ideas, organisational policies etc. We argue that the "social" attribute of enterprise "Web 2.0" tools, the fact that by design are intended to provide for interaction and communication, presents an opportunity for enhancing explorative knowledge strategies.

Often the design of enterprise IT/KM systems focuses on rigid procedural tasks and routine information in a structured manner. In transactional or computational business information systems this is can be desirable (e.g. Enterprise Resource Planning, Management Information System, Business Intelligence, etc). Pre-defined categorisation of users, access rights management and specified up front roles together with process replication mechanisms are all vital functionalities of such enterprise information systems. Yet, these functionalities are – by design – more focused on knowledge distribution and application. They convey the embodiment of available organisational knowledge resources in the firm's products, services and procedures for the creation of a process-based unified work environment (Brynjolfsson & McAfee, 2007). However, social computing tools can enhance knowledge exploration strategies, leveraging knowledge creation, validation and presentation processes.

Knowledge Creation Process

Knowledge creation is essentially associated with individual creativity and innovation capabilities (Bhatt et al., 2005). An organisation can create new knowledge through the embodiment of a deeper level of understanding that occurs when individuals question their own and shared mental models (Guzman & Wilson, 2005; Metaxiotis et al., 2005). As Argyris and Schon (1978) point out, knowledge creation effectively takes place when there is a conflict between one's "espoused theory" (i.e. mental models concerning values, behaviour, leadership style, etc), and one's "theory-in-use" (i.e. what an individual actually does). Enterprise social software can act as a dynamic and emergent repository of digital content where contributions can be under circumstances widely visible and persistent and invoke conversations and divergence of ideas and thoughts. The basic categorisation of user roles in enterprise social computing tools, as well as the absence of rigid structures of the knowledge resources which are meant to capture, in a sense can promote dissent or debate, or otherwise a conflict between one's "espoused theory" and "theory-in-use". These platforms through their conversation engagement functionality appear to compose a model for enhanced contextual understanding of the underlying philosophy of established organisational norms and routines: a critical process for achieving new knowledge creation (Bhatt et al., 2005; Argyris and Schon, 1978).

Knowledge Validation Process

As realities in the inner or outer organisational environment can be rapidly altered, knowledge validation process drives a continuous examination and supervision of available organisational knowledge assets (Bhatt, 2001). In this way outdated knowledge should be revised or discarded. Enterprise social software consists of digital environments which are initially freeform and largely avoid the "binary logic" of imposed roles, identities, workflows, or interdependencies. The social design element of these technologies can help generate flexible and experimenting practices inside businesses. Knowledge workers can be empowered to create, adjust and dismantle their processes across the organisation. McAfee (2006) calls the procedure of presenting "untested" knowledge using social computing tools and the subsequent dialectic examination and revision of such resources "knowledge episodes". Knowledge episodes are explained as the recordings of both the interactions of knowledge workers in a particular matter, as well as the actual output of their work practices (McAfee, 2006). The participatory design element of social computing tools as well as their initially freeform and loosely-structured character constitutes a promising element for element for maintaining both the relevance and currency of organisational knowledge.

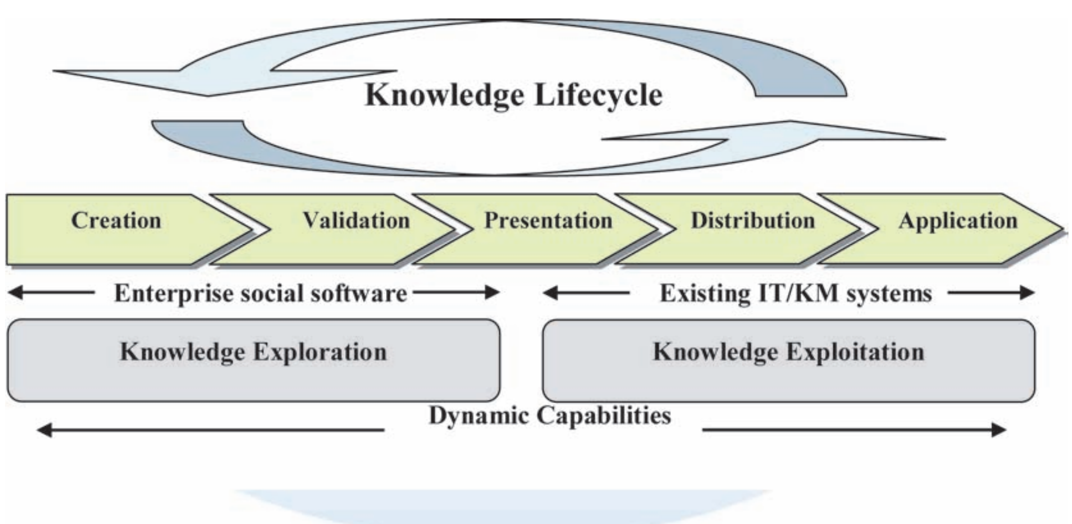
Knowledge Presentation Process

With regards to the knowledge presentation process, enterprise social software can contribute to the development of a unified work place and co-exist with other corporate IT systems. The functionality of enterprise Web 2.0 software of creating widely and permanently visible content appears to promote an integrated presentation scheme of organisational knowledge resources, regardless of corporation location, media and work practice. The goal of universally visible and persistent content within the organisation can effectively reinforce the rigidities of existing organisational boundaries, actively promoting the exploration of new knowledge.

"Legacy" enterprise IT/KM systems jointly with enterprise social software seem to effectively leverage all activities of the knowledge lifecycle. Social computing tools can be used in order to promote knowledge creation and validation through open discussion, communication and ideas exchange. On the other hand, traditional business information systems can focus on process replication mechanisms, such as the knowledge distribution and application processes. Hence, the combination of enterprise social software with existing corporate IT/KM systems can lead to an integrated view of the knowledge lifecycle process in organisational settings. This interaction of "legacy" IT systems and enterprise social computing in relation to the knowledge process management is depicted in the following figure. It presents the complementary role of enterprise social software in knowledge lifecycle and organisational learning in respect of dynamic capabilities formation.

Participative enterprise social software can co-exist with "legacy systems", such as Enterprise Resource Planning (ERP), Customer Relationship Management (CRM) and Human Resource Management (HRM) (Brynjolfsson & McAfee, 2007; McAfee, 2006). These business information systems will continue to play a major role in everyday organisational operations (payments, orders, expense submissions, etc). Decision-making processes should still be based on highly structured systems and processes leaded by knowledge-based assets and business objectives (Goh, 2005). Yet, in parallel to these business operations, we suggest that knowledge workers should utilise social software technologies in order for informal collaboration and person-to-person interaction to take place. Structured data and information from "legacy systems" can be communicated and con-

Figure 2. Integrating knowledge strategies with existing and social software technologies.



sistently available through emergent participative technologies. Free-form and pre-defined structure can co-exist in bounded organisational environments employing an integrated setting in which knowledge exploitation and knowledge exploration strategies can effectively interact.

In the following cases the reader is introduced to some examples of social software utilization inside business boundaries. The cases illustrate the generic attributes of enterprise social software as pointed by McAfee (2006):

- Digital environments in which content can be persistent and widely visible.
- Lightweight deployment, in the sense that they are easy to implement and use.
- Emergent categorization of content in an evolving and self-organizing manner.
- Based on SLATES functionalities (search, links, authoring, tags, extensions, and signals).
- Can provide widely accessible content on both the process as well as the final output of collaborative work practices.
- Reliant on social constructs of organizations (e.g. individuals, teams, networks, etc).

International Bank Case

The international investment bank of the first case is established in Europe (London and Frankfurt) and provides a range of financial services. The company has approximately 6.000 employees internationally.

Employees of the company in different departments and geographical locations were used to working in a "walled garden" approach. Although groupware tools were formerly being used, they had only limited impact on content sharing and wider user engagement. Information was often isolated and not easily accessible. Therefore, the main challenge was to create a knowledge sharing digital environment without compromising on security issues. The company started with internal wikis and blogs deployment. At the beginning only the IT department employees were using these applications. However, the aim was to transform these technologies into a central hub for all departments – technical and non technical – to participate. A bottom-up publicisation approach was selected, mainly through e-mails and word-of-mouth. The first encouraging results did not take long to appear. Employees from a wide variety of backgrounds and responsibilities started to follow and contribute to the internal wiki articles and blog postings. Previously undiscovered knowledge resources were starting to be revealed. Employees with different competences were starting to add value to various subjects outside their every-day tasks. This is in line with the view of McAfee (2006) in which enterprise social software can accumulate widely and permanently visible knowledge assets through flexible and experimentation practices. Also the participation empowerment of the internal wiki deployment in this case agrees with the view in which enterprise social software encourages knowledge workers to create, adjust and dismantle processes across the organisation (McAfee 2006). Ideas, solutions to problems and knowledge assets were generated from various employees from different departments, levels and geographical locations. This "demand-driven" operational model of social software could potentially invoke new organisational competencies and empower expertise creation.

As the users of the internal enterprise social tools grew the company decided to offer short and informal training sessions. The fact that the guidance to use of these tools was speedy and "unofficial" agrees with the view of McAfee (2006) that social computing tools are easy to use and they require only a little or no training at all.

Legacy technologies were soon after integrated with enterprise social computing environment. Old intranet documents were transferred on wiki articles and employees of the bank revised out of date contents. With the help of the wiki there have been a continuous examination and supervision of available organisational knowledge assets as the knowledge validation procedure asserts. In this way outdated knowledge was revised and updated or discarded accordingly.

Furthermore, the wiki was used in order to effectively present inter-departmentally information of various types. Allegedly, the employees found the use of the wiki for presentation purposes more effective than other applications. The functionality of enterprise Web 2.0 software of creating widely and permanently visible content appears to promote an integrated presentation scheme of organisational knowledge resources, regardless of corporation location, media and work practice. Also, using the wiki the employees had the opportunity to collaboratively create, validate and present knowledge assets, developing therefore iterations between the exploration stages of the knowledge lifecycle.

In this case, social computing tools facilitated the creation of an open environment where content was permanently and widely visible, with employees creating, validating and distributing knowledge assets asynchronously and in parallel. Management played a significant role. Executive staff was the first to explore the use of such tools. They transfer information from the intranet to wiki articles and championed the use of social computing tools for various purposes (e.g. presentations, reporting, briefings, etc). Moreover, management planed for future utilisation of social computing tools. Their vision was not only to expand the use of such tools inside the firewall, but also to develop a dedicated area outside the company's intranet for customers and partners in order to promote discussion and to collaboratively develop documentation. This scope agrees with the suggestion of Shuen (2008) that in order to develop and sustain dynamic capabilities organisations should connect and interact with other companies and generate open ecosystems for managing digital syndications.

International Broadcasting Company Case

The broadcasting company of the second case is arguably one of the oldest and largest established broadcasting organisations world-wide. It is a multi-billion globalised corporation and offers many national television stations, international, national and local radio stations. Relationships and not static documents were seen as the essence of employees' daily knowledge work. The challenge in managing knowledge in such an organisation was to enhance its already relationship-based and conversational culture.

Contrary to the established approach of managing knowledge in such multifaceted and complex environments, the organisation did not select to deploy a large and expensive knowledge management system. What they focused on was the means by which they could facilitate relationship building and enhance conversational links among employees all over the world. Although that the company possessed centralised and formal directories with human resources and business information, they were rarely updated and did not reflect the dynamic connections between employees.

The organisation started experimentally to deploy social computing tools for the employees of all levels: blogs, wikis and social-networking tools. The first step in the social software deployment venture was the set up of fora and blogs. These tools were created with virtually no enforcement of work categorisation, output or structure. The ultimate goal was to empower flexibility, risk and experimentation. Employees of all levels used these tools for various reasons from setting up meetings and company excursions to discussing key strategy decisions. Blogs were deployed in a bottom-up fashion. Individuals, teams and executives that wished to create and maintain a blog, were free to do it with no other requirement except basic commitment to avoid unprofessional conduct. This implementation approach agrees with the view of McAfee (2006) that freeform and loosely-structured enterprise social computing tools, allow knowledge to eventually self-organise through day-to-day work practices.

The next step was to deploy company-wide internal wikis. The library department envisioned to generate a dynamic "knowledge base" in order to reflect the active relationships and linkages among business, units, teams and individuals inside the organisation. Although that an intranet infrastructure existed beforehand, the content was never updated in time and did not reflect the changes in the corporation. This would only happen if the information provided was easily updated from anyone inside the organisation. The library department should initiate the content creation procedure, yet the information had to be dynamically updated from members of all levels and departments. As a result, there were continuous iterations in which employees inside the organisation created, validated and presented knowledge assets in a collaborative and widely visible manner. The organisation had perhaps for the very first time a massive amount of knowledge assets created in a decentralised and speedy fashion. This outcome is aligned to what McAfee (2006) suggests on the facilitation capabilities of enterprise social software, i.e. that these tools can make experimentation procedures, interaction and knowledge exchange widely available inside organisations. This recorded output could eventually lead to the creation of new knowledge and novel organisational competences.

The corporation of this case proceeded with the utilisation of social computing tools for other purposes as well. Collaborative document editing and project management related tasks were also facilitated with the use of these technologies.

Again the role of the management played a key role. In this case executives started to use social computing tools and presented an early strategic intent, an act that gave the example to the corporation's units and individuals. Furthermore, these technologies were approached as a long term competitive advantage for the company and not as a short term and merely tactical tools. Business and technology executives of the organisation envisioned from the early beginning creating an ecology of open and conversational digital spaces for all partner-companies, units, teams and individuals.

Discussion

This chapter has explored the role of enterprise social software, not only as a novel perspective concerning the integration of knowledge exploitation and knowledge exploration strategies, but also its potential and a catalyst for effective dynamic learning capabilities leverage in corporate environments. It is argued that its demand driven and knowledge worker centric approach, allied with a capability to enable "on demand" knowledge management techniques offer the flexibility required to support the formation of knowledge exploration strategies (Bibikas et al, in press). At the same time, enterprise social software is amenable to integration with legacy systems that may already support well the exploitation of existing knowledge resources, leading in effect, to an approach that will enable to underlie the management of overall knowledge lifecycle activities in organisations.

There are practical managerial implications for the implementation of a strategy that encompasses this type of approach: in a first instance, this requires the adoption of an incremental process, starting with pilot and informal initiatives, allowing for collaboration and bottom-up process improvement; secondly, it entails the formation of an adaptive knowledge management strategy, based upon the study of existing formal and informal work practices of knowledge workers and their community interaction, as well as existing innovation process management activities; thirdly, there is the need for awareness towards a clear rationale for the allocation of resources for both exploitative and explorative activities. The direction and implementation of such strategies and the balance to be achieved needs to be contextual to the requirements of each organisation, depending upon environmental driving forces that affect it, such as policy, market and technology dynamism, as well as internal structures, know-how resources and culture. Further research, particularly at the empirical level, is required in order to identify how these balances are achieved, in a variety of organisational contexts, which strategies can effectively support them and how these new developments in enterprise social software can concretely underpin them.

KEY TERMS

Dynamic Capabilities: It is the firm's ability not only to exploit its existing resources and organisational capabilities, but also its ability to renew and develop its organisational capabilities.

Enterprise Social Software/Enterprise 2.0: The use of social computing tools in organisational settings.

Knowledge Exploitation: Knowledge exploitation strategies consist of organisational learning practices for the optimisation of existing processes and the improvement of pre-existing knowledge assets.

Knowledge Exploration: Knowledge exploitation can be viewed as the employment of organisational learning activities involving the employment of resources the firm already holds on its possession.

Organisational Capabilities/Core Competences: Critical knowledge assets that form the basis for products and services offered by the firm.

Chapter 6.6
Interrelationships Between Professional Virtual Communities and Social Networks, and the Importance of Virtual Communities in Creating and Sharing Knowledge

Fernando Garrigos
Universitat Jaume I, Spain

ABSTRACT

This chapter presents the interrelationships between professional virtual communities and social networks, and analyzes how, and in what ways, these communities play a crucial role in the creation and sharing of knowledge. The chapter begins by outlining how virtual communities are gaining importance in the new environment. It explains what we understand as a professional virtual community and its importance and also the relevance of social networks in today's Knowledge Management age. The study then analyses how the development of social networks is crucial to the improvement of professional virtual communities, and also how virtual organizations can promote the improvement of social networks. Finally, the study examines how virtual communities are vital as mechanisms for creating and sharing knowledge.

INTRODUCTION

The importance of information and knowledge as increasingly key aspects of competitive advantage in the activities of both individuals and organizations, is widely recognized by authors and practitioners. Modern society, based on systems of information and communication, has experienced vast changes that have affected society, industry, and "all economic entities, including people, organisations, and technologies" (Okkonen, 2007:7). Rapid progress in information and multimedia technologies, and the increasing acceptance and use of Internet, Intratet and Extranet, are paving the way for gradual innovation in diverse areas, generating flatter corporations with novel and improved communication platforms, as well as creating new business models for inter-corporation transactions of goods and knowledge, and cooperation. The new platforms are changing work practices and processes in corporate settings to support the lifestyle of individuals in their daily routines, and are also stimulating the proliferation of small offices and home offices. "New business styles based on such concepts as virtual teams and virtual community are representative of such a trend" (Kodama 2005:895).

The proliferation of network access and the rise of the Internet have facilitated the rapid growth of virtual communities (Chiu et al., 2006:1872), "as a new business model for online collaboration, as demonstrated by the proliferation of trading and education communities" (Moor and Weigand, 2007:223). Scholars such as Moor and Weigand (2007) point out that "virtual communities, such as e-business platforms and research networks, are crucial instruments for collaboration in today's networked and globalizing society" (p.244). According to these authors, "in an increasingly networked society, with ever more need for global and flexible ways of professional interactions, virtual communities are natural candidates to fill collaborative gaps in traditional, hierarchical organizations. With the advent of more user-friendly and powerful Web applications, business is also discovering the power of virtual communities" (ibid, p.223).

However, although "they could bring a lot of value and profit to the companies and most of the experiences studied have demonstrated very positive results" (Loyarte and Rivera, 2007:76), "formal research on Communities of Practice and their impact on organizations has been limited both in the way of finding results and in the research method used" (ibid, pp. 68). Similarly, Lin et al. (2007) agree that research into virtual communities, an extension of communities of practice, is still in its initial stages, and many areas remain open for researchers to investigate.

In an attempt to fill this gap, the present chapter will try to analyze the importance of virtual communities, and specifically professional virtual communities, explaining how they develop from communities of practice, and their interrelationships with social networks.

PROFESSIONAL VIRTUAL COMMUNITIES IN THE KNOWLEDGE MANAGEMENT AGE

Kalpic and Bernus (2006) state that "the pace of adoption of internet technology, especially the establishment of intranets, extranets, Web portals, etc., has created a networking potential that drives all of society and corporations to work faster, create and manage more interdependencies, and operate on global markets" (p.41). Above all, the importance of new networks is stressed in the role they play in developing Knowledge Management tools.

Perrin et al. (2007) identify "three different types of knowledge networks: technological networks (supported by technological strategy), social networks (socialization strategy), and individualized networks (personalization strategy)" (p.159) that may be related to different strategies. Their work is based on Hansen et al.'s, (1999) typology of knowledge strategies, which is the most widely supported and referenced typology and distinguishes between personalization and codification of knowledge, but with the inclusion of a third type that combines the previous two. Briefly, they distinguish: 1. technological, codification (Hansen et al., 1999), system-oriented strategy (Choi and Lee, 2003), or the technocratic school, which relies on technology and databases. Individuals make their knowledge explicit in order to transfer it via the database. According to Meroño-Cerdan et al. (2007:63), the codification strategy focuses on codifying knowledge using a “people-to-document” approach, with a heavy emphasis on information technologies. Moreover, system “orientation emphasizes codified knowledge, focuses on codifying and storing knowledge via information technology and attempts are made to share knowledge formally”. 2. Personalization, related to the spatial school (Earl, 2001), and which is conceived as a human-orientation approach (Choi and Lee, 2003), designed to promote the emergence of knowledge and dependent on face-to-face contact (Hansen et al., 1999). According to Meroño-Cerdan et al. (2007), the “personalization strategy focuses on dialogue between individuals, not knowledge objects in a database. Knowledge is transferred in brainstorming sessions and one-to-one conversation”, in addition, “human orientation emphasizes dialogue through social networks and person-to-person contacts, focuses on acquiring knowledge via experienced and skilled people and attempts are made to share knowledge informally” (p.63) 3. “The purpose of socialization combines both technological and personalization strategies and relies on communities of practices”, or communities of practice. “People inhabiting the same knowledge space share knowledge and experience in order to improve business processes” (Perrin et al., 2007:159).

However, according to Perrin et al. (2007), “KM theory has evolved this last decade from the technological dominance to the human orientation” (p.159). For instance, when Meroño-Cerdan et al. (2007) compare the two abovementioned strategies, they find that “personalization strategy is predominant in all kinds of firms, probable due to be more feasible in first KM adoption stages”(p.70). Perrin et al. (2007) compare the use of the three strategies in 1998, 2000, 2002 and 2004, and conclude that “our results are consistent with the human and social network trend” (p.159), since although the technological strategy was predominant in 1998, “62 per cent of firms surveyed are now using a mixed strategy based on socialization”… “socialization strategy asks for the better knowledge of the “knower”, the “sender” of the practice and the “receiver””(ibid, p.160).

The focus on this trend in the literature has stressed the importance of teams, communities of practice, and finally virtual communities and their human or social side, in order to enhance organizations’ capability to create and share knowledge, facilitate creativity and innovate.

Meroño-Cerdan et al. (2007:62) define a team as a small number of people with complementary skills who are committed to a common purpose, set of performance goals, and approach for which they hold themselves mutually accountable (Katzenback and Smith, 1993). These authors point out that team structure facilitates the assembling, integration, and implementation of individuals’ diverse knowledge and expertise at various locations, and by using their different functional knowledge, skills, perspectives, and backgrounds, they provide ideal conditions for generating new and useful products and processes. However, “formal departments, operational and project teams within an organization seem to become insufficient for prosperous creation, dissemination and utilization of knowledge. They require support of less formal communities” (Pavlin, 2006:136).

Another type of group used particularly in the KM context (Meroño-Cerdan et al., 2007), and considered as one of the most reputable (Pavlin 2006), is known as a community of practice (CoP) (Leve and Wenger, 1991; Wenger, 1999). The term “describes an activity system that includes individuals who are united in action and in the meaning that action has for them and for the larger collective” (Leve and Wenger, 1991; Loyarte and Rivera, 2007:67). Although there could be several CoPs within a organization, and most people belong to many of them, a CoP can be defined as a volunteer, or informal, group of practitioners, with common interests, values and beliefs, engaged in sharing and learning about a concern, a common set of problems, or with a passion for a certain subject, who work on the same topic but not necessarily on the same project, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis (Campbell, 1999; Meroño-Cerdan et al., 2007; Pavlin, 2006:136-137; Wenger et al., 2002:4). These authors argue that CoPs are categorized by their primary business intents. They can also be considered as "social spaces of learning", that "facilitate the integration of dispersed knowledge through informal social relationships irrespective of formal intra- and inter-organizational hierarchies" (Pyöriä, 2007:18), the purpose of which is to provide a forum for community members to help each other in solving problems in employment, to build, develop, exchange and disseminate best practice, guidelines and procedures, to turn practical information into knowledge and to develop members' capabilities, and their abilities to learn. Their target is to use, organize, manage and steward a body of knowledge from which the community members can benefit, to innovate, and create ideas, knowledge and practices. Loyarte and Rivera (2007:67, 72) define communities of practice as informal entities that exist in the mind of each member, that focus on thinking together to solve problems, that help to foster a collaborative environment in which knowledge can be used to solve problems naturally and to promote and improve effectiveness, efficiency, learning and innovation. These communities last as long as their members want them to last (Wenger and Snyder, 2000), and although frequency and formalization of collaboration vary substantially, they always make use of collaborative tools such as face-to-face meetings, or Web-enabled tools in order to facilitate interaction (Pavlin, 2006).

Finally a virtual community "includes anyone actively interested in, or associated with, a group formed around a particular domain of interest. Dispersed or local, the community requires electronic support to implement a continuous meta-improvement strategy in its services" (Bieber et al., 2002:14). A virtual community could be defined as a technology-supported cyberspace, centered on the communication and interaction of its participants and the building up of relationships among members, to generate specific domain knowledge that enables the participants to perform common functions and to learn from, contribute to, and collectively build upon that knowledge (Hsu et al., 2007:153; Lin et al., 2007). "The impact of virtual communities is increasingly pervasive, with activities ranging from economic and marketing to the social and educational" (Chiu et al., 2006:1872). However, the two most widespread types are virtual professional communities and education communities (Bieber et al., 2002:14; Moor and Weigand, 2007:223). According to Lin et al. (2007), professional communities can differ from general communities in many aspects. Members of a professional community generally share norms and values, carry out critical reflection, and continue professional dialogues with one another.

Professional virtual communities derive from or can be viewed as extended communities of practice (Bieber et al., 2002:14; Lin et al. 2007; Loyarte and Rivera, 2007:67). According to Bieber et al. (2002), "a professional society is a special kind of virtual community, in which members participate to better understand its domain and improve the way they perform community-related tasks. The virtual community of a professional society may include nonmembers and organizations and often is many times larger than the professional society's membership" (p.14). A professional virtual community aggregates and gathers together a dispersed group of people who share expertise and common interest in a specific topic and collaborate to achieve common objectives (Bressler, 2000; Hagel and Armstrong, 1997; Lin et al. 2007). Like virtual communities, communities of practice use the support of communication technologies to allow people to talk about their experiences and solve problems (Loyarte and Rivera 2007:67). However, traditional communities of practice use face-to-face interaction more frequently, and are usually intra-organizational entities, while virtual communities are inter-organizational systems.

SOCIAL NETWORKS

As pointed out above, although virtual communities are based on technological networks, the human or social part of the network plays an increasingly important role. As Pyöriä (2007) notes, "human relations are now more crucial than ever before due to the growing knowledge intensity of work and due to the deeper immersion of work organizations in information technology" (p.17).

Network analysis has developed from perspectives originating in the fields of psychology, anthropology and sociometry (Bradbury and Bergmann Lichtenstein 2000), and they have been studied extensively in the literature in these fields. In the management literature, network analysis, particularly the personal and social aspects of networks, is an increasingly relevant area of study. The ability to promote a context of psycho-social help (James 2000), the interconnections between managers and other individuals, and other aspects related to the importance of different networks are factors that are increasingly emphasized in the literature (Ellis and Mayer 2001). Its importance in the managerial literature began to grow following the work of Granovetter (1973), who stressed "the strength of weak ties", or Bandura's (1989) Social Cognitive Theory, that highlights an individual's behavior as a product of his or her social network (Chiu et al., 2006: 1873)[1].

The relevance of human or social networks in the Knowledge Management -or intellectual capital- arena derives from the works by Grant (1996) or Nonaka (1994). Nonaka (1998, cited by Girard, 2006) suggests that "new knowledge always begins with an individual" (p.26). Social networks are essential for organizations, because "tacit-to-tacit or person-to-person knowledge transfer is the most effective way to share tacit, complex knowledge.... Person-to-person knowledge sharing is also more likely to be internalized by the receiver than, for example, person-to-document-to-person knowledge transfer" (Endres et al., 2007:94). The development of research on the social capital of organisations, one of the three main "intellectual capitals" that researchers consider in organisations together with human and structural capital (Palacios and Garrigos, 2003) also stresses this aspect. Social capital is defined as "the sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit" (Nahapied and Ghoshal, 1998:243).

The importance of human relations and networks has recently been studied in teams, communities of practice, different alliances between enterprises and virtual organisations. In this line, Lytras and Pouloudi (2006:66) point out that "knowledge flow is a dynamic concept... that relates to the characteristic of humans to constitute teams that share a common objective and thus facilitate the exchange of knowledge". Maguire et al. (2007:41) study the importance of Knowledge Management and communities of expertise within small and medium enterprises (SMEs), arguing that "small companies... tend to rely on formal and informal networks rather than utilising publicly funded sources of support". From their empirical research with a sample of over 200 enterprises, these authors find that SMEs tend to create tacit knowledge that "was derived from personal experience and wisdom, organically created and shared amongst individuals in the relevant department.... [and find] no evidence that a method to capture and acquire cultural knowledge has been used". However, Pyöriä (2007) states that "individual knowledge workers from "communities of practice" or professional subcultures... transcend formal and clear-cut organizational boundaries" (p.18). It is important to note that networking activities occur not only in firms, institutions or banks, or amongst lawyers and accountants (to name just a few) in a formal way (Das and Teng 1997); the formal and informal relationships between entrepreneurs, managers, organizational representatives, colleagues outside work (Paauwe and Williams 2001), personal relationships, families and other business contacts are also essential. Social relationships are important, because, according to (Hillman et al., 2000), one of the main tasks facing managers is to provide networks through their connections with the social environment. In this vein, Burt, Hogarth and Michaud (2000) argue that managers with links in separate groups are rich in the social capital of information and control the benefits associated with relationships that overcome the "structural gaps" in their information. In addition, social networks can be extended to all parts of organisations to embrace all personnel. Chiu et al. (2006:1875) report that Tsai and Ghoshal (1998) empirically justify how social capital facilitates resource exchange and production innovation within the organization, while Yli-Renko et al. (2001) examine the effects of social capital on knowledge acquisition and exploitation in young technology-based firms In addition, Wasko and Faraj (2005) examine how individual motivations and social capital influence knowledge contribution in electronic networks of practice. Kodama (2005) points out that "one of the keys to producing innovation in a knowledge based society is how organizations can organically and innovatively network different knowledge created from the formation of a variety of SCs (strategic communities, a concept similar to relationships between firms) inside and outside the organization, and acquire the synthesizing capability through dialectical leadership they need to generate new knowledge" (p.907). Finally, according to Perrin et al. (2007: 158), "best practices… may develop through benchmarking…, learning… or by "gleaning" skills from strategic alliance partners" (Hammel and Prahalad, 1988).

What, then, are the main components of social capital? In Chiu et al. (2006:1873), Nahapied and Ghoshal (1998) define three distinct dimensions of social capital: structural (the overall pattern of connections between actors), relational (the kind of personal relationships people have developed with each other through a history of interactions), and cognitive (those resources providing shared representation, interpretations, and systems of meaning among parties). Wasko and Faraj (2005) also follow Nahapiet and Ghoshal (1998) to classify social capital in three dimensions (structural, relational, and cognitive) but do not adopt Nahapied and Ghoshal's manifestations of each of these dimensions.

To begin with the structural dimension, authors such as Chiu et al. (2006:1873) or Nahapiet and Ghoshal (1998) use the construct "social interaction ties" in order to measure this dimension of social capital. Social interaction ties are considered as channels for information and resource flows (Tsai and Ghoshal, 1998), "network ties provide access to resources" (Nahapiet and Ghosal, 1998:252), and the more social interactions undertaken by exchange partners, the greater the intensity, frequency and breadth of information exchanged (Larson, 1992; Ring and Van de Ven, 1994). In summary, Chiu et al. (2006) conclude that "strong community ties could provide important environmental conditions for knowledge exchange" (p.1875). Granovetter (1973) describes tie strength as a combination of the amount of time, the emotional intensity, and intimacy (mutual confidence), and the reciprocal services that characterize the tie. Chiu et al. (2006) state that social interaction ties represent the strength of the relationships, the amount of time spent, and frequency of communication among members of virtual communities.

To consider the relational dimension, Chiu et al. (2006:1873), again following Nahapiet and Ghoshal (1998), use the constructs of "trust", "norm of reciprocity" and "identification" to measure this dimension of social capital. According to Al-Alawi et al. (2007:23), interpersonal trust is known as an individual's or group's expectation that the promises or actions of other individuals or groups can be relied upon. Trust is a powerful mechanism in coordinating group behavior, although it has some constraining factors such as longevity, especially in the context of knowledge work teams (Pyöriä, 2007:23, 26). However, trust between co-workers is an extremely essential attribute in organizational culture (Al-Alawi et al., 2007; Hsu et al., 2007; Pyöriä, 2007), which is believed to have a strong influence on knowledge sharing (Al-Alawi et al., 2007:23). In addition, "the effectiveness of IT in actualizing KM and organizational learning is significantly dependent on sustaining trust" (Sherif, 2006:75), where trust is identified as a "key element in fostering the level of participation or knowledge sharing in virtual communities" (Chiu et al., 2006:1875). Norms of reciprocity refers to knowledge exchanges that are mutual and perceived by the parties as fair (Chiu et al., 2006:1877). Chiu et al. (2006:1875, 1877-1879) report that authors such as Dholakia, Kankanhally or Bock find that group norms have a strong effect on we-intentions (group intentions) to participate in virtual communities and that reciprocity is positively related to the usage of electronic knowledge repositories by knowledge contributors, and have a positive effect on attitude and intention to share knowledge. If we finally consider identification, according to Chiu et al. (2006), "some studies found that a sense of community… and social identity…can enhance the likelihood of members' contribution and participation in a virtual community" (pp.1875-1879).

As regards the cognitive dimension of social capital, Chiu et al. (2006:1873), again following Nahapiet and Ghoshal (1998), use the constructs "shared vision" and "shared language" to measure the cognitive dimension of social capital (see also ibid, pp. 1878-1880). In addition to these three dimensions, other social capital dimensions not considered by these authors may be the diversity and breadth of relationships, the strength of the relationships, the quality of the relationships, or the emphasis on social ties such as information from friends and families (Garrigos, 2002).

IMPORTANCE OF SOCIAL NETWORKS IN DEVELOPING VIRTUAL COMMUNITIES

According to Lin and Hsueh (2006), "learning in virtual communities can be facilitated by the transactive memory system" (p.552), which consists of three components: knowledge map (represented by knowledge objects and their dependencies); social networks (formulated by individuals, their relationships, and the strength of relationship); and mnemonic functions (which include knowledge allocation, social network updating, knowledge maintenance and collaborative knowledge retrieval). From very diverse points of view, numerous authors stress the importance of many characteristics of social networks, and in general "the human side", in order to create, maintain and develop virtual communities. Many explanations have been given for the importance of these networks. Firstly, they stress the human side, which is increasingly important to understand the functioning of virtual organisations. Secondly, because these networks are heterogeneous, they can bring new perspectives and sources of knowledge to the virtual organisations, thereby increasing knowledge creation and creativity. Thirdly, "personal and organizational networks play an important role in accessing knowledge" (Christensen, 2007:38). The fourth reason given is that the establishment of social networks can increase trust or ties, thus helping to increase knowledge sharing and enriching virtual organisations. Finally, the common identity of the members of a social network can facilitate knowledge sharing. Some of these reasons are now analysed.

Lin et al. (2007) argue that humans are social beings and tend to form groups and alliances for protection and pleasure, and due to the rapid progress of technology, the concept of community has been extended to a virtual form. However, Pyöriä (2007:25) points out that "the field of information systems has traditionally been plagued by high implementation failures because the understanding of socially situated practices in knowledge work is incomplete" (Schultze, 2000:4). According to Pyöria, (ibid, p. 26) "one of the biggest challenges of the information age is that the more deeply we are immersed in IT, and the more routine work is transferred from men to machines, the more important it is to understand the human side of work…. In this respect there is a need for research that combines perspectives from technical, behavioral and social scientific disciplines".

More specifically, Pavlin (2006:138) emphasizes the importance of communities of practice and networks, and their heterogeneity as essential instruments to increase creativity and learning. Based on the work of Wenger (1999), Pavlin states that the structure of communities of practice is grounded on three components: (1) knowledge, "the domain as the area of knowledge that brings the community together"; (2) people or "the community as the group of people for whom the domain is relevant"; and (3) experience "the practice as a body of knowledge, methods, tools and stories that members share and develop together. On this basis, Pavlin considers networks to be essential because "the number of qualified experts (managers, scientists, ICT personnel, etc.) in a single organization (regardless of the size) may be insufficient to support the knowledge of a certain domain, that is not usually the case in a well-established network that associates the members from different organizations". According to Pavlin (2006) "acting within the same knowledge domain but from a different perspective can be an advantage for established practice. The members of our community are filling the holes in social structure between certain organizations… Networking across structural holes is clearly a form of social capital… in such a manner that competitive advantage is created for the members of the community and also for the organizations where they work. The theory of social capital emphasizes that the difference (as for example in education, occupation, employee organization) is the precondition for creativity and informal learning… we are not arguing that in the professional network the common experiences are not important, but that a "bit of difference in parity" is crucial" (p.139).

According to Christensen (2007), "without networks there is no opportunity for accessing knowledge" and similarly, "the sharing of knowledge is facilitated by some kind of personal or virtual network" (p.38). As we point out in this chapter, we believe that social and virtual communities can reinforce each other. In this vein, Christensen points out that these "networks can be maintained by formal or informal face-to-face meetings, or – the latest trend – by physical structures that do not allow individual cubicles, but emphasize transparent community spaces" (p.38).

On similar lines, Chiu et al. (2006) state that "the social interaction ties among members of a virtual community allow a cost-effective way of accessing a wider range of knowledge sources" (pp.1876-1877). Nahapiet and Ghoshal (1998) argue that "network ties influence both access to parties for combining and exchanging knowledge and participation of value through such exchange" (p.252). Furthermore, network ties provide the opportunity to combine and exchange knowledge. Recent studies have provided empirical support for the influence of social interaction ties on interunit resource exchange and combination (Tsai and Ghoshal, 1998), knowledge sharing among units that compete with each other for market shares (Tsai, 2002), and knowledge acquisition (Yli-Renko et al., 2001).

According to Endres et al. (2007), "when individuals are embedded in a strong social network, they are motivated to more freely share knowledge (Wasko and Faraj, 2005)" (p.96). As Hsu et al. (2007:154) point out, membership of virtual organisations is open, members voluntary contribute their knowledge without receiving monetary rewards, and most members are invisible, they do not provide guarantees that others will behave as they are expected to, and there is a lack of face to face communication and legal guarantees, which makes it harder for members to share their knowledge. It therefore follows that the existence of the social network, previous to the creation of the virtual community, is crucial for it to be effective, as this is a better way of creating and sharing knowledge.

Following similar criteria, Loyarte and Rivera (2007:72) stress the importance of "Social identity theory" in order to "cultivate communities of practice". "The concept of communities of practice has in recent years become one of the most popular tools for enhancing knowledge sharing – even though no one actually knows how to practice, or cultivate, a community of practice" (Christensen, 2007:37). Loyarte and Rivera (2007) illustrate the importance of social identity theory with some examples: "open software communities (i.e. Linux, Apache, etc.) are good examples where… members are motivated and not for lucrative purposes, but because they get to nourish their esteem. People have to feel valuable and they need to trust other members (World Bank). In this sense, it can be difficult… if members feel they can lose their hierarchical power or status… in an organization change or in an innovation process" (p.72).

According to Hsu et al. (2007), the biggest challenge in fostering virtual communities is the willingness to share knowledge with other members. In this respect, two issues are involved: personal cognition, which is based on self-efficacy and outcome expectation, and social influence, based on trust. They argue that knowledge sharing is affected by trust, "an implicit set of beliefs that the other party will behave in a dependent manner… and will not take advantage of the situation" (pp.153-154). The importance of trust, in all its varieties, together with the other two variables, is crucial in the social networks literature. Hence, all the literature about trust in the social networks literature is essential to better understand the behavior of a virtual organization, as Hsu et al. (2007) point out. For instance, these authors use a social cognitive theory-based model to explore the knowledge sharing behaviors within the virtual communities of professional societies, and suggest that further research should extend their model using the social capital theory "as a broad view in exchanging and combining intellectual capital—including structural, cognitive and relational dimensions".

The study by Chiu et al. (2006) also "draws on both the Social Cognitive Theory and the Social Capital Theory to investigate the influence of outcome expectations and facets of the three dimensions of social capital on knowledge sharing in virtual communities in terms of quantity and quality" (p.1873). Chiu et al., (2006) point out that "without rich knowledge, virtual communities are of limited value… clearly, the biggest challenge in fostering a virtual community is the supply of knowledge, namely the willingness to share knowledge with other members. It is then important to explain why individuals elect to share or not to share knowledge with other community members when they have a choice" (p.1873). In order to explain this fact, they use the Social Cognitive Theory and the Social Capital Theory. They argue that "it is the nature of social interactions and the set of resources embedded within the network that sustains virtual communities. Therefore studies on virtual communities address issues related to both personal cognition and social network and should be different from the … studies concerning computer use and internet behaviors, which focus only on personal cognition" (p.1873). In addition, they also introduce the Social Capital Theory to supplement the Social Cognitive Theory[2]. They point out, referring to Nahapiet and Ghoshal (1998), that "the Social Capital Theory suggests that the social capital, the network of relationships possessed by an individual or a social network and the set of resources embedded within it, strongly influence the extent to which interpersonal knowledge occurs"[3]. According to Chiu et al. (2006), "virtual communities differ notably from conventional organizations. There is no concrete reward system in place to reinforce the mechanisms of mutual trust, interaction, and reciprocity among individuals. However, online knowledge sharing activities cannot be successful without the active participation of online members. Lack of motivation from a knowledge contributor impedes the knowledge sharing. Under such circumstances, social capital becomes all the more important, because the resources inherent in the online social network mediate between the individuals and hence foster their intention and activeness to perform this voluntary behavior" (p.1876). Finally, the results of Chiu et al.'s (2006) study indicate that "outcome expectations and facets of social capital are helpful in explaining knowledge sharing in virtual communities"[4] (pp. 1884-1885). Hence, they conclude that "managers interested in developing and sustaining knowledge exchange through virtual communities should develop strategies or mechanisms that encourage the interaction and the strength of the relationships among members"[5] (ibid, p. 1885).

According to these measures, Moor and Weigand (2007) state that "virtual communities… are not governed by such a hierarchy, but instead should allow the interests of their members to be balanced by their unique social norms. To reduce these problems, systematic methodological support is needed for the required legitimate user driven specification process" (p.244). Hence, these authors argue that in order to improve virtual communities 1) "trust is essential for collaboration in these communities to occur" 2) "well-defined formalizations can help in the administration and facilitation of the change process, and the resolution of any breakdowns" and 3) "clear formalizations help to adapt the methodology without generating inconsistencies and incompletions" (p.244).

Finally, social networks facilitate virtual organisations because a common identity is shared between their members. In this vein, "common identity often facilitates knowledge sharing since individuals within one specialist group understand each other better than people from outside the group – they are more or less believed to possess the same absorptive capacity" (Christensen, 2007). According to this author, "apparently, a community makes it much easier to share knowledge, because people really care about their practice, are embedded in the same practice and, hence, talk the same (technical) language" (p.38).

IMPORTANCE OF VIRTUAL COMMUNITIES IN DEVELOPING SOCIAL NETWORKS, AND AS A MECHANISM TO CREATE AND SHARE KNOWLEDGE

Following the analysis of the importance of social networks for the development of virtual communities, we now demonstrate that virtual communities in today's environment are also a crucial instrument to create and maintain social networks, and a valuable system to create and share knowledge.

As Chiu et al., (2006) point out, "people who come to a virtual community are not just seeking information or knowledge and solving problems; they also treat it as a place to meet other people, to seek support, friendship and a sense of belongingness… In other words, they attempt to develop social relationships with other people inside the community" (p.1874). From an analysis of the Business Week / Harris Poll, these authors find that 35% of people involved in a virtual community consider their community as a social group.

A further important question is how virtual communities, with the use of new technologies, can be essential instruments to codify and disseminate certain knowledge. On this point, Sherif (2006) states that "tacit knowledge is best leveraged through social interaction… whereas explicit knowledge can be codified, captured, and disseminated electronically" (p.74). Hence, virtual communities can be used by their members as a mechanism to continually obtain new knowledge from new people and at the same time, codify and select this knowledge and the social network that is of interest at each given moment. This facet is important, since authors such as Girard (2006) refer to studies where managers complain of information overload and of wasting time in locating information, thus delaying decisions because of too much information and no mechanism to select this information. According to this author, managers "dwell on information that is entertaining but not informative, or easily available but not of high quality", which becomes a major problem since "the amount of data and information available will increase in the future" (p.27) . Girard (ibid) maintains that "this mountain of unprocessed data is becoming so large that it is smothering itself and preventing its metamorphosis to knowledge. Recent research suggests that it may be quicker for scientists to repeat experiments rather than search for previous results … One wonders how organizations that invested millions of dollars in programs to manage knowledge are now discovering that their managers are less efficient than before the implementation" (p.28).

Social networks can help to avoid this problem, and the use of virtual communities can also help in the development of these social networks, or as a mechanism to create or access the most relevant social networks for managers at each specific moment.

Social networks, more than merely the use of technology, and with them, the use of virtual organisations, is crucial, because, according to Pyöriä (2007) "technology as such is of little direct help in the process of augmenting human collaboration in knowledge work" (p.23). There is a "false conception of the utility of IT for enhancing interpersonal interaction by constructing new communication channels parallel to old ones… The true revolutionary nature of IT lies in its capacity to overcome limitations in our natural physical and mental capabilities by eliminating the need for communication"[6]. "Therefore, the elimination of useless interactions… can save time for developing its true creative strengths, which constitute the core of knowledge work. … It is in this distinctively human territory of creative problem solving and non-routine decision making where IT as such is least capable of increasing productivity" (ibid, p.24). Pyöriä (2007) stresses that "general beliefs in the communicative advantages of IT are highly overvalued… the speed with which these applications are being introduced, coupled with knowledge workers' lack of time and resources to internalize them, have resulted in a more or less chaotic situation….. for example, as numerous studies indicate, groupware and other intranet-base solutions rarely, if ever, work exactly as planned, and the systems are often used in an uncontrolled and impulsive manner" (p.26).

The debate about the importance of new technologies and Internet and whether it is useful in creating social capital is also considered by Chiu et al. (2006:1875). According to these authors "Putnam (2000) suggested that the Internet decreases social capital, while Wellmen et al. (2001) indicated that Internet use supplements social capital by extending existing levels of face-to-face and telephone contacts. Uslaner (2000) concluded that the Internet neither destroys nor creates social capital". However, these and other authors point out the importance of virtual communities to overcome these problems.

Firstly, Hsu et al. (2007) point out that the Internet facilitates the creation of professional virtual communities that enable knowledge sharing without their participants ever meeting. Hence, it facilitates the creation and development of networks. According to Djordjevic et al. (2007), virtual communities or organisations "span across organizational boundaries and enable the enactment of collaborative processes that integrate services, resources and knowledge in order to perform tasks that the virtual organizations partners could not undertake on their own" (p.634).

Kodama (2005) points out that "the dilemma faced by organizations is the need to reconcile rapid access and synthesis of relevant new knowledge, with the long time frames needed for knowledge creation and synthesis". In this vein, "Networked Strategic Communities based on deep inter-organization collaboration can offer a possible solution" (p.904). According to Kodama (2005), "knowledge, or management resources, aimed at innovation is created from SCs, a wide range of knowledge both inside and outside the company, including customers and strategic partners, is synthesized via the network, and new knowledge that never existed before is created to become a new source of competitive advantage" (p.906).

Bieber et al. (2002) state that "many researchers have observed that Knowledge Management primarily is about people and cultural change rather than technical development". They also maintain that "research on online communities concerns itself explicitly with supporting people networking together to achieve a goal. Through this networking, knowledge is created and exchanged. Technology now plays an important role by supporting activities, recording knowledge, and developing organizational memory" (p.15).

In this vein, two factors facilitate the growth of networks subsequent to the use of professional communities; the fact that participation in these communities is voluntary and involves members of different organisations, and the fact that in professional communities members are used to participating openly.

In relation to the importance of voluntary participation in virtual communities, Chiu et al. (2006) mention that "members in virtual communities differ from general Internet users in that virtual community members are brought together by shared interests, goals, needs or practices" (p.1875). With this premise, Endres et al. (2007) point out that "volunteer organizations or informal organizations outside normal firm boundaries may better facilitate fluid knowledge transfer at the individual level than within the traditional organization structure" (p.93). This fact can avoid the problem that knowledge inside closed organisations is more restricted than the knowledge found in open organisations. For instance, Endres et al. (2007) explain that "in contrast to the free and fluid flow of tacit knowledge in the Open Source community[7], knowledge sharing is often limited in organizations, especially knowledge that is complex and tacit" (p.97). In addition, Kodama (2005) points out that "the act of transcending boundaries stimulates deep, meaningful learning, which in turns opens possibilities for the generation of new knowledge" (p.904).

However, Chiu et al. (2006) mention that the character of virtual communities "begs the key question [of] whether the social capital developed in virtual communities is strong enough to stimulate members to overcome the barriers of complex knowledge sharing process and then share valuable knowledge, especially when no extrinsic reward is provided" (p.1875) . Nevertheless, this problem can be avoided, according to Endres et al. (2007), because although members in virtual communities may be unpaid, a person may acquire some degree of status and may have the opportunity for financial gain based on their in-demand persona. "The reward is not formal or assured, but may be a motivator to participate" (p.98). This fact, in addition, can strengthen the social network of community members, who know each other better, following their contributions to virtual organisations.

The second important point is the open participation in professional communities. According to Lin et al. (2007), community members can communicate and collaborate as groups. Members participate in virtual communities either openly or anonymously, depending on the kind of community it is. However, Lin et al. (2007) point out that in the professional virtual community, members participate in community activities openly rather than anonymously for professional purposes. This fact can go further to facilitate the importance of these virtual communities in enhancing social networks, and to facilitate the creation and sharing of knowledge.

Examples of communities of practice and virtual communities are various. For instance, in a case study, Pavlin (2006:137) shows how a small organization was able succeed in building an extensive network of top researchers, professors, high government officials, journalists and even interested individuals who share a passion or are differently influenced by the common knowledge domain. This author also mentions that the literature presents numerous cases of communities of practice and virtual communities, mainly in large international corporations such as Ford, IBM, Airbus, British Petroleum, Cap Gemini, Ernst & Young, Clarica, Hewlett Packard, McKinsey, Mercedes-Benz, Shell Oil, Siemens, Chevron, Xerox, etc.

To summarize, with the development of Internet technology, professionals and the public at large can communicate with each other via the Internet regardless of geographical distance (Lin and Hsueh, 2006:551). However, the importance of professional virtual communities lies in their value to create and share knowledge. For instance, according to Randeree (2006), "information systems researchers are currently looking at knowledge creation, knowledge acquisition and knowledge sharing" (p.145). Lin and Hsueh (2006) state that "the virtual community enabled by the World Wide Web (WWW) facilitates knowledge sharing and creation for communities of practice" (p.551). Hsu et al. (2007:153) point out that today, an increasing number of individuals participate in virtual communities to acquire knowledge to resolve problems at work, and that virtual communities are valuable systems that hold the key to Knowledge Management. Finally, authors such as Lin et al. (2007) study the knowledge sharing and creation process in a virtual community.

We now highlight the importance of virtual communities in creating and sharing knowledge.

Knowledge Creation

According to Sherif (2006), "knowledge creation is considered the most important of all KM processes (Lapre and Van Wassenhove, 2001)" (p.75). "Knowledge creation is concerned with the development of new organizational knowledge in the firm", although knowledge integration and exploitation can also contribute to the development of new organizational knowledge through (Nielsen, 2006:62). In the generation of knowledge, the actors translate the assembled array of tacit and explicit knowledge into a form suitable for transfer to others (Geisler, 2007:86)[8].

Sherif (2006) points out that "the general belief is that knowledge creation is an inherent trait of some organizations, an art of continuous change (Brown and Eisenhardt, 1998) that the majority of organizations may fail to imitate (Quin et al., 1996)… the majority conquer with the proposition that the process is highly tacit and cannot be captured" (p.75). However, virtual organisations can play a crucial role in the creation of knowledge.

Kodama (2005) argues that the rigidities of formal organizations make them a "poor vehicle for learning"; rather, in this situation the sources of innovation lie exclusively within firms' relationships. "Knowledge creation occurs in the context of a community that is fluid and evolving rather than tightly bound or static". "Knowledge creation is an extremely important issue that sees knowledge as a property of communities of practice…, ba…, communities of creation…, and networks of collaborating organizations… rather than as a resource that can be generated and possessed by individuals. When the knowledge base of an industry is both complex and expending, and the sources of expertise are broadly dispersed, the locus of innovation will be found in networks of inter-organizational learning rather than in individual organizations" (p.896).

Loyarte and Rivera (2007) state that "when people participate in the problem solving and share the knowledge necessary to solve the problems, it is possible to speak about the generation of knowledge in Communities of practice" (p.67). The same occurs with virtual communities. According to Pavlin (2006), the main purpose of communities of practice "is creating a platform, for supporting a structure for running the knowledge cycle (as described for example by Nonaka and Takeuchi,…..) within, among and between organizations. The community helps to disseminate and create knowledge, whilst the use (and also further creation and dissemination) of knowledge belongs to other more formal organizational structures like projects groups and teams" (p.141)[9].

Finally, Lin and Hsueh (2006), following Nonaka, point out that "organizational knowledge creation may start from the individual level via the collective (group) level tothe organizational level, and sometimes reach out to the inter-organizational level", in this way, "the inter-organizational learning process facilitated by a virtual community information system constructs distributed explicit knowledge, and weaves the social networks to connect tacit knowledge owned by individuals across organizations" (p.552).

Knowledge Sharing

According to Al-Alawi et al. (2007), "the process of Knowledge Management involves several activities" (p.22). The most commonly discussed activity in the process of Knowledge Management nowadays is knowledge transfer (knowledge sharing). The sharing of knowledge is a knowledge process that has been recognized as a subject of some interest by scholars (Geisler, 2007). According to this author, "the mode of transfer of knowledge is a component of the process in which actors in the organization transfer, share, and diffuse the knowledge they possess" (p.86). Randeree (2006:153) claims that knowledge sharing involves the dissemination of information and knowledge throughout the business unit or organization. From the same point of view, Hsu et al. (2007) state that "knowledge sharing is the behavior when an individual disseminates his acquired knowledge to other members within an organization" (p.154) . Virtual organisations can also help this process, since "the goal of knowledge sharing can either be to create new knowledge by differently combining existing knowledge or to become better at exploiting existing knowledge" (Christensen, 2007:37), and since they make available the use of new sources of knowledge .

Virtual communities can help in the process of sharing knowledge, both because of the importance of their social side in sharing knowledge, and also because of the fact that "knowledge is often shared with the help of the technology" (Wenger, 1999; Perrin et al., 2007:159). According to Lin and Hsueh (2006), "in the Internet era, explicit knowledge exists generally in hypertext on the Web or texts on the Intranet… . In order to shorten the learning cycle, an individual can exploit the experience of others to enlarge his or her experiences, which can be carried out by sharing explicit knowledge on the Internet". "Besides, well-structured knowledge objects reveal the relationship among knowledge, and reduce information overloading on knowledge sharing and creation" (p.552) . In addition, according to Randeree (2006) "knowledge sharing is as much of a people issue as it is technological". In this way, "technology can act as both a facilitator and a control mechanism to protect knowledge", and "firms see benefits to sharing knowledge and establish motivational approaches and communication mechanisms to share knowledge" (p.153). In addition, Endres et al. (2007) argue that there is an "inherent co-occurrence of informal and formal social networks in organizations… In a given organization, tacit-to-tacit knowledge sharing may occur in some groups but not in others. In addition, some informal, strong social networks that effectively transfer knowledge may be embedded in otherwise formal structures" (p.100). Hence, the use of technological and social sides can complement and strengthen the process of knowledge sharing.

Christensen (2007:38) identifies five problems in the literature inherent in organizational knowledge sharing: (1) the "stickiness" of knowledge, that refers to the epistemologically different faces of knowledge (mainly tacit versus explicit knowledge); (2) the absence of a common identity between the people who are trying to share this knowledge, a fact that hinders the knowledge sharing process; (3) the lack of any relation between the receiver and sender of knowledge; (4) a lack of willingness to share knowledge, an issue that mainly "deals with social dilemmas...as the trade of commons, and the power of possessing knowledge"; (5) and the lack of knowledge about knowledge[10].

Hsu et al. (2007) state that "prior research has highlighted the various factors that affect an individual's willingness to share knowledge, such as costs and benefits, incentive systems, extrinsic and intrinsic motivation, organization climate and management championship" (p.154). In the same vein, different authors have created models that emphasize the importance of various variables in the sharing of knowledge.

For instance, Al-Alawi et al. (2007:25-26) create a model including certain cultural factors that influence knowledge sharing, specifically: trust, communication between staff, information systems, reward system, and organization structure. According to their results, "trust, communication, reward system and organization structure all received strong literature support. However, information systems/technology received mixed support" (ibid, p.39). They state that "the relationship that proved to exist between knowledge sharing and trust communication, information systems, reward system and organization structure indicates the importance of such factors as prerequisites of the success of knowledge sharing" (ibid, p.37), and recommend and suggest some ways of emphasizing these aspects in the firm.

Lin et al. (2007) conducted a three-phase study on a teachers' virtual community in order to understand the knowledge flows among community members from different organisations. The objective of their study was to identify essential factors in individual, group, organization, and environmental contexts, which affect knowledge sharing and creation in the professional virtual community. Specifically, their model categorizes these factors as environmental, information technology, project, organizational, group and individual contexts, and defines the process of knowledge sharing and creation by the sequence of causal conditions[11], action/interaction strategies, and consequences (at the individual, group and organizational level)[12].

Finally, according to (Chiu et al., 2006), "some studies... suggested that individuals would share knowledge within virtual communities with the expectation of enriching knowledge, seeking support, making friends, etc. Butler et al... suggested that the primary reason for individuals to share knowledge is their expectation of being seen as skilled, knowledgeable or respected. Other studies suggested that individuals share knowledge with the expectation of helping the virtual community to accumulate its knowledge, continue its operation, and grow..." (p.1875)

However, literature and empirical studies that thoroughly address the problem are scarce; in addition, according to Lin et al. (2007), few studies have addressed the knowledge sharing and creation processes successfully by collecting data from commercial companies, and further research is therefore necessary.

CONCLUSION

The development of new technologies and information and communication systems, the expansion of network access, and the rise of the Internet have led to the proliferation of new business styles based on information and knowledge. This trend has facilitated the growth in importance of the construction of strong social networks and advances and effective professional virtual communities as a mechanism that can enhance competitive advantage for organisations.

Professional virtual communities can be conceived as an evolution of teams, and communities of practice, that combine a technological and a human orientation. The technological side is crucial to promote communication and to cross organizational borders in order to enhance knowledge creation and sharing capabilities, while the human and social side, which has emerged as the most important, stresses the relevance of social and informal relationships as a source of creativity and innovation.

With the increasing relevance of the human side, the understanding of social networks, as a source and as a consequence of the development of virtual communities, is stressed by the literature. Network analysis has developed from perspectives in the fields of psychology, anthropology and sociometry, and is an increasingly relevant issue in the literature of management because of the importance of individuals and their social relations and cultural aspects related to networks such as ties, trust, sense of community, shared vision or the existence of diverse relationships inside and outside the enterprise, to generate and share knowledge.

In the same vein, social networks, and all aspects related to their development, are crucial to developing virtual communities. Social networks can facilitate learning, collaboration, knowledge sharing and creation in virtual communities. The main aspects explaining the importance of networks in virtual communities are: the fact that they stress the importance of the human side of these communities; the importance of heterogeneity of networks to bring new perspectives and sources of knowledge to virtual communities, which increase knowledge creation and creativity; their importance because of their role in accessing crucial or tacit knowledge; and because of the importance of increasing trust, ties, motivation, willingness, and a common identity, facts that contribute to increasing the creation and sharing of knowledge.

However, virtual communities are also important in the development and maintenance of social networks and as an essential mechanism or valuable system for creating and sharing knowledge in today's technological society. In this way, virtual communities are essential places to meet other people with different perspectives, to seek support, friendship, and a sense of belonging, and in summary, to develop social relationships with other individuals. They are useful mechanisms to obtain a constant flow of new knowledge from new people, and essential instruments to codify and disseminate different knowledge, avoiding information overload and wasting time by their members in the search for selecting information. They are essential mechanisms to create or access the most relevant social network for managers or other professionals at each given moment, gaining more time to develop its true creative strengths. In addition, they can help to eliminate limitations in our natural physical and mental capabilities. The use of new technologies by virtual communities also helps to extend existing levels of face-to-face and telephone contacts, maintaining and developing social interactions, and facilitating the creation and development of networks across organizational boundaries, and collaboration among their members. They help to integrate services, resources and knowledge in order to perform tasks that the members of virtual communities could not undertake on their own, supporting people networking together to achieve a goal. The voluntary participation, and the shared interests, goals, needs or practices of virtual organizations members, together with the open participation of the professional members, enhance social networks, as well as facilitating the creation and sharing of knowledge.

If we turn to the importance of virtual communities in creating and sharing knowledge, creation is promoted by the open, voluntary and fluid character of virtual organisations, because through them, individuals can access broadly dispersed sources of expertise, and because they act as a platform that supports the running of the knowledge cycle, helping to combine different sources of ideas. In addition, the sharing process is encouraged as virtual organisations help to make available the use and exploitation of existing knowledge or new sources of knowledge. By combining the social side with the motivational approaches, with the help of technology that facilitates the communication and control of knowledge, the sharing of knowledge is promoted. In this vein, all the above-mentioned processes in virtual communities facilitate the common identity of their members, the relationships between the senders and receivers of knowledge, the communication and information systems, the trust and motivation to share knowledge, and the knowledge of knowledge, facilitating knowledge sharing.

FUTURE RESEARCH DIRECTIONS

This chapter has highlighted the relationships between virtual communities and social networks, and how they can enhance each other's development. Furthermore, the importance of virtual communities to create and share knowledge has been expounded. However, further research is necessary: firstly theoretical research that can complement and develop the ideas suggested in this chapter; and secondly, empirical research to develop hypotheses and test them with data from a range of virtual communities.

ENDNOTES

1 According to Bandura (1989) and Chiu et al. (2006), "The Social Cognitive Theory argues that a person's behavior is partially shaped and controlled by the influences of social network (i.e., social systems) and the person's cognition (e.g., expectations, beliefs)…" "Through close interactions, individuals are able to increase the depth, breadth, and efficiency of mutual knowledge exchange" (pp. 1874-1873). In addition, Lytras and Pouloudi (2006) point out that "Behavioral change… enlightens the way in which individuals transform their behavior according to feedback they gain from participation in bigger social construction" (p.68).

2 Chiu et al. argue that "Social Cognitive theory is limited in addressing what components are within a social network and how they influence an individual's behaviour"

3 Hence, as Chiu et al. (2006:1875) state, "according to the Social Cognitive Theory, the question—why do individuals spend their valuable time and effort on sharing knowledge with members in virtual communities, should be addressed from the perspectives of both personal cognition and social network".

4 "Facets of social capital positively relate to the quantity of knowledge sharing or the quality of knowledge shared by members…. Outcome expectations can contribute to knowledge sharing to some extent, but it is the social capital factors (e.g. social interaction ties, trust, norm of reciprocity, identification, shared language and shared vision) that lead to greater level of knowledge sharing in terms of quantity or quality…social interaction ties were significant predictors of individuals' knowledge sharing in terms of quantity".

5 For instance, "holding face-to-face meetings or seminars.. as a way of enhancing the social interaction ties among members.. or providing personal message boards and blogs as tools for enhancing online communication and interaction among members" .

6 According to this author, (ibid, p.24) "the efficient use of IT simply enables the automation of routine tasks and helps us to avoid useless communication…is the only way to win more time for collaborative problem-solving and other tasks that resist "the logic of the binary code""

7 "The purpose of the "Open Source" software community is essentially knowledge sharing and collaboration… the goal … is to develop, distribute, redistribute, and share source code of software that benefits individuals and organizations, with no discrimination and with restricted licensing (www.opensource.org) Software developed with a General Public License creates the freedom for people to copy, study, modify and redistribute software. It forbids anyone to forbid others to copy, study, modify and redistribute the software"… .According to this organisation (ibid, p.98), well-known Open source projects include the Linux operating system, Apache server software, Python coding language, and OpenSSL system secure communication software.

8 Geisler's paper proposes a model that links the generation of knowledge with its users. These process or "four modes or stages of knowledge processing are: generation, transfer, implementation and absorption" (ibid, pp.90-91).

9 According to this author, communities of practice, such as the virtual organisation, can link members to the strategic knowledge domain of the organization, develop core organisational competency through collaboration and learning, provide common development needs, distribute functional expertise, facilitate cross-generational and cross functional exchange of knowledge (Saint-Onge and Wallace, 2003:36-91), "CoP can present a toll of alignment in organizations, a forum for problem solving, center for knowledge creation, type of corganizational infrastructures" (Saint-Onge and Wallace, 2003:71).

10 According to Christensen (2007)… "the five problems are caused by either social dilemmas or knowledge dilemmas"; the two first represent knowledge dilemmas caused by the epistemologically different faces of knowledge, such as tacit knowledge making it somewhat difficult to both identify and transfer knowledge, while the other three are "social dilemmas caused by the behaviour, or misbehaviour – of persons" (p.38).

11 At an individual level (active asking for help, habit of cooperation, propensity to share, perception of communication media) and group level (group roles, knowledge creation roles, group norms, cohesiveness, and leadership style).

12 Their study revealed that different strategies, including collaboration strategies, using IT strategies, and knowledge sharing and creation strategies, led to different consequences. In addition, they identified phenomena of knowledge flow discontinuities, and designated possible causes which contribute to these discontinuities, proposing the concept of the knowledge buckle (based on the SECI model put forward by Nonaka, which views knowledge creation as a spiralling process of interactions between explicit and tacit knowledge, and the study by Lin et al. which traces knowledge flows (or the knowledge buckle) among socialization, externalisation and combination activities) to address these problems and to gain insight into the knowledge sharing and creation process.

This work was previously published in Connectivity and Knowledge Management in Virtual Organizations: Networking and Developing Interactive Communications, edited by C. Camison; D. Palacios; F. Garrigos; C. Devece, pp. 1-22, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of social computing. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters discuss ethical issues in social networking, security concerns that arise when individuals share personal data in social networks, and reducing social engineering impact. Overall, contributions within this section ask unique, often theoretical questions related to the study of social computing and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1
Cyberspace's Ethical and Social Challenges in Knowledge Society

Maria Ranieri
University of Florence, Italy

INTRODUCTION

During the last years the issue of *digital divide* has received particular attention from international bodies like the UN, UNESCO, OECD (Bindé, 2005; OECD, 2001; UN, 2006). These organizations acknowledge that our planet is divided into "information haves" and "information have-nots" and that the effort to bridge this global gap is one of the main challenges of society today.

Interest in digital divide is also widely present in literature. In these last five years, research and empirical surveys on this subject have notably increased (Baker, 2001; Hargittai, Di Maggio, Neuman, & Robinson, 2001; Ranieri, 2006; Rallet, 2004; Sartori, 2006; van Dijk, 2005).

What does digital divide mean? What are the causes of the digital gap? How can education and technological research contribute to facing this challenge?

In this chapter, we shall first develop this concept, identifying through literature reviews its dimension and causes. We shall then focus our attention on the possible roles that education and technological research can play in order to overcome the gap, suggesting four main directions to be followed, with the help of concrete examples.

DEFINING DIGITAL DIVIDE: A LITERATURE REVIEW

The *Oxford English Dictionary Online* (2004) registered the first occurrence of the term "digital divide" in an article published in 1995 in the *Columbus Dispatch* (Ohio), giving the following definition: "the gulf between those who have ready access to current digital technology (esp. computers and the Internet) and those who do not; (also) the perceived social or educational inequality resulting from this."

Still during the mid-1990s, the term recurred in the reports of the U.S. National Telecommunications and Information Administration (NTIA) regarding the inequality of access to telecommunications.

DOI: 10.4018/978-1-59904-845-1.ch018

NTIA published six reports from 1995 to 2004 in a series entitled *Falling through the Net*. In the third NTIA report (1999) the profile of the *have-nots* was introduced and defined, and the following five different levels of inequality in Internet usage were identified: (1) between the minority of connected and the majority of unconnected; (2) between those who use the Internet for a wide range of activities with advantageous effects and profit and those who do not use the Internet; (3) between those who can use paid services and those who use the Internet's free research engines; (4) between those who use the net for e-commerce and those who do not effect any transactions on the Internet; and (5) between those who benefit from the broadband and those who cope with only slow connections.

In the following years the term became a very commonly used expression in European debates and eventually extended also to the developing countries. Some authors underline the ambiguous character of the term *digital divide* which is a very wide concept (going from access and non-access to telecommunication infrastructures and educational programs) used in reference to most diverse situations involving nations, regions, organizations, social groups, individuals, and so forth (Rallet & Rochelandet, 2004; Yu, 2002).

In the attempt to clarify it's meaning, three different accentuations can be identified in debates and in literature.

Initially, the accent was placed on technological equipment, and digital divide was conceived as a form of exclusion of those who did not have access to the information and communication technologies (ICTs).

A wider perspective enriches the semantic range of the term with other meanings. This vision is based not only on having or not having of the ICTs, but on the effective ability to use them. In this perspective, it is not important to increase the number of technological equipment and Internet connections, but to evaluate and improve their uses. If we considered the contextual, cultural, and knowledge resources available to individuals and groups, digital divide would therefore be the consequence of pre-existing inequalities and defines the gap between the ICTs users and those who do not use them. It would moreover be legitimate to speak not only of digital divide but also of digital inequality referring to the social and knowledge gaps that influence the diffusion and adoption of technologies (Sartori, 2006).

A third approach focuses on contents (knowledge, information, expertise) and the services to which the ICTs give access, independently from the technologies. Digital divide is therefore defined as the gap between those who have access to contents and services offered by the Internet and those who do not.

More generally, according to Baker (2001):

The digital divide can be conceptualized from a *user* standpoint as a suboptimal condition of access to technologies (the initial conceptualization of the digital divide), orientation on hardware, networking, and access to advanced IT/Telecom services:

- Content available, that is, what services and information can be accessed and
- Utility/awareness which relates to the actual value as well as the perceived value or awareness of the user/citizen/business of the use of ICTs and associated services.

The definition proposed by the OECD and to which the most part of studies refer, includes the various elements highlighted up to now: "the gap between individuals, households, businesses and geographic areas at different socioeconomic levels with regard to both their opportunities to access ICTs and to their use of the Internet for a wide variety of activities. The digital divide reflects various differences among and within countries. The ability of individuals and businesses to take advantage of the Internet varies significantly across the OECD area as well as between OECD and non-member countries" (OECD, 2001, p. 5).

In synthesis, according to this last definition the concept of digital divide is applied on a universal level, goes back to various geographic dimensions (international and intranational) and includes two distinct problems, that of access and use of the ICTs, and is ultimately conditioned by access to the resource infrastructures.

UNDERSTANDING DIGITAL DIVIDE

Digital divide is a multidimensional phenomenon. In order to examine the factors influencing its evolution, it would be useful to distinguish between two different levels of analyses: a macro analysis level, aimed at globally identifying the diverse economical, social and political conditions which characterize industrialized and developing countries; and a microanalysis level, aimed at evaluating the individual characteristics of Internet users (Sartori, 2006, p. 51).

The comparison between the industrialized and the developing countries shows that elements like income, education and training, investments in the sectors of research and development, and the costs of infrastructures, are crucial factors that can prevent or facilitate the diffusion of the Internet in various countries. An effective comprehension of the phenomenon is in fact possible only by integrating the various elements.

Let us start from the first factor. The degree of development of a country is certainly a decisive factor. For example, in observing trends in the map showing the extent of the use of the Internet by countries, we can see that its coverage goes hand in hand with geographic development. In other words, there is a close relationship between inequality in industrial development and inequality of access to information (Bindé, 2005). However, the wealth of a country, as fundamental as it can be, is not sufficient in itself to increase the use of the Internet (Norris, 2001).

Besides, digital literacy is fundamental. The international organizations agree that it constitutes, along with the educational background and the knowledge of languages, a prerequisite that can positively or negatively influence access to the Web.

In addition, the factors related to offers of new technologies are to be considered. Availability of infrastructures and the costs of computers and connections have a direct impact on the opportunities of individual users to access the Web. The costs are still very high especially in developing countries, where they are higher than in developed countries (Bindé, 2005).

Obviously, directives from local governments regarding public policies in the ICTs sector also affect costs. They can more or less be oriented towards the liberalization of services to favour greater competition between the *providers* with the consequent reduction of costs for the single user, or in support of a major intervention of the state and international organizations in defining tariff policies. The debate on the most effective policies to adopt for cost reduction is, however, still underway (Rallet et al., 2004).

An additional dimension to consider on the macro level is the relationships between politics and Internet, whereby some governments enact preventive censuring measures by filtering the information resources available and reducing universal access to information.

Going on to consider the differences between individuals and social groups, the main factors of access inequality are to be traced to family and individual income, age, degree of instruction, gender, language, residential geographic areas, professional status, and the physical-psychological abilities of the people involved (Bindé, 2005).

As mentioned earlier, the *costs* of computers, software, and connections can be discriminating for individuals and families with low income, both on the global and local level. Along with income, age can represent an obstacle when considering single users. The youth are often avant-garde in technological innovation and their applications, but are also more exposed to economic and social problems. As to the elderly people, the possibility of their education on the use of new technologies could be impossible due to the lack of specific training courses.

Besides age, *gender* also holds a relevant importance. Inequality between men and women in the face of new technologies constitutes another feature of digital divide. Almost two-thirds of the world's illiterate are women. In the developing countries, an average of one out of two women, is illiterate. If in the industrialized countries women represent a consistent part of the Internet users, there is a very high risk that in the developing countries women may accumulate disadvantages, thus losing almost all possibilities of access to the Net.

Another barrier is the affirmation of English as the language vehicle of globalization, leaving no room for other languages in World Wide Web. Together with language, educational, and social-cultural backgrounds play a most meaningful role in favouring or not, access to the Net. In the future, the post-industrial societies may require great investments to favour education and training, with the objective of reducing educational barriers, and cultural and linguistics gaps (knowledge gaps) that make the Internet an inaccessible goal for those populations living at the margin of globalization processes.

Another factor of inequality regards asymmetry between urbanized areas and rural zones. The latter, especially in developing countries, has remained excluded from the digital revolution that has taken over the urbanized areas. The nomadic technologies can offer great opportunities to allow the rural zones to move out of their isolation but their diffusion in these areas is still insufficient.

Ultimately, another element to be considered regards individuals with disabilities. The most part of ICTs results to be scarcely accessible, thus producing the exclusion of a great part of users with special needs. The ICTs instead could devise for these people, instruments which will allow them to participate in social life, continue to carry out their work activities and have access to training experiences.

THE ROLE OF EDUCATION AND TECHNOLOGICAL RESEARCH

How should digital divide be faced? What contributions can education and technology offer to face this problem?

Current literature shows a wide agreement on the importance of interventions in the area of training and education, in reducing the digital gap between individuals and social groups, either by offering free access to technological equipment or by delivering computer literacy programs. On the technological level, the adoption of open source approaches and investments in research geared towards enabling technologies are emerging as the most suitable solutions in the long run, especially in civil society. We here present some initiatives.

The Internet as a Public Service

The availability of public access to the network represents a preliminary condition in allowing economically disadvantaged individuals to make use of the ICTs. The Internet should be considered as a "public information service and not only as a commercial product" (Beccalli, 2004, p. 113).

Therefore, well-equipped schools and libraries can play an important role. They can in every way take part in solving the problem also for the countries of the OECD area, as already indicated in the 1995 NTIA report. In the industrialized countries many interventions have been implemented to this end.

In the developing countries the experiences of the Community Multimedia Centre (CMC) and the communitarian telecentres, have been significant (Guttman, 2003). The creation of the CMC was promoted in the last years by UNESCO. The CMC combines the use of local radios with that of computers connected to the Internet, e-mail, faxes and photocopy engines. Besides being free of charge and allowing shared access, the CMC experience is characterized by the notion that a relevant contribution to solving digital divide can be offered through the oldest media like books, radio or television. Old and new technologies do not substitute for one another, but are complementary. The former effectively contributes to the diffusion of knowledge by facilitating access to the latter.

The communitarian telecentres promoted for example by the Brazilian administration, are free-of-charge public centres in which people can access computers, printers, Internet, and so forth. One of the features is their location in peripheral and disadvantaged zones, and are autonomously self-managed by the community. There are already a number of examples of such structures globally, especially in Latin America, the Caribbean and Africa. They are often equipped with free software. Besides the lowering of costs of licenses, the use of free software allows the use of hardware that is not of the last generation, recovering in this way, the resources which would otherwise be lost. In addition, the opportunity to access the source code of the software enables technicians to intervene autonomously in technological problem solving and in the subsequent implementation of software, thus starting off a process which will also be sustainable in the long term.

Open Software and Content

As seen in the Brazilian experience with telecentres, the adoption of open-source software may constitute a crucial mean for equal opportunity to access. It promotes a kind of digital solidarity fundamental to bridging the technological gap. As observed by Berra and Meo (2001):

Through a modifiable technology distributed at low prices, if not free of charge, it would be possible to concretely conceive policies that can limit the social and geographical discontinuities in their diffusion and use. [...] The dream of reducing the "technological gap" seems to be more easily fulfilled through the diffusion of open-source software rather than by the world-scale extension of closed-source software produced by the big monopolistic industries.

As commonly known, free software is based on the freedom to modify the program according to one's own needs, and to distribute the modified versions so that the community may profit from the improvements implemented (Stallman, 2003). Thanks to this, free software is proving to be a solution that is particularly suitable to the contexts in which there is need to control the technologies used, the resources are limited, and it is necessary to find specific solutions.

The "openness philosophy" and software-sharing practices are also growing in the educational field. In the Internet there are a great variety of open source software (often free of charge) for education, that is, educational software, content management system (CMS) and/or learning management system (LMS) like for example Moodle, blog, wiki, and so forth.

While the open source regards the software, the open content adopts its philosophy but applies it to products like Websites, music, films, photographs, literature, and also educational contents. In this case, the author preserves the work's copyright, but allows its use by third parties under an open content license. There are various types of open content licenses. Usually the users can copy, publish and redistribute the work, provided that attribution is given to the original author and all modifications to the work are identified. The advocates of open content believe that the availability of free contents promotes collaborative work and contributes to increasing knowledge while reducing individual efforts. In addition, open content in education allows the improvement of instructional materials, and facilitates its reuse and adaptation. One of the most important initiatives is the Open Course Ware program promoted by the Massachusetts Institute of Technology (MIT). The program which began in 2002, provides free online access to educational course materials and contents. In the same year UNESCO introduced the term "open educational resources" at the Forum on the Impact of Open Courseware for Higher Education in Developing Countries.

Enabling Technologies

An ulterior step could be the development and implementation of technologies aimed at satisfying the needs of various global users, and therefore favouring and funding researches to this end. The design and implementation of innovative technologies more oriented towards the demands of currently excluded users, formulated in their tongue and distributed at low costs, could moreover find a market which is ready to receive them.

An example is the Simputer, a device which supports the functions of a PC, but in a simpler way. The Simputer does not need a keyboard and allows the user to interact with the PC by touching the screen to send commands and listening to its answers (vocal messages).

If the Simputer responds to the need of developing technologies enabling illiterate people in developing countries, the project *One Laptop per Child*, promoted by Media Lab of MIT in Boston, represents an effort to find enabling solutions for people living in zones without electricity, or wherever saving energy results to be important or decisive. Negroponte, Director of Media Lab, on the occasion of the second session of the World Summit on Information Societies (Tunisy, 2005), demonstrated the prototype of a laptop costing $100, that could allow thousands of children in developing countries to use a personal computer, thanks to expedients that reduce energy consumption and a lever device that can temporarily recharge the batteries.

Promoting Digital Competence

Access to an education, which includes computer literacy in the curricula, ultimately plays a crucial role. The European Community for example, has moved in this direction during the last five years. The Lisbon European Council (2000, March 23-24) emphasized that "Every citizen must be equipped with the skills needed to live and work in this new information society" and that it is therefore necessary that "a European framework should define the new basic skills to be provided through lifelong learning: IT skills, foreign languages, technological culture, entrepreneurship and social skills."

The ICT skills are expressly indicated by the Council of Lisbon as a basic skill. Coherent with this purpose, the key competencies framework was redefined, changing the number of required competencies from three to eight and including "digital competence" as one of the five new competencies. In the definition of this competence, it is pointed out that, "Digital competence involves the confident and critical use of electronic media for work, leisure and communication. These competences are related to logical and critical thinking, to high-level information management skills, and to well-developed communication skills. At the most basic level, ICT skills comprise the use of multi-media technology to retrieve, assess, store, produce, present and exchange information, and to communicate and participate in networks via the Internet" (European Union - Working Group B "Key Competences", 2004, p. 7). In other words, digital competence does not only include the simple procedural skills, but also encompasses high-level abilities in logical and critical thinking, information management, and communication.

Moreover, in the field of initiatives undertaken to promote online education, the European Council Parliament started off the *e-Learning* program (2004-2006), to stress the need "to address the problems of social exclusion resulting from the inability of some individuals to take full advantage of the benefits offered by information and communication technologies (ICT) and the Internet in the knowledge society, the so-called "digital divide" which often affects young people, the disabled and elderly, and social categories who are already victims of other forms of exclusion". The program provides as frontline action the promotion of digital literacy. Action in this field must cover both conceptual and practical issues, from the understanding of digital literacy to the identification of remedial actions for specific target groups: "Digital literacy is one of the essential skills and competences needed to take an active part in knowledge society and the new media culture. Digital literacy also relates to media literacy and social competence, as they have in common, objectives such as active citizenship and the responsible use of ICTs." (Decision No 2318/2003/EC of the European Parliament and of the Council of 5 December 2003).

Two meaningful trends emerge from these recommendations. The first regards the need to promote educational programs on ICTs based on a wider concept of computer literacy. It should include not only procedural skills (as contemplated in ECDL), but also and above all the critical use of ICTs in daily life. This is also coherent with the concept of computer literacy suggested by ETS (2004), which developed a framework for ICT Literacy at international levels, commissioned by OECD.

The second concerns the currently emerging relationship between media/digital and social competencies: if citizens are to exercise a real citizenship in Knowledge Society, they must be enabled to read the new alphabets, decode the new languages, and the "cognitive citizenship" which both media and digital competencies help to acquire

CONCLUSION

Digital divide is one of the most urgent challenges today. In a world where information and knowledge represent an indicator of wealth, the exclusion from electronic networks within which these goods circulate, results in evermore-dramatic forms of social and cultural exclusions.

Educational systems and technological researches can contribute to facing the problem by:

1. Providing public access to ICTs
2. Adopting open approaches to ICTs and content delivery
3. Promoting technological research, oriented towards design and implementation of enabling technologies
4. Implementing educational and training actions in order to develop digital competence.

An area of great interest in the educational field is the designing of programs aimed at developing the ability to benefit ICTs in a critical way. Such a vision involves the notion of digital competence, which surpasses the traditional concept of computer literacy advocated by the ECDL and certainly opens out to new challenges in educational research.

KEY TERMS

Digital Competence: Digital competence involves the confident and critical use of electronic media for work, leisure and communication. These competencies are related to logical and critical thinking, high-level information management skills, and well-developed communication skills.

Digital Divide: "The gap between individuals, households, businesses and geographic areas at different socio-economic levels with regard to both their opportunities to access ICTs and their use of the Internet for a wide variety of activities" (OECD, 2001, p. 5).

Open Content: As indicated in Wikipedia, this term "describes any kind of creative work (including articles, pictures, audio, and video) or engineering work (i.e., open machine design) that is published in a format that explicitly allows the copying and the modifying of the information by anyone […]" (Retrieved July 30, 2007, from: http://en.wikipedia.org/wiki/Open_content).

Open Educational Resources (OER): Refer to "educational materials and resources provided freely and openly for anyone to use and under some licenses re-mix, improve and redistribute." Open educational resources include learning content (i. e., course materials, learning object, documents etc.), tools (i.e., software for creation, delivery, use and improvement of open learning content) and implementation resources (i.e., intellectual property licenses) (Wikipedia. Retrieved July 30, 2007, from: http://en.wikipedia.org/wiki/Open_educational_resources)

Open-Source Software: A computer software with a source code available under a license that allows users to change and improve the software, and to redistribute it in modified or unmodified form. It is often developed in a public and collaborative way.

Simpute: An acronym for "Simple, In-expensive, Multilingual, People's Computer". It is a small hand-computer, designed and implemented for use in developing countries. The device was designed by the non-profit organization, Simputer Trust, founded in 1999.

INTRODUCTION

Web-based social networks (WBSNs) are online communities that allow users to publish resources (e.g., personal data, annotations, blogs) and to establish relationships, possibly of a different type ("friend," "colleague," etc.) for purposes that may concern business, entertainment, religion, dating, and so forth. In the last few years, the usage and diffusion of WBSNs has been increasing, with about 300 Web sites collecting the information of more than 400 million registered users. As a result, the "net model" is today used more and more to communicate, share information, make decisions, and 'do business' by companies and organizations (Staab et al., 2005).

Regardless of the purpose of a WBSN, one of the main reasons for participating in social networking is to share and exchange information with other users. Recently, thanks to the adoption of Semantic Web technologies such as FOAF and other RDF-based vocabularies (Brickley & Miller, 2005; Davis & Vitiello, 2005; Golbeck, 2004), accessing and disseminating information over multiple WBSNs has been made simpler (Ding, Zhou, Finin, & Joshi, 2005). If this has been quite a relevant improvement towards an easier sharing of information, it makes more urgent that content owners have control over information access. In fact, making available possibly sensitive and private data and resources implies that they can be used by third parties for purposes different from the intended ones. As a matter of fact, users' personal data and resources are regularly exploited not only by companies for marketing purposes, but also by governments and institutions for tracking persons' behaviors and opinions, and in the worst case, by online predators (Barnes, 2006).

It is then a challenging issue to devise security mechanisms for social networks, able to protect private information and regulate access to shared resources. In this article, besides providing an overview of the characteristics of the WBSN environment and its protection requirements, we illustrate the current approaches and future trends to social network security, with particular attention paid to the emerging technologies related to the so-called Web 2.0.

BACKGROUND

Usually, a social network is defined as a *small-world network* (Watts, 2003), consisting of a set of individuals (persons, groups, organizations) connected by personal, work, or trust relationships. Social networking is then a quite broad and generic notion, which in the Web context might be applied to any kind of virtual community. For instance, users registered to a Web service, such as Web mail, online journals, or newspapers requiring a subscription, can be considered as a social network. In the following, we adopt the definition provided by Golbeck (2005), according to which an online community's Web site can be considered a Web-based social network only if it satisfies the following conditions:

- Relationships are explicitly specified by its members, and not inferred from existing interactions (e.g., a mailing list can be used to infer implicit relationships).
- Relationships are stored and managed by using technologies, such as database management systems, allowing relationship analysis and regulating access and retrieval of relationship data.
- Members are able to access relationship information, at least partially.

Born in the late 1990s, in the last few years WBSNs gained increasing interest and diffusion. Although the first and most successful ones, such as MySpace, Friendster, and Facebook, were formerly designed for entertainment and socialization purposes, they are currently establishing themselves as a business model, through which institutions and organizations can set up a collaborative environment for specific purposes, and where it is possible to share resources at an intra- and inter-organizational level. Due to the great amount of collected data, WBSNs are currently the subject of great interest for statistical analysis (Wasserman & Faust, 1994; Freeman, 2004), since they may provide useful information not only to social researchers, but also for marketing purposes.

WBSNs may provide different kinds of services, ranging from information and contact sharing, to collaborative rating, collaborative work environments, and so on. However, independently from the specific purposes of a WBSN, members' relationships are the core information on which all the provided services are based. In fact, they can be used not only to create connections among people sharing similar interests, but also to customize WBSN services themselves. This is particularly true in WBSNs supporting collaborative rating: in such a context, ratings may be given different weights, depending on the relationships existing between WBSN members. For instance, it may be the case that a given WBSN member m_1 considers more relevant (or trustworthy) the opinions of member m_2 than, say, those of member m_3. For this purpose, some WBSNs allow their members not only to specify personal relationships (e.g., "friend of," "colleague of") but also to establish *trust* relationships, which express how much they trust the other members either with respect to a specific topic (*topical trust*) or in general (*absolute trust*). For a thorough discussion on trust relationships and how they can be used, we refer the reader to the work by Golbeck and Hendler (2006).

As far as security is concerned, current WBSNs enforce simple protection mechanisms, which only allow their members to label given information as public or private, or to make it available to WBSN members with whom there exists a direct relationship of a given type (friend, colleague, etc.). However, these solutions on one hand may dramatically reduce the possibility of sharing information, which is the basic function of a WBSN, and on the other hand, they do not necessarily grant the required protection to personal information. In fact, giving to WBSN members just the choice of stating whether a given resource is public or private may result in hiding a huge amount of information. Moreover, it may frequently happen that WBSN members make publicly available resources that are accessed by people different from the ones they intended—the most typical case is a student publishing photos or blogs in recreational WBSNs, without considering that they can be accessed by his or her teachers.

Additionally, personal information and relationships among WBSN members must be protected when WBSN data are analyzed by data mining tools, that is, tools capable of analyzing massive datasets of personal information with the purpose of extracting models of social and commercial interest.

SECURITY AND PRIVACY REQUIREMENTS IN SOCIAL NETWORKS

In this section we consider the security and privacy issues related to WBSNs from two different points of view. First, we discuss the privacy-preserving techniques adopted to allow statistical analysis on social network data without compromising WBSN members' privacy, and then we illustrate the current approaches aimed at enforcing privacy protection when performing access control.

Privacy-Preserving Social Network Analysis

Data collected by WBSNs are an important source for social and marketing analysis, which may provide useful information on the evolution of a social community, collaborative problem solving, information distribution, and so on. Additionally, they can also be used to optimize social network services and customize them with respect to users' preferences and interests. However, when analyzing WBSN data for statistical purposes, it is necessary to avoid as much as possible disclosing private information about WBSN members.

So far, this issue has been addressed by anonymizing the network graph according to two main strategies, namely, *node anonymization* and *edge perturbation*. The former strategy aims at hiding members' identities by labeling the corresponding network nodes with random identifiers (naïve anonymization). In case nodes are associated with attributes which can be used to identify the corresponding user, the possibility of using techniques based on k-anonymity (Sweeney, 2002) has been discussed−see, e.g., Zheleva and Getoor (2007). By contrast, edge perturbation performs a set of random edge deletions and insertions, which prevent an attacker from inferring the identity of network nodes based on the existing relationships but, at the same time, preserve the utility of the graph for network analysis.

It has been noticed that the proposed solutions to node anonymization do not grant total privacy protection. In particular, Backstrom, Dwork, and Kleinberg (2007) carried out an extensive analysis of the possible attacks, and argued that the most effective strategies for privacy protection are those based on *interactive* techniques. According to this approach, the anonymized network graph is not disclosed; rather it is analyzed by the social network management system itself upon submission of a query, and then the result is perturbed by adding noise to the real answer.

By contrast, edge perturbation, when combined with node anonymization, grants a greater degree of protection. Examples of how such techniques are applied are provided by Frikken and Golle (2006), Hay, Miklau, Jensen, Weis, and Srivastava (2007), and Zheleva and Getoor (2007). In particular, Hay et al. (2007) report experimental results which show that random edge deletions and insertions grant graph anonymity when the perturbation affects a percentage of graph edges ranging from 5% to 10%. By contrast, a perturbation rate greater than 10% dramatically increases information loss, thus making useless the results obtained by analyzing the perturbed graph. Although Zheleva and Getoor (2007) do not provide experimental results, they enhance the edge perturbation strategy by considering the different possible methods according to which it can be performed, and by evaluating the obtained perturbed graph with respect to information loss and link re-identification attacks.

Note, however, that graph anonymization is based on the assumption that the only information that can be obtained by an attacker is the one publicly released by the social network service. By contrast, this strategy is useless when applied to social networks, as most WBSNs are, to which any Web user can register, and where each member has a total or partial view of the network graph. In such a case, attackers can infer the network structure and members' identity with more or less accuracy by using techniques like *node bribing*, that is, by obtaining access to the partial view of the WBSN graph of one or more of its members, as illustrated by Korolova, Motwani, Nabar, and Xu (2008). The authors argue that it is possible to reduce the effectiveness of such attacks by limiting the neighborhood visibility of a member (his or her *lookahead* ℓ) to his or her neighbors ($\ell = 0$), and to the neighbors of his or her neighbors ($\ell = 1$). By contrast, in case $\ell > 1$, the possibility of obtaining correct information on the WBSN graph exponentially increases.

In conclusion, available privacy-preserving techniques, both those based on graph anonymization and those limiting WBSN members' lookahead, have the goal of preserving users' privacy when network data are analyzed through data mining tools. An additional issue is to enable a WBSN user to state which information should be public or private, and which members are authorized to access it. In this respect, current WBSNs enforce very naïve default protection mechanisms which cannot be personalized by WBSN members. We elaborate more on this issue in the next section.

Privacy-Aware Access Control

WBSN resources have protection requirements that cannot be enforced by simple mechanisms, as those currently adopted by WBSNs. An access control model for WBSNs should therefore take into account the specific characteristics of the application domain, in order to devise the most suitable access control strategies. In the following, we first discuss the main requirements for an access control mechanism tailored to WBSNs. Then, we survey the solutions proposed so far.

According to the traditional approach, access control requirements are expressed by *authorizations,* which in their basic representation are tuples of the form $\langle s, p, o \rangle$, where s is the subject authorized to access object o under privilege p (Bertino & Sandhu, 2005). However, such an approach is not suitable for dynamic and distributed environments, as WBSNs are, since a member may be required to update the authorizations applying to his or her resources whenever he or she knows new members, or if relationships he or she participates in are revoked. In such a scenario, it is preferable to *intensionally* denote authorized members by specifying the *requirements* they must satisfy to access a given resource. According to this strategy, whenever any modification to the state of the WBSN structure occurs, the set of authorized members will dynamically change, without the need to modify the existing authorizations.

So far, a variety of access control models have been proposed, which denote authorized users in terms of their characteristics, and not only by their identities. The role-based model (Ferraiolo, Kuhn, & Chandramouli, 2003) is the most popular one; others are those based on credentials (e.g., Winslett, Ching, Jones, & Slepchin, 1997; Agarwal, Sprick, & Wortmann, 2004) or certificates (e.g., Thompson et al., 1999; Palomar, Estevez-Tapiador, Hernandez-Castro, & Ribagorda, 2006). An analogous approach can be applied to WBSNs. In fact, WBSN members usually publish resources having in mind a specific audience consisting of, for example, their friends or colleagues. Therefore, in a WBSN context, *relationships* can be used to intensionally denote authorized members.

The enforcement of relationship-based access control requires addressing two main issues. First, it must be possible to verify the authenticity and reliability of information about relationships, in order to avoid security attacks based on forging faked relationships. Second, relationship information may have privacy protection requirements, and thus mechanisms should be enforced to regulate their disclosure.

A further requirement is related to the support of content-based access control (Adam, Atluri, Bertino, & Ferrari, 2002). Actually, the practice of 'tagging' resources is currently diffused among WBSN members, and content analysis is another possible solution to enforce content-based access control. However, since resource rating is performed by each single member and content analysis gives only probabilistic results about the actual content of a resource, strategies should be devised in order to obtain accurate and unambiguous descriptions, usable for access control purposes.

Finally, access permissions should take into account the possible operations to be performed on WBSN resources. Besides the traditional 'read' privilege, in collaborative environments WBSN members may be authorized to modify/delete a resource or add content to it. In such a case, it may be useful to support different types of 'write' privileges, such as 'modify' (authorized members can modify existing content or add new content), 'delete', and 'append' (authorized members can only add content, but not modify existing content). Additionally, when supporting 'write' privileges, it is important that any modification performed on a resource can be associated with the member who performed it. This means that supporting different privilege types requires enforcing accountability in the WBSN framework.

A last issue to be addressed concerns the access control architecture to be adopted. According to the traditional approach, access control is enforced on the side of the content provider. However, this solution may not be suitable to WBSNs, which may have millions of registered members and, as a consequence, the WBSN management service would be a bottleneck to the whole system.

As far as we are aware, the only two proposals of an access control mechanism based on WBSN relationships are the ones by Carminati, Ferrari, and Perego (2006) and Hart, Johnson, and Stent (2007).

In the proposal by Carminati et al. (2006), access control requirements are expressed by *access conditions,* which denote authorized members not only in terms of relationship types (e.g., friend, colleague), but also with respect to the relationship *depth* and *trust level.* The depth of a relationship corresponds to the distance between two members, considering only the edges labeled with a given relationship type. Thanks to this, it is possible to specify authorizations stating that a given resource can be accessed only by the friends of Alice, or by the friends of Alice's friends. By contrast, the trust level denotes how much confidence a member has on the fact that another given member does not reveal protected information to unauthorized members.

As far as access control enforcement is concerned, Carminati et al. (2006) adopt the rule-based approach proposed by Weitzner, Hendler, Berners-Lee, and Connolly (2006). More precisely, access authorizations are expressed by Horn-like clauses (rules), and it is the requestor who is in charge of demonstrating to the content provider of being authorized to access a given resource, by providing a proof of the corresponding access rules. WBSN resources and the corresponding access rules are managed by the resource owner, whereas relationship certificates are stored in a central directory, stored and managed by the WBSN management system. Whenever an access control request is submitted, the resource owner sends back to the requestor the set of associated access rules. The requestor then contacts the WBSN management system, in order to retrieve the relationship certificates concerning the relationships denoted by the received access rules. Then, he or she computes a proof, if any, demonstrating that he or she satisfies the rules. The resource owner sends the resource to the requestor only in case the provided proof is valid.

Also the access control model proposed by Hart et al. (2007) in their position paper uses existing WBSN relationships to denote authorized members, but only the direct relationships they participate in are considered, and the notion of trust level is not used in access authorizations. In addition, differently from Carminati et al. (2006), resources are not denoted by their identity, but based on their content. Information about resources' content is derived based on users' tags and content analysis techniques. Hart et al. (2007) do not provide any information about access control enforcement.

Both the approaches by Carminati et al. (2006) and Hart et al. (2007) assume that relationships are public. Later, Carminati et al. (2007) have extended their earlier research (Carminati et al., 2006) by proposing a privacy-aware access control mechanism, where the existing relationships are protected by a set of rules, called *distribution rules.* Such rules are used to regulate the distribution of relationship certificates to authorized members. Carminati et al. (2007) also address the issue of protecting relationship information that may be inferred by access rules, when enforcing access control. In fact, if an access rule states that, in order to be able to access a given resource, the requestor must be a friend of Alice, it is possible to infer that Alice participates in at least one relationship of type *friendOf,* otherwise no member will be able to access that resource. In order to deal with this issue, WBSN members are equipped with a set of group keys (Rafaeli & Hutchinson, 2003), called *relationship keys,* used to encrypt access conditions. More precisely, each WBSN member *m* holds a key for each type of relationship he or she participates in. These keys are shared by all the WBSN members in his or her social network group, that is, all the WBSN members connected to *m* by paths labeled with those relationship types. Whenever *m* receives an access request to a resource he or she owns, he or she does not send the corresponding access rules in plaintext. Rather, each access condition in the access rule is encrypted with the corresponding relationship key. For instance, if an access condition puts a constraint on relationships of type *friendOf, m* will encrypt it with the key corresponding to that relationship type. As a consequence, the requestor will be able to read that access condition only when he or she belongs to the same group of type *friendOf m* participates in.

It is important to note that all the approaches we have described so far support 'read' privileges only. Of course, they can be extended with other types of access modes, but enforcing accountability would require a relevant extension to the access control mechanisms described above.

FUTURE TRENDS

WBSN security and privacy is quite a new and challenging research area, and as such, the proposals discussed in this article are just a starting point. It is then difficult, given the state of the art, to provide an exhaustive summary of all the possible future trends and research directions. However, some general considerations can be done on the main open issues with respect to the topics discussed in the previous sections.

First of all, it is clear that privacy-preserving social network analysis and privacy-aware access control address WBSN privacy from two different points of view: the former, from an *external* perspective—that is, the one of an analyst carrying on social network analysis; the latter, from an *internal* perspective—that is, the point of view of WBSN members themselves. In privacy-preserving data mining, the goal is to provide, on average, an acceptable degree of privacy (e.g., by using anonymization techniques) to all the WBSN members to whom the data refer. By contrast, in privacy-aware access control, each WBSN member can explicitly state his or her privacy and/or access control requirements—for instance, some members may have stricter privacy requirements than others. This means that potential conflicts between social network analysis tools and WBSN privacy requirements may arise. Therefore, in the future it is desirable that these two research directions find some common points, in order to proceed towards the definition of a comprehensive framework, able to address all the privacy and security requirements of WBSNs. It must also be taken into account that social network analysis is carried out based on the assumption that the social network management system is able to release periodically, or upon demand, the network graph (or a perturbed version of it). This implies that the existing relationships must be stored in a central repository, accessible by the social network management system itself. However, this is not always the case. For instance, privacy protection mechanisms enforced in a WBSN might adopt approaches according to which relationship information is stored by WBSN members themselves, to avoid that the social network management system infers private information from the existing relationships. Therefore, privacy-preserving data mining tools must also take into account the different architectures according to which access control is enforced.

As far as privacy-aware access control is concerned, we argued in the previous sections that, when adopting a relationship-based approach to specify access control requirements, it is necessary at the same time that access to relationship information is regulated by proper protection mechanisms. The strategy proposed by Carminati et al. (2007) addresses this issue, but other solutions are also possible. For instance, instead of assuming that relationship information is directly distributed by the WBSN members involved in them, as in Carminati et al. (2007), an alternative is to support negotiations and privacy policies, similar to those provided by P3P (Cranor et al., 2006) and trust negotiation mechanisms. According to this approach, relationship information is held by WBSN members and released upon request after having verified whether the requestor satisfies given privacy protection policies, and/or whether he or she can be considered trustworthy about the use he or she will make of such information and the protection he or she can assure to it.

Content-based access authorizations are one of the other open issues. By using content-based access control, it is possible to simplify the task of policy specification as well as to express access control requirements related to the semantics of the protected objects. However, applying it to distributed environments such as WBSNs, where any member can use any vocabulary and any language (either standard or user defined) for describing resources, might make such strategy ineffective for access control purposes. Using content analysis tools has similar drawbacks, since, independently of the efficiency and effectiveness of the adopted tools, it may happen that a given resource is incorrectly described, thus granting unauthorized access to it or denying access to authorized members. Finally, the trade-off between accuracy and complexity in describing resources must be taken into account. Inaccurate and ambiguous descriptions are useless for access control purposes, but evaluating too complex descriptions may have computational costs that make unfeasible, in practice, the enforcement of content-based authorizations.

We think that a solution to this issue must satisfy two main requirements. First, resource descriptions should be encoded by using standard schemes, and the vocabularies used for describing resources must enforce semantic interoperability. Second, mechanisms should be devised that are able to confirm the actual validity of a description.

As far as the former issue is concerned, a possible solution might be provided by the outcome of the work currently carried on by the W3C working group named, "Protocol for Web Description Resources" (POWDER, 2007), which aims at defining a standard metadata format for describing the content/characteristics of a group of resources. In addition, POWDER aims at granting the accountability of such descriptions, referred to as *description resources* (DRs, for short), thus making any Web user able to verify their trustworthiness. Finally, DRs provide a simple mechanism for enforcing semantic interoperability. In fact, any Web user describing a resource can state that such description, independently of how it is specified, is equivalent to one or more given DRs released by other users.

However, POWDER DRs by themselves do not ensure the trustworthiness of resource descriptions. A possible solution is to use a content analyzer to validate the description provided by a given user. However, the results of a content analyzer are reliable when applied to resources all belonging to a given content domain, which is not the case of WBSNs. An alternative is to use social networking itself in order to validate resource descriptions, by exploiting *collaborative rating.* According to this strategy, WBSN members, on one side, can express their opinions on the trustworthiness of a description, and on the other side, can specify their personal descriptions of the same resource. The result is that, for the same resource, more descriptions are available, whereas a description is associated with ratings stating whether it is trustworthy. Given the huge population of WBSNs, it is possible to collect a data set having a size suitable to perform statistical analysis, which can provide a more accurate measure of how much the claims made by a given description can be trusted. Such an approach is currently under development in the framework of the QUATRO Plus EU project (*http://www.quatro-project.org*).

Support for different types of access privileges is another of the issues not addressed by Carminati et al. (2006, 2007) and Hart et al. (2007). As we mentioned, a key issue is the support for accountability, in order to be able to identify who performed which access operation on which resource. This is extremely important for 'write' operations, especially in collaborative environments where the members of the working group should be able to identify, for instance, who inserted/modified/deleted given portions of a shared document. Finally, it is worth noting that future WBSNs may rely on architectures different from the current one, where the WBSN management service is in charge of running almost all the supported services. In fact, from the privacy protection and access control approaches proposed by Carminati et al. (2006, 2007), it comes out that a decentralized architecture grants a more accurate protection to WBSN data. In such a scenario, WBSN members themselves store and manage their personal data, relationships, and resources, and are in charge of carrying on most of the tasks concerning relationship establishment/revocation and the enforcement of privacy and access control policies. By contrast, the WBSN management system provides just basic services, such as user registration, and may be used as a common space from which it is possible to access all the information WBSN members wish to share publicly. Such decentralized architectures pose challenging research issues with respect to security and privacy protection as well as efficiency.

CONCLUSION

With the increasing diffusion and usage of online social networks, protecting personal data and resources of their members is becoming a fundamental issue. Contributions to this research area are currently very limited, and can be grouped into two main classes: on one side, anonymization techniques able to protect the privacy of social network members when performing social network statistical analysis, and on the other side, privacy-aware access control mechanisms, making social network members able to regulate access to their data, relationships, and resources by, at the same time, protecting the privacy of their relationships. The proposed solutions are far from addressing all the privacy and security requirements of social networks, and not all the potential approaches have been investigated. Although it is difficult to predict with enough precision the possible evolution of this new research area, it is very likely that the enforcement of security and privacy mechanisms for social networks, more sophisticated than the ones currently available, may have two main relevant results. First, it might lead to the development of new security paradigms able to address the distributed nature of social networks. Moreover, it might determine a dramatic modification of current online social networks into a decentralized architecture, where the management of social network information, and of the social network itself, will be carried out collectively by its members inside a collaborative framework.

KEY TERMS

Edge Perturbation: Graph anonymization technique aimed at hiding the actual social network relationships by performing a set of random edge deletions/insertions in the network graph.

Graph Anonymization: Technique aimed at hiding private information about social network members when performing social network analysis. Node anonymization and edge perturbation are the two main graph anonymization techniques currently used.

Node Anonymization: Graph anonymization technique aimed at hiding social network members' identities by labeling the corresponding nodes with random identifiers (naïve anonymization), or, in case nodes are associated with attributes which can be used to identify the corresponding user, by using techniques based on k-anonymity (Sweeney, 2002).

Privacy-Aware Access Control: In the context of social networks, denotes an access control paradigm where access control requirements of social network members are enforced without disclosing private information about the relationships they participate in.

Relationship Trust Level: In a social network, denotes the value associated with a trust relationship, providing a measure of how much a given member considers another member trustworthy. Depending on the purpose for which it is used, this notion may have different meanings. For instance, in a collaborative rating environment, it denotes how much a given member trusts the opinions of another member with respect to a specific topic (*topical trust*) or in general (*absolute trust*) (Golbeck & Hendler, 2006). By contrast, in an access control context, it has some similarities to the notion of *security level* used in mandatory access control models (Carminati et al., 2006, 2007).

Relationship-Based Access Control: An access control paradigm specifically tailored to social networks, according to which social network members authorized to access a given resource are denoted in terms of the relationships they must participate in to get the access.

Social Network: A *small-world network* (Watts, 2003) consisting of a set of individuals (persons, groups, organization) connected by personal, work, or trust relationships. Usually modeled as a graph, where nodes correspond to social network members, whereas edges denote the relationships existing between them.

Social Network Analysis: A discipline aimed at collecting statistical data from the analysis of social network topology (Wasserman & Faust, 1994; Freeman, 2004).

Social Network Relationship: A relationship concerning two members of a social network. In WBSNs, besides personal/work relationships (e.g., friend/colleague), also trust relationships may be supported which denote how much a one member trusts another. In the graph representation of a social network, relationships are usually denoted by edges, labeled with a relationship type and/or a relationship trust level.

Web-Based Social Network: A Web-based system that allows its registered members to establish relationships with other members and to share different types of information (e.g., personal data, contacts, multimedia resources). A precise, but not normative definition of Web-based social network has been provided by Golbeck (2005).

Chapter 7.3
Social and Legal Dimensions of Online Pornography

Yasmin Ibrahim
University of Brighton, UK

INTRODUCTION

The dialectics between private pleasures and public needs raise various dilemmas, especially in the domain of the erotic and aesthetics. These are relative and abstract terms that can vary from individual to individual. However, in the public spaces of the Internet, the need for community standards of decency, acceptability, and taste often drag many of the debates about the Internet into a legal space, despite its description as a virtual sphere and the libertarian endeavours to keep it free from government and organizational control. While the Internet is a global resource it is often ruled through the laws of its physical embeddedness, and the global nature of the Internet also means that it is consumed and assessed through the differing cultural practices and norms that prevail in various parts of the world. The Internet as a communication and information platform is then subject to varying codes of ethical and moral conduct by different communities whether online or off-line. While the realm of the erotic is often equated with individual pleasure and psyche, the proliferation of pornography on a public platform raises social, moral, and legal concerns for communities, states, and governments. One significant element in the development of the Internet as a market place has been the availability of explicit sexual material, and these electronic networks continue to feed the pornography boom and facilitate new methods for consumers to interact with sexual content as "porn" (Spencer, 1999). These networks highlight the "privatising" potential of technology, especially in relation to sexual matters, while illuminating new forms of formal and informal exchanges (Jacobs, 2004, p.72; Spencer, 1999). The Internet, from being a rather unregulated enterprise a few years ago, has recently become the focus of multiple ethical concerns and debates and in some cases, it has amounted to moral panic (Bkardjieva & Feenerg, 2000; Cavanagh, 1999).

BACKGROUND

The emergence of gaming culture and the simulation of reality through the design of gaming technology raises the age-old issues about image and representation; the effects it can have on our cognitive senses, and how these can, as a result, affect or mediate our ability to reason and engage with interactive technology. These questions become ever more salient with regard to online pornography or sexually explicit material. The distinctive element about online porn is its use of multimedia, its ubiquity, and consumer access to it. Due to the anonymity of the Internet and the difficulties in regulating this transnational and anonymous medium, transgressive forms of entertainment, including pornography, have flourished online. According to Spencer (1999), the Internet is structured at one level around the economics and politics of consumption, at another level around the politics of individuality, and at another around communitarian concerns (p. 242).

Online pornography has been acknowledged as a relatively new form of pornography. Authors Stack, Wasserman, and Kern (2004) point out that there were about 900 pornography sites on the Web in 1997 and just a year later, the figure had burgeoned to between 20,000 to 30,000 sites, with revenues reaching US$700 million by the late 1990s. Its growth has been attributed to the "triple a-engine" of accessibility, affordability, and anonymity (Cooper & Griffin-Shelly, 2002, p. 11). Fisher and Barak (2001) agree that "spectacular growth in availability of sexually explicit material on the Internet has created an unprecedented opportunity for individuals to have anonymous, cost-free, and unfettered access to an essentially unlimited range of sexually explicit texts, moving images and audio materials" (p. 312). This increased accessibility and convenience, as well as the exploiting of e-commerce by pornographers, means that the Internet makes it easier for individuals to come into contact with porn. Some suggest that this has enabled the normalization of practices that may have otherwise been stigmatized in traditional markets, leading to a mainstreaming of cyberporn through its visibility and presence (See Cronin & Davenport, 2001, p.35; O'Toole, 1998). In the last few years, undoubtedly, there has been increasing heterogeneity and decentralization on the Internet as a wider variety of producers and consumers participate in the making of globalized markets, and a contemporary notion of pornography should capture such networked sexual agency and politics (Jacobs, 2004).

MAIN FOCUS

Diane Russell (1998) defines sexually explicit material as that which "combines sex and/or the exposure of genitals with abuse or degradation in a manner that appears to endorse, condone or encourage such behaviour" (p. 3). James Check (1985), on the other hand, terms pornography as "sexually explicit material" without further qualifying it. The Internet poses new questions about the reality, regulation, definition, and availability of pornography, as it has dramatically increased the accessibility of pornography, and of violent pornographic images in particular (Gosset & Byrne, 2002). The danger of pornography to adults is much more disputed, and often the arguments for pornography include freedom of speech and the expression of civil liberties, the right to choose, and the right to privacy (Kuipers, 2006).

Nevertheless, what constitutes pornography is often contested in societies. While in terms of ethics adult pornography is a contested terrain, child pornography, on the other, is almost universally prohibited. But in the online environment, a digital image can be manipulated and altered and consequentially it may be difficult to clearly define the distinction between adult and child images. Jenkins (2001) posits that child pornography can be accessed in various ways in the online environment, where it can be distributed via credit-card access Web sites, bulletin boards, and encrypted e-mails, as well as through peer-to-peer file sharing. These are constitutive of not only the new configurations between producers and users, but also of new forms of abuse (Oswell, 1999, 2006, p. 253).

A report by the Washington-based research and policy group, Third Way, highlights how this accessibility and presence can present new problems for Internet users, particularly children (cf. Whitehead, 2005). According to the report, only 3% of more than 450 million individual porn Web sites ask for proof of age. Additionally, a majority of these Web sites do not carry any warning of adult content, and nearly three-quarters display free teasers of pornography images on their homepages; it is therefore likely that children may accidentally come across a porn site while doing homework or surfing the Web. While child pornography is almost universally illegal, adult pornography is prevalent and easy to access on the Web. Whitehead (2005, p. 18) contends that unlike off-line pornography, which can be curbed through measures imposed by the community such as zoning laws and curfews, the politics of online pornography is very different, as online porn, through its technology, can be seen to be "everywhere and nowhere." This has meant the loss of power for parents to control what their children come into contact with.

The status of a photograph as a verifiable fact continues to linger with the Internet despite the radical impact of digital technology on photographic practice. This has been problematic as digital technology can manipulate and distort images, thus further compounding the relationship between reality and representation. David Oswell (2006) describes this as the ethics of virtual observation, where the referentiality of the image in representing the scene of abuse that is real, and our ethical response to it, is predicated by our perceptions of reality (p. 258).

In discussing the ethics of the virtual, Oswell (1999, 2006) observes that there are often epistemological inconsistencies and disjuncture between knowledge, law, and sociological perspectives. In the context of the US and UK, there is often an implicit understanding that child pornography is the record of actual child sexual abuse, and this has become widely used in legal discourses and public discourses of law enforcement charities and child protection agencies (Williams, 1991, p. 88).

According to Tate (1990), while child pornography has been a problem for decades, until relatively recently it has been a hidden crime (p. 1). In the UK, the principal legislation that addresses the indecent images of children is the Protection of Children Act 1978 (PoCA), which differentiates between different mediums representing the abuse. Photographic images are the subject of this specific legislation that focuses on child pornography, whereas all other mediums are treated as obscene articles and are subject to general obscenity legislation (Gillespie, 2005).

The ontological status of visual depiction has legal ramifications both in the context of the UK and the US. In the US, the Child Pornography Prevention Act (CPPA) of 1996 addresses the legal implications of visual depiction. In 2002, a ruling by the US Court of Appeals for the Ninth Circuit found that the CPPA ruled solely on the image without considering the set of contextual factors catered for in an earlier ruling in 1973, and in view of this, the CPPA's emphasis on the image was "overbroad" and "unconstitutional" (Oswell, 2006). It also reiterated that the proximity or distance of a photograph from the scene of the actual event is an important criterion in the legality of child pornographic images. The court also overruled the argument in the CPPA that virtual child pornography is "intrinsically related" to the sexual abuse of children as the link between the two is contingent and indirect. Harm here does not necessarily accrue from the image but is dependent on the potential for subsequent criminal abuse. The ruling showed the court's unease with the assumption that the image takes up the position of the "modest witness" whose account of the scene is "unadorned, factual and compelling" (Haraway, 1997, p. 26).

Virtual child pornography may have no link to crime or sexual abuse that has actually been committed, and in the same vein, the virtual image has no necessary link to future cases of abuse. As with child pornography, virtual child pornography cannot be prohibited on the basis of its possible harm to some children or the possibility some children may be exposed to it. In this sense, the CPPA defies the "principle that speech within the rights of adults to hear may not be silenced completely in an attempt to shield children from it" (Oswell, 2006, p. 251). In April 2002, the US Supreme Court found the Child Pornography Prevention Act (CPPA) unconstitutional. Though it remains illegal to make, show, or possess sexually explicit material of children, the court found that there were not compelling reasons to prohibit the manufacture or exhibition of pictures that merely appear to be children. As a consequence, two categories of pornography that were prohibited under the act are now permitted in the US. These include sexually explicit pictures of actual models who appear to be younger than they are and computer-generated sexually explicit pictures of children (Gillespie 2005; Levy, 2002; Oswell, 2006).

In contrast, the UK treats indecent pseudo-photographs of children "as indecent photographs of children." In the UK, the term pseudo-photography was introduced by the Criminal Justice and Public Order Act of 1994. This act defines a "pseudo-photograph" as "an image, whether made by computer graphics or otherwise, which appears to be a photograph" (cf. Gillespie 2005, p. 435). With the police finding images on computers that could not be readily verified as those of a child or an adult, the 1994 amendment became the rationale for addressing this problem (Hansard, 1994, cf. Gillespie, 2005, p. 435).

In UK legislation, while the indecent photograph and the indecent pseudo-photograph are not identical, they are treated as identical. This means that the act of downloading child pornography constitutes a crime, regardless of whether these images are records or not of actual abuse. This legal response to pornography intrinsically associates an image and a crime and provides a legal platform for the authorities to act. In contrast, the actual images are illegal in the US but not the virtual. Oswell (2006, p. 252) points out that such an equivalence creates challenges in a court of law as reservations can be raised as to the evidential status of the image, i.e. as to whether the image is an image of the incident of sexual abuse at all. Oswell contends that the photograph becomes the measure of the real and its observation, and hence, the implicit prioritization in UK law of virtual child pornography means the crime of possession, making, or distribution of child pornography (whether virtual or real) is a crime not only against a particular child but against all children, invoking it as a universal crime against childhood. The debates on adult pornography often delineate between the vague boundaries of erotics and aesthetics but these distinctions can be subjective and may influenced by the context of the immediate society, making them arbitrary criteria.

Prior to the Internet, the debate about pornography in the US centred on the First Amendment, and the need to regulate pornography was stressed on the grounds that pornography violates community standards. Under the US Constitution, it is legal for adults to own and distribute most types of pornography. However, since the 2002 Supreme Court Ruling over COPA (Child Online Protection Act), the US government has made serious efforts to monitor and impose restrictions on Internet pornography traffic by arguing that juveniles or minors (18 years or less) are automatically exposed to and harmed by pornographic images (Jacobs, 2004). As Taylor and Quayle (2003, pp. 159-163) point out, one of the principal elements of Internet-facilitated child pornography is an exponential growth in the size of the individual collection. Here the imaging and archiving features of Internet technology cannot be overlooked. In the UK, for example, legislation does not distinguish between accessing images for personal use (including downloading) and the creation and distribution of images (Gillespie, 2005).

Often censorship and obscenity laws have provided the basis to tackle pornography on the Internet, and this has been the case in the US, Australia, the UK, and France. In Australia, the Western Australia Censorship Act (1996) is designed to protect the local and state territory from the influx of pornographic material over the Internet (Jacobs, 2004:, p.71). On the other hand, South Australia's Censorship Act criminalizes any content that is deemed "unsuitable for children online," even if the content is intended for adults. This leaves content open to police interpretation, as authorities can evaluate and arrest users who post information that is deemed offensive to children.

Akedeniz (2002) stresses that there is a difference between illegal and harmful content, as the former is criminalized by national law while the latter is merely deemed offensive or disgusting by some sections of society. In tandem with this, Jacob (2004) queries whether community standards of decency can be transmitted from one place to another. With the Internet being perceived as a global resource, the issue of community standards creates different cultural and legal approaches to solving the issues at hand.

While there is often a societal acknowledgement of child pornography as a heinous and universal crime, there is, nevertheless, a difficulty in defining what constitutes child pornography as different jurisdictions can define it differently, and equally, the issue of obscenity can also be culturally mediated in different environments. The consensus in terms of what constitutes child pornography can emerge within the context of supra-national agencies such as the Council of Europe, which defines child pornography as "any audiovisual material which uses children in a sexual context" (Oswell, 2006, p. 246).

Akdeniz (2001) points out that the legal regulation of this sort of Internet content may differ from country to country, and this is certainly the case within the European Union, where member countries have taken different approaches to sexually explicit material. Akdeniz streses that in terms of Internet content and young users, harm remains a criterion, and this is accepted within the jurisprudence of the European Court of Human Rights. Harm in societies again is culturally defined. In terms of illegal or harmful content, the UK adopts a multilayered approach with the involvement of both national and international levels. The government also favours a coregulatory approach in which there is a role to be played by the industry's own self-regulation.

Before the Internet, the US already had some antipornography legislation that has since been applied to the Internet. In the US, pornographic sites are legally obliged to refuse access to minors (Kuipers, 2006). Until recently, further attempts to penalize or regulate Internet pornography failed due to the fact they conflicted with the First Amendment. Beyond legal restraints, countries can also encourage the use of technology to filter undesirable content deemed harmful to children. In June 2003, the Child Internet Protection Act (CIPA) was approved by the US Supreme Court to force libraries and schools to block pornographic sites. The CIPA requires public libraries to filter their computers if they want to retain federal funding, but such software is not completely reliable. Judith Levine (2002) has argued that it is important to promote media literacy and moral intelligence rather than to deal with the Internet through technology. This means that governments and societies should also invest in public awareness and education campaigns instead of phasing out controversial sexuality debates that can polarise the public.

FUTURE TRENDS

Online pornography in many countries has been regulated through existing censorship and decency laws. However, due to the complexity of the Internet environment and the availability of different technologies on one platform, there has been a need to enact and revisit what a photograph or "psuedo-photograph" can constitute in the digital environment and the consequences of admitting it as evidence in courts. The legal trajectories in the US and UK highlight the complexities of the digital image and its treatment in different legal contexts. In the future, new forms of technologies and the convergence of these on the Internet will pose more challenges for the legal domain. Societies would then have to enact new legislation to cope with legal systems that predate modern technologies and the challenges they present. It illuminates the sort of legal and moral dilemmas that have emerged from the Internet environment.

The criminalization of child pornography and the ubiquity of pornography on the Web raise legal issues for users as their private actions in their personal domain can have legal consequences. On an international level, in the domain of child pornography there has been cooperation at a global level between governments to share databases of perpetrators involved in child trafficking and pornography. The future as such alludes to both centralization and surveillance to curb criminal behaviour on the Web as well as to the rise of fragmented and diverse forms of pleasure-seeking on the Internet.

CONCLUSION

The issues of online pornography are entangled with private pleasures, community standards, increasing commercialisation of the Internet, and a proliferation of sites and images offering sexually explicit content. It raises the need to address numerous concerns and issues with regard to online pornography. Concepts of privacy, harm, offence, taste, decency, legality, and protection of children as a universal ideal as well as the evidential status of the digital image on the Internet compound the problems of online pornography. Online digital images, and their referential authenticity to the actual event or person, capture the complexities of the Internet as a medium where convergence of technologies and amalgamation of sound and images, as well as editing technologies, enable simulated realities and new forms of gaze and pleasures. These will continue to pose new moral panics and debates in societies and communities, particularly in terms of protecting the vulnerable and the young while catering to a well-established market that has capitalised on e-commerce and new forms of voyeurism.

KEY TERMS

Cyber Porn: Sexually explicit material that is available on the Internet

Digital Image: A visual content constructed through pixels which can be altered or manipulated through technology.

Ethics: The code of conduct in a society or community that may be tacit or explicitly expounded

Pornography: Sexually explicit material that may be available in any medium

Regulations: Formal rules and legislation that are enacted to address a particular issue.

Chapter 7.4
Social Networking Site:
Opportunities and Security Challenges

Tom S. Chan
Southern New Hampshire University, USA

ABSTRACT

Social networking has become one of the most popular applications on the Internet since the burst of the dot-com bubble. Apart from being a haven for teenagers and online marketers, social networking sites are increasingly adopted by the corporate community. The trend makes viable many new business models and applications. The popularity of these sites has altered the way society interacts, but it also greatly heightened the threats of cyber crime. Safety and crime issues aside, the massive amount of user-generated content in these Web 2.0-enabled social networking sites are becoming fertile grounds for viruses. Furthermore, these sites pose great challenges on how to protect copyrighted works as they are havens for digital content sharing. Society must learn to balance the benefits of social networking with its drawbacks as the phenomenon is an inescapable global trend, expanding at the speed of light.

INTRODUCTION

A social networking site is a category of websites with user profiles and persistent public commentary forming a traversable networked virtual community. A user profile contains identifiable information about the participant, such as, age, gender, interests and etc. The profiles have unique URLs that can be visited directly. Site visitors can also post comments or other information for everyone to see. Network participants have the ability to list other profiles as "friends", link to friend's profiles, and see comments posted by others. The comments are semi-permanent because they may disappear over a period of time or upon removal. All of the above functions generate a virtual network for social interaction where each node contains a link to the profile of the other person so that individuals can traverse the network through friends of friends.

Social networking sites bring people together in a virtual community to talk, gossip, exchange ideas, share interests and making new friends. The sites typically provide tools for posting messages, sharing photos and creating personal pages. The Internet is made of people, and people are social by nature. Embraced mostly by teenagers and young adults who find it irresistible, MySpace.com, a social networking site, launched only four years ago is now one of the world's most popular. In U.S., it ranks second only to Yahoo in page views, drawing almost 5% of all site visits, ahead of even Google, which drew only a little over 4%. According to a recent web metrics report (Tatham, 2006), one in every twenty U.S. Internet visits went to one of the top twenty social network sites in September 2006.

The popularity of social networking has altered the way society interacts, but it also greatly heightened the threats of cyber crime. Safety issues aside, the massive amount of user-generated contents in the Web 2.0 enabled sites are becoming fertile grounds for viruses. Furthermore, these sites pose great challenges on how to protect copyrighted material as they are now havens for digital content sharing. Society must learn to balance the benefits of social networking with its drawbacks as the phenomenon is an inescapable global trend, expanding at the speed of light.

Social Network Theory and Social Network Analysis

"Social network", a term coined by J.A. Barnes (1954), represents a web of relationships and flows between people, groups, organizations, animals, computers or other information processing entities. Social network theory differs from traditional sociological studies. In traditional theories, attributes of individual actors are assumed to matter the most. Social network theory takes a different approach, where individual attributes are less important than their relationships and ties with others within the network. Social network theory in Social Sciences began with the urbanization studies of the Manchester School (Barth, 2005). Started as an attempt to quantify social relationships, social network theory has been helpful in explaining many real life phenomena, from the success of individual business to the rise of political powers, and from the process of how juries reach consensus to the decision that countries pattern their trade.

Social network theory, deeply rooted in Sociology, has recently found a home in many business applications. Social network analysis helps us to understand the dynamic of informal networks. Social network analysis theory views social relationships in terms of nodes and ties. Nodes are individuals within the networks, ties are the relationships between the individual, and a social network is a map of all of the relevant ties between the nodes being studied (Scott, 1991). The International Network for Social network Analysis, http://www.insna.org/, is an academic association of social network analysts. New visualization tools are constantly being developed and many are available online for scholars to study the patterns of complex social interaction using graphical images of network models. A social networking service is a website specifically focused on providing and supporting online social networks for whatever purpose. As of April 2006, social networking sites claim an estimate of 68.8 million unduplicated unique participants, reaching 45% of active web users (Nielsen, 2006).

A Short History of Social Networking Site

Hammersley (2003) noted, "Given the right knowledge of the people between us, I could probably plot a chain of people between myself and you, wherever you are. If such information was available, and it turned out it might be advantageous for us to chat, then we could ask each of the middlemen in turn for an introduction and get on with it. Or we could skip the middle guys altogether. That's the idea of the growing number of social network sites on the net today."

The non-digital form of social networking has existed as long as human civilization. As the cliché goes, "It is not what you know, but who you know". The Small World Theory, or the Six Degrees of Separation, speculates that there are only six degrees, or levels, of separation between a person and everybody else in the world (Barabasi, 2003). A degree of separation is defined as an acquaintance or friend who separates one from someone else. Thus, zero degree of separation exists between one and one's immediate friends. It is a common human practice to use a network of friends to exchange information, enhance job prospects, or further one's career. With advent of the Internet, it is only natural that the traditional social network ceded the spotlight to digital social network, from contacting friends who might be able to help nearby, to friends in a broader sense on the Internet, i.e., the ultimate "network of networks".

Emerging technology always affects the society around it, and social networking site carries no exception. As technologies become more dynamic and participative, the social networks form around these communication channels also become more complex. The Internet can trace its roots back to the ARPANET, the first computer-mediated communication networks developed in the 1960s (Wellman, et al., 1996). The earliest digital social networks emerged on the ARPANET are small tightly-bounded groups making up of specially trained users. In the 1970s, e-mail mailing lists and bulletin board systems (BBS) were some of the pioneer technologies that enable mass social collaboration and interaction online. UseNet and Internet Relay Chat (IRC) extended the concept of messaging and enable newsgroup of users with common interest to dialogue in relatively unrestricted ad hoc manner. UseNet, the first virtual community in existence, was estimated to have over 8.1 million participants in 2000 (Rheingold, 2002). Instant messaging (IM) emerged in 1996, creating an almost synchronous messaging environment by fusing the functionality of real-time chat and e-mail (Huang & Yen, 2003). Unlike the UseNet which restricts membership to a global list, IM empowers users to define and maintain the social networks themselves. IM users maintain a list of people which they have a relation or desire to communicate, and individually, they can negotiate to add new contacts, restrict or remove the addition of one's name to other's list.

The earliest social networking commercial website was launched in 1995 (Wikipedia, 2007). Classmate.com, http://classmates.com/, was the first website that aimed at assisting members to find past friends and acquaintances from school, work and military throughout the U.S. and Canada using the Internet. Members were searchable by name, age, hometown, and institutions. The site provided a vehicle for friends to re-connect and keep-in-touch with tools such as personal websites, message boards and other tools for event planning and email exchange. With the success and growing popularity of Classmate.com, a new movement was spawned towards initiating and cultivating new relationships online. SixDegrees.com, from 1997 to 2001, followed Classmate's lead, but with added dimension of allowing members to meet their friends' friends. Modeled after the "Six Degrees of Separation" concept, members could send and post messages to people in their first, second, and third degrees, and see their connection to any other users on the site. The first site that really garnered popular appeal was Friendster.com, http://www.friendster.com/, launched in 2002, and it was followed by MySpace.com in 2003. MySpace.com allows users to personalize their profiles by uploading photographs and music as well as personalizing the backgrounds of their pages. Catered to teenage population much more effectively than previous sites, MySpace.com has attracted a huge membership from teens and young adults. It has become such a success that the company was acquired by News Corporation for $580 million in 2005 (Carr, 2007).

Most commercial social networking sites allow everybody to join, but some only allow those who are invited by an existing member. In any case, all the sites have certain mechanism to restrict links that are made with existing members. There are several common features in addition to the registration and invitation process. Each new member is asked to provide a profile of who they are: their interests, hobbies, skills, professional affiliations, and etc. The other members may browse through their personal network of linked members, or search for members within the network by any combination of the user-defined demographic and interest criteria. Members can then make inquiries using an internal interface, a form of anonymous messaging supported within the site's communication framework, to negotiate for unknown but potential relations. Increasingly, social networking sites are focused on providing a multitude of web content presentation supports, including journals and ratings; and the presentation of multimedia including graphics, photos, audio and video.

SOCIAL NETWORKING FOR BUSINESSES AND CORPORATIONS

While young people propel MySpace.com to become the most popular website on the Internet, there are now social networking sites for practically every niche. Some are by invitation only, and some are even for very pragmatic and practical purposes. Fueled by a stagnant job market, online business networking has generated serious attentions. A business professional joins a site by creating a personal profile, then e-mail friends and associates inviting them to set up their own profiles. Each person who accepts the invitation becomes a member of the personal social network. As other members solicit their own friends and colleagues to join, the person's network grows exponentially. These sites provide the benefit of an inherent filtering system and personal privacy is somewhat protected as network memberships are by invitation only (Kandra, 2003). Social networking sites are no longer just for making friends and meeting new people. People are using the sites for professional purposes: searching for jobs, making professional contacts, and expanding one's current business reach.

Social networking has profoundly impacted the corporate world, though most of the current hype and attention are focused on individual Internet users. Companies and organizations can capitalize on the growing trend of meeting people and maintaining relationships online just as much as individuals are benefited from using these sites. A recent study showed the top reasons for business blogging included publishing content and ideas, building community, promoting thought leadership, and getting information and feedback quickly to and from customers (Backbone, 2005). Similarly, a corporation can use social networking internally for applicant and staff research, and team build; and externally for the maintenance of business to consumer (B2C) and business to business (B2B) relationships.

The Internet is a public domain. If one can use the Internet to search for information on others, others can also be searching for one's information online. What if those others are law enforcement, principal, parents, spouse and even current and possible future employers? Social networking sites allow users to search for each other once registered and logged into service. Once an individual is found, their pages, posting blogs, pictures, messages and etc., are essentially open for public viewing. Companies can make certain inferences and stereotypes regarding someone's productivity and potential distractions from these materials. While the practice may be ethical questionable, it would be naïve to assume employers are not using them as a source of information on current and perspective employees (Finder, 2006).

The corporate intranet has long established as a platform for team building and delivering updated information to employees (Bansler, et al., 2000). Social networking allows an organization to broaden the scope of their intranets to encompass more interactive activities and streamline their internal business value chain. Connecting employees in a collaborative manner via an internal network can foster trust and reinforce organizational identification. They promote the company culture, organize events to unite employees, and help them connect in new non-work ways, all of which can boost company morale. Multinationals are at the forefront of applying this innovation because they are facing the challenge of connecting thousands of employees worldwide, who are speaking many different languages.

The popularity of social networking sites has made them magnets for advertising dollars. Corporations are constantly looking for the most efficient manner available to build their brand or push a new product. Web advertising now competes head to head with both print and television ads, and is an important component in any overall campaign. Companies are starting to use social networking and blogs as a way to promote their products and services. Some simply send their marketing people online to participate in blogs and social networking sites masquerading as consumers. Such tactic is unwise and can be serious backfired. They are often discovered and reported, and end up causing serious embarrassments and damages to the company's reputation (Barbaro, 2006). Honesty is always the best approach. A company can create its own social networking site, tell consumers who they are and what they want from them. Ask for opinions from visitors and give them current information about the company's products and services. Companies can get plenty valuable feedbacks by telling their potential customers about their products and new ideas in an open forum.

Apart from the traditional empowerment of employees to share their contacts and build relationships outside of the company, some organizations are using social networking sites for "crowdsourcing". Crowdsourcing is a new business model that delegate internal works to the outside of the company. Unlike outsourcing that is typically done by lower paid professionals, crowdsourcing relies on a combination of volunteers and temporary participants who use their spare time to create content, solve problems, or even research and development. For example, corporations can use their social network to outsource a complex scientific challenge facing the company to leading researchers from around the globe. Rather than invest in expensive research and development, the social network allows companies to build upon the previous, current, or future work of experts from all over the world. Potentially, this approach can produce a huge saving in time and money, and to solve even the most perplexing problems (Howe, 2006). Why reinvent the wheel if someone out there already has the answer?

Social networking sites are also becoming a valuable platform for entrepreneurs and professionals to connect with one another to find new partners, suppliers, and ultimately increase their own customer base. Musicians, celebrities, filmmakers, authors and comedians are already using these sites to promote their work and reach a larger audience or reinforce the fan base they already have. Professionals can network online to grow their current business and their own career network. Entrepreneurs can network to compensate for their lack of resources and remain competitive with larger firms. Small businesses can locate potential partnerships, share experiences, and leverage a global network of opinions and advices online. Several niche social networking sites cater just for such purposes. For example, LinkedIn.com (http://www.linkedin.com/) provides the ability for its members to host a "virtual trade show", overcoming the traditional resource barriers for conducting such events for individuals and small business owners.

Popular social networking sites such as MySpace.com are also creating its own ecosystem. Just like EBay, MySpace.com is populated with small businesses that do everything from helping users to decorate their profiles to creating tools that let advertisers target site members (Rosmarin, 2006). Companies are also developing new technology and business model to take advantage of the social networking phenomenon. For example, wallop.com, http://www.wallopcorp.com/, was started as a research project at Microsoft, which provides users a more lively and vivid experiences with Flash-based applications; eSnips.com, http://www.esnips.com/, is a startup social media sharing site where members can share any digital content they want, including photos, video, text and links. Progressively, people will have more options for interacting with other people. Furthermore, devices will automate an increasing variety and amount of intrapersonal communications. These new technologies have already changed the manner in which people meet, share information, do business and organize their lifestyles.

A NEW PARADIGM FOR SOCIAL INTERACTIONS

Social networking sites have a huge impact on the American society. They change the definition of networking, from that of face-to-face interpersonal event, to virtual meeting on the global village. Rather than meeting someone in person with the traditional physical contact, people are now using technology to interact and network from their very own homes anywhere in the world. Without the face-to-face exchanges that are the hallmark of traditional physical social interaction, computer mediated communication is based only on written text. The complexity and diversity of techno-modern life makes it difficult to evaluate the effect of social networking sites on the society. Some scholars believe virtual communities reinforce existing social ties because they enable easy reach to others. At the same time, others worry the reduction of face-to-face exchanges will have a detrimental effect on interactions between people.

Proponents of social networking sites note the many benefits offered by these sites to their users and to the society. These sites provide opportunities for users to meet new people with similar interests, essentially linking members of society together who may never have gotten the chance to interact (Wellman & Gulia, 1999). Social networking sites are not only valuable sources of information. They are also sources for companionship, social support, and most importantly, a sense of belonging. Because social networking sites provide simple and quick access to many people, these sites encourage more interpersonal interactions instead of lessen them. There are other benefits cited by proponents of these virtual communities. For instance, they provide simple and quick access to people and an endless amount of people to reach. Furthermore, relationships and dialogues can be built upon intellect and common interests, without the assumptions and bias of race or gender (Fernback & Thompson, 1995). Finally, these sites provide the opportunity for individuals to express themselves and preserve their uniqueness despite the conformity constraint imposed upon by the physical society. Such freedom of expression is important because liberty, autonomy and selfhood are the bedrock of any free society.

Traditional approaches to community are perhaps inapplicable to virtual spaces, but urbanization and modernization do threaten the traditional patterns of social life (Bender, 1978). While social networking sites allow one to connect with others more conveniently, they could conceivably encourage people to remain in their homes and away from other people. "Mouse potatoes" will replace "couch potatoes" and people will continue to hide from real life. Not only is there a loss of physicality, but the convenience of the Internet will also discourage people to interact face-to-face. Some scholars argue computer mediated communication is not a legitimate way to socially interact. "True" interpersonal communication explicitly reveals emotion. It is not that empathy, tenderness, reassurance, flirtation, sadness or happiness cannot be expressed in written text. Rather, it is the matter of eye contact, body language, facial expressions, vocalization and hugs that would be sorely missing (Nie, Hillygus & Erbring, 2002).

When one talk about networking, one tends to assume that more connectivity at lower costs are always better than less connectivity at higher costs. Such assumption may be incorrect. A lot of low cost friendships might simply means many low quality friendships. The arrival of online social networks has changed the social landscape by creating a new level of social structure. While the long term impact remains to be determined, oversimplifying and exaggerating of any new phenomenon are without exception dangerous. When telephone first became popular, some researchers suggested that people would no longer leave their houses, thus automobile traffic would be reduced dramatically. Yet, it turned out that people would not only use the telephone to call each other; but also to arrange meeting each other physically. It actually increased the level of face to face social activity.

Social networking has become one of the most popular applications on the Internet since the burst of the dot-com bubble. By serving the needs of a specific population, social networking sites enable advertisers to reach niche audiences. But looking beyond banner ads and page views, online marketers see social networks as free focus groups and social networking sites as treasure troves of consumer data. Big players such as Google have started to add social networking applications on top of the existing features, for example, utilizing existing buddy lists and connecting them to profiles. The scope of social networking is expanding at hypersonic speed. While some people may not be technologically savvy enough or feel comfortable enough to network online. The trend setting demographic of 15 to 40 year old, who have spent most of their lives using the Internet, are undoubtedly avid online social network users. It is unavoidable that the society must come to terms with balancing the benefits of such new networking opportunities verse its inherent risks.

Privacy, Web Safety and Cyber Crime

Social networking can create an illusion of privacy where none actually exists. By not really knowing who is watching, one could easily post more information on one's profile than one would otherwise give to a common stranger. This leaves users, especially younger ones, susceptible to those with ill intentions. The phenomenal popularity of social networking sites has greatly heightened the concerns over sexual predators lurking in them. Parents, educators and police have become increasingly worried that teens are finding troubles at these sites. MySpace.com has gotten the brunt of the publicity given its prominent position and with 20% of its members under the age of 18. In June 2006, the mother of a 14-year-old who said the 14-year-old was sexually assaulted by a 19-year-old user sued MySpace.com, seeking $30 million in damages. The lawsuit, filed in a Texas state court, claims the 19-year-old lied about being a senior in high school in order to gain the child's trust; and MySpace.com is not doing enough to protect minors from sexual predators (Rawe, 2006).

Self-reported identity system is often problematic but reliable verification requires expenditures and restricting access results in a smaller user base. For example, a credit card can be used to demonstrate a user's age, but credit verification incurs cost, and not everyone has a credit card. Although more robust techniques can verify user provided addresses, birth dates and other information against public databases, but minors do not possess as many unique identifiers as adults do, and their records are strictly under guard by states and schools for privacy and security reasons. To create a safer environment, social networking sites can restrict access only to those with a valid e-mail address from a school, college or participating company. It can even require parents to submit identity vouching for their children.

On a positive note, social networking sites can be a helpful tool for law enforcement. For example, police officers can set up sting operations by posing as teens that are targeted online by adult predators (Cressman, 2006). The government is also developing new laws regulating these websites. The Deleting Online Predators Act of 2006, or HR 5319, was brought before the U.S. Congress as an amendment to the Communications Act of 1934 (Fitzpatrick, 2006). The statue requires schools and libraries to limit and monitor a minor's access to social networking sites. Ultimately, parents must be proactive, by setting limits on how much time their children can spend on social networking, what activities they can participate in, and what the appearance and messages are in their profiles.

While the dangers minors facing on social networking sites have been well documented, adults' behaviors on social networking sites could also increase their risk of becoming a victim of cyber crime and identity theft. In a recent survey by the National Cyber Security Alliance, 83% adults who use social network exposed themselves to hackers by downloading and opening unknown files from these sites, 74% have given out some sort of personal information such as their email address, name, birthday, and some even their social security number, 57% received unsolicited or phishing emails asking for money, requesting account information, informing users of lottery winnings, or asking users to download a video. Surprisingly, 31% of those who received such emails actually responded to them (Russell, 2006).

In this Information Age, personal information is a highly valued commodity. It is captured and compiled, bought and sold in ways never imagined before. The level of privacy one can expect from offline activities usually is clear from the nature of that activity. Online activities are less obvious. Many users expect their online activities to be anonymous and private. In reality, they are not. Social networking sites are billboards in cyberspace, so it is important to guard one's financial, personal and other sensitive information with extra care. Since it is hard to judge people by self-posted photos or information, one should be cautious about meeting a new cyber friend in person. Social networking sites are fast becoming the hunting ground for criminals to hack into financial records and compromise personal information to commit identity thefts and frauds. For this reason, people need to beware of the scams and con artists lurking in them.

Creating a safe virtual community has its costs and appeals. Managing a limited population and keep them all safe, instead of looking for a million unique members, can be a viable business model. Safety experts warn that creating too many barriers could drive teens to other social networking sites with fewer controls, or perhaps free-for-all chat rooms. Furthermore, ineffective solutions could give parents and children a false sense of security, ending up increase dangers. While technology alone would not be the solution, it could be very helpful in resolving the dilemma. Perhaps some sort of V-chip technology can be devised just as when violence on television was the hot button issue of the day. Other promising technology may involve blog patrol armed with artificial intelligence that scan and approve every posted word. Parents must also get more involved in what their children are doing. In the end, education is the only way that teaches children to be proactive, which will stay with them forever even when social networking is replaced by the next big fad.

Web 2.0, Hackers and Malwares

Safety and crime issues aside, security experts worry the massive amount of user-generated content in social networking sites make fertile grounds for viruses. It may even make such content sharing sites a more common vehicle than e-mail for virus propagation. As users flocked to social networking sites, it is only a matter of time before these sites attract the interest of hackers. In the past year alone, MySpace's visitors have been the repeated target of attacks, falling prey to everything from cross-site scripting (XSS) to phishing. MySpace.com was forced to shut down hundreds of user profiles after a combination worm and phishing attack that compromises the visitor's "About me" page (Kawamoto, 2006). Last fall, the site was hit by the Samy worm, the first attack to exploit a XSS vulnerability (Mook, 2005). This attack highlights the opportunity for a self-propagating worm to take advantage of the XSS technologies. The malicious code injects itself into sites with the aim of being parsed and/or executed by browser or e-mail clients.

XSS is a type of second generation Internet based software coined as Web 2.0, which emphasizes online collaboration and sharing among users (O'Reilly, 2005). Lacking a precise definition, Web 2.0 is an umbrella term uses to describe a number of technologies that empowered websites to be more than just plain, static pages. The key to Web 2.0 is a programming technique called AJAX, or "Asynchronous JavaScript and XML." AJAX enables web pages to render without a complete page refresh by decoupling user interaction with the browser from the browser's interaction with the web server.

AJAX builds web applications by combining Extensible Hypertext Markup Language (XHTML) and Extensible Stylesheet Language (XSL) standards for presentation; and using Extensible Markup Language (XML) and XSL Transformation (XSLT) for data interchange. AJAX follows the Document Object Model (DOM) to interact with items on a webpage by treating the items as platform and language independent objects. Finally, the XMLHttpRequest (XHR) is used by AJAX to establish asynchronous exchange of data to and from the web server using standard Hypertext Transfer Protocol (HTTP) connection; with JavaScript to bind and tie all these components together (MDC, 2007).

In a standard web application, the interaction between browser and server is synchronous. When a user clicks on a link on the browser, a request is sent to the web server. The server then processes the request and sends data back to the browser while the user waits. Under AJAX, the presentation control logic is embedded as JavaScript code in the webpage. When a page is loaded, AJAX handles most of the basic tasks such as data validation, data manipulation and display rendering. Requests from the user does not necessary have to wait for a request respond cycle to the server. If additional data is needed from the server, AJAX will do so using an asynchronous request without the interrupting the user's interaction with the browser. AJAX allows interaction with the browser and user asynchronously and independently; and the transfer of data between browser and server is not dependent upon actions of the user.

While offers richer user experience, AJAX enables XSS attacks that anti-virus software, intrusion detection system and firewall are ill equipped to protect against. One could lose control of one's site in the rush to create an attractive surfing experience. By exploring poorly designed AJAX code, a hacker can initiate XSS by downloading and running script on the victim's browser. The malicious script might steal cookies, launch phishing attacks or even make request as that user. Such XSS attacks can be activated either by a user unwittingly clicking on a fraudulent link or by simple visiting a webpage with embedded malicious code. Typically, a hacker will create multiple profiles and the links on their sites. Each link can take the unsuspected users to sites that will either download or drive-by download the malware. Websites that permit users to manipulate code is inherently flaw and posting a huge security risk to everyone (Kaplan, 2007).

Rich Site Summary (RSS) is another type of XML document which often used to share web contents. RSS has been adopted by news syndication services, weblogs, webcasting and online information services. RSS is thus also known as "Really Simple Syndication". While around for many years, RSS is now quickly gaining momentum due to its active "content-push" technology. It has become a staple of the Web 2.0 pantheon.

However, RSS is susceptible to malicious script being embedded in the XML feeds too, particularly for one with a vulnerable feeder (Microsoft, 2006). Users should refrain from routinely accepting feeds, putting the RSS readers in their Outlook, and downloading content automatically into their mailboxes without security control and validation.

While Internet users can protect themselves to some extent using PC security software, such applications are typically effective only after an attack has surfaced as they are mostly signature based system. Firewalls are not designed to prevent software installed internally from doing what it is supposed to. A firewall's function is to keep external intruders out. The ultimate countermeasure against malicious code has to be security awareness and the practice of safe browsing. At a minimal, browser's Internet Security settings should be set to medium or higher with the following options for ActiveX and plug-in objects:

- Disable initialization and scripting ActiveX controls that are not marked as safe
- Prompt signed and disable unsigned download of ActiveX controls
- Prompt running of ActiveX controls and plug-ins
- Prompt scripting ActiveX controls marked as safe

While AJAX makes web pages and sites more interactive, it also opens ways for hackers to hack into a web server, exploit the site and attack its visitors. If enterprises do not demand basic security capability in Web 2.0 applications and do not adapt existing security processes and controls to the new concepts, waves of security incidents and business interruption will wipe out any increase in productivity or customer value provided by the technology. For Web 2.0 developers, they must be careful not to make security an afterthought in the rush to add features and abilities. The key to security is awareness, training and practices. Like all software development, developers should always address security first and build products with the user's best interests in mind.

On a positive note, deploying fixes should be easier in web applications as downloads are automatic and user actions are typically not required. Web 2.0 sites must also be more proactive and work closer with vendors to ensure security, track down problems and get fixes to users promptly. Adjusting to new technology will be invariably challenging. Developers are facing a learning curve as working inside a browser is a departure from the traditional browser/server development environment. Moreover, business adoption could be a slow and long process. While technological savvy users may love the new technology, less experience workers might resist applications that have different controls, layouts, looks and feels (Hoover, 2006).

Copyright in the Age of MySpace.com

New technological developments always pose challenges on how to protect copyrighted works and how to create new business models to deliver those products to consumers securely, conveniently and cost-effectively. Some argue Internet has marked the end of intellectual property and copyright. Countering the trend of downloading illegal copyrighted material on the Web, the Digital Millennium Copyright Act (DMCA) was enacted. The act criminalized both the development and employing hardware or software that cracks digital copy-protection schemes (USG, 1998). While the development of hardware or software may be in itself legal, the action could facilitate others to access materials that are copyright protected, and thus break the copyright laws. Based on DMCA, the Universal Music Group filed a copyright infringement lawsuit against MySpace.com recently, charging that much of MySpace's content is often "user-stolen" intellectual property of others, and MySpace.com is a willing partner in that theft.

It alleges MySpace Videos being a vast virtual warehouse for pirated copies of music videos and songs (Leed, 2006).

Some would argue the current copyright laws, such as DMCA, has become outdated as its provisions never addressed the rampant file-sharing taking place across the Internet. The e-commerce paradigm is both an opportunity and challenge to business. While delivering contents via the Internet can be efficient and economical, content owners risk losing control of their intellectual property. Digital content providers, such as the music industry, are reevaluating their business models, opting to move away from a traditional buy-and-own to a pay-per-use model. Any business that wishes to control access to and use of its intellectual property is a potential user of Digital Rights Management (DRM) technologies. The entertainment industry is leading the charge for DRM adoption as a mean to preserve their copyrights.

DRM refers to protecting the copyright of digital content by restricting the actions a recipient may take with regard to the content. DRM gives owners the ability to securely distribute their valued content and to control the use of this content, preventing it from unauthorized distribution. Whether the content is books, photographs, music or video, DRM can be used to manage access and identify content (Russ, 2001). Encryption is used for setting and automatically limiting user behavior. After downloading the content, one may have the right to use the work, but the user has to authenticate his or her legitimacy whenever and wherever the digital content is used. While DRM does not raise privacy issues in itself, to require server authentication each time digital content is accessed can constitute the worst sort of privacy invasion. Information garnered by DRM systems in our highly networked society can be used to build a dossier of user's preferences and usage patterns. Such information could in turn be sold to online marketers or even obtained by the government to keep a tight watch on its citizens (EPIC, 2002).

Information goods are characterized by negligible marginal costs, making the Internet a perfect medium for their delivery. Few would argue against the right of copyright holders to control how their content is distributed and for how much. Social networking sites put the end-user at the center of the digital universe, but those who wish to consume and share digital media are hamstrung by a pre-digital age copyright law and business model. Content owners need to come up with a digital age business model that discourages piracy but does not alienate consumers. Undoubtedly, social networking sites and media companies stand to benefit by working together. While a reexamination of the DMCA may be in order, government mandates must be fashioned with great care because they may limit the ability of innovators to introduce new technologies as well as the ability of consumers to purchase goods on the free market (McCullagh, 2006).

FUTURE TRENDS AND CONCLUSION

Society is learning to balance the benefits of social networking with its drawbacks. Apart from security risk, potential problems might include loss of productivity at school or workplace and an overall lack of real human interaction. A knee jerk reaction to social networking sites may be to severely restrict its availability, blocking access from the home, school or corporate networks. This reactive solution is only a band-aid on a much larger problem, as resourceful users can always find ways around access restrictions. Moreover, government regulations will unlikely be enforceable as international companies are not abided by American laws assuming the servers are hosted outside of the U.S.

The Metcalfe's law states that the value of a telecommunications network is proportional to the square of the number of users of the system. Metcalfe's Law can be applied to more than just telecommunications devices. It can be applied to almost any computer systems that exchange data, including telephones, facsimiles, operating systems, applications and even to social networking websites. Society's future consists of a vastly expanding landscape of online social networks. The current phenomenon is only at its infancy. As more people participate in these sites, the more powerful they will become. Although most people are aware of the phenomenon, most participants are relatively young. Will social networking persist as these participants grow older, develop professionally, and start families? Is this a phenomenon just for relationship hungry college kids? Such questions remain awaiting for answers. An inescapable reality is that online social interaction forums are not a U.S. specific phenomenon. As popular as these sites are for Americans, they will have equal appeal abroad. Online social networking is a global trend, happening before our eyes, and moving at the speed of light.

KEY TERMS AND DEFINITIONS

Cross-Site Scripting (XSS): Cross-site scripting is a type of computer security vulnerability typically found in web applications which allow code injection by malicious web users into the web pages viewed by other users.

Digital rights management (DRM): Digital Rights Management is anti-piracy technology that allows digital copyright owners to control who and how gets to access and copy their work.

Instant Messaging: Instant messaging is the ability to exchange messages in real time with others over the Internet. Typically, it requires one to be connected to the Internet and with access to instant messaging software.

Social Network: Social networks are a way to describe systems as composed of multiple elements. Each element, or node, may or may not have a relationship with the other nodes. The most common social network is a node of people and relation between them.

Social Network Analysis: Social Network Analysis is the techniques used to study social networks. While traditionally sociologists focus on the individual elements in their study, social network analysis emphasizes more on relations between individuals.

V-Chip Technology: V-chip is a technology that blocks objectionable television for younger viewers. The V-Chip reads information encoded in the rated program and blocks programs from the set based upon the rating selected by the parent.

Virtual Community: An online or virtual community is the gathering of people, in an online virtual space where they come, communicate, connect, and get to know each other better over time.

Web 2.0: Web 2.0 is based on the idea of the Web as a platform. Instead of thinking of the Web as a place where browsers viewed data through small windows on the readers' screens, the Web was actually the platform that allowed people to do things.

Chapter 7.5
Emerging Cybercrime Variants in the Socio-Technical Space

Wilson Huang
Valdosta State University, USA

Shun-Yung Kevin Wang
Florida State University, USA

ABSTRACT

This chapter examines the gaps that arise between reactive social control systems and proactive technology systems. The authors further link these gaps to cybercrime patterns and growth, by a theoretical framework that depicts the role that cybercrime plays in different gaps. This further suggests a typology of cybercrime, based on instrumental vs. expressive differences between offenses. Recent and emerging criminal activities and formal and informal control responses are reviewed and evaluated to illustrate this cybercrime framework and typology. The result is proactive strategies that can help prevent cybercrime from occurring in the disjoints between social and technical systems.

The world has become too dynamic, complex and diversified, too cross-linked by the global immediacies of modern communication, for stability of thought or dependability of behaviour to be successful.

—Timothy Leary (1920-1996).

DOI: 10.4018/978-1-60566-264-0.ch014

INTRODUCTION

The advent of the Internet has undoubtedly revolutionized the way we work, communicate, entertain, learn, and think in the physical world. The Internet and its associated technology have created numerous, unprecedented forms of human interaction in a new, virtually constructed space, known as **cyberspace**. This social cyber milieu is invisible and intangible, but like oxygen, we know it exists in the human community (Rho, 2007). Relying on the Internet's interconnected computer networks, users can practically transmit information to one or countless recipients any time of the day or night over continents without physical constraints. This unbounded ability to communicate has created virtually limitless opportunities for innovators, resulting in new ways of human relations and interactions expressed in a variety of forms.

Yet like most innovations which have a tendency to crime (Merton, 1968), the Internet holds potential for misuse and abuse of information in human interactions. Crimes committed on or through the Internet, so-called **cybercrime**, are common and indeed soaring (Cisco, 2007). A survey of computer security officials discovered that about half of responding companies experienced increased numbers of security incidents between 2004 and 2006 (Computer Security Institute, 2007). The survey further showed that as the incidents of cybercrime increased, the financial losses caused by these crimes escalated as well. These facts attest to the rising severity of crime resulting from the social system's inability to match the rapidly progressing technical system. How is this mismatch between the social and technical systems formed? How has cybercrime grown and expanded in this gap between the two systems? Finding answers to these questions is an important step in combating cybercrime and in some way helping to achieve a balance between the social and technical systems.

This chapter attempts to examine the evolution and growth of cybercrime in the gaps existing in the socio technical space. The chapter starts with a conceptualization of cybercrime and the creation of a classification scheme. The classification explains the role that information plays in variations of cybercrime. Next, a framework is introduced to depict how types of cybercrime have evolved in the socio-technical space. Recent cybercriminal activities are evaluated to illustrate the framework. Social responses in terms of formal and informal controls are also examined to assess their effectiveness in cybercrime mitigation. The main purpose of the analyses is to identify strategies which can better control crimes already active on the information superhighway and prevent the emergence of new variants of cybercrime.

DEFINING CYBERCRIME

The term cybercrime can be defined in a variety of ways depending on the perspective from which research is taken. The prefix "cyber" in Greek refers to navigation (Pangaro, 1991). Literally, cyber techniques are an art of steersmanship (Guilbaud, 1959). The cybernetics literature has built the foundation for the notion of a cyber system (Parsegian, 1972). In this cybernetic frame of reference, complex systems of technology, sociology, biology, psychology, communication, and many other fields can be combined to explain interconnectedness of human and machine. Cybercrime, as a member of the interrelated network, is thus confounded with numerous elements in the social and technical systems.

From a sociological point of view, cybercrime is not different from other types of crime. (Emanuelsson-Korsell & Söderman, 2001). Both are crimes of opportunity committed by a motivated offender against a suitable target under an unguarded condition (Cohen & Felson, 1979). However, cybercrime is also a technology offense. As Brenner (2007:386) stated, it is "the use of computer technology to commit crime." Because of the continuous breakthroughs in Internet technology, cybercrime can evolve into a new generation of criminal acts unseen and inexperienced. In this chapter, we take into account the socio technical aspects of cybercrime, and define it as a law violation involving abuse or misuse of information explicitly on or through the Internet. The specific function that information plays in a cybercrime can determine the nature and type of the illegal act. For instance, a 1994 report published by the U.S. Department of Justice included the following three categories of **digital crimes**: information as contraband, information as an instrumentality, and information as evidence (Casey, 2004). In this classification, a cybercrime is investigated based on the presence or absence of contraband information (e.g., an encryption software), information means (e.g., virus codes), and records of information (e.g., Internet access logs). A study by Emanuelsson-Korsell & Söderman (2001) focused on five types of information-technology crimes: computer viruses, unlawful access to computer systems, manipulation of data, theft of information, and fraud. Criteria relating to abused data or financial gains were employed to classify these crimes. Similarly, Moitra's study (2004) of cybercrime taxonomy categorized crimes and victims by type of harm—either physical or information related. Each of the two types of harm can further be categorized as individual, such as spamming, or essentially organizational such as defacement of a corporate webpage. Moitra also provided a classification for cyber criminals according to their motivations. These include material and symbolic gains; examples are money, thrills, reputation and ideology.

Cybercrime, nonetheless, does not exist in the cyberspace. But information does. In the virtual ecosystem, information is infused to facilitate each and every aspect of digital interchanges. Information is passed around in all directions for human expression and interrelation. This infusion can be propagated for psychological gratification, monetary gain, or other fruits of crime (Casey, 2004) such as illegal software. The content of the information in a crime therefore reveals the motivation of the offender and type of targets to which the information is delivered. Given that cybercrime is substantiated by the information embodied, it is imperative to consider the target and potential gains of such information in the construction of a cybercrime typology.

Table 1 displays a taxonomy for a dichotomy of instrumental and expressive cybercrime. The classification logic is similar to the categorization initially adopted by Chambliss (1967) in his analysis of effects of differential sanctions on instrumental and expressive crimes. According to Chambliss, crime for gain is "instrumental to the attainment of some other goal" (1967:708), and expressive crime is committed because "the act was satisfying in and of itself" (1967:718). Likewise, **instrumental cybercrime** is committed primarily for material gain; the goal is to maximize the profit with minimum effort. Gains may vary from the acquisition of money, merchandise, and data, to non-tangible items like services and confidential information. **Expressive cybercrime**, on the other hand, focuses on human relations rather than profit. These crimes maybe committed for fascination, friendship, revenge, or other interpersonal reasons such as pleasure. Expressive cybercrime may also be related to political ideology, environmentalism, or passion for social justice. Both categories of cybercrime can be further broken down into either individual or organizational types, depending on the target being victimized. Individual cybercrime is more likely to occur than its organizational counterpart because of the larger potential pool of Internet users and their weaker resources for protection. The four cybercrime categories are classified generally according to the basis of potential gains obtained from the crime, and the victim type.

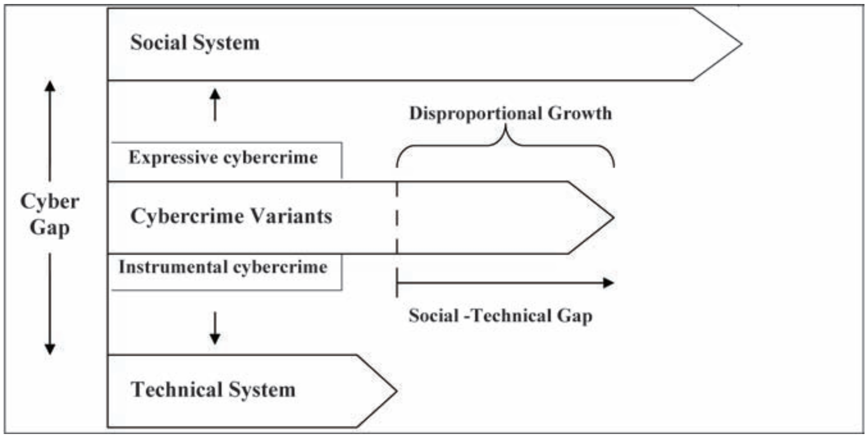
Table 1. Cybercrime classification and examples

Target of the misused information	Instrumental Cybercrime	Expressive Cybercrime
Individual	Crimeware Identity theft	Child exploitation Online stalking
Organization	Denial of service attack Corporate espionage	Warfare terrorism Website defacement

CYBERCRIME IN DIFFERENT GAPS

As Internet technology and innovation continue to progress with high demand from the general public, cybercrime evolves quickly with new information absorbed during the progression. This evolution is evident by the recent adjudication of cases by the U. S. Department of Justice (2007) and from studies by computer companies (Cisco, 2007; Symantec, 2007). While cybercrime is growing at high speed, responses of the criminal justice and legal systems are ordinary and passive. The essence of social and legal responses is mainly reactive, regardless of the nature or seriousness of cybercrime variants. In contrast, the technological system is a proactive one driven by initiation,

Figure 1. A cybercrime framework of social and technical systems



competition, and expertise of innovators. Once a technological product is invented and manufactured, social control agents then respond to the technological innovations by applications on crime prevention and criminal justice administration. This lag is inherent between social responses and innovative technologies.

In addition to the response difference between the reactive and proactive systems challenging cybercrime mitigation, the freedom of personal space on the Internet poses another hazard to social control. The proximity and scope that traditionally have restricted offenders to local crimes with single victims have broadened to international arenas where the number of victims is at liberty (Jones, 2007). The general axiom of offender-to-victim relation of a physical crime has also changed in cybercrime (Schlegel & Cohen, 2007). Personal acquaintance and socio-economic similarity between offenders and victims, which traditionally have been factors in crime, do not apply to cybercrime. These revolutionary features associated with the cyber technology have not only produced new crimes but also propel these emerging crimes at a rapid rate. This discrepancy between the proactive/fast Internet technology and the reactive/slow social system in the virtual space has created a cyber gap which breeds crime. The triple-A Engine of accessibility, affordability, and anonymity of the Internet (Cooper, 2002) may have been advantageous to offenders rather than the police in this cyber gap.

Figure 1 depicts the cybercrime gaps that form between and along the social and technical systems. The Figure is based on a theoretical framework initially developed by Ackerman (2000), Whitworth and de Moor (2003), and Whitworth (2006). The socio-technical gap in their studies of online community refers to a mismatch between what the social system is supposed to do and what the technology can support. They maintained that individuals in the social system have utilized the web of computer networks for interaction, expression, communication, expectation, and other needs. In their views, the needs of society have not been met because of the deficiencies in technology capabilities.

In the framework of cybercrime as diagrammed in Figure 1, we maintain a similar assumption that agents of the social system manage and propel elements in the technical system. However, the Figure implies that the technical system represents not only the computer hardware, software and their associated technology, but also the virtual space defined by the interrelated networks of machines. The socio-technical gap in this cybercrime framework is a lagging condition of the social control system correspondent with a less-supportive technology.

This lack of technological support has resulted in such a gap where nonconformities and outlaws have increased too fast to be kept under control by the social response system. As indicated by the horizontal lag, the disproportional growth is conditioned on the developmental speeds of the social and technical systems.

Another margin of space shown in the Figure is the upright, virtual distance called the **cybergap** located between the social and technical systems. This gap signifies the inherit discrepancy existing between the physical and virtual environments. Like the socio-technical gap, nonconformists can exploit this cybergap, victimizing individuals and organizations over the Internet for either gratification or instrumental reasons. The Figure suggests that crime variants in the cybergap are distributed according to the nature and kind of **human computer interactions**. The degree of variations will increase with both the importance of human relationships in the social system and the diversity of invented products in the technical system. The popularity and dominance of either system in the cybergap to some degree determine the share of the cybercrime distributions.

As Figure 1 suggests, expressive cybercrime will take over more space in the cybergap when human relations in the social system are intensified. Imagining an information warfare between two countries, website defacements could be a highly common tactic used by either side. By the same token, a greater proportion in the cybergap will lean toward instrumental cybercrime when the technology system is more prominent than the social system. For example, the popularity of peer-to-peer (P2P) file sharing platforms has led to overwhelming illegal downloads of copyrighted products in our generation. This global prevalence is infused mainly through technology instead of meaningful human interactions. The current cybergap is obviously dominated by violations committed for instrumental gain rather than human expression.

EMERGING AND GROWING CYBERCRIME VARIANTS

The following examples illustrate in more detail the role of social and technological interconnections in defining the modern variants of cybercrime. Two examples of instrumental crime—crimeware, identity theft—and one for crime of expression—child exploitation—are examined. These crimes have been forecasted to be more threatening in the near future (Taylor, Caeti, Loper, Fritsch & Liederbach, 2006).

Crimeware

The uninvited interference codes that enter a computer system have evolved over time by methods of intrusion and motivation. In their first generation, unwanted codes are penetrated into a user's computer by means of disks, email attachments, graphs, and downloads. These malicious codes turn into viruses, worms, trojans, and time bombs attacking the computer's memory and storage, leading to the breakdown of computers, servers and even the entire network. Since the mid-1990s, when more Windows-based programs became available, we have witnessed screen pop-ups generated by adware and spyware as we have surfed on the Internet. These unwelcome pop-up ads represent a transition from hidden codes to visible advertisements, and from not-for-profit hacking to commercialization for profit. In response to the vast presence of these unwelcome advertisements, computer hardware and software have been developed to enhance the protection of computers from unauthorized intrusion. The appearance of unwanted materials on screen has reduced significantly due to these protection devices. But as the security environment improves, the technology that controls access to the computer and Internet become more sophisticated. Wireless connection coupled with the P2P file sharing networks, in particular, provide abundant windows of opportunity for criminals to invade and control someone's computer from a distance.

In recent years, we have observed a new round of transformation in which **malware** is able to take possession of an infected computer and use it to perform illegal activities. The computer security industry has warned that this new type of attack, performed by "botnets," is one of the top threats to Internet security (Cisco, 2007; Symantec, 2007). Short for robot, a bot is a computer program used to gain unauthorized access to vulnerable computers through P2P sharing channels or trojans. Botnet refers to a network of compromised computers called "zombies" configured to launch attacks from command-and-control servers operated by remote hackers. A botnet can infect millions of computers via the formation of the army of zombies. Botnet herders can also use the unnoticed codes to track signals of keystrokes entered on the infected computers, scan credit card numbers and owner names, uncover account names and passwords, and steal other confidential information. Furthermore, botnet owners can use the zombie computers to launch spamming or initiate denial of service attacks on behalf of others, harvest email addresses, and engage in many other schemes including wiretapping and defrauding banks. Recent "botware" products have begun to create zombies through channels used by MySpace and MSN Messenger (Vaas, 2007). Considering the potentially large number of users of these services, the attacks can be more extensive as bot intrusion techniques advance.

The evolution of malware from virus to botnet suggests that the exploited information by criminals is moving toward more control and greater gains. The real driving force of the movement is profit. Viruses, worms, trojans, and many malicious codes have been commercialized for sale; spyware and adware are popular tools for marketing products. In this profit-driven process, both technology and socially defined gains have mutually created new variants of crimeware.

Identity Theft

An introduction of how we identify individuals in the civilized world is necessary before analyzing changing features of identity theft. Crume (2000) and Foster (2005) have discussed three general principles commonly used to determine or verify the identity of an individual. The first principle is that the individual must *know* something, such as his or her ID and password in order to access information. This method has been broadly applied to secure email accounts and other types of personalized services, such as online banking and financing. The second is that the individual must physically *have* something, such as a key, a piece of a document or a smart card. Holding a passport to go through customs is an example. The third is that the person must *be*—biologically—who they are claiming to be. In this method verifying a person's identity involves the use of biologic characteristics such as fingerprints, iris, odor, voice, and hand geometry. The third method may be the most secure method of the three, but it is also probably the most expensive because of the advanced technology required and the relatively large space needed to store identity information. Two or more of these principles can be adopted simultaneously to better protect personal information and belongings. The ATM card is an example of the combination of the first two identification principles — a user needs to present an ATM card (*have* something) and type in a password (*know* something). This dual combination can increase the level of protection of personal access (Crume, 2000).

Today, the majority of online activities only use the first layer (*know* something) to verify a user's identity. Hence, obtaining information about an individual—including but not limited to a user name and password, government-issued identification numbers, bank account numbers and credit card numbers—has become the only requirement for potential identity thieves to access others' personal information and pretend to be another person online. Further financial and credit damages can be done easily once a thief gains access to critical information, such as Social Security number and date of birth. For instance, identity thieves may "**breed**" further identities, creating more widespread and long-lasting damage. In this context, the term "breed" refers to the unauthorized use of identification means to generate and/or acquire additional fraudulent means of identification. It has been estimated that the financial harm toward victims is seven times more than the visible financial loss if the stolen identities are used by breeders to open new accounts, compared to abusing just existing accounts (Synovate, 2003). The above mentioned activities can be done easily and exhaustively in the cyberspace.

A recent example which illustrates the large scale of identity stealing acts is the underground online market for warehousing and selling stolen information. Symantec (2007) reported that underground economy servers, which are used by criminals and criminal organizations to sell stolen identity information of individuals, have emerged as a growing problem. For example, Symantec observed more than eight thousands unique credit cards advertised for sale in the first half of 2007. In addition, underground data warehouses have exchanged bank accounts, email addresses and passwords, Social Security numbers, and some other confidential personal information. The "price" of this illegally obtained information ranges from US$30 to $400 for a bank account, $5 to $7 for a Social Security number, and $0.5 to $5 for a credit card. The digital information of different kinds of identities stored in underground market servers has generated unprecedented opportunities to make profits from illegal transactions of this information.

Another widely used technique to steal personal identity information is **phishing**. The term phishing originated in early 1996 on the alt.2600 hacker newsgroup, where members discussed computer hacking and telephone phreaking on the posting board (Anti-Phishing Working Group, 2007). Hackers who knew how to crack the telephone network to make free long distance calls were called phreakers, and a hacked account was named "phish." During the early stage of phishing, phreakers routinely traded active AOL phish for free software. But just as crimeware evolved into profit-making practices, the simple stealing of AOL dialups has become a greedy act solely for monetary gain. The contemporary operation of phishing scams has adopted spamming emails in conjunction with fraudulent websites to steal pieces of confidential personal information. This stealing form, also known as a **social engineering**, is where fraudsters design and implement logical procedures to persuade victims to supply confidential information to a spoofed entity (Rhodes, 2006).

As the social aspects of phishing scams diversify (i.e., growth in the number of fraudulent emails, websites, and the types of targeted financial institutions), so does phishing technology. A variety of techniques have been used by phishers to evade anti-spamming or other phishing detections. For example, one evasion technique used by a phisher is to deliver the deceitful message in an email as a picture rather than text to avoid text-based anti-phishing filters. This hiding technique has been expanded to other formats such as PDF, MP3, Excel files (Mail-Filters, 2007). Technical sophistication is also reflected in the recently discovered toolkits studied by Symantec (2007). These toolkits are highly automated in terms of creating and sending phishing email messages and setting up websites that can spoof legitimate entities of different brands. The professionally-made kits can establish multiple fraudulent websites on the same compromised computer. These features enable phishers to generate a large number of phishing emails and fake multiple brands in a short period of time.

Complicating the social engineering scheme is voice phishing, known as **vishing**. Vishing goes beyond routine phishing by using Internet telephony's voice messages to facilitate the social engineering engagements with victims. This new scheme emerges as a result of the IP-based voice technology VoIP, short for Voice over Internet Protocol. With the assistance of VoIP technology, it is easy for phishers to increase automation and versatility in contacts with victims while maintaining their anonymity. In addition to emails, phishers employ mobile text messaging, voice-mail, and live phone calls to initiate and execute their attacks (Ollmann, 2007). The full-fledged employment of these verbal and non-verbal methods is expected to gain a much higher rate of success than text-based phishing. Ironically, this more personalized scheme is accomplished mainly through automated harvesting on victim data. The professionalization of phishing products combined with the personalization of vishing will undoubtedly increase the chances of success of this type of instrumental theft.

Child Sexual Exploitation

Sexual exploitation of children and the Internet have become almost inseparable in this information age. During the pre-Internet era, child sexual images shown in photographs, films, and videocassettes were distributed through traditional delivery methods such as the postal service, adult stores, or commercial dealers. Although these conventional means of distribution remain operational, their role has been replaced largely if not entirely by Internet transmissions. Sentinel data have clearly demonstrated a persistent upward trend in the distribution of **online child exploitation** images over the past decade (Internet Watch Foundation, 2006).

A great concern accompanying this growth is the blending of the child pornography producer and victim. A New York Times reporter (Eichenwald, 2005) in his investigation of Webcam child pornography discovered that several hundred pornographic websites were created by teens to advertise pornographic showings of themselves. Within a week, Eichenwald was able to identify Webcam images of 98 teenagers. This discovery suggests that gratification from money, gifts, fame, and other profits received by the operating teenagers, plus the ease of site creation and networking, will drive more youngsters to operate online pornography businesses by themselves. To predators, the interactive nature of live broadcasting makes sexual displays more exciting and participative. Instant images also allow predators to evaluate whether the subject is a minor or not. Webcam technology has made the delivery of images more appealing to predators, while making it more difficult for the police to catch pornography consumers with decoy operations.

The growing popularity of social networking sites such as MySpace, Facebook, LiveJournal, Xanga, MyYearbook, Friendster, etc. have worsened the nature and scope of child exploitation. Some online child pornographers have gradually changed their role from passive possessors to aggressive producers or predators (Taylor and Quayle, 2003). It is well known that peer networking sites, especially MySpace, have been utilized by perpetrators to target and groom children for erotic and sexual behaviors. Our keyword search on cases related to child pornography and MySpace in the LexisNexis newspaper database resulted in only 14 records in 2005. The same search criteria generated 244 records in 2006 and 349 records for 2007. The increasing numbers suggest that social networking sites have been utilized as a platform by predators for preying on minors. Online profiles, which teenagers post on the websites, provide entry points for predators to connect with their targets. Blogs, photos, videos, and chat rooms featured at the sites have unfortunately become tools exploited by predators to enhance their interpersonal relationships with innocent children. This exploitation in any form must be punished and prevented in a social system of civil expression.

SOCIAL RESPONSES TO PROACTIVE TECHNOLOGY

The fundamental difference between the proactive technology system and the reactive social control is given by nature. The question, therefore, is not whether the gap is removable, but how we can better control the emerging and progressing technology with the tendency to breed new forms of crime in the gaps. Answers to this question may first be addressed through a review of current efforts of social control, followed by a discussion of proactive approaches of social control.

Reactive Social Control

A society can exercise controls over its members through formal (e.g. courts and law enforcement agencies) and informal (e.g. community and personal networks) paths (Garland, 2001). In the "real" world, people have opportunities to craft physical interactions in which controls are enforced and reinforced. In the borderless and largely anonymous cyberspace, the types of interaction are more abstract and subtle. As a result, social control activities in the cyberspace are usually executed by conventional means in the physical world but are barely enforced online. This section demonstrates the emerging phenomenon of adopting internet technology as a formal means for greater **social control**, particularly crime control.

Traditionally, our crime control system has been designed to record and trace offenders based on their physical, demographic, and other characteristics on the assumption of a real space. The recording devices include those for identification purposes and relational systems in support of the investigation and apprehension of criminals. The Automatic Fingerprint Identification System, Combined DNA Information System, Facial Recognition Technology, and other biometric measures enable the social control system to identify offenders accurately with digitalization technology. Once an identity is confirmed, relational databases can be sought to check records, such as pending warrants, prior arrests, aliases, driver's license, and vehicle registrations, that associate with the particular individual.

Nowadays the police can use not only automated technology but also surveillance software to investigate crimes involving the Internet. Controversial programs such as Carnivore and Magic Lantern allow officers to intercept email communications or install spyware for capture of keystroke signals (Foster, 2005). Investigators can also use public data on the Internet to search for valuable information on suspects. For instance, Anywho.com can find information on prior addresses and relatives of a fugitive; Whois.com stores information about registered owners and their usage of websites; the Wayback Machine searching tool can look for unused Web pages published before a present investigation (National Institute of Justice, 2007). The supports for social control and information gathering have been improved and expanded continuously over the years; some collaborations have also been made to integrate various automated systems (Griffith, 2005).

But so far this reactive formal control system remains small scale and limited to traditional criminals. Factors like platform and data comparability continue to restrict social control agencies in information sharing at various levels of governments (Griffith, 2005). A noticeable amount of survey studies have indicated that many police agencies lack the equipment and resources to tackle the needs for enforcement of computer-related crimes (Burns, Whitworth, & Thompson, 2004; Hinduja, 2004). Police officers have perceived training in operating system, networking, and forensic tools as critically needed (Hinduja, 2004). These results suggest that today's formal control system is too slow to fill the gaps with resources and training to meet the social needs. Offenders in the cyberspace are at large exploiting a wide array of technological innovations in their crime commission while law enforcers are chasing behind.

Proposed Proactive Social Responses

One approach to narrow the gap is to move forward the reactive response of social control by introducing more proactive, informal practices. **Online community** policing has been suggested that computer users or third party actors can actively contribute to the prevention and deterrence of cybercrime (Jones, 2007; Williams, 2007). One strategy derived from Jones' (2007) user-based crime control model is to increase the distribution and use of open-source software that enables users to help defend the Internet system. Advances in system technology should be able to increase the security and reduce the opportunity for offenders (Williams, 2007). The other strategy of the user-based crime control model is to invite citizens participate in criminal detection and investigation online, which has been practiced recently by law enforcers and citizens. Through the posting of pictures or videos of offenders on MySpace and YouTube, police have received tips of suspects or gathered criminal evidence to make successful arrests (Kasindorf, 2007). MyYearbook and a few other social networking sites have begun to post the "Report Abuse" icon on every page of their sites. Still another proactive strategy under this framework is to utilize the multimedia-interactive features and informative resources of the Internet. Foster (2005) and Griffith (2005), for instances, have suggested that social control agencies should accelerate their pace in e-government to provide crime prevention services appealing to common citizens.

Another proactive approach to countering cybercrime may be to resort to private sectors in the technology industry. As the inventors and producers of computer hardware, software, and related equipment, these providers are adaptive to the constantly challenging environment and have the professional knowledge to supersede computer savvy criminals. The private sector's supporting role in digital and automated technology, therefore, can complement police tasks in many aspects (Rebovich & Martino, 2007). Forensic toolkit development, construction and management of databases, system integration, and digital monitoring are just a few examples. Byrne and Rebovich (2007) have envisioned an expansion of private sectors taking over the crime control role of public sectors in the areas of crime prevention, offender control and monitoring.

One shortcoming of this approach is the uncertainty over how much the public sector should be held accountable in a highly hybridization of private and public sectors in crime control (Marx, 2007). The recent civil litigation of the wiretapping orchestrated by AT&T and the nation's preeminent cryptology center National Security Agency (NSA) is a vivid example of such constitutional breach (Electronic Frontier Foundation, 2008). Without a warrant, private communications were rerouted to a NSA office with AT&T's technical assistance for surveillance. The question concerning the degree to which the social control system can police the technology ought to be answered and examined thoroughly by federal legislators and the U.S. courts. This requires a transparency system that oversees the twin entities to be institutionalized to protect interests of the citizens.

A more radical, direct approach to tackling cybercrime is the "strike-back" method used to retaliate against offending perpetrators (Rebovich and Martino, 2007). One of the well-known instances was a denial-of-service attack that was launched against the host of the World Trade Organization (WTO) website in late 1999 when the WTO had its meeting in Seattle, Washington. The WTO's hosting Web service was able to detect early and repel the attacks, subsequently redirecting the incoming packets to the source server for revenge. However, this approach has been criticized by security professionals for its possible wrongful attack against innocent servers and it may also lead to a series of backfires (Landergren, 2001).

DISCUSSION & CONCLUSION

The social control mechanism is constructed on the assumption of people's rational choice from alternative actions and their assessments of consequences. Within this system full of rationality, the next highly relevant question is: Is cybercrime deterrable?

In his taxonomy of instrumental and expressive crimes, Chambliss (1967) argued that punishments may have differential effects on instrumental and expressive crimes. Instrumental offenses, being the crimes of gains, are rational and predictive. These offenses are more responsive to deterrence. Expressive crimes, on the contrary, are less deterrable due to their innate, psychological nature. Assuming this thesis holds, instrumental cybercrime such as crimeware exploitation, identity theft, and Internet fraud are subjected to deterrence via a more severe, certain, and swift punishment. On the other hand, control and prevention of expressive cybercrime will be most effective with the inclusion of the behavioral aspects of treatments. Online child sexual predators and digital terrorists are the least deterrable group given that their commitment to conventional "crimes as a way of life" is low (Chambliss, 1967: 713). However, child pornography distributors who gain profits from the instrumentation of child exploitation are deterrable because of the highly conventional rationality in their offenses.

The invention and power of the Internet have undoubtedly expanded the scope, opportunity, and distribution of crime. As computer hardware and software continue to ameliorate, a new generation of cyber deviance will develop greater challenges to the technical system. These challenges can be best addressed by collaborative efforts involving governments, private sectors, and Internet designers. Online community, groupware, and other collaboration technology ought to be employed to increase human interactions via computer among experts and concerned professionals (Mulder and Slagter, 2002; O'Day, Bobrow, & Shirley, 1998). The cooperative groups can be transformed into an open and informal social networking where connections and dependability of the above stakeholders are established to reduce cybercrime in the gap between the social and technical systems.

As to the strengthening of the formal control, it must be sensitive enough to align sanctions and enforcements with proactive consideration of the essence of cybercrime. Crime control agencies should work to cooperate professionally with Internet industry providers in the investigation and conviction of cybercrime cases. Law makers have to act more quickly to keep up the full control of the Internet outgrowth. Educators and public libraries can offer Internet safety awareness programs to teach students, their parents, and the general public about the hazards of online communication. Meanwhile, citizens should be vigilant in reporting criminal acts in the cyberspace to hotlines and authorities. Only by a fully cooperative effort can the social system help to protect the citizens, users, and infrastructure of cyberspace.

KEY TERMS AND DEFINITIONS

Breed: to use without authorization identification means to generate and/or acquire additional fraudulent means of identification.

Cybercrime: law violations involving abuse and misuse of information conducted on or through the Internet.

Cybergap: the virtual discrepancy between the proactive technology and reactive social control systems.

Expressive Cybercrime: a type of Internet crime committed mainly for gratification purposes such as fascination, revenge, ideology fulfillment, social justice, or other reasons for human expression.

Identity Theft: the act of obtaining another person's identifying information and using it without the person's knowledge to commit crimes.

Instrumental Cybercrime: an indication of how and to what extent Internet technology is used as an instrument for the pursuit of profit or gain from the crime.

Internet Child Sexual Exploitation: the production, possession and/or distribution of digital child pornography and other sexual offenses against a minor through the Internet.

Organizational Cybercrime: criminal attacks against organizations via the Internet.

Phishing: a scam using fraudulent emails and websites to steal personal information for financial gain.

Social engineering: the design and implementation of logical procedures to persuade victims to supply confidential information to a spoofed entity.

This work was previously published in Handbook of Research on Socio-Technical Design and Social Networking Systems , edited by B. Whitworth; A. de Moor, pp. 183-194, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 7.6
A New Approach to Reducing Social Engineering Impact

Ghita Kouadri Mostefaoui
Oxford University Computing Laboratory, UK

Patrick Brézillon
LIP6, Paris 6, France

ABSTRACT

In recent years, the security research community has been very active in proposing different techniques and algorithms to face the proliferating security vulnerabilities. However, social engineering remains an alarming threat to the most secured networks. Security administrators are certainly aware of the gravity of the human factor, whatever is the strength of the technological measures. The human factor is still a difficult-to-surround notion and a difficult to quantify concept. It is rarely considered in the early stages of the development lifecycle of software, assuming traditional security considerations have been taken into account. In this chapter, we discuss the added-value of context as a way to deal with social engineering. Based on a case study describing a typical attack, we provide a first attempt to model this parameter.

DOI: 10.4018/978-1-60566-132-2.ch012

INTRODUCTION

Most of us have already been the target of social engineering attacks, whatever they succeeded or not. Emails asking for bank accounts passwords, grabbing user credentials by directing him to fake websites, or extracting passwords by false pretext phones are all examples of social engineering attacks. Kevin Mitnick in his book "*The art of deception: controlling the human element of security*" states that "*Social engineering uses influence and persuasion to deceive people by convincing them that the social engineer is someone he isn't, or by manipulation. As a result, the social engineer is able to take advantage of people to obtain information with or without the use of technology.*" (Mitnick & Simon, 2003). Even if some application like medical systems and bank websites are more targeted than others to such attacks, social engineering is gaining ground in other fields. Curiosity, trust and intimidation are all examples of human weaknesses the social engineer takes advantage of. For example, the well-known "ILoveYou" virus email exploited the weakness that curious people would click on an e-mail attachment with such an attractive subject was one of the factors that allowed this virus to have such a big impact (Edmead, 2002) even if it also used technological tools. A worsening factor for social engineering impact is the discrepancy with the technical dimension i.e. the evolution of ICT (Information and Communication Technology) often left an increasing number of persons on the side. The social-technical gap is the difference between social needs/expectations and computer system capability. It is the degree software fails to meet social requirements. Additionally, the fact that duration of work with others is limited, and the turnover is increasingly important and that on the Internet one is not always sure of the identity of the other (use of pseudo), trust becomes a key element in all transactions.

In this chapter, we discuss the added-value of context as a way to deal with social engineering. Two things are worth developing, the focus and its context of validity. Generally in security one is concerned by the focus only. Our claim is to learn how to recognize the context of the current focus, to identify it and to determine what the legal actions are authorized in relationships to the focus in the current context. For example, some attacks use URLs or Web pages very close from those of enterprises. One example is "BankOfAmerica" instead of "Bank_of_America". Another example is to write the real URL on a web page and hide another link when the user clicks.

As social engineering is now admitted to be the weakest link in the security chain, several efforts have been made in order to study its different ways of operation and to try finding defenses against this threat. From these contributions, users' awareness to information security and training emerge as the agreed upon ways for facing the attacks. Related work includes (Lafrance, 2004) which considers psychology as a valuable security tool. The author argues on the understanding of employees' psychology in order to be able to face their potential attacks. He proposes a set of 'psycho-security tips' and shows how they can apply to real situations. More focused on information security awareness, (Manjak, 2006) examines the various social engineering tactics targeting employees that an InfoSec Awareness campaign is designed to counter.

In this chapter, we will first define context and show how it can be considered as an operational factor for modeling the human element in security. Based on a case study of an attack preparation and execution, we show how the previous list of countermeasures (user's awareness, training) can be extended. A list of best practices is derived for the sake of reducing the impact of human element on information security. Then, a summary of previous contributions on the use of context in security is presented. Finally, the last section concludes the paper with a summary of future research.

BACKGROUND ON CONTEXT

This Section is intended to provide a summary of theoretical study of context.

The term context has been extensively defined and commented in recent research. However, there is not yet a commonly accepted definition of context (Bazire & Brézillon, 2005). Nevertheless, a consensus begins to appear around "*Context is what constrains a problem solving without intervening in it explicitly*" (Brézillon & Pomerol, 1999). This definition suggests that the context is always let implicit and tacit, and is rarely mentioned explicitly.

Then, the authors consider it by extension as the focus of an actor. Several elements justify this definition, the three main elements being that:

1. Context is relative to the focus,
2. As the focus evolves, its context evolves too, and
3. Context is highly domain-dependent. As a consequence, one cannot speak of context in an abstract way.

In a recent publication, Brézillon (2007) shows that the focus at a given stage, allows the division of the context into external knowledge and contextual knowledge. The latter constitutes a kind of tank where the contextual elements are to some extent related to the focus in a flat way, whereas the former has nothing to do with the focus. At this conceptual level, the focus acts as a discriminating factor on knowledge in a similar way as for social networks. The focus evolves because a new event occurs (e.g. an unpredicted event) or as a result of a decision made at the previous stage of the focus. The notion of context impacts more on the relationships between knowledge pieces than upon the pieces themselves. The following publication (Brézillon & Brézillon, 2007) provides greater detail about the relationship between a context and a focus.

A context-based formalism has been developed and is introduced in (Brézillon, 2005). This formalism known as contextual graphs allows a uniform representation of elements of reasoning and of contexts. A contextual graph is a representation of a task execution. Contextual graphs are oriented, acyclic, without circuits, with exactly one input and one output, and a general structure of spindle. A path (from the input to the output of the graph) represents a type of execution of the task with the application of selected methods. There are as many paths as practices. Different solutions can be associated with the unique output corresponding to the current context. A contextual graph is an acyclic graph because user's tasks are generally in ordered sequences. For example, the activity "Make the train empty of travelers" is always considered at the beginning of an incident solving on a subway line, never at the end of the incident solving. A more drastic divergence in the type of output (e.g. the execution of the task is stopped like "Error 104" in information retrieval) must be considered at a upper level in which the contextual graph at hand is a branch of an alternative (a contextual element such as "Are the conditions required for the task execution present? If yes got to the contextual graph otherwise does not consider this contextual graph). In contextual graphs, the two types of context identified earlier can be easily distinguished. Namely, contextual knowledge, which is represented in the graph by a set of contextual elements, and proceduralized context which is an ordered set of instantiated contextual elements.

In this chapter, we point out that the consideration of context in security is getting importance. The need for taking into account the *security context* has been dictated by the need for changing policies according to changes into the environment. In a previous work, we define a security context as "*set of information collected from the user's environment and the application environment and that is relevant to the security infrastructure of both the user and the application.*" (Kouadri, 2004) The word relevant means that has direct or indirect effect on the security policy. What is really relevant is application-dependent. This information may include user's identity, membership, resource location, date, time, the user's interaction history with the system, social situation, etc.

Wireless applications and on-demand services have been the main consumers of security context as we will show in Section "Related Work". As a result, context-based access control and adaptive authentications schemes emerged as solutions to the security requirements of these specific environments.

In our previous work on context-based security (Kouadri, 2004), we noted that it should be considered as "*a new trend that may face future more subtle security attacks.*" We also stated that *"the force of a good security system should not rely only on the force of security protocols but also on the way it copes with new and completely unpredictable situations or at least learn from new situations and updates its behavior accordingly.*"

In prior contributions related to this idea, we mainly concentrate on context-based access control solutions and proposed in (Kouadri &

Brézillon 2006) the contextual graphs formalism discussed earlier as a model for security contexts. Contextual Graphs have been used in various real-world applications. They allow a uniform representation of elements of reasoning and of contexts for describing different human tasks such as troubleshooting and interpretation. In our situation, a contextual graph represents a security task realization. These tasks include access to remote services, establishing a secure communication between heterogeneous communicating parties, etc. Its paths represent the different ways of reaching this realization, each way corresponding to a practice developed by an actor realizing the task. Our focus was on expressing fine-grained requirements for dynamic security policies.

In this chapter, we extend the other aspect of security context and discuss its role in reducing the impact of social engineering in information systems.

CONTEXT PROFILE IN SOCIAL ENGINEERING

In order to demonstrate the relevance of our claim, we stress in the following the typical modus operandi of a hacker for realizing a security attack. It should be noted that the described scenario represents a generic case-study with an internal environment protecting some assets and served by actors with different roles.

We summarize the process into four steps. The next sections show how context is used to grab this process and then, how it can be used for profiling social engineering attacks.

Attack Preparation and Execution

- First, the attacker tries to get closer to an actor in the target enterprise in order to get familiar with the different aspects of the enterprise. Such actor may represent an employee or any tier person involved into the activities of the enterprise. This step aims at developing a shared context by establishing privileged relationships with the tier. This shared context may be based upon common and general interests such as political/ideological preferences, sport, etc.

In an alternative way, the focus could be pushed on a specific topic in order to find an agreement (e.g. I like science-fiction, political men are all the same, TV is boring, etc.). The aim of manipulating the shared context is to develop strong ties with the other, the attacker looking for a tie of which the nature will be important for the tier as discussed in the area of social network (Granovetter, 1983). Note that here the shared context is not related to the hacker's focus but tries exhibits some general ties between the two actors.

- The hacker than tries to shrink this shared context into a more restrained one around professional interests by exploiting some of the various psychological approaches. For instance, by establishing a neophyte-expert relationship (i.e. I don't have enough knowledge in this field but you do). Or, by pretending the need for help to solve a given problem. This is achieved by establishing a community of practice between peers (i.e. we are both in the same domain, so if I have a problem you can help me solve it) always embedded in the general shared context established previously. In the second step, the hacker begins by moving the shared context by introducing contextual elements related to the hacker's focus (I have a problem that is certainly a toy problem for you because I know that from our shared context building).
- The hacker then tries dragging the tier person along to the focus of the shared context developed earlier. In practice, this is equivalent to the hacker getting closer to the focus of interest (i.e. the target asset to attack). Here the goal is to introduce in

the shared context a foreigner element in a way apparently normal, when in a usual situation the tier will react against it. This situation is very close from medicine and biology with virus. This third step is a kind of synthesis of the two first steps by introducing the focus (i.e. hacker's focus) in the initial shared context, that is in the opposite way that two normal actors interact (with first agreeing on the common focus, and then developing a shared context around this focus).

- When the attack is launched, the hacker locks the system in a way that prevents the abused tier from establishing a connection with the information he/she provided (i.e. the context focus) and which are for the tier a set of unrelated contextual information given in an extra-professional circumstance. In this fourth step, the hacker puts the tier to accept that the "sensible" focus in the shared context is naturally explainable in term of the shared context elements, when in the real context of the focus; the tier will react in a totally different way.

While the presented scenario can be seen as an industrial-espionage attack, it actually, represents a pattern for attacks in any information-based system. The differences are mainly the assets: business documents, credit card numbers, healthcare private information, etc. The tier may represent respectively: a business partner, an employee, a nurse in a hospital, etc. Also, most of these domains make use of computer-based systems, so even if they take benefit of human weaknesses, the assets are typically stored as digital data, so the attacks are mainly performed using technological means as discussed earlier.

Defenses

The main approach to reduce the number and/or the impact of social engineering attacks is to break the process described in the previous section. This can be achieved by following the set of countermeasures described in the following. Where some of them are technical, others are more social-oriented.

- ***Information Security Awareness***: A common error made by actors is to think that as long as the two "individual" contexts (related to the enterprise and the hacker respectively) are not intersecting, the risk of attacks is small. In fact, this risk is increased using his/her own context. Indeed, the actor's context intersects with both other contexts and constitutes the shared one which connects the two others. It is thus, important to establish an effective users' awareness of the context of their tasks within the enterprise, especially the different changes of this context as a consequence of external events. With the notion of shared context, one needs to develop a notion of exclusive contexts. As a concrete example, a nurse should be aware of the different cases (context) where information about patients is likely to be disclosed. A concrete precaution is to prevent copying patients' records to personal devices or sending it outside the hospital network.

In practice, it is important to learn how to maintain disjoint contexts and how to identify any new contextual element that may provoke a shift of the working context.

- ***Managing Internal Actors***: Statistics show that most of the social engineering attacks are performed by internal actors or through their help. The enterprise should be aware of conflicts and dissatisfaction of actors within the enterprise in order to avoid expressing their dissatisfaction outside the enterprise boundaries causing the internal context to flood outside.

- ***Minimum Processes Principle***: This principle suggests running the minimum set of computer processes for a specific task within the enterprise. This implies blocking unnecessary ports and assigning minimal privileges on assets for users. This is equivalent to reducing the context attached to each task, reducing this way the type of attacks that can be performed. A special attention should be given to the underlying sub-tasks, the data they handle and the information they send over the internet.
- ***Fine-Grained Security Solutions***: to constraint the actor context with fine-grained security in a way that make the latter an integral part of its tasks. An example of fine-grained security is context-based access control where access is no longer *only* dependent on users' credentials but also constrained by the time of the access, geographical location of the requester, the frequency of access requests, etc. This approach helped several banks to detect credit cards frauds by comparing the geographical locations of a requester during a short time interval. Here a short time is relative to the reasonable time a credit card owner needs to travel from a location to another. Thus, a use by the same card in France and than in China in a day interval is somehow suspicious and leads to alerting the issuing bank for a potential problem.
- ***Prepare the coming of new ICT in the enterprise***: The increase need for higher computer performance and more complicated software functionalities leads enterprises to continually adopt new technologies. It is of primordial importance to prepare the actors (employees) to these new technologies in order to give them the right information about potential threats on the software and how to face them.
- ***Use a modeling of actors' activities in a formalism allowing a uniform representation of elements of reasoning and of contexts***: This guideline suggests an explicit consideration of contextual information in controlling actors' actions on assets. An example of such formalism is contextual graphs. Information on contextual graphs may be found on the web site dedicated to it (CxG's Software, 2007).
- ***Consider the context of a focus like a dressing of this focus****:* which allows the identification of differences between the behavior prescribed by security policies and the effective behaviors of actors. A detailed discussion of this aspect with an example in road safety domain is given in (Brézillon & Brézillon, 2007).
- ***Contextualize identities instead of trying to personalize the users*** A possibility could be to reinforce the technology-mediated approach of social systems.

A similar work to our current contribution is presented in the paper by (Gragg, 2002) which proposes a multi-level defense against social engineering. The author discusses the psychological triggers leading to a successful social engineering attack. He then lists a set of defense measures to handle these weaknesses. While the objective is the same, this specific work aims at incorporating social psychological research into the task of resisting social engineering.

RELATED CONTRIBUTIONS: CONTEXT IN SECURITY

The first attempts to integrate context into security systems put the focus on context-based RBAC (Role-Based Access Control). A related contribution was made by (Masone, 2002) who designed and implemented a simple programming language RDL (Role Definition Language) to describe roles in terms of contextual information. The strong characteristics of RDL are simplicity of use and extensibility. An extended form of authorization policies where conditions corresponding to context are represented using programs rather than expressions is proposed by (McDaniel, 2003). (Georgiadis & al., 2001) propose TMAC which stands for team-based access control. It provides an access control model that supports collaborative activity being accomplished by teams of users and includes contextual information.

Another related contribution is C-TMAC; a hybrid access control model that takes advantage of role-based permission assignment of RBAC and yet provides the flexibility for fine-grained activation of permissions for individual users on individual object instances. This fine-grained access control is dictated by a set of constraints (or context). For example, in a healthcare setting a doctor may have the permission to prescribe certain medications. However, the doctor should not be allowed to prescribe for anyone. Rather, he/she should be allowed to prescribe only for the patient's he/she is taking care of.

In the same direction, (Covington et al., 2001, 2002) propose an approach to design security services that use security-relevant "context" in order to provide flexible access control. The main application of their approach is intelligent home environments such as the Aware Home described in (AHRI, 2007). The authors make use of the context toolkit (Dey, 2000) a software that aims at leveraging the development of context-aware applications and provides software components for collecting environment variables and interpreting their associated values. Access policies are based on environment roles (Covington et al., 2001) and encoded into the eXtensible Markup Language (XML). The contributions towards integrating context with a security service other than access control are fewer. It is worth mentioning the work by (Pierson et al., 1999) which introduces context-agile encryption as a technique that provides a different encryption (in terms of key lengths, type of encryption algorithm, etc) according to the applications needs and to hardware capabilities. For example, some web services in high speed communication networks may be able to tolerate long times to encrypt/decrypt information, but may also need to protect that information for a long period of time. Other types of web services, dealing with data that is sensitive while useful, but quickly becomes stale, might benefit from short encryption/decryption times that may accompany a less cryptographically robust algorithm.

Bellavista et al. propose a context-centric access control middleware for mobile environments called COSMOS (Bellavista et. al., 2003). The middleware dynamically determines the contexts of mobile proxies, and rules the access to them based on a set of data such as user profile and system/user-level authorization policies. COSMOS has been tested in the design and implementation of a context-centric movie assistant which aim is to allow mobile users to find nearby cinemas and to exchange opinions about cinema characteristics such as seat comfort, air-conditioning, sound and screen resolution.

As one can deduce from the previous summary of earlier work, the consideration of context in security has been mainly encouraged by the need for security to fit within the very nature of emergent applications. Adaptability to users' needs and preferences and to hardware capabilities has imposed a need for security solutions following the same pattern of flexibility. However, these contributions towards integrating context into security have been proposed without being explicit about its broader use.

CONCLUDING REMARKS AND FUTURE WORK

In this chapter, we presented a novel approach to understanding social engineering using context as an operational parameter. Our aim was twofold: a) to give a generic view over the diverse social engineering attacks. This is approached by looking at a common parameter – context -, and b) to help giving the abstract nature of a social attack a concrete face so further investigations can be pursued in order to reduce the impact of these attacks.

As stated in the chapter, the definition of *context* is tightly related to the application domain. For example, in an e-health application, the role of the user within the hospital (i.e. treating physician, nurse, administrator, etc) is a relevant contextual information used to regulate the access to patients' records. In the other hand, it is difficult to exhaustively enumerate its content. However, a good practice is to identify the maximum of this context by learning from similar applications before setting up a security solution so it becomes possible to block most attacks or, a least not create back doors to hackers.

It is interesting to note the interest of the security community in social engineering and in the same time the lack of effective solutions. Daily news and technical publications are full of real stories describing security attacks where human deception is the main tool. In the other hand, and apart from users training, there is no concrete parameters the security community can use to model and thus to study and evaluate proposed solutions. In the current chapter, we sketched the context profile during an attack and deduced a list of countermeasures.

This new approach is a first attempt to quantify the social aspect of security for the sake of a better understanding and management. In the following we summarize the main research directions that may be pursued as a future work.

- Developing techniques for the automatic discovery of relevant security contexts. For example, in the credit card fraud scenario discussed earlier, data mining techniques and case-based reasoning can be used to devise what context is worth taking into account. The location from where the user uses his card for e-transactions, his buying preferences, are examples of common elements emerging in fraud scenarios. They can be used to profile the use of a card by a hacker.
- Developing tools for the visualization of context evolution during an interaction scenario (e.g. access to a resource). This may help for a better understanding of the role of context. The tool can be used as a training mean for information security awareness.
- Devising techniques for the formal verification of the completeness of security context for a given application i.e. to devise the percentage of the contextual information already taken into account in the establishment of the security solution and thus deducing the percentage of missing context.
- Devising ways for establishing trust with context providers. Since a security context is built from a set of information (e.g. user' location, interaction history with the system) gathered from different sources, the system to secure should be able to gather context only from trusted sources.
- Proposing a uniform way for documenting social engineering attacks and their corresponding involved context for each specific application. These reports can be used to help similar applications to develop a defense against these attacks. This is equivalent to antivirus that needs to update its virus definition file regularly.

Having presented our proposal in considering context as a key element in profiling social engineering attacks, we believe that further investigations may shed the light on other factors that can be combined with context, for the sake of better understanding of social engineering and thus, being able to face the proliferating attacks. It is our hope that this first step provides a starting point for further advancements.

KEY TERMS AND DEFINITIONS

Case-Based Reasoning: A technique that helps solving a specific problem based on past similar ones.

Data Mining: A set of techniques that analyze data for the sake of finding patterns and relationships.

E-Health: Electronic health is the result of the involvement of electronic in providing health services such as patient record and health plan description.

Human Factor: Influence of human behavior on information security.

Security Asset: Any valuable resource protected by a computerized infrastructure.

Security Context: Set of information collected from the user's environment and the application environment and that is relevant to the security infrastructure of both the user and the application.

Trust: The degree of confidence an entity has in another entity.

Chapter 7.7
Effects of Digital Convergence on Social Engineering Attack Channels

Bogdan Hoanca
University of Alaska Anchorage, USA

Kenrick Mock
University of Alaska Anchorage, USA

ABSTRACT

Social engineering refers to the practice of manipulating people to divulge confidential information that can then be used to compromise an information system. In many cases, people, not technology, form the weakest link in the security of an information system. This chapter discusses the problem of social engineering and then examines new social engineering threats that arise as voice, data, and video networks converge. In particular, converged networks give the social engineer multiple channels of attack to influence a user and compromise a system. On the other hand, these networks also support new tools that can help combat social engineering. However, no tool can substitute for educational efforts that make users aware of the problem of social engineering and policies that must be followed to prevent social engineering from occurring.

DOI: 10.4018/978-1-60566-036-3.ch009

INTRODUCTION

Businesses spend billions of dollars annually on expensive technology for information systems security, while overlooking one of the most glaring vulnerabilities—their employees and customers (Orgill, 2004; Schneier, 2000). Advances in technology have led to a proliferation of devices and techniques that allow information filtering and encryption to protect valuable information from attackers. At the same time, the proliferation of information systems usage is extending access to more and more of the employees and customers of every organization. The old techniques of social engineering have evolved to embrace the newest technologies, and are increasingly used against this growing pool of users. Because of the widespread use of information systems by users of all technical levels, it is more difficult to ensure that all users are educated about the dangers of social engineering. Moreover, as digital convergence integrates previously separated communications channels, social engineers are taking advantage of these blended channels to reach new victims in new ways.

Social engineering is a term used to describe attacks on information systems using vulnerabilities that involve people. Information systems include hardware, software, data, policies, and people (Kroenke, 2007). Most information security solutions emphasize technology as the key element, in the hope that technological barriers will be able to override weaknesses in the human element. Instead, in most cases, social engineering attacks succeed despite layers of technological protection around information systems.

As technology has evolved, the channels of social engineering remain relatively unchanged. Attackers continue to strike in person, via postal mail, and via telephone, in addition to attacking via e-mail and online. Even though they arrive over the same attack channels, new threats have emerged from the convergence of voice, data, and video. On one hand, attacks can more easily combine several media in a converged environment, as access to the converged network allows access to all media types. On the other hand, attackers can also convert one information channel into another to make it difficult to locate the source of an attack.

As we review these new threats, we will also describe the latest countermeasures and assess their effectiveness. Convergence of voice, data, and video can also help in combating social engineering attacks. One of the most effective countermeasures to social engineering is the continued education of all information systems users, supplemented by policies that enforce good security practices. Another powerful countermeasure is penetration testing, which can be used to evaluate the organization's readiness, but also to motivate users to guard against social engineering attacks (see for example Argonne, 2006).

Throughout this chapter we will mainly use masculine gender pronouns and references to maleness when referring to attackers, because statistically most social engineering attackers tend to be men. As more women have become proficient and interested in using computers, some of the hackers are now female, but the numbers are still small. Nonetheless, there are some striking implications of gender differences in social engineering attacks, and we discuss those differences as appropriate.

SOCIAL ENGINEERING

Social engineering includes any type of attack that exploits the vulnerabilities of human nature. A recent example is the threat of social engineers taking advantage of doors propped open by smokers, in areas where smoking is banned indoors (Jaques, 2007). Social engineers understand human psychology (sometimes only instinctively) sufficiently well to determine what reactions they need to provoke in a potential victim to elicit the information they need. In a recent survey of black hat hackers (hackers inclined to commit computer crimes), social engineering ranked as the third most widely used technique (Wilson, 2007). The survey results indicate that 63% of hackers use social engineering, while 67% use sniffers, 64% use SQL injection, and 53% use cross site scripting.

Social engineering is used so widely because it works well despite the technological barriers deployed by organizations. Social engineers operate in person, over the phone, online, or through a combination of these channels. A report on the Australian banking industry in *ComputerWorld* claims that social engineering leads to larger losses to the banking industry than armed robbery. Experts estimate these losses to be 2-5% of the revenue, although industry officials decline to comment (Crawford, 2006). Social engineering is also used in corporate and military espionage, and no organization is safe from such attacks. A good overview of social engineering attacks and possible countermeasures can be found on the

Microsoft TechNET Web site (TechNET, 2006).

According to Gragg (2003), there are some basic techniques common to most social engineering attacks. Attackers tend to spend time building trust in the target person. They do that by asking or pretending to deliver small favors, sometimes over an extended period of time. Sometimes, the trust building is in fact only familiarity, where no favors are exchanged, but the victim and attacker establish a relationship. Social engineering attacks especially target people or departments whose job descriptions include building trust and relationships (help desks, customer service, etc). In addition to asking for favors, sometimes social engineers pretend to extend favors by first creating a problem, or the appearance of a problem. Next, the social engineers can appear to solve the problem, thus creating in a potential victim both trust and a sense of obligation to reciprocate. They then use this bond to extract confidential information from the victim. Finally, social engineers are experts at data aggregation, often picking disparate bits of data from different sources and integrating the data into a comprehensive, coherent picture that matches their information gathering needs (Stasiukonis, 2006b; Mitnick & Simon, 2002).

Although the description might seem complex, social engineering can be as simple as just asking for information, with a smile. A 2007 survey (Kelly, 2007) showed that 64% of respondents were willing to disclose their password in exchange for chocolate (and a smile). Using "good looking" survey takers at an IT conference led 40% of non-technical attendees and 22% of the technical attendees to reveal their password. Follow up questions, drilling down to whether the password included a pet name or the name of a loved one elicited passwords from another 42% of the technical attendees and 22% of the non-technical ones. While the survey respondents might have felt secure in only giving out passwords, user names were easier to obtain, because the full name and company affiliation of each survey respondent was clearly indicated on their conference badge. An earlier survey cited in the article reported similar statistics in 2004.

Another paper urging organizations to defend against social engineering illustrates the high levels of success of even simple social engineering attacks. Orgill (2004) describes a survey of 33 employees in an organization, where a "researcher" asked questions about user names and passwords. Only one employee of the 33 surveyed escorted the intruder to security. Of the 32 others that took the survey, 81% gave their user name and 60% gave their password. In some departments, all the employees surveyed were willing to give their passwords. In one instance, an employee was reluctant to complete the survey. A manager jokingly told the employee that he would not get a raise the next year unless she completes the survey. At that point, the employee sat down and completed the survey. This is a clear indication that management can have a critical role in the success or failure of social engineering attacks.

Statistically, an attacker needs only one gullible victim to be successful, but the high success rates mentioned above indicate that finding that one victim is very easy. If such "surveys" were to be conducted remotely, without a face to face dialog or even a human voice over the phone, success rates would likely be much lower, but the risks would also be lower for the attacker. Convergence of data, voice, and video allows attackers to take this alternative route, lower risk of detection at the expense of lower success rate. Given the ability to automate some of the attack avenues using converged media, the lower success rate is not much of a drawback. We will show how most social engineering attacks resort to casting a broad net, and making a profit even of extremely low success rates.

The basic tools of the social engineer include strong human emotions. Social engineers aim to create fear, anticipation, surprise, or anger in the victim, as a way to attenuating the victim's ability to think critically. Additionally, information overload is used to mix true and planted information to lead the victim to believe what the social engineer intends. Reciprocation is another strong emotion social engineers use, as we described earlier. Finally, social engineers combine using guilt (that something bad will happen unless the victim cooperates), transfer of responsibility (the social engineer offers to take the blame), and authority (where the social engineer poses as a supervisor or threatens to call in a supervisor). These are basic human emotions used in all social engineering attacks, whether using converged networks or not. This chapter will focus on how attackers use these emotions on a converged network, combining data, voice, and video.

SOCIAL ENGINEERING ON CONVERGED NETWORKS

Social engineering has seen a resurgence in recent years, partly due to the convergence of voice, data, and video, which makes it much easier to attack an organization remotely, using multiple media channels. The proliferation of computer peripherals and of mobile devices, also driven by network convergence, has further opened channels for attacks against organizations. In this section we discuss new attack vectors, combining some of the classical social engineering channels (in person, by phone, by e-mail) and show how they have changed on a converged network.

Social Engineering Attacks Involving Physical Presence

The classical social engineering attack involves a social engineer pretending to be a technical service person or a person in need of help. The attacker physically enters an organization's premises and finds a way to wander through the premises unattended. Once on the premises, the attacker searches for staff ID cards, passwords or confidential files.

Most of the in-person social engineering attacks rely on other information channels to support the in-person attack. Convergence of voice and data networks allows blended attacks once the attacker is within the victim's offices. Before showing up at the company premises, the attacker can forge an e-mail message to legitimize the purpose of the visit; for example, the e-mail might appear to have been sent by a supervisor to announce a pest control visit (applekid, 2007). Alternatively, the attacker might use the phone to call ahead for an appearance of legitimacy. When calling to announce the visit, the attacker can fake the telephone number displayed on the caller ID window (especially when using Voice over IP, Antonopoulos & Knape, 2002).

After entering the premises, an attacker will often try to connect to the organization's local area network to collect user names, passwords, or additional information that could facilitate subsequent stages of the attack. Convergence allows access to all media once the attacker is connected to the network; even copiers now have network connections that a "service technician" could exploit to reach into the organization's network (Stasiukonis, 2006c). Connecting to the company network using the port behind the copier is much less obvious than using a network port in the open. Finally, another powerful attack may involve a social engineer entering the premises just briefly, connecting a wireless access point to the organization's network, and then exploring the network from a safe distance (Stasiukonis, 2007). This way, the attacker can remain connected to the network, but at the same time minimize the risk of exposure while in the organization's building.

Social Engineering via Email, News, and Instant Messenger

One example of how convergence is changing the information security threats is the increased incidence of attacks using e-mail, HTML, and chat software. This is attractive to attackers, because it bypasses firewalls and allows the attacker to transfer files to and from the victim's computer (Cobb, 2006). The only requirement for such attacks is a good understanding of human weaknesses and the tools of social engineering. The attackers spend their time devising ways to entice the user to open an e-mail, to click on a link or to download a file, instead of spending time breaking through a firewall. One such attack vector propagates via IRC (Internet relay chat) and "chats" with the user, pretending to be a live person, assuring the downloader that it is not a virus, then downloading a shortcut to the client computer that allows the remote attacker to execute it locally (Parizo, 2005).

Because of the wide use of hyperlinked news stories, attacks are beginning to use these links to trigger attacks. In a recent news story (Naraine, 2006b), a brief "teaser" concludes with a link to "read more," which in fact downloads a keylogger by taking advantage of a vulnerability in the browser. This type of attack is in addition to the fully automated attacks that involve only "drive by" URL, where the malicious content is downloaded and executed without any intervention from the user (Naraine, 2006c). Analysis of the code of such automated attacks indicates a common source or a small number of sources, because the code is very similar across multiple different attack sites.

Convergence allows e-mail "bait" to use "hooks" in other applications. For example, an e-mail message with a Microsoft Word attachment may take advantage of vulnerability in Word and rely on e-mail as the attack channel (McMillan, 2006). Other vulnerabilities stem from more complex interactions between incompatible operating systems and applications. The recently released Microsoft Vista operating system has vulnerabilities related to the use of non-Microsoft e-mail clients, and requires user "cooperation" (Espiner, 2006). As such, Microsoft views this as a social engineering attack, rather than a bug in the operating system.

Other attacks are purely social engineering, as in the case of e-mail messages with sensationally sounding subject lines, for example, claiming that the USA or Israel have started World War III, or offering views of scantily clad celebrities. While the body of the message is empty, an attachment with a tempting name incites the users to open it. The name might be video.exe, clickhere.exe, readmore.exe, or something similar, and opening the attachment can run any number of dangerous applications on the user's computer (Gaudin, 2007). Other e-mail messages claim that the computer has been infected with a virus and instruct the user to download a "patch" to remove the virus (CERT, 2002). Instead, the "patch" is a Trojan that installs itself on the user's computer. The source of the message can be forged to make it appear that the sender is the IT department or another trusted source.

Finally, another way to exploit news using social engineering techniques is to send targeted messages following real news announcements. An article on silicon.com cites a phishing attack following news of an information leak at Nationwide Building Society, a UK financial institution. Soon after the organization announced the theft of a laptop containing account information for a large number of its customers, an e-mail began circulating, claiming to originate from the organization and directing recipients to verify their information for security reasons (Phishers raise their game, 2006). This is a much more pointed attack than the traditional phishing attacks (described next), where a threatening or cajoling email is sent to a large number of potential victims, in hope that some of them will react. Such targeted attacks are known as "spear phishing."

Phishing

Phishing is a special case of e-mail-based social engineering, which warrants its own section because of its widespread use (APWG, 2007). The first phishing attacks occurred in the mid 1990's and continue to morph as new technologies open new vulnerabilities. The classical phishing attack involves sending users an e-mail instructing them to go to a Web site and provide identifying information "for verification purposes."

Two key weaknesses of the user population make phishing a highly lucrative activity. As a larger percent of the population is using Web browsers to reach confidential information in their daily personal and professional activities, the pool of potential victims is greatly increased. At the same time, the users have an increased sense of confidence in the information systems they use, unmatched by their actual level of awareness and sophistication in recognizing threats.

A survey of computer users found that most users overestimate their ability to detect and combat online threats (Online Safety Study, 2004). A similar situation is probably the case for awareness of and ability to recognize phishing attacks. As phishers' sophistication increases, their ability to duplicate and disguise phishing sites increases, making it increasingly difficult to recognize fakes even by expert users.

More recently, pharming involves DNS attacks to lure users to a fake Web site, even when they enter a URL from a trusted source (from the keyboard or from a favorites list). To mount such an attack, a hacker modifies the local DNS database (a hosts file on the client computer) or one of the DNS servers the user is accessing. The original DNS entry for the IP address corresponding to a site like www.mybank.com is replaced by the IP address of a phishing site. When the user types www.mybank.com, her computer is directed to the phishing site, even though the browser URL indicates that she is accessing www.mybank.com. Such attacks are much more insidious, because the average user has no way of distinguishing between the fake and the real sites. Such an attack involves a minimal amount of social engineering, although, in many cases, the way the attacker gains access to the DNS database might be based on social engineering methods.

In particular, pharming attacks can rely on converged media, for example, using an "evil twin" access point on a public wireless network. By setting up a rogue access point at a public wireless hotspot and by using the same name as the public access point, an attacker is able to hijack some or all of the wireless traffic though the access point he controls. This way, the attacker can filter all user traffic through his own DNS servers, or more generally, is able to mount any type of man-in-the-middle attack. In general, man-in-the-middle attacks involve the attacker intercepting user credentials as the user is authenticating to a third party Web site and passing on those credentials from the user to the Web site. Having done this, the attacker can now disconnect the user and remain connected to the protected Web site. True to social engineering principles, these types of attacks are targeted at the rich. Evil twin access points are installed in first-class airport lounges, in repair shops specializing in expensive cars, and in other similar areas (Thomson, 2006).

Social Engineering Using Removable Media

In another type of social engineering, storage devices (in particular USB flash drives) might be "planted" with users to trick them into installing malicious software that is able to capture user names and passwords (Stasiukonis, 2006a). This type of attack is based on the fact that users are still gullible enough to use "found" storage devices or to connect to "promotional" storage devices purporting to contain games, news, or other entertainment media. Part of the vulnerability introduced by such removable storage devices is due to the option of modern operating systems to automatically open certain types of files. By simply inserting a storage device with auto run properties, the user can unleash attack vectors that might further compromise their system. In addition to USB flash drives, other memory cards, CDs, and DVDs can support the same type of attack.

Social Engineering via Telephone and Voice Over IP Networks

Using telephone networks has also changed. The basic attack is often still the same, involving a phone call asking for information. Convergence, in particular the widespread use of digitized voice channels, also allow an attacker to change his (usually) voice into a feminine voice (bernz, n.d.), which is more likely to convince a potential victim. Digitally altering one's voice will also allow one attacker to appear as different callers on subsequent telephone calls (Antonopoulos & Knape, 2002). This way, the attacker can gather information on multiple occasions, without raising as much concern as a repeat caller.

The wide availability of voice over IP and the low cost of generating and sending possibly large volumes of voice mail messages also enable new types of attacks. Vishing, or VoIP phishing (Vishing, 2006) is one such type of attack that combines the use of the telephone networks described with automatic data harvesting information systems. This type of attack relies on the fact that credit card companies now require users to enter credit card numbers and other identifying information. Taking advantage of user's acceptance of such practices, vishing attacks set up rogue answering systems that prompt the user for the identifying information. The call number might be located in a different location than the phone number might indicate.

The use of phone lines is also a way for attackers to bypass some of the remaining inhibitions users have in giving out confidential information on the World Wide Web. While many users are aware of the dangers of providing confidential information on Web sites (even those who appear genuine), telephone networks are more widely trusted than online channels. Taking advantage of this perception in conjunction with the widespread availability of automated voice menus has enabled some attackers to collect credit card information. Naraine (2006a) describes an attack where the victim is instructed via e-mail to verify a credit card number over the phone. The verification request claims to represent a Santa Barbara bank and directs users to call a phone number for verification. The automated answering system uses voice prompts similar to those of legitimate credit card validation, which are familiar to users. Interestingly, the phone system does not identify the bank name, making it possible to reuse the same answering system for simultaneous attacks against multiple financial institutions.

A vishing attack even more sophisticated than the Santa Barbara bank attack targeted users of PayPal (Ryst, 2006). PayPal users were sent an e-mail to verify their account information over the phone. The automated phone system instructed users to enter their credit card number on file with PayPal. The fraudulent system then attempted to verify the number; if an invalid credit card number was entered, the user was directed to enter their information again, bolstering the illusion of a legitimate operation. Although this type of multichannel attack is not limited to VoIP networks, such networks make the automated phone systems much easier to set up.

As VoIP becomes more prevalent we may begin to see Internet-based attacks previously limited to computers impact our telephone systems (Plewes, 2007). Denial of service attacks can flood the network with spurious traffic, bringing legitimate data and voice traffic to a halt. Spit (spam over Internet telephony) is the VoIP version of e-mail spam which instead clogs up a voice mailbox with unwanted advertisements (perhaps generated by text to speech systems) or vishing attacks. Vulnerabilities in the SIP protocol for VoIP may allow social engineers to intercept, reroute calls, and tamper with calls. Finally, VoIP telephones are Internet devices that may run a variety of services such as HTTP, TFTP, or telnet servers, which may be vulnerable to hacking. Since all of the VoIP phones in an organization are likely identical, a single vulnerability can compromise every phone in the organization.

SOLUTIONS AND COUNTERMEASURES TO SOCIAL ENGINEERING ATTACKS

Following the description of attacks, the chapter now turns to solutions. The first and most important level of defense against social engineering are organizational policies (Gragg, 2003). Setting up and enforcing information security policies gives clear indications to employees on what information can be communicated, under what conditions, and to whom. In a converged network, such policies need to specify appropriate information channels, appropriate means to identify the requester, and appropriate means to document the information transfer. As the attacker is ratcheting up the strong emotions that cajole or threaten the victim into cooperating, strong policies can make an employee more likely to resist threats, feelings of guilt, or a dangerous desire to help.

In addition to deploying strong policies, organizations can use the converged network to search for threats across multiple information channels in real time. In a converged environment, the strong emotions associated with social engineering could be detected over the phone or in an e-mail, and adverse actions could be tracked and stopped before an attack can succeed. In other words, convergence has the potential to help not just the social engineer, but also the staff in charge of countering such attacks.

Anti-Phishing Techniques

A number of anti-phishing techniques have been proposed to address the growing threat of phishing attacks. Most anti-phishing techniques involve hashing the password either in the user's head (Sobrado & Birget, 2005; Wiedenbeck, Waters, Sobrado, & Birget, 2006), using special browser plugins (Ross, Jackson, Miyake, Boneh, & Mitchell, 2005), using trusted hardware (for example on tokens) or using a combination of special hardware and software (e.g., a cell phone, Parno, 2006).

All the technological solutions mentioned involve a way to hash passwords so that they are not reusable if captured on a phishing site or with a network sniffer. The downfall of all of these schemes is that the user can always be tricked into giving out a password through a different, unhashed channel, allowing the attacker to use the password later on. A good social engineer would be able to just call the victim and ask for the password over the phone. Additionally, even though all these solutions are becoming increasingly user friendly and powerful, they all require additional costs.

Voice Analytics

We discussed earlier the negative implications of VoIP and its associated attacks (vishing). A positive outcome of data and voice convergence in the fight against social engineering is the ability to analyze voice on the fly, in real time as well as on stored digitized voice mail.

Voice analytics (Mohney, 2006) allows caller identification based on voice print, and can also search for keywords, can recognize emotions, and aggregate these information sources statistically with call date and time, duration, and origin. In particular, voice print can provide additional safeguards when caller ID is spoofed. At the same time, given that the social engineer has similar resources in digitally altering her voice, the voice analytics could employ more advanced techniques to thwart such attacks. For example, the caller could be asked to say a sentence in an angry voice or calm voice (to preempt attacks using recorded voice data). Attacks by people who know and avoid "hot" words can be preempted by using a thesaurus to include synonyms.

Blacklisting

Another common technological solution against social engineering is a blacklist of suspicious or unverified sites and persons. This might sound simple, especially given the ease of filtering Web sites, the ease of using voice recognition on digital phone lines, and the ease of using face recognition (for example) in video. However, maintenance of such a list can be problematic. Additionally, social engineers take precautions to disguise Web presence, as well as voice and physical appearance. Even though a converged network may allow an organization to aggregate several information sources to build a profile of an attack or an attacker, the same converged network will also help the social engineer to disperse the clues, to make detection more difficult.

Penetration Testing

Penetration testing is another very effective tool in identifying vulnerabilities, as well as a tool for motivating and educating users. As mentioned earlier, users tend to be overconfident in their ability to handle not just malware, but social engineering attacks as well. By mounting a penetration testing attack, the IT staff can test against an entire range of levels of sophistication in attack.

An exercise performed at Argonne National Labs (Argonne, 2006) involved sending 400 messages inviting employees to click on a link to view photos from an open house event. Such e-mail messages are easily spoofed and could be sent from outside the organization, yet they can be made to seem that they originate within the organization. Of the 400 recipients of the e-mail, 149 clicked on the link and were asked to enter their user name and password to access the photos, and 104 of these employees actually entered their credentials. Because this was an exercise, the employees who submitted credentials were directed to an internal Web site with information about phishing and social engineering.

A more complex and more memorable (for the victims) example of penetration testing was reported on the DarkReading site (Stasiukonis, 2006d). The attacker team used a shopping card to open the secure access door, found and used lab coats to blend in, and connected to the company network at a jack in a conference room. Several employees actually helped the attackers out by answering questions and pointing out directions. As part of the final report, the team made a presentation to the employees, which had a profound educational impact. Six months later, on a follow up penetration testing mission, the team was unable to enter the premises. An employee, who first allowed the attackers to pass through a door she had opened, realized her mistake as soon as she got to her car. She returned, alerted the security staff and confronted the attackers.

Palmer (2001) describes how an organization would locate "ethical hackers" to perform a penetration testing exercise. The penetration testing plan involves common sense questions, about what needs to be protected, against what threats, and using what level of resources (time, money, and effort). A "get out of jail free card" is the contract between the organization initiating the testing and the "ethical hackers" performing the testing. The contract specifies limits to what the testers can do and requirements for confidentiality of information gathered. An important point, often forgotten, is that even if an organization performs a penetration testing exercise and then fixes all the vulnerabilities identified, follow up exercises will be required to assess newly introduced vulnerabilities, improperly fixed vulnerabilities, or additional ones not identified during a previous test. In particular, despite the powerful message penetration testing can convey to potential victims of social engineering, there is always an additional vulnerability a social engineer may exploit, and there is always an employee who has not fully learned the lesson after the previous exercise.

Additionally, social engineering software is available to plan and mount a self-test, similar to the Argonne one reported earlier (Jackson Higgins, 2006a). Intended mainly to test phishing vulnerabilities, the core impact penetration testing tool from Core Security (www.coresecurity.com) allows the IT staff to customize e-mails and to use social engineering considerations with a few mouse clicks (Core Impact, n.d.).

Data Filtering

One application that may address social engineering concerns at the boundary of the corporate network is that proposed by Provilla, Inc. A 2007 Cisco survey identified data leaks as the main concern of IT professionals (Leyden, 2007). Of the 100 professionals polled, 38% were most concerned with theft of information, 33% were most concerned about regulatory compliance, and only 27% were most concerned about virus attacks (down from 55% in 2006). Provilla (www.provilla-inc.com) claims that their DataDNA™ technology allows organizations to prevent information leaks, including identity theft and to maintain compliance. The product scans the network looking for document fingerprints, on "every device...at every port, for all data types," according to the company. The channels listed include USB, IM, Bluetooth, HTTP, FTP, outside email accounts (Hotmail, Gmail, etc). Conceivably, the technology could be extended to include voice over IP protocols, although these are not mentioned on the company Web site at this time.

Reverse Social Engineering

Another defensive weapon is to turn the tables and use social engineering against attackers (Holz & Raynal, 2006). This technique can be used against less sophisticated attackers, for example, by embedding "call back" code in "toolz" posted on hacker sites. This can alert organizations about the use of such code and about the location of the prospective attacker. Alternatively, the embedded code could erase the hard drive of the person using it—with the understanding that only malevolent hackers would know where to find the code and would attempt to use it.

User Education

Among the tools available against social engineering, we saved arguably the most effective tool for last: educating users. Some of the technologies mentioned in this section have the potential to stop some of the social engineering attacks. Clearly, social engineers also learn about these technologies, and they either find ways to defeat the technologies or ways to circumvent them. Some experts go as far as to say that any "no holds barred" social engineering attack is bound to succeed, given the wide array of tools and the range of vulnerabilities waiting to be exploited. Still, educating users can patch many of these vulnerabilities and is likely to be one of the most cost-effective means to prevent attacks.

We cannot stress enough that user education is only effective when users understand that they can be victims of attacks, no matter how technologically aware they might be. Incidentally, penetration testing may be one of the most powerful learning mechanisms for employees, both during and after the attack. Stasiukonis (2006c) confesses that in 90% of the cases where he and his penetration testing team get caught is when a user decides to make a call to verify the identity of the attackers. The positive feelings of the person "catching the bad guys" and the impact of the news of the attack on the organization are guaranteed to make it a memorable lesson.

Educating the users at all levels is critical. The receptionist of a company is often the first target of social engineering attacks (to get an internal phone directory, to forward a fax or just to chat about who might be on vacation, Mitnick & Simon, 2002). On the other hand, the information security officers are also targeted because of their critical access privileges. An attacker posing as a client of a bank crafted a spoofed e-mail message supposedly to report a phishing attack. When the security officer opened the e-mail he launched an application that took control of the officer's computer (Jackson Higgins, 2006b). A social engineering attack may succeed by taking the path of least resistance, using the least trained user; at the same time, an attack might fail because one of the best trained users happened to notice something suspicious and alerted the IT staff.

Educational efforts often achieve only limited success and education must be an ongoing process. A series of studies by the Treasury Inspector General for Tax Administration (2007) used penetration testing to identify and assess risks, then to evaluate the effectiveness of education. The study found that IRS employees were vulnerable to social engineering even after training in social engineering had been conducted. In 2001, the penetration testers posed as computer support helpdesk representatives in a telephone call to IRS employees and asked the employees to temporarily change their password to one given over the phone. Seventy-one percent of employees complied. Due to this alarming rate, efforts were made to educate employees about the dangers of social engineering. To assess the effectiveness of the training, a similar test was conducted in 2004, and resulted in a response rate of 35%. However, another test in 2007 successfully convinced 60% of employees to change their password. One bright spot is that of the 40% of employees who were not duped by the social engineers, 50% cited awareness training and e-mail advisories as the reason for protecting their passwords, indicating that user education has the potential for success. In response to the latest study, the IRS is elevating the awareness training and is even emphasizing the need to discipline employees for security violations resulting from negligence or carelessness.

Clearly, user education is not limited to social engineering attacks that take advantage of converged networks. Any social engineering attack is less likely to succeed in an organization where employees are well informed and empowered by well-designed security policies. Education becomes more important on converged networks, to account for the heightened threat level and to allow users to take advantage of the available converged tools that may help prevent attacks.

CONCLUSION

Despite the negative press and despite the negative trends we discussed in this chapter, the good news is that the outlook is positive (Top myths, 2006a). The media is often portraying the situation as “dire” and reporting on a seemingly alarming increase in the number of attacks. For one, the number of users and the number and usage of information systems is increasing steadily. That in itself accounts for a staggering increase in the number of incidents reported. Additionally, the awareness of the general population with respect to information security issues in general and with respect to social engineering in particular is also increasing. The media is responding to this increased interest by focusing more attention on such topics. Surveys indicate that in fact the rate of occurrence of computer crime is actually steady or even decreasing, and that only the public perception and increased usage make computer crime seem to increase. A typical analogy is the seemingly daunting vulnerabilities in Microsoft operating systems, which are in fact only a perceived outcome of the increased usage base and increased attractiveness for attackers (Top myths, 2006b).

Whether the rate of computer crime is increasing or not, social engineering remains a real problem that needs to be continually addressed. Convergence in telecommunications makes it easier for users to access several information channels through a unified interface on one or a small number of productivity devices. This same trend makes it easier for attackers to deploy blended attacks using several information channels to a potential victim, and makes it easier to reach the user through the same converged interface or productivity device. By its nature, convergence means putting all one’s eggs in one basket. The only rational security response is to guard the basket really well.

If there is one point we have tried hard to make painfully clear in this chapter, education, rather than technological solutions, appears to be the best answer to the social engineering problem. Users who are aware of attack techniques, who are trained in following safe usage policies, and who are supported by adequate technological safeguards are much more likely to recognize and deflect social engineering attacks than users who rely only on technology for protection.

ABSTRACT

Social tagging is the process of assigning and sharing among users freely selected terms of resources. This approach enables users to annotate/describe resources, and also allows users to locate new resources through the collective intelligence of other users. Social tagging offers a new avenue for resource discovery as compared to taxonomies and subject directories created by experts. This chapter investigates the effectiveness of tags as resource descriptors and is achieved using text categorization via support vector machines (SVM). Two text categorization experiments were done for this research, and tags and Web pages from del.icio.us were used. The first study concentrated on the use of terms as its features while the second used both terms and its tags as part of its feature set. The experiments yielded a macroaveraged precision, recall, and F-measure scores of 52.66%, 54.86%, and 52.05%, respectively. In terms of microaveraged values, the experiments obtained 64.76% for precision, 54.40% for recall, and 59.14% for F-measure.

DOI: 10.4018/978-1-59904-879-6.ch025

The results suggest that the tags were not always reliable indicators of the resource contents. At the same time, the results from the terms-only experiment were better compared to the experiment with both terms and tags. Implications of our work and opportunities for future work are also discussed.

INTRODUCTION

The increasing popularity of Web 2.0-based applications has empowered users to create, publish, and share resources on the Web. Such user-generated content may include text (e.g., blogs, wikis), multimedia (e.g., YouTube), and even organization/navigational structures providing personalized access to Web content. The latter includes social bookmarking/tagging systems such as del.icio.us and Connotea.

Social tagging systems allow users to annotate links to useful Web resources by assigning keywords (tags) and possibly other metadata, facilitating their future access (Macgregor & McCulloch, 2006). These tags may further be shared by other users of the social tagging system, in effect creating a community where users can create and share tags pointing to useful Web resources. Put differently, tags function both as content organizers and discoverers. Users create and assign tags to a useful resource they come across so that it would be easy for them to retrieve that resource at a later date. At the same time, other users can use one or more of these tags created to find the resource. The same tags may also be used to discover other related and relevant resources. In addition, through tags, a user can potentially locate like-minded users who hold interests in similarly-themed resources, leading to the creation of social networks (Marlow, Naaman, Boyd, & Davis, 2006).

Social tagging provides an alternative means of organizing resources when compared with conventional methods of categorization based on taxonomies, controlled vocabularies, faceted classification, and ontologies. Conventional methods require experts with domain knowledge and this often translates to a high cost of implementing such systems. They are also bound strictly by rules to ensure their classification schemes remain consistent (Morville, 2005). As the system becomes larger, the rules tend to be more complicated, leading to possible maintenance and accessibility issues. In contrast, the classification scheme in social tagging systems is deregulated. Instead of relying on (a few) experts, they are supported by a (possibly large) community of users. At the same time, tags are "flat," lacking a predefined taxonomic structure, and their use relies on shared, emergent social structures and behaviors, as well as a common conceptual and linguistic understanding within the community (Marlow et al., 2006). Tags are therefore also known as "folksonomies," short for "folk taxonomies," suggesting that they are created by lay users, as opposed to domain experts or information professionals such as librarians, and may in fact be more effective in describing the resource

While social tagging systems have become popular, it is not known if tags created by ordinary users (as opposed to experts) are useful for the discovery of information. A few studies have investigated the use of tags as resource descriptors. Examples include comparing the use of tags against author-assigned index terms in academic papers (Kipp, 2006; Lin, Beaudoin, Bui, & Desai, 2006), examining the ability of tags to classify blogs using text categorization methods (Sun, Suryanto, & Liu, 2007), and investigating the ability of del.icio.us tags to classify Web resources in a small scale study (Razikin, Goh, Cheong, & Ow, 2007). However, to be best of our knowledge, no large scale work has been conducted with del.icio.us, one of the earliest and more popular social tagging sites. The site has a diverse set of tags and Web resources, and its main function is to store, organize, and share bookmarks among a community of users.

The goal of this present chapter is to investigate if tags are useful in helping users to access relevant Web resources. Specifically, we obtain Web pages and their associated tags from del.icio.us and study whether the tags are good descriptors of these resources. Here, we adopt from techniques in text categorization (Sebastiani, 2002) and argue that an effective tag is one in which a classifier is able to assign documents to with high precision and recall. The rationale here is that if a classifier is able to accurately assign documents to their respective tags, then such tags are useful for organizing resources, implying that users would be able to utilize them for accessing information. The remainder of this chapter is organized as follows. In the next section, research related to this work is reviewed. A description of our experimental methodology and the results are then presented. We then provide a discussion of the implications of our findings and conclude with opportunities for future work in this area.

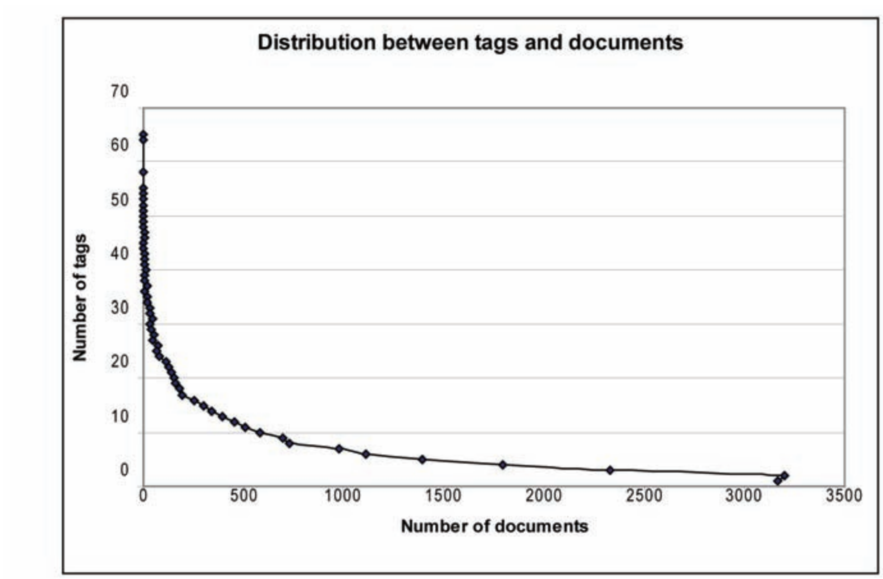
RELATED STUDIES

The use of tagging has become a popular way of organizing and accessing Web resources. Sites such as del.icio.us, Flickr, YouTube, and Last.fm offer this service for their users. Correspondingly, social tagging has also attracted much research, and work has mainly concentrated on the architecture and implementation of systems (e.g., Hammond, Hannay, Lund, & Scott, 2005; Puspitasari, Lim, Goh, Chang, Zhang, Sun, et al., 2007), usage patterns in tagging systems (e.g., Golder & Huberman, 2006; Marlow et al., 2006), user interfaces (e.g., Dubinko, Kumar, Magnani, Novak, Raghavan, & Tomkins, 2006), and the use of social tagging in search systems (e.g., Yanbe, Jatowt, Nakamura, & Tanaka, 2007) among others.

In particular, as tagging becomes an accepted practice among Web users, there is growing interest in investigating whether tags are a useful means for organizing and accessing content. For example, comparing tags with controlled vocabularies provide a basis for evaluating how tags differ from keywords assigned by experts. Lin et al. (2006) compared tags from Connotea and medical subject heading terms (MeSH terms) and found that there was only 11% similarity between MeSH terms and tags supplied by the users. The authors argued that this is because MeSH terms serve as descriptors while tags primarily focus on areas that are of interest to users. Kipp (2006) compared tags with author supplied keywords and indexing terms to determine the overlap in terms of usage. Results indicated that about 35% of the tags were related to the terms supplied by the authors and indexing terms. However, the relationship between tags and terms were not defined formally in thesauri.

An early work on automatic text categorization in social tagging systems was done by Brooks and Montanez (2006). Their study employed articles from the blogosphere. The authors used 350 popular tags from Technorati and 250 of the most recent articles of the collected tags. Using TF-IDF to cluster documents and pairwise cosine similarity to measure the similarity of all articles in each cluster, they found that tags categorize articles in the broad sense and users in a particular domain will not likely be able to find articles with a tag relating to a specific context. Sun et al. (2007) focused on classifying whole blogs with tags, and compared the classification results based on tags alone, tags together with blog descriptions (short abstract), and blog descriptions alone. It was found that tags together with descriptions had the best classification accuracy, while tags alone were more effective than blog descriptions alone for classification. Finally, in departure from the study of tags in blogs, Razikin et al. (2007) conducted a small scale study of the effectiveness of using tags to classify Web resources in del.icio.us. Using a support vector machine (SVM) classifier, relatively high precision and recall rates of 90.22% and 99.27%, respectively, were obtained.

Figure 1. The distribution of tags over the number of documents



METHODOLOGY

Tags and Web pages from del.icio.us were mined from the site from August 2007 to October 2007. During this period, we randomly collected 100 tags and 20,210 pages that were in the English language. Pages that were primarily nontextual (e.g., images and video) were discarded. Consistent with the work of Brooks and Montanez (2006), we started mining the tags from the popular tags page. As such, our tags will be biased towards the more commonly used ones. The popularity of a tag indicates that there are a significant number of documents related to it, and therefore provide a sufficient size for the training and testing of the text classifier.

In our dataset, each tag was associated with an average of 1,331 documents, and each document was associated with an average of 6.66 tags. The minimum number of tags for a document was 1 while the largest number of tags for a single document was 65. Figure 1 shows the distribution of the tags for the number of documents. It clearly demonstrates that power law distribution applies. Interestingly, the same was observed for blogs (Sun et al., 2007). In the figure, there are 3,167 documents with one tag each while there is only a single document with the largest number of tags (65).

Two text categorization experiments were conducted in the present research. The SVM was the machine learning classifier selected for our work as it is a popular machine learning classifier used in Web-based text categorization studies with good performance. Specifically, the SVM^{light} package (Joachims, 1998) was used. Being a binary classifier, we created one classifier for each tag with the examples comprising Web pages belonging (positive examples) and not belonging (negative examples) to that tag. In total, 100 classifiers were trained with the default options of the package. The performance of the tags was evaluated based on the macroaveraged and microaveraged precision, recall, and F-measure.

The first experiment, which served as a baseline, used the terms from the Web pages as the features while the second experiment included tags, in addition to terms, as part of its feature set. The pages in our dataset were processed by removing the hypertext markup language (HTML)

elements, JavaScript codes, and cascading style sheets elements. This is followed by the process of stop word removal and stemming of the remaining words. TF-IDF values of the terms were then obtained and these values were used as the feature vector for the SVM classifier. For each tag, we selected all the pages that were tagged with the keyword and these were grouped as the positive samples for the particular tag. An equal amount of pages, which were tagged with a different tag, were selected as negative samples. From this set of positive and negative samples, two-thirds of the pages were used as the training sample while the rest were part of the test set.

The second experiment augmented the first with additional features added with the aim of determining if these new features to the dataset would improve the results. The setup for the experiment was similar to that done for Experiment 1. The only difference is the addition of the document's tags to the feature set. The TF-IDF values for the tags were obtained and used as the feature values. Likewise in this experiment, the default parameters of the SVM package were used.

RESULTS FOR EXPERIMENT 1 – TERMS ONLY

Table 1 shows the top 15 tags which scored the highest F-measure obtained from Experiment 1. Table 2 shows the bottom 15 tags with the lowest F-measure obtained from the same experiment. In both tables, the extreme right column shows the difference in the F-measure values obtained in both. Entries in bold indicate an increase in the F-measure value for Experiment 2. The results are ranked in ascending order according to the tag's F-measure values obtained in this experiment.

As seen in Table 1, the top 15 tags that obtained the highest F-measure values had very broad meaning in that we were not able to determine a specific context with respect to the tag. Examples include "reference," "howto," and "politics." On the whole, the top 15 tags had better recall than precision values, indicating that the classi-

fier was able to correctly assign the documents which actually belong to the tag more than 75% of the time. However, the bottom 15 tags paint a different picture (see Table 2). These tags appear to have a narrower definition in contrast to the top 15 tags. For example, the term "adobe" has a more objective and precise meaning than "fun." The recall values for these tags were lower than its precision values, implying the classifier tended to predict more true negatives than true positives. In other words, the number of pages that did not belong to the category was higher than the pages belonging to it.

Table 3 presents the macroaveraged and microaveraged values for precision, recall, and F-measure. The macroaveraged precision and recall were 52.66% and 54.86%, respectively, while the standard deviation for precision was 4.21 and 19.05 for recall. In contrast with the standard deviation for precision, the standard deviation for recall varied greatly and a reason could be contributed by the classifier's tendency to misclassify a page which actually belongs to the tag. The macroaveraged F-measure was 52.05% and suggests that the classifier managed to predict at least half of the test data correctly with a 10.99 standard deviation across tags.

Microaveraged values show how the classi-

Table 3. Macroaveraged and microaveraged values for Experiments 1 and 2

	Experiment 1			Experiment 2		
	Precision	**Recall**	**F-measure**	**Precision**	**Recall**	**F-measure**
Macroaveraged	52.66 (s = 4.21)	54.86 (s = 19.05)	52.05 (s = 10.99)	50.77 (s = 6.06)	45.24 (s = 20.75)	45.77 (s = 13.21)
Microaveraged	64.76	54.40	59.14	56.47	54.93	55.69

fier performed based on each document. Here, the microaveraged precision was 64.76% while recall was 54.4%. From the F-measure value, the document had a 59.14% chance of being correctly classified. As shown in Table 3, both the macroaveraged and microaverage F-measure values were quite close. However, the F-measure value suggests that the users are not exactly good tag creators in the sense that other users would not be able to locate related resources using these tags. It was discussed previously that a large group of users would provide more reliable tags for resource description in contrast to expert individuals, yet this is not the case as indicated by our results. We surmise that the underlying reason is that tags can have multiple meanings and that there is no agreement on their usage in del.icio.us. As a result, the Web documents that are associated with a tag are not semantically related to each other, which in turn reduces the classifier's precision. The vocabulary problem (Furnas, Landauer, Gomez, & Dumais, 1987) is another reason that could contribute to our results. In other words, a tag would be associated with a diverse set of pages, and most of these pages may have been tagged only once with a particular tag.

RESULTS FOR EXPERIMENT 2 – TERMS AND TAGS

The results obtained in this Experiment 2 are shown in the right columns of Tables 1 and 2. The same tags that were selected in Experiment 1 are again shown in the table. In addition, the difference between the F-measures obtained in both experiments for the selected tags are shown, and entries in bold show an increase in values from those obtained in Experiment 1. Here, only eight of the selected tags have an increase in their F-measure values. The tag "icons" has the largest gain with 18.29. Documents belonging to this tag have an increased chance of 18.29% to be selected than before. On the other hand, the tag "ajax" suffered the largest drop in F-measure value with a decrease of 22.27%.

Table 3 shows the macroaveraged and microaveraged values for precision, recall, and F-measure obtained for this experiment. On average, all the categories had precision and recall values of 50.77% and 45.24%, respectively. The standard deviation for precision was 6.06, smaller than that for recall at 20.75. This was similar to the values obtained in the previous experiment. The F-measure score suggests that the classifier only managed to predict 45.77% of the pages correctly for each category on average, with a standard deviation of 13.21. For microaveraged values, the classifier managed to predict the relevance of each document with a precision and recall of 56.47% and 54.93%, respectively. The microaveraged value for F-measure was 55.69%.

It can be seen from Table 3 that the macroaveraged and microaveraged values obtained in Experiment 2 were lower than those obtained in Experiment 1, implying that the addition of tags as part of the feature set did not help in improving the precision, recall, and F-measure values. This is an interesting outcome, as making use of the terms only resulted in better performance than having terms together with tags. Although tags are words themselves, they may degrade the performance of the classifier because they appear in every document associated with these tags, causing them to have smaller TF-IDF weights in the document collection.

DISCUSSION AND CONCLUSION

In contrast to taxonomies and subject directories, social tagging is an alternative means of organizing Web resources. It is growing in popularity and is being used in a number of Web sites. In this chapter, we have investigated the effectiveness of tags in assisting users to discover relevant content by employing a text categorization approach. Here, we considered tags as categories, and examined the performance of an SVM classifier in assigning a dataset of Web resources from del.icio.us to their respective tags. Two experiments were conducted. The first examined the use of document terms only as features while the second added the document's tags in addition to the previous feature set. Surprisingly, results from the first experiment were better than the second. The macroaveraged F-measure obtained from Experiment 1 was 52.05% while the F-measure from Experiment 2 was 45.77%. The microaveraged values from both experiments were 59.14% and 55.69%. Put differently, the use of terms only yielded slightly better results than using terms and tags.

The relatively low values for precision, recall, and F-measure suggest that not all tags are reliable descriptors of the document's content. Our findings are similar to Sun et al.'s (2007) work. In that study, the range of macroaveraged F-measure values obtained for the description-only experiments ranged from 32% to 41%. Perhaps the much lower values were a result of using a shorter length of text as descriptions. It was reported that the description contained an average of only 14.8 terms for each blog. While the work of Razikin et al. (2007) was similar to the present work, the results obtained in that study were better. A reason for this could be the fact that the tags chosen were not from the popular list, and thus the Web pages that were associated with these tags tended to be more specifically related to the tags themselves. As the present work used the more popular tags, the likelihood of pages being incorrectly assigned to a tag could have been much higher because of greater usage by a diversity of users, thereby contributing to the poorer performance scores.

Some implications can be drawn from our present study. First, proponents of social tagging argue that the knowledge from a group of users could be much better than those provided by an expert (Suroweicki, 2004). However, our results have shown that this may not be applicable for all the tags, as some tags were found to be good descriptors and some were not. Future research could investigate the specific characteristics that make tags good descriptors for resource discovery. For example, one could examine whether tags with objective meanings might yield better performance than those with subjective meanings. Next, because not all tags are created equally for resource discovery, a social tagging system could assist users by suggesting tags in addition to supporting free keyword assignment. For example, after identifying characteristics of tags that serve as good resource descriptors, such tags could be used as recommendations to a tag creator for a given Web resource. In addition, a social tagging system might recommend different tags depending on whether the tag would be for public access, in which case, the recommendations would focus only on "good" tags, or for private use, in which case the recommendations could include tags that have meaning only to the creator.

In conclusion, our findings have shown different levels of effectiveness of tags as resource descriptors. There are however, some limitations to our study that provide opportunities for future work. The first concerns the use of terms and tags of the documents. These might not be the only features that could be used. Additional features like the document's title and the anchor text could prove useful for classification. Different weight schemes could be attempted for different features as well. Further, our corpus had an average of 1,331 documents per tag and future work could look into increasing the number of documents per tag, and utilize tags other than those that were popular.

KEY TERMS

Social Tagging/Social Bookmarking: The process of sharing and associating a resource, such as Web pages and multimedia, with tags.

Support Vector Machines: A vector-based machine learning technique which makes use of the maximum distance between vector classes as a decision boundary.

Text Categorization: The process of assigning documents to predefined labels using various techniques such as statistical and vector space models.

Web 2.0: Web applications that enable the sharing or creation of resources by a group of users. Some of these applications include Weblogs, wikis, and social bookmarking sites.

This work was previously published in Handbook of Research on Digital Libraries: Design, Development, and Impact, edited by Y. Theng, S. Foo, D. Goh, J. Na, pp. 251-260, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 7.9
Representing and Sharing Tagging Data Using the Social Semantic Cloud of Tags

ABSTRACT

Social tagging has become an essential element for Web 2.0 and the emerging Semantic Web applications. With the rise of Web 2.0, websites that provide content creation and sharing features have become extremely popular. These sites allow users to categorize and browse content using tags (i.e., free-text keyword topics). However, the tagging structures or folksonomies created by users and communities are often interlocked with a particular site and cannot be reused in a different system or by a different client. This chapter presents a model for expressing the structure, features, and relations among tags in different Web 2.0 sites. The model, termed the social semantic cloud of tags (SCOT), allows for the exchange of semantic tag metadata and reuse of tags in various social software applications.

DOI: 10.4018/978-1-60566-368-5.ch046

INTRODUCTION

With the rise of Web 2.0, websites which provide content creation and sharing features have become extremely popular. Many users have become actively involved in adding specific metadata in the form of *tags* and content annotations in various social software applications. While the initial purpose of tagging is to help users organize and manage their own resources, collective tagging of common resources can be used to organize information via informal distributed classification systems called *folksonomies* (Mathes, 2004; Merholz, 2004).

Studies of tagging and folksonomies can be divided into two main approaches: (a) semantic tagging concentrates on folksonomies that are inconsistent and even inaccurate because a large group of untrained users assign free-form terms to resources without guidance. Since this approach aims to resolve tag ambiguities, a wealth of ideas and efforts is emerging regarding how to use and combine ontologies with folksonomies (Weller, 2007); (b) social networking focuses on a community of users interested in a specific topic that may emerge over time because of their use of tags (Mika, 2005). The power of social tagging lies in the aggregation of information (Quintarelli, 2005). Aggregation of information involves social reinforcement by reinforcing social connections and providing social search mechanisms. Thus, a community built around tagging activities can be considered a social network with an insight into relations between topics and users.

Using freely determined vocabularies by a participant is less costly than employing an expert (Sinclair & Cardew-Hall, 2007) and a cognitive load of tagging in comparison with taxonomies or ontology is relatively low (Merholz, 2004). However, tagging the data from social media sites without a social exchange is regarded as an individual set of metadata rather than a social one. Although tagging captures individual conceptual associations, the tagging system itself does not promote a social transmission that unites both creators and consumers. To create social transmission environments for tagging, one needs a consistent way of exchanging and sharing tagging data across various applications or sources. In this sense, a formal conceptual model to represent tagging data plays a critical role in encouraging its exchange and interoperation. Semantic Web techniques and approaches help social tagging systems to eliminate tagging ambiguities.

BACKGROUND

Social Tagging

Social tagging and folksonomies have received much attention from the Semantic Web and Web 2.0 communities as a new way of information categorization and indexing. Among the most popular websites that employ folksonomies are Del.icio.us[1] (social bookmarking system) and Flickr[2] (photo-sharing network). CiteULike, using a similar approach to Del.icio.us, focuses on academic articles.[3] There are a number of multimedia sites that support tagging, such as Last.fm[4] for music and YouTube[5] for video.

Although the idea of a *tag* is not new, most people agree that a tag is no longer just a keyword. There is semantic information associated with a tag (Weller, 2007). A tag represents a type of metadata used for items such as resources, links, web pages, pictures, blog posts, and so on. Tagging can be defined as a way of representing concepts through keywords and cognitive association techniques without enforcing a categorization. The term *folksonomy* is a fusion of the two words *folk* and *taxonomy* (Vander Wal, 2004); it became especially popular with the proliferation of web-based social software applications, such as social bookmarking or annotating photographs. Building on the above definitions, folksonomy can be considered as a collaborative practice and method of creating and managing tags for the purpose of annotating and categorizing content (Mathes, 2004).

Advantages and disadvantages of social tagging present an issue for discussion. Although social tagging and folksonomies have much to offer users who utilize tags in various social media sites, there are important drawbacks inherent within the current tagging systems: for example, there is no formal conceptualization to represent tagging data in a consistent way and no interoperability support for exchanging tagging data among different applications or people (Marlow et al., 2006; Kim et al., 2007). The simplicity and accessibility of tags may lead to a lack of precision resulting in keyword ambiguity caused by misspelling certain words, as well as using synonyms, morphologies, or over-personalized tags. Since there are many different ways of using tags, it may be easy to misunderstand the meaning of a given tag.

Aside from these problems, social tagging systems do not provide a uniform way to share and reuse tagging data amongst users or communities. There is no consistent method for transferring tags between the desktop and the web or for reusing one's personal set of tags between either web-based systems or desktop applications. Although some folksonomy systems support an export functionality using their Open APIs (Application Programming Interfaces) and share their data with a closed agreement among sites, these systems do not offer a uniform and consistent way to share, exchange, and reuse tagging data for leveraging social interoperability. Therefore, it may be difficult to meaningfully search, compare, or merge similar tagging data from different applications.

With the use of tagging systems increasing daily, these limitations will become critical. The limitations come from lack of standards for tag structure and the semantics for specifying the exact meaning. To overcome the current limitations of tagging systems, it may be beneficial to take into account not only standards for representing tagging data but also develop interoperable methods to support tag sharing across heterogeneous applications.

SEMANTIC TAGGING APPROACHES

Folksonomy vs. Ontology

In general, a *taxonomy* is the organization of a set of information for a particular purpose in a hierarchical structure. An *ontology* is set of well-defined concepts describing a specific domain. It has strict and formal rules for describing relationships among concepts and for defining properties. The distinction between an ontology and a taxonomy is sometimes vague. A simple ontology without properties and constraints (i.e., concept hierarchy) could be considered a taxonomy, but a heavyweight ontology should clearly specify its capabilities.

From a classification perspective, folksonomies and ontologies can be placed at the two opposite ends of the spectrum. When compared to a traditional classification system, a folksonomy can be seen as a set of terms forming part of a flat namespace; that is, a folksonomy is a completely uncontrolled and flat system (Tonkin, 2006). To its disadvantage, folksonomy has no hierarchy and there are no directly specified parent-child relationships between the varying descriptions of the same object. Despite these limitations, the usefulness of folksonomies has been acknowledged: a folksonomy is a user-generated classification created through a bottom-up consensus.

Tag Ontology

There are certain disagreements on the merits of folksonomies and traditional classifications (see, for example, Hendler, 2007; O'Reilly, 2005; Shirky, 2004; Spivack, 2005). Shirky (2004) makes an argument that ontological classification or categorization is overrated in terms of its value. Shirky views folksonomies as emergent patterns in users' collective intelligence and claims that they can be harnessed to create a bottom-up consensus view of the world. According to Shirky, traditional classification systems have been structured using hierarchical taxonomies by experts studying a particular domain. Therefore these systems do not satisfy user-specific ways of thinking and organizing information. Meanwhile, Gruber (2005) criticizes Shirky's approach in that he fails to point out that a folksonomy has limitations to represent, share, exchange, and reuse tags and confuses "ontology-as-specified-conceptualization" with a very narrow form of specification. Hendler

(2007) also argues that Shirky misunderstood how ontologies could be built on the principles of the Semantic Web. Spivack (2005) asserts that folksonomies are just specific, highly simplistic cases of ontologies with minimal semantics.

Despite conflicting differences between folksonomies and ontologies, the Semantic Web and ontologies can be seen as a complement to folksonomies. Gruber (2005) and Spivack (2005) emphasize the importance of folksonomies and ontologies working together. In particular, Gruber (2005) proposes the "Tag Ontology." This aims at identifying and formalizing a conceptualization of the activity of tagging, and building technology that commits to the ontology at a semantic level. This approach is a good starting point to bridge Web 2.0 and the Semantic Web:

- **Gruber's Conceptual Model:** Suggests a model that defines a tagging activity including an object, a tag, a tagging, and a source.
- **Richard Newman's Tag Ontology:** Defines the three core concepts of Tagger, Tagging, Tag for representing the tagging activity (Newman, 2005) and is based on a tripartite tagging (i.e., user, resource, and tag).

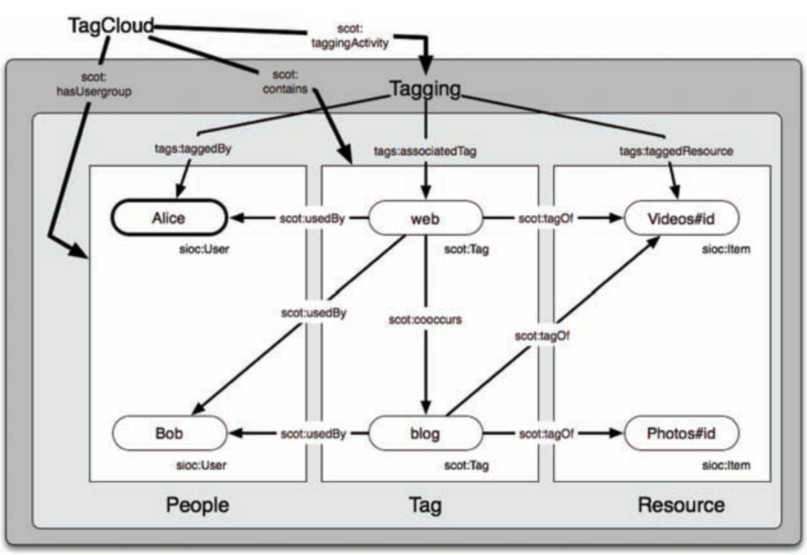
The two approaches are focused on tagging activities or events that people used to tag in resources using terms. Therefore the core concept is Tagging. The concept of tagging has a relationship, as a concept, with Tagger and Resource to describe people who participate in a tagging event and objects to where a tag is assigned. However, there are no ways to describe the frequency of tags in these ontologies.

SCOT: Social Semantic Cloud of Tags

SCOT (Social Semantic Cloud of Tags) is an ontology for sharing and reusing tag data and representing social relations among individuals. It aims to describe the structure and the semantics of tagged data as well as offer interoperability of data among different sources.

Figure 1 illustrates the relations among the elements as well as a tagging activity. The vocabularies can be used to make explicit a collection of users, tags, and resources; they are represented by

Figure 1. Terms and relations in SCOT that can be used to describe tagging activities



a set of RDF classes and properties that can be used to express the content and structure of the tagging activity as an RDF graph.

The TagCloud, which represents a conceptual model of a folksonomy, has a connection point to combine other concepts (i.e., tag, tagging, tagger, and so on.) and can be connected with other tag cloud with a unique namespace. The scot:TagCloud is a subclass of sioc:Container. All information consisting of relationships among taggers, items, and all tags is connected to this class. This class has the scot:contains and the scot:hasUsergroup properties. The former represents tags in a given domain or community while the latter describes taggers who participate in a tagging activity. A tagger may not be a single person according to contexts. For instance, if multiple taggers in a certain community generate a tag cloud, this tag cloud should contain all taggers. The scot:hasUsergroup property represents a person with a container. The scot:composedOf property describes a part of a TagCloud. In particular, if a TagCloud has more than two tag clouds, the property identifies each tag cloud. The scot:taggingActivity property present a relationship between a TagCloud and a Tagging.

The scot:Tag class, a subclass of tags:Tag (Tag class of Tag Ontology), allows users to assert that a tag is an atomic conceptual resource. A tag is a concept associated with a piece of information. The concept has many different variations according to taggers' cognitive patterns. Tag ambiguities, one of the most critical problems, result from this reason. The SCOT ontology provides several properties such as scot:spellingVariant, scot:synonym to solve this problem. It is called the "linguistic property" since these properties focus on representing the meaning of a tag and the relationships between each tag. In addition, the ontology has properties to describe occurrence of a tag (i.e., scot:frequency). A tag itself has its own frequency. The frequency is not unique, but it is an important feature to distinguish or compare with other tags. We called it a "numerical property." The properties have their own numerical values by computing. The properties in Figure 1 show high-level properties in the SCOT ontology.

In addition to representing the structure and the semantics of tags, the model allows the exchange of semantic tag metadata for reuse in social applications and interoperation amongst data sources, services, or agents in a tag space. These features are a cornerstone to being able to identify, formalize, and interoperate a common conceptualization of tagging activity at a semantic level.

SCOT aims to incorporate and reuse existing vocabularies as much as possible to avoid redundancies and to enable the use of richer metadata descriptions for specific domains. The ontology has a number of properties to represent social tagging activity and relationships among elements occurring in an online community.

- DC, or Dublin Core, provides a basic set of properties and types for annotating documents. In SCOT, we use the properties dc:title for the title of a TagCloud, dc:description to give a summary of the TagCloud, dc:publisher to define what system is generating the TagCloud, dc:creator to link to the person who created this set of tags. dcterms:created, from the Dublin Core refinements vocabulary, is used to define when a TagCloud was first created.
- FOAF (Brickley & Miller, 2004), or Friend of a Friend, specifies the most important features related to people acting in online communities. The vocabulary allows us to specify properties about people commonly appearing on personal homepages, and to describe links between people who know each other. foaf:Person is used to define the creator of a particular TagCloud. foaf:Group can be used to define a group of people who have created a group TagCloud.
- SIOC (Breslin et al., 2005), Semantically-Interlinked Online Communities, provides

the main concepts and properties required to describe information from online communities (e.g., message boards, wikis, blogs, etc.) on the Semantic Web. In the context of SCOT, sioc:Usergroup can be used to represent a set of sioc:User who have created the tags contained within a particular group TagCloud. A TagCloud is also a type of sioc:Container, in that it contains a set of Tags (subclass of sioc:Item).

- SKOS (Simple Knowledge Organization Systems) provides specifications and standards to support the use of vocabularies, such as thesauri, classification schemes, subject heading lists, taxonomies, other types of controlled vocabulary as well as terminologies and glossaries (Miles & Bechhofer, 2008). Tag is a subclass of skos:Concept, and a number of SKOS properties are used to define the relationships between Tags: broader, narrower, and so on.

Int.ere.st: Platform for Tag Sharing

Int.ere.st is a website where people can manage their tagging data from various sources, search resources based on their tags which were created and used by themselves, and leverage a sharing and exchanging of tagging data among people or various online communities.[6] The site is a platform for providing structure and semantics to previously unstructured tagging data via various mashups. The tagging data from distributed environments (such as blogs) can be stored in a repository, such as SCOT, via the Mashup Wrapper, which extracts tagging data using Open APIs from host sites. For instance, the site allows users to dump tagging data from Del.icio.us, Flickr, and YouTube; these tagging data are transformed into SCOT instances on a semantic level. Thus, all instances within Int.ere.st include different tagging contexts and connect various people and sources with the same tags. In addition, users can search people, tags, or resources and can bookmark some resources or integrate different instances. Through this iterative process, the tags reflect distributed human intelligence into the site.

Int.ere.st is the first OpenTagging Platform[7] of the Semantic Web, since users can manage a collection of tagging data in a smarter and more effective way as well as search, bookmark, and share their own as well as other's tagging data underlying the SCOT ontology. Those functionalities help users exchange and share their tagging data based on the Semantic Web standards. The site is compatible with other Semantic Web applications, and its information can be shared across applications. This means that the site enables users to create Semantic Web data, such as FOAF, SKOS, and SIOC automatically. RDF vocabularies can be interlinked with the URIs of SCOT instances that are generated in the site and shared in online communities.

FUTURE TRENDS

Social computing enables building social systems and software; it also allows for embedding social knowledge in applications rather than merely describing social information. Within social network analysis, traditional approaches have focused on static networks for small groups. As the technologies move forward, a major challenge for social network analysis is to design methods and tools for modeling and analyzing large-scale and dynamic networks. In particular, folksonomies are inherently dynamic and have different contexts among sources.

To facilitate the development of a social network for folksonomies, it is important to pay attention to social information. Although SNA allows analyzing phenomenon of social behavior at both individual and collective level, we do not have a solution that represents the relations among elements and reflects them to the objects. Tag ontologies are promising in providing the tools and formalism for representing social information including users, resources, tags, and their relationships.

Social search has become an active area in academic research as well as industry. Social search is a type of search engine that determines the relevance of search results by considering user interactions, contributions, or activities, such as bookmarking, tagging, and ranking. For instance, Del.icio.us and Spurl[8] (social bookmarking services) rely on user rankings, while Technorati[9] and Bloglines[10] (tag aggregators) analyze blogs and feed-based content. In particular, Swicki[11] and Rollyo[12] offer a community-based topic search as well as "searchles"[13] (these allow users to tag, group, and save links and create their own "SearchlesTV" channels through video mashups).

Most approaches, however, are limited to different types of resources and to show a comprehensive perspective on social relations across different applications. For instance, if users are involved in two different social spaces such as Del.icio.us and YouTube, one cannot build an integrated social network unless the two services have a mutual agreement. This issue, to some degree, is related to social information representation, since both websites have different aspects and events for building social connections. Thus, if one has a common conceptualization for social events, it is easy to build social connections among different spaces and to search them from different sources. Since tag ontologies are suitable to represent common conceptualization of social events, a social search can adopt Semantic Web technologies. We believe that a social search can benefit from a formal conceptualization of social knowledge, including tagging data based on the Semantic Web.

CONCLUSION

Tags have become an essential element for Web 2.0 and the Semantic Web applications. There is a vast collection of user-created content residing on the web. Tagging is a promising technological breakthrough offering new emerging opportunities for sharing and disseminating metadata. The critical issues discussed in this chapter offer many implications and challenges for representing tagging data semantically and exchanging them socially. With emphasis placed on tag ontologies and opportunities, these issues must be confronted without delay. Creators and consumers of folksonomies, as well as service providers, will profit from effective and efficient tagging methods that are socially and semantically enhanced.

KEY TERMS AND DEFINITIONS

Folksonomy: A practice and method of collaboratively creating and managing tags for the purpose of annotating and categorizing content. The term *folksonomy* is a fusion of two words: *folk* and *taxonomy.* Folksonomies became popular with the introduction of web-based social software applications, for example, social bookmarking and photograph annotating.

Mashup: Involves web services or applications combining data from different websites. In general, mashup services are implemented by combining various functionalities with open APIs.

Ontology: Is set of well-defined concepts describing a specific domain.

Open API (Application Programming Interface): Is used to describe a set of methods for sharing data in Web 2.0 applications.

Semantic Web: Is an extension of the current World Wide Web that links information and services on the web through meaning and allows people and machines use web content in more intelligent and intuitive ways.

Social Computing: Is defined as any type of collaborative and social applications that offer the gathering, representation, processing, use, and dissemination of distributed social information.

Social Semantic Cloud of Tags (SCOT): Is an ontology for sharing and reusing tagged data and representing social relations among individuals. It aims to describe the structure and the semantics of data and to offer the interoperability of data among different sources.

Social Software: Can be defined as a range of web-based software programs that support group communication. Many of these programs share similar characteristics, for example, open APIs, customizable service orientation, and the capacity to upload data and media.

Social Tagging: Also known as *collaborative tagging*, refers to assigning specific keywords or *tags* to items and sharing the set of tags between communities of users.

Tag: A type of metadata used for items such as resources, links, web pages, pictures, blog posts, and so on.

Tagging: A way of representing concepts through tags and cognitive association techniques without enforcing a categorization.

Taxonomy: A method of organizing information in a hierarchical structure using a set of vocabulary terms.

Chapter 7.10
Anomaly Detection for Inferring Social Structure

Lisa Friedland
University of Massachusetts Amherst, USA

INTRODUCTION

In traditional data analysis, data points lie in a Cartesian space, and an analyst asks certain questions: (1) What distribution can I fit to the data? (2) Which points are outliers? (3) Are there distinct clusters or substructure? Today, data mining treats richer and richer types of data. Social networks encode information about people and their communities; relational data sets incorporate multiple types of entities and links; and temporal information describes the dynamics of these systems. With such semantically complex data sets, a greater variety of patterns can be described and views constructed of the data.

This article describes a specific social structure that may be present in such data sources and presents a framework for detecting it. The goal is to identify *tribes*, or small groups of individuals that intentionally coordinate their behavior—individuals with enough in common that they are unlikely to be acting independently.

While this task can only be conceived of in a domain of interacting entities, the solution techniques return to the traditional data analysis questions. In order to find hidden structure (3), we use an anomaly detection approach: develop a model to describe the data (1), then identify outliers (2).

DOI: 10.4018/978-1-60566-010-3.ch007

BACKGROUND

This article refers throughout to the case study by Friedland and Jensen (2007) that introduced the tribes task. The National Association of Securities Dealers (NASD) regulates the securities industry in the United States. (Since the time of the study, NASD has been renamed the Financial Industry Regulatory Authority.) NASD monitors over 5000 securities firms, overseeing their approximately 170,000 branch offices and 600,000 employees that sell securities to the public. One of NASD's primary activities is to predict and prevent fraud among these employees, called registered representatives, or *reps*. Equipped with data about the reps' past employments, education, and "disclosable events," it must focus its investigatory resources on those reps most likely to engage in risky behavior. Publications by Neville et al. (2005) and Fast et al. (2007) describe the broader fraud detection problem within this data set.

NASD investigators suspect that fraud risk depends on the social structure among reps and their employers. In particular, some cases of fraud appear to be committed by what we have termed *tribes*—groups of reps that move from job to job together over time. They hypothesized such coordinated movement among jobs could be predictive of future risk. To test this theory, we developed an algorithm to detect tribe behavior. The algorithm takes as input the employment dates of each rep at each branch office, and outputs small groups of reps who have been co-workers to a striking, or anomalous, extent.

This task draws upon several themes from data mining and machine learning:

Inferring latent structure in data. The data we observe may be a poor view of a system's underlying processes. It is often useful to reason about objects or categories we believe exist in real life, but that are not explicitly represented in the data. The hidden structures can be inferred (to the best of our ability) as a means to further analyses, or as an end in themselves. To do this, typically one assumes an underlying model of the full system. Then, a method such as the expectation-maximization algorithm recovers the best match between the observed data and the hypothesized unobserved structures. This type of approach is ubiquitous, appearing for instance in mixture models and clustering (MacKay, 2003), and applied to document and topic models (Hofmann, 1999; Steyvers, et al. 2004).

In relational domains, the latent structure most commonly searched for is clusters. Clusters (in graphs) can be described as groups of nodes densely connected by edges. Relational clustering algorithms hypothesize the existence of this underlying structure, then partition the data so as best to reflect the such groups (Newman, 2004; Kubica et al., 2002; Neville & Jensen, 2005). Such methods have analyzed community structures within, for instance, a dolphin social network (Lusseau & Newman, 2004) and within a company using its network of emails (Tyler et al., 2003). Other variations assume some alternative underlying structure. Gibson et al. (1998) use notions of hubs and authorities to reveal communities on the web, while a recent algorithm by Xu et al. (2007) segments data into three types—clusters, outliers, and hub nodes.

For datasets with links that change over time, a variety of algorithms have been developed to infer structure. Two projects are similar to tribe detection in that they search for specific scenarios of malicious activity, albeit in communication logs: Gerdes et al. (2006) look for evidence of chains of command, while Magdon-Ismail et al. (2003) look for hidden groups sending messages via a public forum.

For the tribes task, the underlying assumption is that most individuals act independently in choosing employments and transferring among jobs, but that certain small groups make their decisions jointly. These tribes consist of members who have worked together unusually much in some way. Identifying these unusual groups is an instance of anomaly detection.

Anomaly detection. Anomalies, or outliers, are examples that do not fit a model. In the literature, the term anomaly detection often refers to intrusion detection systems. Commonly, any deviations from normal computer usage patterns, patterns which are perhaps learned from the data as by Teng and Chen (1990), are viewed as signs of potential attacks or security breaches. More generally for anomaly detection, Eskin (2000) presents a mixture model framework in which, given a model (with unknown parameters) describing normal elements, a data set can be partitioned into normal versus anomalous elements. When the goal is fraud detection, anomaly detection approaches are often effective because, unlike supervised learning, they can highlight both rare patterns plus scenarios not seen in training data. Bolton and Hand (2002) review a number of applications and issues in this area.

MAIN FOCUS

As introduced above, the tribe-detection task begins with the assumption that most individuals make choices individually, but that certain small groups display anomalously coordinated behavior. Such groups leave traces that should allow us to recover them within large data sets, even though the data were not collected with them in mind.

In the problem's most general formulation, the input is a bipartite graph, understood as linking individuals to their affiliations. In place of reps working at branches, the data could take the form of students enrolled in classes, animals and the locations where they are sighted, or customers and the music albums they have rated. A tribe of individuals choosing their affiliations in coordination, in these cases, becomes a group enrolling in the same classes, a mother-child pair that travels together, or friends sharing each other's music. Not every tribe will leave a clear signature, but some groups will have sets of affiliations that are striking, either in that a large number of affiliations are shared, or in that the particular combination of affiliations is unusual.

Framework

We describe the algorithm using the concrete example of the NASD study. Each rep is employed at a series of branch offices of the industry's firms. The basic framework consists of three procedures:

1. For every pair of reps, identify which branches the reps share.
2. Assign a similarity score to each pair of reps, based on the branches they have in common.
3. Group the most similar pairs into tribes.

Step 1 is computationally expensive, but straightforward: For each branch, enumerate the pairs of reps who worked there simultaneously. Then for each pair of reps, compile the list of all branches they shared.

The similarity score of Step 2 depends on the choice of model, discussed in the following section. This is the key component determining what kind of groups the algorithm returns.

After each rep pair is assigned a similarity score, the modeler chooses a threshold, keeps only the most highly similar pairs, and creates a graph by placing an edge between the nodes of each remaining pair. The graph's connected components become the tribes. That is, a tribe begins with a similar pair of reps, and it expands by including all reps highly similar to those already in the tribe.

Models of "Normal"

The similarity score defines how close two reps are, given the set of branches they share. A pair of reps should be considered close if their set of shared jobs is unusual, i.e., shows signs of coordination. In deciding what makes a set of branches unusual, the scoring function implicitly or explicitly defines a model of normal movement.

Some options for similarity functions include:

Count the jobs. The simplest way to score the likelihood of a given set of branches is to count them: A pair of reps with three branches in common receives the score 3. This score can be seen as stemming from a naïve model of how reps choose employments: At each decision point, a rep either picks a new job, choosing among all branches with equal probability, or else stops working. Under this model, any given sequence of n jobs is equally likely and is more likely than a sequence of $n+1$ jobs.

Measure duration. Another potential scoring function is to measure how long the pair worked together. This score could arise from the following model: Each day, reps independently choose new jobs (which could be the same as their current jobs). Then, the more days a pair spends as co-workers, the larger the deviation from the model.

Evaluate likelihood according to a Markov process. Each branch can be seen as a state in a Markov process, and a rep's job trajectory can be seen as a sequence generated by this process. At each decision point, a rep either picks a new job, choosing among branches according to the transition probabilities, or else stops working.

This Markov model captures the idea that some job transitions are more common than others. For instance, employees of one firm may regularly transfer to another firm in the same city or the same market. Similarly, when a firm is acquired, the employment data records its workforce as "changing jobs" en masse to the new firm, which makes that job change appear popular. A model that accounts for common versus rare job transitions can judge, for instance, that a pair of independent colleagues in Topeka, Kansas (where the number of firms is limited) is more likely to share three jobs by chance, than a pair in New York City is (where there are more firms to choose from); and that both of these are more likely than for an independent pair to share a job in New York City, then a job in Wisconsin, then a job in Arizona.

The Markov model's parameters can be learned using the whole data set. The likelihood of a particular (ordered) sequence of jobs,P(Branch A → Branch B → Branch C → Branch D)isP(startat Branch A) • P(A → B) • P(B → C) • P(C → D)

The branch-branch transition probabilities and starting probabilities are estimated using the number of reps who worked at each branch and the number that left each branch for the next one. Details of this model, including needed modifications to allow for gaps between shared employments, can be found in the original paper (Friedland & Jensen, 2007).

Use any model that estimates a multivariate binary distribution. In the Markov model above, it is crucial that the jobs be temporally ordered: A rep works at one branch, then another. When the data comes from a domain without temporal information, such as customers owning music albums, an alternative model of "normal" is needed. If each rep's set of branch memberships is represented as a vector of 1's (memberships) and 0's (non-memberships), in a high-dimensional binary space, then the problem becomes estimation of the probability density in this space. Then, to score a particular set of branches shared by a pair of reps, the estimator computes the marginal probability of that set. A number of models, such as Markov random fields, may be suitable; determining which perform well, and which dependencies to model, remains ongoing research.

Evaluation

In the NASD data, the input consisted of the complete table of reps and their branch affiliations, both historical and current. Tribes were inferred using three of the models described above: counting jobs (JOBS), measuring duration (YEARS), and the Markov process (PROB). Because it was impossible to directly verify the tribe relationships, a number of indirect measures were used to validate the resulting groups, as summarized in Table 1.

Table 1. Desirable properties of tribes

Property	Why this is desirable
Tribes share rare combinations of jobs.	An ideal tribe should be fairly unique in its job-hopping behavior.
Tribes are more likely to traverse multiple zip codes.	Groups that travel long distances together are unlikely to be doing so by chance.
Tribes have much higher risk scores than average.	If fraud does tend to occur in tribe-like structures, then on average, reps in tribes should have worse histories.
Tribes are homogenous: reps in a tribe have similar risk scores.	Each tribe should either be innocuous or high-risk.

The first properties evaluate tribes with respect to their rarity and geographic movement (see table lines 1-2). The remaining properties confirm two joint hypotheses: that the algorithm succeeds at detecting the coordinated behavior of interest, and that this behavior is helpful in predicting fraud. Fraud was measured via a risk score, which described the severity of all reported events and infractions in a rep's work history. If tribes contain many reps known to have committed fraud, then they will be useful in predicting future fraud (line 3). And ideally, groups identified as tribes should fall into two categories. First is high-risk tribes, in which all or most of the members have known infractions. (In fact, an individual with a seemingly clean history in a tribe with several high-risk reps would be a prime candidate for future investigation.) But much more common will be the innocuous tribes, the result of harmless sets of friends recruiting each other from job to job. Within ideal tribes, reps are not necessarily high-risk, but they should match each other's risk scores (line 4).

Throughout the evaluations, the JOBS and PROB models performed well, whereas the YEARS model did not. JOBS and PROB selected different sets of tribes, but the tribes were fairly comparable under most evaluation measures: compared to random groups of reps, tribes had rare combinations of jobs, traveled geographically (particularly for PROB), had higher risk scores, and were homogenous. The tribes identified by YEARS poorly matched the desired properties: not only did these reps not commit fraud, but the tribes often consisted of large crowds of people who shared very typical job trajectories.

Informally, JOBS and PROB chose tribes that differed in ways one would expect. JOBS selected some tribes that shared six or more jobs but whose reps appeared to be caught up in a series of firm acquisitions: many other reps also had those same jobs. PROB selected some tribes that shared only three jobs, yet clearly stood out: Of thousands of colleagues at each branch, only this pair had made any of the job transitions in the series. One explanation why PROB did not perform conclusively better is its weakness at small branches. If a pair of reps works together at a two-person branch, then transfers elsewhere together, the model judges this transfer to be utterly unremarkable, because it is what 100% of their colleagues at that branch (i.e., just the two of them) did. For reasons like this, the model seems to miss potential tribes that work at multiple small branches together. Correcting for this situation, and understanding other such effects, remain as future work.

FUTURE TRENDS

One future direction is to explore the utility of the tribe structure to other domains. For instance, an online bookstore could use the tribes algorithm to infer book clubs—individuals that order the same books at the same times. More generally, customers with unusually similar tastes might want to be introduced; the similarity scores could become a basis for matchmaking on dating websites, or for connecting researchers who read or publish similar papers. In animal biology, there is a closely related problem of determining family ties, based on which animals repeatedly appear together in herds (Cairns & Schwager, 1987). These "association patterns" might benefit from being formulated as tribes, or even vice versa.

Work to evaluate other choices of scoring models, particularly those that can describe affiliation patterns in non-temporal domains, is ongoing. Additional research will expand our understanding of tribe detection by examining performance across different domains and by comparing properties of the different models, such as tractability and simplicity.

CONCLUSION

The domains discussed here (stock brokers, online customers, etc.) are rich in that they report the interactions of multiple entity types over time. They embed signatures of countless not-yet-formulated behaviors in addition to those demonstrated by tribes.

The tribes framework may serve as a guide to detecting any new behavior that a modeler describes. Key aspects of this approach include searching for occurrences of the pattern, developing a model to describe "normal" or chance occurrences, and marking outliers as entities of interest.

The compelling motivation behind identifying tribes or similar patterns is in detecting hidden, but very real, relationships. For the most part, individuals in large data sets appear to behave independently, subject to forces that affect everyone in their community. However, in certain cases, there is enough information to rule out independence and to highlight coordinated behavior.

KEY TERMS AND DEFINITIONS

Anomaly Detection: Discovering anomalies, or outliers, in data.

Branch: In the NASD schema, a branch is the smallest organizational unit recorded: every firm has one or more branch offices.

Branch Transition: The NASD study examined patterns of job changes. If employees who work at Branch A often work at Branch B next, we say the (branch) transition between Branches A and B is common.

Latent Structure: In data, a structure or pattern that is not explicit. Recovering such structures can make data more understandable, and can be a first step in further analyses.

Markov Process: Model that stochastically chooses a sequence of states. The probability of selecting any state depends only on the previous state.

Registered Representative (rep): Term for individual in the NASD data.

Tribe: Small group of individuals acting in a coordinated manner, e.g., moving from job to job together.

Chapter 7.11
Emerging Online Democracy:
The Dynamics of Formal and Informal Control in Digitally Mediated Social Structures

Todd Kelshaw
Montclair State University, USA

Christine A. Lemesianou
Montclair State University, USA

ABSTRACT

The emergence and development of Web 2.0 has enabled new modes of social interaction that are potentially democratic, both within and across digitally mediated venues. Web-based interaction offers unlimited opportunities for organizing across geographic, demographic, and contextual boundaries, with ramifications in professional networking, political action, friendships, romances, learning, recreation, and entertainment. The authors conceptualize the democratization of Web-based social structures, defining online democracy as an imperfect balance of formal and informal modes of discursive control. The wrangling between formal and informal modes of discursive control ensures perpetual dynamism and innovation; the wrangling also offers the promise that diverse voices are not only welcome but also potentially responsive and responsible. The conclusion advocated is the importance of paying attention to these tendencies since they demonstrate that the Web's proclivities for decentralization and pluralism do not necessarily lead to relativistic and nihilistic hypertextuality but to potentially novel forms of shared social control.

INTRODUCTION

With the advent of web-based social interaction technologies, new opportunities have arisen for user control and interactivity. These opportunities range widely in their relational complexities, spanning information gathering and opinion sharing, the formation of interpersonal relationships and online communities, and the development and maintenance of sophisticated organizational and global networks. Across these varied modes of interactivity, control of the technology, the media, and the communicative

DOI: 10.4018/978-1-60566-368-5.ch036

content is becoming increasingly decentralized and populistic. It is necessary, therefore, to address what is commonly called the "democratization" of the web.

Democracy, as conceived here, is not characterized by wholly unregulated chaos, despite the relativistic potential of hypertextual communication. Whereas interactivity in digitally mediated venues may range in quality from "anything goes" anarchy to rigid authoritarianism, this chapter addresses the emergence of democratic moderation, in which online participants "concertively" regulate their communication. Here we identify some past research and thoughts on the Internet's democratic qualities;[1] describe and illustrate online contexts as potentially democratic social structures that experience interplay between formal and informal communicative forces; and anticipate future trends of theory, empirical research, and practice.

BACKGROUND

The introduction of a new generation of social interaction technologies opens a possibility of the transformation of structural and social reality (McLuhan & Fiore, 1967; Ong, 1982). Since its emergence, the Internet[1] has been approached, theoretically and empirically, as a momentous and consequential social, cultural, economic, and political force (DiMaggio, Hargittai, Neuman, & Robinson, 2001; Wilson & Peterson, 2002). Some have theorized that the Internet might drastically transform the self, interaction, and social order and serve as a catalyst for social justice, empowering individuals to find spaces within which their voices may count (Negroponte, 1995). Others have cautioned that the Internet constrains and disempowers individuals within structured routines and cultural norms. They have argued that in the new virtual world some would emerge as winners (e.g., transnational corporations and interests) and others as losers (Beniger, 1996). Castells (1996), for instance, proposed that the Internet would follow the commercial path of its media predecessors and predicted a web "populated by two essentially distinct populations, *the interacting* and *the interacted*" (p. 371): the first group exemplifying the web's fragmentation potential and, the second, its reproduction of traditional media's massification patterns; and both groups reflecting the divide between the information rich and poor.

Studies on the Internet's potential to rearrange social, cultural, economic, and political life have focused on such issues as access to open information flows across national and global systems (Bimber, 2000; Norris, 2001; Schiller, 1995), identity construction (Cutler, 1996; Morse, 1998; Turkle, 1995), community formation and mobilization (Foster, 1997; Rheingold, 1993; Zappen, Gurak, & Doheny-Farina, 1997), and civic and political participation and deliberation (Putnam, 2000). The potential of the Internet to promote civic engagement and political democracy have also gained attention (e.g., Agre, 2002), especially since the 1990s when United States' congressional, state, and presidential candidates began deploying campaign websites (Hurwiz, 1999). The increased opportunities for interactivity among citizenries through blogs, chat rooms, and Internet forums are now being investigated (e.g., Best & Krueger, 2005; Dahlgreen, 2000; Endres & Warnick, 2004) as are the perceived public risks posed by such online participation (Andrejevic, 2006; Best, Krueger, & Ladewig, 2007). While some suggest that the Internet has the potential to mobilize "netizens" in new ways and to support democratic processes (Carpini, 2000; Deuze, 2006; Min, 2007), at times lending authorial voice to marginalized constituents and concerns, there is also increased support for the polarization of the public and the unfulfilled potential of deliberative democracy (Noveck, 2000; Selnow, 1998; Streck, 1998; White, 1997; Wilhelm, 2000). Still others point out that online deliberative democracy can be actualized, but its impact is greatly diminished when positioned within a dominant commercialized and individualized culture (Dahlberg, 2001).

On a more micro-analytic level, various studies have explored language, communication practices, and social interaction and relations on the Internet (e.g., Crystal, 2001). These inquiries address the emergence and negotiation of "netiquette" rules that socialize online participants, as well as more subtle self-imposed or community-imposed levels of informal control that undermine the Internet's democratic potential. McLaughlin, Osborne, & Smith (1995) identified early misconduct on Usenet that included misuse of technology, bandwidth waste, factual errors, inappropriate violation of language guidelines, newsgroup-specific conventions, and ethical codes. The extent to which the Internet liberates or simply reproduces patterns of expression and participation, in relation to gender, race, and sexual politics, continues to interest participants, observers, and researchers (Bromseth, 2001; Dibbell, 1993; Herring, 1996; Herring & Paolillo, 2006; Kendall, 2000; Lessig, 1999; Miller, 1995; Stivale, 1997) as do the Internet's descriptive and prescriptive rules and various interactive forms, where behaviors range from disruption and hostility (e.g., flaming) to disciplinary control and normalization (Dutton, 1996; Lee, 2005; Phillips, 1996; Thompsen, 1996). Much of the research has examined online contexts such as MUDs, MOOs, and Usenet communities that are now being replaced in prominence by new Internet venues.

Janack (2006) studied how participants of *Blog for America*—a feature of the 2000 U. S. presidential candidate Howard Dean's campaign website—discursively disciplined themselves. That study echoes this chapter's focus: While new social media feature pluralistic participation, interactivity, and ungrounded hypertextuality, they operate within both formally structured and emergent frameworks of values, practices, and expectations that significantly reaffirm and rewrite authority and control. In Janack's study, for instance, blog participants behaved as gatekeepers, a role traditionally enacted by campaign staffers, to silence Dean's critics through various rhetorical strategies (e.g., ignoring or minimizing critical comments, *ad hominem* attacks). If Internet-enabled discourse may be described in Bakhtin's (1984) language as "carnivalesque," we can see how it potentially brings people together as equals to revel in liberation from exogenous constraints (legal, governmental, religious, and so on) and social stratifications. At once, though, it is necessary to recognize that the carnival, no matter how liberating, is a social order nonetheless. Its playfulness, unpredictability, populism, and multi-voicedness are inevitably bounded and regulated. This moderation is a hallmark of online democracy, and an important potential characteristic of web-based interaction.

ONLINE DEMOCRACY'S MODES OF SOCIAL CONTROL

Online communication occurs within and across diverse contexts and forms, ranging from relatively simple information posts to highly sophisticated social and political commentary. Accordingly, discursive qualities vary greatly throughout the web. Some utterances are noisily and chaotically ungrounded whereas others are kept orderly by the moderator's iron fists. Of interest is what happens somewhere between these extremes, when administrative and lay users participate together to negotiate and maintain their shared social orders.

To understand such potentially democratic qualities, it is necessary to define online democracy and to address how it may be enacted. This section begins with the general idea that all online interaction is governed by tensional interplay between formal and informal modes of control. Then we define online democracy as a particular mode of dialectical tension, and illustrate this dynamic—and the general potential for online democracy in Internet-mediated venues—by exploring some actual online interaction.

Online Social Structures and Democracy

Any social structure is continuously rebuilt through participants' communication (Giddens, 1984). This applies not only to face-to-face and other traditional social contexts but also to emerging venues that are digitally mediated, such as online forums, discussion boards, blogs, wikis, and social networking sites. These online settings may be thought of as both nouns and verbs; they are as much solid frameworks of norms as they are fluid interactions among people. In Giddens' terms, such simultaneously solid and fluid structures comprise socially made rules (implicit and explicit formulas for action) and resources (participants' commoditized abilities, knowledge, designated roles, etc.) that at once permit and limit interaction. The constant "reinscription" of rules and resources occurs not just within a given social structure as a demarcated and unitary body but also *across* overlapping structures that may mediate and contradict each other.

One way to understand this complex nature of social structures is to address how they are enabled and constrained by a dialectical interplay of social forces—what Bakhtin (1981) characterizes as "centripetal" and "centrifugal." Centripetal forces are authoritative, stabilizing, decisive, and preserving of traditions. Directives, punishments, and behaviors that concretize stratified roles are instances of centripetally leaning talk. Conversely, centrifugal forces are insurgent, destabilizing, equivocally open-ended, and change-minded. Questions, evasions, and behaviors that challenge authority are centrifugally leaning.

When examining online interaction, each discrete utterance (e.g., a blog post) manifests a quality that is roughly mappable along the *centripetal—centrifugal* continuum. Directives and pronouncements, for instance, tug the discourse centripetally whereas questions and invitations for response pull things centrifugally. In looking at a communicative context's utterances in aggregate, it is possible to recognize a particular meta-dynamic, the cumulative tugging of which defines the social structure's general character. How imbalanced are its forces? How do they tend?

If a given online setting experiences a preponderance of explicit rules, web forum moderator-enforced censorship, gate-keeping, and other centripetally-leaning discourses, the social structure tends toward autocracy or authoritarianism as an organizational form. Its social order is maintained by verbal and nonverbal talk that enforces centralized control while stifling insurgence. Leaders are typically designated and recognizable as established roles, and control mechanisms tend to be formally explicit and enforceable as codified rules. At the other end of the sliding scale—the centrifugal one—a given online venue with few (or no) explicit regulations, disciplinary procedures, and plenty of cacophonous interaction leans toward anomie or anarchy as the basis of social (dis)order. Discursive struggles occur through decentralization of authority and destabilization of public order. Leadership is emergent and fluid, and social norms—which are likely implicit—are negotiated among participants rather than imposed from atop or outside of the social structure.

Online Democracy

Whereas social forms such as anarchy and autocracy inhabit the continuum's two dialectical extremes, online democracy hovers (however imprecisely) near the middle. Online democracy may be defined as the quasi-counterbalance of normalizing and destabilizing discursive forces; a subtle and messy negotiation of control in which centripetal and centrifugal pushes and pulls more-or-less even out. The "more-or-less" characteristic of this equilibrium reflects the general idea that social structures, which are constantly remade in participants' interaction, are always dynamic and never static. For this discussion of online venues—which are potentially democratic but certainly not always—this definition is important. Given the seemingly pluralistic decentralization of discourse in web-based settings, the Internet appears to come to life as a noisy "marketplace of ideas" (Mill, 1956); a panoply of public "sphericules" (Gitlin, 1998) in which interaction is most easily described as ungrounded. The risk of these characterizations is that they may overemphasize centrifugal forces while denying or trivializing the emergence and functions of social control.

Control within and among online social structures is ubiquitous, and it comes in two generally different modes that are dialectically engaged. The first mode is what Spitzer (1982) describes as "formal," embodying centripetal qualities with their hierarchical stratification. The second, "informal" mode advances centrifugal qualities that disrupt hierarchical structures in socially emergent ways. As formal and informal modes of control interact within a democratic social system, discourses that "seem to weaken hierarchies of power may actually establish new channels through which those hierarchies can be strengthened, extended, and made more responsive to the complexities of modern social administration" (Spitzer, 1982, pp. 187-188). Accordingly, in addressing the democratization of online social spheres, it would be a mistake to highlight a presumed absence of discursive control. Instead it is important to acknowledge how control functions, both formally and informally.

Formal Control in Online Democracy

Democratic online venues are, in part, maintained by formal discursive control. There are many common instances of formal control in contemporary Internet life. Registration forms that are created and processed by centralized (usually institutional) website managers, for instance, require prospective users to provide their names, contact information, and other identifiers to gain access to the venue. Often, registrants are required to accept explicit terms and conditions. The contents of posts are filtered, either by moderators or automatically. Rules for conduct are stated, as are enforcement mechanisms, which range from message flagging to censorship to banishment. In short, formal control is usually obvious to participants, manifesting in "power-down" policies and actions that demand and enforce respect while constraining behavior.

Informal Control in Online Democracy

In roughly equal measure, informal control mechanisms also fulfill important functions in web-based democracies. Unlike formal control, which maintains social order authoritatively, informal enactments of control are essentially disruptive. They may directly undermine explicit authority, as do acts of spamming, flaming, hacking, and impersonation. They may also rewrite, reframe, or appropriate the online venue's content and norms to shift power away from the institution or privileged users. Informal control may be recognized in tagging and other XML-enabled tools that users apply to customize and order online content according to their own preferences.

But this disruption is not as chaotic, unregulated, and destructive as one might assume. If formal control is "top-down" then informal control is "bottom-up," manifesting what Foucault (1995) addresses in terms of a "panopticon"—an invisible mode of omniscience. Fostered online by the blurring of private and public identities within contexts that are rife with mutual voyeurism, panoptic omniscience compels participants to discipline not only each other, but also themselves. Barker (1999) describes the effect in organizational settings as "concertive control," through which team members in a "supervisorless culture" develop communicative patterns such as "informal hierarchies, particular power relationships, and team norms" (p. 13). In this negotiation there is both disruption and discipline—as well as the (re) construction of order. So informal control may be understood as emergent and participant-centered co-regulation.

THE DYNAMICS OF FORMAL AND INFORMAL CONTROL IN ONLINE DEMOCRACY: A CASE OF JUICYCAMPUS.COM

One specific case that offers an insightful view of how formal and informal kinds of control play out on the Internet is JuicyCampus.com, a website that aims to enable "online anonymous free speech on college campuses" (JuicyCampus.com, About Us). The website claims to provide a forum "where college students discuss the topics that interest them most, and in the manner that they deem most appropriate" (JuicyCampus.com, About Us) and promotes itself as the "world's premier college gossip site" that attracts "nearly one million unique visitors per month, while serving 500 campuses across the country" (JuicyCampus.com, Official Blog Announcements). Critics view the website as a gossip mill and compare it to "a dorm bathroom wall writ large, one that anyone with Internet access can read from and post to" (Morgan, 2008). However controversial it may occur to an outside observer, JuicyCampus.com represents a growing number of unmoderated online forums that promise anonymity to the users. The provision of general communicative guidelines coupled with the absence of gatekeeping and censorship-minded monitoring results in rich meta-discussions among participants about what kinds and styles of talk are appropriate. In the course of this site's interaction and meta-interaction, an illustration emerges of the carnival that is web-based democracy.

The Web as a Borderless System of Social Structures

JuicyCampus.com was founded in 2007 by Matt Ivester, a Duke University graduate who characterized the site as an attempt to cultivate "gossip 2.0" (cited in Morgan, 2008). The site does not require participants to register, and posts are anonymous. The site has spread to 500 college campuses in the U.S. and has been the center of a number of controversies with regard to its function and nature of participation. For the purposes of this analysis we focus on one of the most discussed JuicyCampus.com's threads, *The Yale Women's Center is Genius*, which as of March 2008 had generated 153 responses.

The Internet's borderlessness and carnivalesque qualities become apparent when one traces the emergence of this forum: a group of Yale students, members of the Zeta Psi fraternity, posed in front of the Yale Women's Center holding a sign reading, "We love Yale sluts" (Abrahamson, 2008). The photograph was uploaded on Facebook.com on January 16, 2008 and came to the attention of the Yale Women's Center members and the university community. On January 21 the Center declared an intention to pursue legal action (Abrahamson, 2008). On the same day, a blog posting appeared on IvyGateblog.com (O'Connor, 2008) that generated 216 responses from January 21 to February 28. On February 29 the forum's thread, entitled *The Yale Women's Center is Genius*, was posted on JuicyCampus.com with entries followed by the authors until March 16. The list of responses that have emerged or directed attention to this case is not meant to be exhaustive but rather an indication of the dynamic and hypertextual way in which discourse unfolds.

The discursive positions and moves of participation in all these social networks simultaneously invoke, reflect, co-opt, and control the Internet's carnivalesque potential and offer a macro-analytic glimpse of the centripetal and centrifugal forces that are generally at work in public online interaction. Participants' posts on JuicyCampus.com exemplify the range of potential discursive positions from which democratic talk can unfurl—with appeals to legal issues and ramifications, celebrations of freedom of expression and feminist ideology, references to sexual and gender politics, concerns about advertising and the economies of cyberspace, and, of course, frequent mention of netiquette rules and what constitutes appropriate discourse. It is to this exploration of the formal and informal enactments of control that we now turn.

Enactments of Formal Control

JuicyCampus.com's official policies straddle the legal and contextual. The site has an official policy outlining terms and conditions of use, an intellectual property policy, and a privacy policy. Although the site's *Privacy & Tracking Policy* page claims, "we do not track any information that can be used by us to identify you" (JuicyCampus.com, Privacy & Tracking Policy), the site managers have assisted police in identifying individuals who have made explicit threats (see, for example, Morgan, 2008). The site also has frequent announcements by the site managers that contextualize much of the more formal legal language, at times in contradictory ways. For example, the site outlines specific *Terms & Conditions* with regard to user conduct that also address defamation. However, on the *Frequently Asked Questions* page the site creators note: "Facts can be untrue. Opinions can be stupid, or ignorant, or mean-spirited, but they can't be untrue. And we believe everyone is entitled to their opinion" (JuicyCampus.com, Frequently Asked Questions). Site managers' specific announcements have tackled the issue of defamation (December 9, 2007; December 11, 2007); anonymity (December 9, 2007); use of real names of people being discussed (January 29, 2008); copyrighted material; the posting of contact information; spamming; and what constitutes "juicy," which the site founder says is *not hate* (February 29, 2008).

What is notable in reviewing these announcements is the celebration of the carnival—the recognition that online democracy's nature and form are contested and emergent. What is even more noteworthy is that it is the *institution* that enacts this celebration of carnival. As JuicyCampus.com (Official Blog Announcements, February 29, 2008) states, "Ultimately, JuicyCampus is created by our users, and we ask that you please take this responsibility seriously." So, at once the site managers are doing two things: advancing and maintaining formal control by inviting and permitting emergent and user-controlled discourse (invitation and permission being particular modes of control); and delimiting discourse in a way that protects themselves legally while defining the parameters of "juiciness."

Enactments of Informal Control

Anonymous users enact emergent and decentralized control in various ways throughout JuicyCampus.com's *The Yale Women's Center is Genius* discussion. Most basically, informal control is typified in users' ability to initiate discussion threads and reply without fear of monitoring, filtering, censorship, or expulsion. The important point about this is that, whereas users are liberated from formal oversight, they are subject to one another's responses. This cultivates a mode of discipline that emerges among participants, akin to Foucault's (1995) "panopticon" and Barker's (1999) "concertive control." Participants exercise discipline on issues ranging from who can participate, how they may appropriately do so, and why. Informal enactments of control are manifest in various strategies such as name-calling, threats, irony, caution, silencing, confrontation, and othering, among others (see Table 1):

Disciplining potentially defamatory talk (relating mostly to the Women's Center coordinator), participants argue from various positions that engender much more than just the legal perspec-

Table 1. Types of informal control

Participation issue	Strategy	Illustration of informal control
Who?	Name-calling	you a * get off the site. "impartial observer?" NEWSFLASH: everyone here is * invested. stop slowing the dialogue down. (3/4/08)
What?	Threat	the author of the other thread – "someone needs to * chase o-m till she cries" and the post on this thread of the same name - should be found, shamed, and lethally injected. how dare you speak of her? (2/29/08)
Where?	Caution	as a fan of the women's center: can we not talk about their strategies online, let alone on this site? FOR BLARINGLY OBVIOUS REASONS. (3/6/08)
When?	Irony	i just hate feminists and wrongly assumed it was safe to post at 5 a.m. because I wrongly assumed that they would be asleep. but now i see my mistake: they didn't have any sex so they couldn't fall asleep. (3/4/08)
Why?	Othering	i just wanted to express my opinion. I am not like any of you crazies. (3/4/08)

tive witnessed at the formal level of administrative control of the site (see Table 2):

Here we see the carnival's explosively disruptive potential as competing languages and perspectives struggle to frame the legitimacy of participation. We also see the attempts to control, rein in, redirect, and reframe the discussion's boundaries. The tension between formal (centripetal) and informal (centrifugal) modes of control is evident throughout the JuicyCampus.com site and the Yale Women's Center forum thread, and point to web-based democracy's inherent messiness. In these matters, there will be no "resolution." And, in these matters, as one participant observes, the carnival comes to life meta-discursively: "i love that the most discussed thread on juicycampus is about the women's center's attempt to destroy juicycampus" (3/4/08).

FUTURE TRENDS

As the Internet has emerged in popular use and evolved into Web 2.0, it has become less a medium for the sheer expression and transference of *information* and more a setting for *relationship-making*. Web-based interaction offers unlimited opportunities for organizing across geographic, demographic, and contextual boundaries, with ramifications for professional networking, po-

Table 2. Illustrations of informal control

What counts as defamation?	Illustration of informal control
Moral perspective	The * making these nasty comments about people should be thoroughly ashamed of themselves! (2/29/08)
Democratic perspective	these big anonymous sites make everybody forget that the people we are talking about are not public property, that their lives are not performed for our benefit, that the warriors are people too. * is as good a person as she is a warrior. let's make sure we remember that. (2/29/08)
Relational Perspective	WHY ARE ALL YOU PEOPLE SICKOS???? SHE IS MY * SISTER. I HAVE HELPED HER FIND TEDDY BEARS THAT SHE HAS LOST FOR YEARS. SHE IS * AWESOME. (3/2/08)
Public Domain Perspective	i am totally in awe of * and i became a feminist since arriving at yale because of two talks i went to at the women's center that she moderated... but she is a celebrity here. you shouldn't nipe at kids for talking about her because she is a public person, like a politician. we do have some right to talk about her as a person in a way that we dont have a right to talk about other people. (3/2/08)
Legal Perspective	dude, why are you mouthing off about girls on this thread? ITS LIKE SUICIDE. dumb *. everyone knows that they are planning to sue the site. EVERYONE knows that they have lawyers cuz of the frat stuff. EVERYONE knows that your * will get subpeonaed and EVERYONE will know who you are. (3/5/08)

litical action, friendships, romances, education, recreation, healthcare, and so on. One example of real but previously unforeseeable use of online interaction is *Naughtie Auties*, a resource center in the Second Life virtual venue where those with autism spectrum disorders can practice social interaction (Saidi, 2008). Theorists, researchers, and practitioners of web-based communication will increasingly have opportunities to engage these new relationship structures' discursive negotiations of control, and to recognize democracy when it occurs and assess its functions and sociologic consequences.

Internet scholars and users will also have increasing opportunities to consider how technological populism contributes to open and democratic discourse. It is noteworthy that means for producing and distributing visual, literary, musical, etc. creations are increasingly accessible. The result is that "authorship," broadly understood, is becoming less elite and more decentralized. It is now quite easy for amateurs to self-produce and distribute their art, ideas, and home videos, and to redefine "celebrity" in populistic terms via so-called "first-person media." As well, through Web 2.0-based technologies, lay people may co-opt, remix, and redistribute canonic pieces of art in ways that redefine authorship and ownership, problematizing notions of intellectual property. This wrangling between formal control mechanisms (e.g., copyright law) and insurgent, populistic inter-activities has everything to do with democracy, and will, in the future, be an important locus of concern.

Generally, the emergent democratization of online discourse is important to study and reflect upon since its social practices both influence and are influenced by life beyond "virtual" space. Democracy as a social order and even as a moral ideal is a historical phenomenon that has yet to be fully realized. It may be enacted in daily life, however imperfectly, throughout many contexts, spanning family, labor, education, entertainment, community, politics, etc. In a sense, participants in online venues that enable democratic interaction have opportunities to learn how to "do" democracy in effective and satisfying ways. There are particular procedures (e.g., deliberative decision making), responsibilities (e.g., shared leadership), and expectations of decorum (e.g., mutual respect, even in light of disagreement) that support effective democratic organizing. How democracy is practiced in online environment has great consequence for many dimensions of 21st century life, including citizenship (national, global, corporate, etc.), community building, resource management, innovation, and so on. In short, the Internet's new opportunities for experiencing and practicing democracy both reflect and contribute to the emerging democratization of broader social life.

CONCLUSION

The authors have approached online interaction as potentially democratic. The discussion's emphasis has not been upon democratic political interaction *per se*, but upon communicative practices of online democracy as they may be enacted in (and across) a wide range of online settings, such as blogs, wikis, and social networks. The definition of online democracy that we advance—a subtle and messy negotiation of control in which centripetal and centrifugal pushes and pulls more-or-less even out—is important for understanding how online contexts, potentially, are neither strictly controlled by their institutional creators/managers nor entirely disrupted by their "mobs" of users. This imperfect balance between formal and informal modes of discursive control ensures perpetual dynamism and innovation, as well as the promise that diverse voices are not only welcome but also potentially responsive and responsible.

Our intentions have been to recognize that, first, as in "real" life, so-called "virtual" interactions and relationships may take various organizational forms that range from anarchy to absolute control; and, second, that the Internet provides some new opportunities that are democratic in quality. It is important to pay attention to these opportunities since they demonstrate that the web's proclivities for decentralization and pluralism do not necessarily lead to relativistic and nihilistic hypertextuality but to potentially novel forms of shared social control. When formal and informal regulatory forces temper each other, there are consequences for the kinds of relationships and communities that interactants may forge. As participants in online venues increasingly engage in online democratic social structures, they may learn to relate on both substantive and meta-discursive levels in order to negotiate mutually recognized rules and resources. Such practice might have great consequence for broader social systems, and for the character of democracy throughout 21st century life.

KEY TERMS AND DEFINITIONS

Carnival: A concept developed by Bakhtin (1984) that illustrates how people come together as a collective of equals and interact in a way that defies exogenous sociologic divisions. In the experience of carnival, there is an air of playfulness and multi-voicedness that invigorates participants' understandings of self and community.

Formal Discursive Control: Communicative currents within a social structure that are institutionally centralizing, and which impose and enforce regulations in a "top-down" manner that is typically explicit (e.g., codes of conduct). Formal control is manifested in what Bakhtin (1981) terms "centripetal" forces, which are authoritative, stabilizing, decisive, and preserving of traditions.

Informal Discursive Control: Communicative currents within a social structure that disrupt institutional authority and enable the negotiation of emergent norms in a "bottom-up" manner that is often implicit and subtle. Informal control is manifested in what Bakhtin (1981) terms "centrifugal" forces, which are insurgent, destabilizing, equivocally open-ended, and change-minded.

Online Democracy: The quasi-counterbalance of normalizing and destabilizing discursive forces; a subtle and messy negotiation of control in which centripetal and centrifugal pushes and pulls more-or-less even out.

Social Structure: A relational system that is both constrained and enabled by norms (beliefs, values, rules, and roles) that are made and remade in participants' interaction. Social structure is partly stable and partly dynamic; at once a thing and a process.

ENDNOTE

Chapter 7.12
Agent Cognitive Capabilities and Orders of Social Emergence

Christopher Goldspink

Robert Kay
Incept Labs, Australia,
University of Technology, Sydney, Australia

ABSTRACT

This chapter critically examines our theoretical understanding of the dialectical relationship between emergent social structures and agent behaviors. While much has been written about emergence individually as a concept, and the use of simulation methods are being increasingly applied to the exploration of social behavior, the concept of "social emergence" remains ill defined. Furthermore, there has been little theoretical treatment or practical explorations of how both the range and type of emergent structures observed may change as agents are endowed with increasingly sophisticated cognitive abilities. While we are still a very long way from being able to build artificial agents with human-like cognitive capabilities, it would be timely to revisit the extent of the challenge and to see where recent advances in our understanding of higher order cognition leave us. This chapter provides a brief recount of the theory of emergence, considers recent contributions to thinking about orders of emergence, and unpacks these in terms of implied agent characteristics. Observations are made about the implications of alternative cognitive paradigms and the position is proposed that an enactivist view provides the most logical pathway to advancing our understanding. The chapter concludes by presenting an account of reflexive and non-reflexive modes of emergence, which incorporates this view.

DOI: 10.4018/978-1-60566-236-7.ch002

INTRODUCTION

Building and working with artificial societies using the methods of multi-agent social simulation serves us in several ways: 1) It allows us to operationalize social theories and to compare simulated behaviors with those observed in the real world; and 2) it allows us to build new theory by exploring the minimal mechanisms that might explain observed social behavior. Most importantly 3) it provides a unique ability to explore the interplay between levels of phenomena and to understand dynamic properties of systems. A great deal can and has been achieved in both these areas with even the simple methods we currently have available. However, Keith Sawyer (2003) has recently reminded us that, to date, we have worked with agents with very limited cognitive capability and that this necessarily limits the range and type of behavior which can be explored. This echoes a sentiment made a decade ago by Christiano Castelfranchi (1998a) that social simulation is not really *social* until it can provide an adequate account of the implication of feedback between macro and micro which becomes possible with higher cognitive functioning of social agents.

In many respects, developments in our capacity to simulate artificial societies have led us to confront anew a long-standing issue within social theory. This is a problem that social science conducted within traditional disciplinary boundaries has become quite adept at avoiding. Indeed it can be argued that the particular form disciplinary fragmentation takes in social science is a primary strategy for avoiding it. The problem is referred to in a number of ways depending on the disciplinary tradition. This chapter begins by revisiting this most important of problems. In terms of the challenge it poses to artificial societies it can be expressed in the following three questions:

1. What are the fundamental cognitive characteristics which distinguish human agents from animal or automaton?
2. How do these characteristics influence the range and type of behaviors agents may generate and the emergent structures which they may give rise to?
3. How can we theorize about the relationship between cognitive capability and categories of emergent form?

These questions form the focus for this chapter. We begin to address them by revisiting the contribution of alternative schools of thought to our understanding of the nature and origins of emergent structure and alternative concepts of orders of emergence. We then discuss the implications of the two competing cognitive paradigms within AI—that of cognitivism and the enactive view. Finally we turn to current research on the development of human cognition and examine its implications for anticipating different orders of emergent structure—proposing what we call reflexive and non-reflexive classes of emergence. Finally a research program for the advancement of understanding in this area is proposed.

This work has its origins in two strands of research with which the authors are currently involved. The first addresses the relationship between micro and macro levels of social behavior and organization directly. Over the past decade we have explored the characteristics of the micro-macro problem (see Chris Goldspink & Kay, 2003, 2004) in pursuit of a coherent and consistent account of the interpenetration (circular causality) between micro and macro phenomena. Our aim is to develop a theory which can provide a substantive account of fundamental social generative mechanisms. To date no such social theory exists that satisfactorily explains this dynamic.

The other strand is one author's involvement with the Centre for Research in Social Simulation and though it the European Union funded project titled Emergence in the Loop (EMIL). The aim of EMIL is to: a) provide a theoretical account of the mechanisms of normative self-regulation in a number of computer mediated communities b) specify the minimum cognitive processes agents require to behave in normative ways c) develop a simulator which can replicate the range and type of normative behavior identified by the empirical research so as to further deepen our understanding of how and under what conditions normative self-regulation is possible and the range and type of environmental factors which influence it.

A BRIEF RECOUNT OF THE THEORY OF EMERGENCE

The notion of emergence has a long history, having been invoked in a number of disciplines with varying degrees of centrality to the theoretical and methodological development of associated fields. Unfortunately the concept has largely remained opaque and ambiguous in its conceptualization, leading to the criticism that it stands as little more than a covering concept – used when no adequate account or explanation exists for some unexpected phenomena. Clayton has argued that the concept covers:

…a wide spectrum of ontological commitments. According to some the emergents are no more than patterns, with no causal powers of their own; for others they are substances in their own right… (Clayton, 2006: 14).

The origin of the concept has been attributed to George Henry Lewes who coined the term in 1875 (Ablowitz, 1939). It subsequently found wide adoption within the philosophy of science but more recently has been advanced within three distinct streams: *philosophy*, particularly of science and mind; *systems theory*, in particular complex systems; and *social science* where it has largely been referred to under the heading of the micro-macro link and/or the problem of structure and agency. Interestingly there has been relatively little cross fertilization of thinking between these streams.

The Contribution from Philosophy of Science

The philosophy of science and philosophy of mind stream is arguably the oldest – some date it back to Plato (Peterson, 2006) but the debate is widely seen as having come to focus with the British Emergentists (Eronen, 2004; Shrader, 2005; Stanford Encyclopaedia of Philosophy, 2006). This school sought to deal with the apparent qualitatively distinct properties associated with different phenomena (physical, chemical, biological, mental) in the context of the debate between mechanism and vitalism: the former being committed to Laplacian causal determinism and hence reductionism and the latter invoking 'non-physical' elements in order to explain the qualitative difference between organic and inorganic matter. This stream remains focused on explaining different properties of classes of natural phenomena and with the relationship between brains and minds (See Clayton & Davies, 2006 for a recent summary of the positions). As a consequence this has been the dominant stream within artificial intelligence. Peterson (2006: 695) summarizes the widely agreed characteristics of emergent phenomena within this stream as follows. Emergent entities:

1. Are characterized by higher-order descriptions (i.e. form a *hierarchy*).
2. Obey higher order *laws*.
3. Are characterized by *unpredictable novelty*.
4. Are *composed of* lower level entities, but lower level entities are *insufficient* to fully account for emergent entities (*irreducibility*).
5. May be capable of *top-down causation*.
6. Are characterized by *multiple realization or wild disjunction* (Fodor, 1974) (alternative micro-states may generate the same macro states).

A key concept within these discussions is that of *supervenience*: a specification of the 'loose' determinisms held to apply between levels such that *'…an entity cannot change at a higher level without also changing at a lower level'* (Sawyer, 2001: 556). Within this stream prominence of place is given to both downward and upward causation. Clayton and Davies (2006) specify downward causation as involving macro structures placing *constraint* on lower level processes hence *'Emergent entities provide the context in which local, bottom up causation takes place and is made possible'* (Peterson, 2006: 697). Davies (2006) argues that the mechanism of downward causation can usefully be considered in terms of boundaries. Novelty, he argues, may have its origin in a system being 'open'. If novel order emerges it must do so within the constraints of physics. He concludes:

…top-down talk refers not to vitalistic augmentation of known forces, but rather to the system harnessing existing forces for its own ends. The problem is to understand how this harnessing happens, not at the level of individual intermolecular interactions, but overall – as a coherent project. It appears that once a system is sufficiently complex, then new top down rules of causation emerge. (Davies 2006: 48).

For Davies then, top-down causation is associated with self-organization and may undergo qualitative transitions in form with increasing system complexity. For Davies also it is the 'openness' of some systems that 'provides room' for self-organizing process to arise, but he concludes, *'openness to the environment merely explains why there may be room for top-down causation; it tells us nothing about how that causation works.'* The devil then, is in the detail of the mechanisms specific to particular processes in particular contexts and particular phenomenal domains. Perhaps then a part of the problem with the concept is that it has been approached at too abstract a level.

The Contribution from Social Science

The micro-macro problem—the relationship between the actions of individuals and resulting social structures and the reciprocal constraint those structures place on individual agency—has long standing in social science as well as in philosophy. The problem is central to many social theories developed throughout the 19th and 20th century. Examples include: Marxian dialectical materialism (Engels, 1934) built upon by, among others, Vygotsky (1962) and Lyont'ev (1978); the social constructionism of Berger and Luckmann (1972); Gidden's structuration theory (1984); and the recent work of critical realists (Archer, 1998; Archer, Bhaskar, Ciollier, Lawson, & Norrie, 1998; Bhaskar, 1997, 1998). These alternative theories are frequently founded on differing assumptions, extending from the essentially objectivist/rationalist theory of Coleman (1994), through the critical theories of Habermas and to the radical constructivism of Luhmann (1990; 1995).

Fuchs & Hofkirchner (2005: 33) have recently suggested a four category schema for classifying social theory according to the ontological position adopted with respect to the micro-macro relationship. The majority of existing social theories, they argue, fall into one or other of two categories which they label *individualism* and *sociologism*. Neither of these 'paradigms' provides a theoretical foundation which supports exploration let alone the possibility of advancing understanding of the interplay between agency and structure, rather the problem is avoided by restricting analysis to one level or the other. A third category, *dualism*, while considering both aspects, insists on the adoption of a dichotomous stance and as a consequence does not support any understanding of the interplay between levels. Only those theories categorized as *dialectical* therefore have relevance. Even here, it is reasonable to conclude that little practical advance has been achieved, as most positions result in a straddling of bottom up and top-down arguments and/or suffer from excessively vague conceptualization. These theories also quickly break down into a dichotomy the moment an attempt is made to make them operational.

What has been largely agreed, despite the very different theoretical and often inadequate handling of this problem, is that structure and agency come together in *activity* or in *body-hood* – the specific psycho-motor state at the instant of enaction. Both Vygotsky and Giddens, for example, focus on action as the point of intersection between human agency and social structures and it is implicit in Bourdieu's *habitus* also.

The Contribution from Systems Theory

Systems language was clearly evident in the work of the early Emergentists and in a great deal of sociology and anthropology which took seriously the structure/agency problem – notably that of Margaret Mead and Gregory Bateson. However, 'systems' as a focus of systematic research arguably took form with von Bertalanffy's attempt to establish a General Systems Theory in 1950 (Bertalanffy, 1950; Bertalanffy_von, 1968). As the science of 'wholes' systems theory stands in contrast to reductionism's concern with parts. Systems theory was put forward as a counter to what was perceived as excessive reductionism dominating scientific discourse during much of the 20th century.

In the early stages of development of the theory systems tended to be modeled as 'black boxes' effectively masking the relationship between micro and macro elements. The application of the concept to social science, in particular through the development by Ernst von Glasersfeld and Heinz von Foerster (Keeney, 1987) of social cybernetics along with soft systems approaches (Checkland, 1988) provided a theoretical lens and methods useful for describing the systemic behavior of social systems. So while the aspiration of GSM to establish a general science of systems is generally regarded to have failed (Jackson, 2000), systems approaches have contributed valuable methods for the study of the interplay between levels in a social system. The Systems view of emergence was founded on:

- Holism; the whole is greater than the sum of its parts.
- A concern with *feedback both positive and negative*.
- A concern with boundaries and boundary conditions.

More recently the development of complex systems theory and its application to natural, social and cognitive phenomena has provided additional concepts upon which much current debate about emergence draws. Many of these concepts and methods have become widely used within the multi-agent modeling community (Castelfranchi, 1998b; Conte, Hegselmann, & Terna, 1997; Gilbert, 1995; Holland, 1998).

Within contemporary debate, and in contrast to the position taken by the British Emergentists who argued that irreducibility was the *exception* (Eronen, 2004), most real world systems are now argued to be non-linear (S. Kauffman, 2000; S. A. Kauffman, 1993, 1996; Stewart, 1990) and hence irreducible. It is non-linearity which contributes to these system's capacity for novelty and unpredictability through the presence of deterministic Chaos (Lorenz, 2001; Williams, 1997) and/or equifinality. Equifinality as it is known within systems theory, or the principle of 'wild disjunction' as it is known in philosophy, refers to a system where a single high level property may be realized by more than one set of micro-states which have no lawful relationship between them (Richardson, 2002a, 2002b; Sawyer, 2001). As there is no a-priori basis by which the likely micro state can be determined, such systems are irreducible and unpredictable in principle.

Observations

The concept of emergence has led to the establishment of a number of general principles which describe the relationship between micro and macro phenomena, as well as some methods and techniques for identifying and exploring it. Specifically, we can conclude that there are systems which are:

- Inherently analytically reducible (to which the concept of emergence does not apply);
- Analytically reducible in principle but difficult to reduce in practice and/or where an advance in science/knowledge is needed for reduction to be possible because the results were 'unexpected' (Chalmers, 2006) (to which the concept of 'weak' emergence can be applied);
- Not reducible in principle (to which the principle of 'strong' emergence is relevant).

We argue that all living systems and all social systems belong to the latter class. Accordingly we agree with McKelvey (1997) that a great deal of social order may be attributable to complex organization involving non-liner relations between elements. It is for this reason that simulation methods are regarded as important but only to the extent that we can construct artificial societies which are reasonable analogues of the social systems we want to understand and this implies agent architectures which are capable of generating the range of social behaviors/structures of interest. The problem here is that we still have a very rudimentary understanding of what cognitive capabilities support or are necessary for what range and types of social structures.

In the following section we draw on the limited prior attention given to this problem and attempt to clarify what is currently known. Throughout the discussion, pointers are provided to where the mechanisms being outlined have, at least in part, been incorporated into computer simulations of artificial intelligence or artificial societies.

ORDERS OF EMERGENCE

A number of authors have identified what they refer to as orders of emergence. Gilbert, for example distinguishes between first and second order emergence. First order emergence includes macro structures which arise from local interactions between agents of limited cognitive range (particles, fluids, reflex action). By contrast, second order emergence is argued to arise *'where agents recognise emergent phenomena, such as societies, clubs, formal organizations, institutions, localities and so on where the fact that you are a member or a non-member, changes the rules of interaction between you and other agents.'* (Gilbert, 2002). This reflects high order cognition on the part of the agent. In particular it reflects a range of capabilities including but not limited to the ability to distinguish class characteristics; assess 'self' for conformity with class characteristics and/or signals from other agents which suggest acceptance or belonging; the ability to change rule associations and behavior as a function of these changes. First and second order emergence then each imply qualitatively distinct mechanisms and suggest a continuum of orders of emergence linked, in biological entities at least, to cognitive capability.

In a similar vein, Castelfranchi (1998a: 27) has distinguished what he refers to as cognitive emergence. *'Cognitive emergence occurs where agents become aware, through a given 'conceptualization' of a certain 'objective' pre-cognitive (unknown and non deliberated) phenomenon that is influencing their results and outcomes, and then, indirectly, their actions.'* This approach is based on a first generation AI (Franklin, 1998) approach to conceptualizing agents: agent cognition is assumed to involve acting on beliefs desires and intentions (BDI). Thus Castelfranchi conceives of a feedback path from macro pattern to micro behavior in much the same way as Gilbert, except that here a cognitive mechanism is specified. Castelfranchi argues that this mechanism has a significant effect on emergence and indeed *'characterises the theory of social dynamics'* – that is, it gives rise to a distinct class of emergent phenomena. In this account, the representations agents have about the beliefs, desires and intentions of other agents plays a causal role in their subsequent behavior and therefore shapes the structures they participate in generating. In this same chapter Castelfranchi argues that understanding this process is fundamental to social simulation: it is where social simulation can make its greatest contribution.

These ideas are more comprehensively reflected in the five orders of emergence suggested by Ellis (2006:99-101). These are:

1. Bottom up leading to higher level generic properties (examples include the properties of gases, liquids and solids)
2. Bottom up action plus boundary conditions leading to higher level structures (e.g. convection cells, sand piles, cellular automata)
3. Bottom up action leading to feedback and control at various levels leading to meaningful top down action - teleonomy (e.g. living cells, multi-cellular organisms with 'instinctive' – phylogenetically determined reactive capability)
4. as per 3 but with the addition of explicit goals related to memory, influence by specific events in the individuals history (i.e. learning)
5. In addition to 4 some goals are explicitly expressed in language (humans).

Ellis's framework makes clear that the range and type of emergence possible in a system depends fundamentally on the range and class of behavior agents are able to generate and that this varies depending on the properties of the agent.

If we consider Ellis' category one emergence, it is apparent that particles have fixed properties and are able to enter into a limited range of interactions (specified by physical laws) based on those properties. Swarms of particles can nevertheless demonstrate some rudimentary self-organization and hence emergence (Kennedy & Eberhart, 2001). Physics has furnished good accounts of many specific examples (Gell-Mann, 1995) but they have limited implication for our understanding of social behavior.

Category two has also recently been well explored as it is the focus of complexity theorists. Examples include the work of Per Bak (1996) on sand piles and earthquakes, Lorenz (2001) on weather systems and Prigogine (1997; 1985) on far from equilibrium systems. Many so called social simulations also belonging here– specifically those which incorporate agents which have fixed behaviors and no capacity for learning (individual or social). These include classic simulations based on swarms (Boids) and/or involving fixed decision criteria or rules such Schelling's segregation model, the cooperation models of Axelrod (1984) or the Sugarscape models of Epstein and Axtell (1996). Some may argue that these models involve agents with goals and therefore represent examples of fourth order emergence. The transition between 3rd order and fourth, as will be argued below, involves a move to agent autonomy that is missing in these models: their goals are designed in and not a result of their own operation it is for this reason that we argue they belong to order two.

It is significant that Ellis provides primarily biological examples for his category three order of emergence. The paradigmatic biological entity which illustrates the processes of reciprocal micro-macro causality and for which we have an excellent description which has been made operational both in vitro and in silico (see for example McMullin & Grob, 2001; F. Varela, Maturana, & Uribe, 1974) is the cell. While the mechanisms of autocatalysis and the metabolic pathways of cell self-production are well known, well documented and closely studied, the most concise articulation of the fundamental processes involved come with the theory of autopoiesis developed by the theoretical biologists Humberto Maturana and Francisco Varela (H. Maturana & Varela, 1980; H. R. Maturana & Varela, 1992; F. Varela, 1979; F. Varela et al., 1974). Unfortunately this account is not widely appreciated even within biology itself[1]. Varela (1997: 78) states:

Autopoiesis is a prime example of a …dialectics between the local component levels and the global whole, linked together in reciprocal relation through the requirement of constitution of an entity that self-separates from its background.

The theory of autopoiesis provides a foundation for understanding other emergent processes, particularly those associated with biological entities. The originating authors themselves extended it to cover multi-cellular entities and to provide a more general theory of cognition. Others have gone so far as to argue that it furnishes a theory of society and/or organization (Niklas Luhmann, 1995; von_Krogh & Roos, 1995; Zeleny, 1991) although this remains controversial (Bednarz, 1988; Mingers, 2002, 2004) and we specifically reject it as incompatible with the original concept and as unnecessary (Goldspink, 2000; Kay, 1999).

Unlike the self-organizing processes which characterize the second order, the defining characteristic of biological self-organization is the attainment of 'strong autonomy' (Rocha, 1998). While Ellis does not say so directly, it would appear that it is the advent of a self-referential operational closure which demarcates third and higher orders of emergence from the lower orders.

Maturana and Varela argue that cognition is associated with this operational closure or autonomy. Autonomy is used here to refer to a *constitutive* process rather than as a *categorical* distinction and cognition is defined as the range of behaviors the agents can generate to remain *viable* or *to retain its identity* as a self-constituting agent (Froesea, Virgo, & Izquierdo, 2007; Thompson & Varela, 2001). For those immersed in symbolic AI it may come as a surprise that a biological cell may thus be described as a cognitive entity. This theme will be developed further in a following section as it is central to the idea of enactive cognition finding increasing uptake within second generation AI, artificial life and robotics (Barandiaran, 2005; Di Paolo & Lizuka, 2007; Di Paolo, Rohde, & De Jaegher, 2007; Moreno & Etxeberria, 1995; Moreno, Umerez, & Ibanes, 1997).

In his third order category Ellis includes a range of capabilities of biological entities up to and including 'instinctive' action. These suggest that this category would pertain to single and multicellular organisms including those with a central nervous system. It may be that this order is too broadly cast. Multi-cellularity is arguably another threshold point as differentiated aggregates of cells display greater capacity to respond to their environment, even where they do not possess a central nervous system, than do individual cells. Furthermore those with a central nervous system enjoy even greater behavioral flexibility. As a consequence each probably originates a distinct macro phenomenology different from that of the cells that constitute them (H. R. Maturana & Varela, 1992).

The primary point of distinction between order three and order four would appear to be between (phylogenetically) fixed individual characteristics and a capacity for an individual agent to have goals and to learn. The mechanisms by which these characteristics are acquired and fixed at the level of individuals (sexual transmission and natural selection) are ignored by Ellis or seen as unimportant from the perspective of emergence. This is reasonable if our concern is with social behavior which manifests over relatively short time cycles in geological terms. When does a capacity to adjust structure in response to an environment as implied by the characteristics of Ellis' third order become the learning ability associated with the forth order?

Ellis explicitly demarcates the goal directedness of the fourth order from apparent goals implied in the teleonomic operation of living things implicit in the third. We must therefore assume he means active goal-setting: the exercise of what we commonly refer to as agency or free will. Agency results from the vastly expanded behavioral plasticity available when an organism develops an advanced nervous system. Also, to learn an agent must have some form of memory. Memory too is generally associated with the existence of a central nervous system and is often seen as involving stored representations. But the idea of 'representations' is highly problematic from a biological point of view. What is it that is represented and how? We consider this problem in the next section.

Ellis would seem to be pointing to a category here which deals with non-human animals but the transition points are not well defined from the perspective of mechanisms of emergence. Learning in animals can stretch from simple operant conditioning to complex evaluative processes involving logical reflexion. Different stages along this continuum would appear to support significantly different forms of emergent structure. Ellis makes no distinction, for example, between individual and social learning.

Ellis marks his final transition from category four to category five by moving from simple learning capability to the capacity for language. Animals such as apes have rudimentary language ability – are they included in here or is this category the human catch-all category? Unfortunately the more closely we look at the jump between fourth and fifth order the more it resembles an abyss.

There has been a considerable research effort directed at understanding the origins and developmental phases associated with the attainment of the distinctive human cognitive capabilities. These are the capabilities which seem to relate to the transition between Ellis' category four and five orders of emergence. Much of this has drawn on comparative neurology, and sociological and psychological study of non-human animals, in particular apes. Insights are available also from developmental psychology and neurology directed at understanding human ontogeny: the phases of development from infant to adult. Note that these may overlap as phylogenetically determined capabilities characteristic of some animals may correspond to early stages of human ontogenetic development. This corpus offers those of us involved with AI two opportunities a) a capacity to aim to better stage the development of agent specifications - aiming to provide a reasonable model for simple intelligence before the more complex and b) a capacity, even before we can effectively model or simulate more advanced intelligence, to theorize about the implications it may have for emergence of social structure.

Some work has already been undertaken in this area, most notably in the area of robotics rather than computer simulation of social phenomena (although robots can be regarded as physical simulations and multi-agent software simulations as simulated robotics). Of particular note here is the work of Dautenhahn (2001; 2002), Bryson (2007; n.d) and Steels (1997; 2005; 1999) in the area of language.

Gardenfors (2006) identifies the following as needing to be explained (presented in order of their apparent evolution).

- Sensations
- Attention
- Emotions
- Memory
- Thought and imagination
- Planning
- Self-consciousness/theory of mind
- Free-will
- Language

These are present to varying degrees in different organisms and develop at different stages in humans as they develop from infancy to adulthood. The degree of interrelatedness is not, however, straight forward. Apes for example demonstrate self-awareness and theory of mind but do both without language whereas in humans language appears to play a significant role in both. For the time being then too little is known about these transitions.

It is perhaps in understanding these transitions that we find the greatest challenges for advancing artificial societies and it is here that we find philosophy may have dealt us an unhelpful turn. The advent of the central nervous system and the observation that cognitive function is correlated with brain size has contributed to a distinctive account of the function of brain and its relationship to mind (Johnson, 1990; Lakoff & Johnson, 1999). In this convention, mind and hence cognition has been argued to originate in brains and to involve symbol manipulation. As we consider the literature on what makes human cognition distinctive, we need to be mindful of the effect of this and alternative paradigms. What are these alternatives and what difference do they make to our understanding of orders of emergence in general and social emergence in particular?

TWO PARADIGMS: TWO POSSIBLE APPROACHES

Within AI there are two alternative and some argue antithetical paradigms of cognition – symbolic and connectionist. Symbolic AI assumes that it is possible to model every general intelligence using a suitable symbol system and that intelligence involves symbol manipulation (Franklin, 1998).

In their book *The Embodied Mind*, Varela & Rosch (1992) state:

The central intuition … is that intelligence—human intelligence included—so resembles computation in its essential characteristics that cognition can actually be defined as computations of symbolic representations (F. Varela, Thompson, & Rosch, 1992: 40).

The symbolic approach inevitably constructs a duality. The environment is experienced as a facticity and acted upon directly, but is also conceived and symbolically represented in the mind. Mind and behaviour are linked as hypothesis and experiment. The mind looks for patterns in representations and tests the degree to which these accord with the outside world.

More recently, this tradition has been challenged. The advent of complexity theory has given greater impetus to connectionist models of mind such as neural networks. Here emergent structure or pattern arises from massively interconnected webs of active agents. Applied to the brain, Varela et al state:

The brain is thus a highly cooperative system: the dense interconnections amongst its components entail that eventually everything going on will be a function of what all the other components are doing (1992: 94).

It is important to note that no symbols are invoked or required by this model. Meaning is embodied in fine-grained structure and pattern throughout the network. Unlike symbolic systems, connectionist approaches can derive pattern and meaning by mapping a referent situation in many different (and context dependent) ways. Meaning in connectionist models is embodied by the overall state of the system in its context. It is implicit in the overall 'performance in some domainre'. Herein lays its major problem from the perspective of multi-agent simulation. In connectionist models the micro-states which support a given macro state is opaque – relatively inaccessible to an observer and difficult to interpret – indeed, there will often be several or many micro configurations compatible with a given macro-state (Richardson, 2002b). Several attempts have been made to address this problem. The first was to consider hybrid systems in an attempt to gain the advantage of each (Khosla & Dillon, 1998). The second has been to find a middle ground. This is apparent for example in Gardenfors' theory of conceptual spaces (Gardenfors, 2004). At the same time the practical value of connectionist systems – their capacity to categorize contexts or situations in a non-brittle way– has been seen as a significant advantage in robotics (Brooks, 1991).

Back in 1992 Varela et al noted that:

…an important and pervasive shift is beginning to take place in cognitive science under the very influence of its own research. This shift requires that we move away from the idea of the world as independent and extrinsic to the idea of a world as inseparable from the structure of [mental] processes of self modification. This change in stance does not express a mere philosophical preference; it reflects the necessity of understanding cognitive systems not on the basis of their input and output relationships but by their operational closure (1992: 139).

They go on to argue that connectionist approaches, while an advance on cognitivism are not consistent with an approach which views biological agents as operationally closed in that *'…the results of its processes are those processes themselves'* (1992, p. 139). They assert:

Such systems do not operate by representation. Instead of representing an independent world, they enact a world as a domain of distinctions that is inseparable from the structure embodied by the cognitive system (1992: 140).

These authors argue for an approach of cognition as 'enaction', an intertwining of experience and conceptualization which results from the structural coupling of an autonomous organism and its environment. Autopoietic theory provided a concrete and operationalizable account of the intertwining of micro and macro at the level of the cell. The enactive theory of cognition goes some way towards providing a basis for understanding this process in multi-cellular animals. Enactive cognition is currently enjoying significant attention and hence conceptual extension as well as experimental grounding in the field of robotics (see for example De Jaegher & Di Paolo, 2007; Di Paolo et al., 2007; Metta, Vernon, & Sandini, 2005). The attraction here is pragmatic – it helps to address longstanding problems within robotics, in particular the problem of symbol grounding (Harnad, 1990). To date it has seen little uptake within social simulation. The implications of enaction go well beyond pragmatics however.

The enactive turn in AI has as an explicit target a resolution of the micro-macro problem. While symbolic AI assumes the existence of an objective independent world and a mental model with some correspondence to the real world, enaction dispenses with this dichotomy. As an autonomous entity, the cognizing agent is concerned only to maintain its viability in an environment. It adjusts its structure to accommodate perturbation from the environment (which includes other cognitive agents) in order to do so. Advanced nervous systems and capabilities such as language simply extend the requisite variety available to the agent extending the range and type of environmental perturbations it can survive. As agents and environments structurally couple they co-determine one another to 'satisfice' the conditions for mutual viability. From this perspective, the importance of environment recedes from determinant to constraint. Intelligence moves from problem solving capacity to flexibility to enter into and engage with a shared world. However, McGee (2005a; 2005b) has recently argued that despite its promise, enactive cognition is not yet sufficiently well articulated to 'speak of hypothetical mechanisms'. The limiting factor here would appear to be as much one of insufficient application as theoretical difficulty. In the final section we attempt a definition of two classes of emergence which we call reflexive and non-reflexive. These draw on the enactive paradigm and attempt to provide a concrete specification of the mechanisms which underlay each.

TOWARDS AN ENACTIVE SPECIFICATION OF ASPECTS OF COGNITION AND THEIR ASSOCIATED ORDERS OF EMERGENCE

How then do we advance our understanding of the effect of different cognitive capability on orders of emergence? A useful strategy may be to simplify the problem. By way of a mental exercise we will take simple extremes and recast the problem in terms of an enactive view. From an enactive position the critical phases of cognitive development appear to be as follows:

- Autonomy (operational closure)
- Structural Coupling
- Reflexivity/self consciousness
- Language/consensual domains

All living beings (from amoeba to humans) are distinguished by autonomy and as autonomous entities they necessarily enter into structural coupling with their environment. We take this as one pole of the continuum and identify the class of emergence which it can support as non-reflexive. This is the enactive equivalent to social order which is a product of emergence *without* the feedback loop from macro to micro which Castelfranchi (1998a) refers to as immergence. The mechanisms are, however, more sophisticated than are currently modeled in Artificial Societies as they involve autonomous agents – these are essentially what Ellis refers to in his category four – i.e. biological agents which can change their structure (learn) in response to environmental perturbation. It should be feasible to simulate this type of agent with current technology or at least to achieve a close proxy although we have not yet managed to do so beyond the most basic chemical system analogues of cell autopoiesis. If we were to achieve it how might we describe the system operation?

Non-Reflexive Social Emergence

Non-reflexive emergence arises from the mechanism of structural coupling between operationally closed (autonomous) agents. Structural coupling will arise between such agents which have sufficient cognitive range (behavioral repertoire) when they are located in a common environment. Assuming that their phylogeny and ontogeny is such that they can co-exist, through the process of recurrent mutual perturbation, each will adjust its structure so as to accommodate the other – their structures will become mutually aligned or structurally coupled. This process has been approximated in a simulation by Stoica-Kluver and Kluver (2006).

An observer may notice regularities in the resulting patterns of interaction and these may be labeled as 'norms' for example although Castelfranchi would refer to them as social functions as they 'work without being understood'. These patterns represent mutual accommodations, and an observer might attribute to those accommodations some social 'function'. The accommodations an agent makes to remain viable in one domain of interaction will need to be reconciled (within its body-hood) against accommodations being made (simultaneously) as it also participates with different agents in other domain/s in which it is simultaneously participating – agency and structure converge and are both instantiated at the point of enaction. The accommodations made will be those that allow the agent to remain viable and to maintain its organization (i.e. which 'satisfice' the constraints and allow conservation of identity) based on its unique ontogeny (structure resulting from its history of interactions in a variety of domains including the current one).

Here the emergent structure can be seen to be 'in' (i.e. internalized within its own cognitive structure) each agent to the extent that each has had to make structural adjustments to operate in the shared domain. The structural adjustment each needs to make in order to persist will, however, be unique. In other words the structural accommodations each has made in order to contribute to the patterns, will *not* be the same. The structure, then, can also be regarded as 'in' the network, as it is the intersection of these disparate agent structures which gives it its particular form at a particular time. As any agent could leave the domain and have minimal effect on the resulting pattern, each agent's 'contribution' will be relatively small. The pattern can be thought about as like a hologram. The whole is in every part (agent) such that removal of parts (agents) reduces the resolution (coherence) but does not constitute loss of overall pattern. However, the loss of too many components may reduce the coupling to the point that the existing pattern de-coheres and transforms into something different. Each agent contributes to the pattern formation, so it is conceivable that the pattern will only be realized with some critical minimal number of agents present which have had a sufficient mutual history to have aligned their structures.

In natural systems, the local level interactions between agents are constrained by the existing structures of the agents and the state of their environment. With biological agents the system is open in that any emergent structure is possible as long as it remains consistent with the biological viability of the agents as living (autopoietic) entities. This biological constraint includes limits to environmental conditions conducive to life (i.e. not too hot or too cold, the need for energy, limitations to sensory channels, channel bandwidths and affective/psychomotor response capabilities etc). These are primarily a product of phylogeny (the evolutionary history of the organism at the level of the species) rather than ontogeny (the history of development at the level of the individual), and are therefore slow to change and not under the control of the emergent social system. As a consequence the basic dimensionality of the phase space of the social system does not change over the time frame of interest for understanding social systems. The dimensionality of the phase space is determined by the dimensions of variability possible by individuals – i.e. the plasticity of their nervous systems and by higher order dimensions which emerge from their interaction.

Reflexive Social Emergence

What changes if we now jump to the opposite pole on our hypothetical continuum? Here we attempt to outline the difference made by agents which are self aware and which can interact in language.

Biological agent's sensory surfaces are selected to be sensitive to difference in dimension of their world relevant to their survival and their cognitive apparatus is thus geared to make distinctions relevant to maintaining their viability in past environments. Once cognitive complexity exceeds a critical threshold (Gardenfors, 2006) these distinctions can be represented in language. Maturana and Varela (1980) describe language as involving the co-ordination of the co-ordination of actions – i.e. language provides a meta process by which agents orientate themselves within a world. Structural coupling can arise purely through behavioral coordination of action (as discussed above), but it can also take place in and through linguistic exchange – the mutual co-ordination of co-ordination of behaviors. This gives rise to a consensual linguistic domain characterized by a more or less shared lexicon. This process has been simulated using both shared referents and simple structural coupling in the absence of objective referents (Gong, Ke, Minett, & Wang, 2004; Hutchins & Hazlehurst, 1995; Steels, 1997, 1998; Steels, 2005; Steels & Kaplan, 1998; Steels & Kaplan, 1999), as has the emergence of a rudimentary grammar (Howell & Becker, n.d; Vogt, n.d).

The advent of language radically increases the behavioral plasticity of agents and has significant implications for the dimensionality of the phase space and of the resulting higher order structures it can generate and support. This is because language makes possible the emergence of domains of interaction which can themselves become the target for further linguistic distinction and hence new domains. In other words, language allows the agent to make distinctions on prior distinctions (to language about its prior language or to build further abstractions on prior abstractions). This supports the possibility of infinite recursion and infinite branching (there are no doubt biological constraints on this in humans). This is an intrinsically social process. Furthermore, a capacity to distinguish (label or categorize) processes supports reification and this simplifies the cognitive handling of processual phenomena and allows the resulting reifications to be treated by the agent in the same manner as material objects.

These capabilities greatly expand the structural flexibility of the agents: they can now invent shared epistemic worlds. The phase space of agent cognition is now based primarily on constraints of ontogeny rather than phylogeny and is hence under the influence of the agent/s.

Language makes possible a further major qualitative difference in natural and human social emergence. Humans (and possibly some other primates, cetaceans and elephants)[2] have developed sufficient cognitive capacity to become self-aware and as such exhibit reflexive behavior. This occurs when the agent is capable of distinguishing 'self' and 'other' i.e. the agent can entertain the notion of 'I' as a concept and treat that concept as an object. The advent of this capacity for reflexive identity also supposes the existence of a range of conceptual operators that act on identity – identity construction and maintenance becomes a part of the agent's world creation. Exploration of this process is proceeding under the title of Neurophenomenology (Rudrauf, Lutz, Cosmelli, Lachaux, & Le Van Quyen, 2003; Thompson & Varela, 2001).
